Abstract

A revision of the New Zealand endemic *Lepidium oleraceum* and allied species is presented. Sixteen species are recognised, 10 of these are new. The new species are segregated on the basis of morphological characters supported by molecular data obtained from three DNA markers (two rDNA and one cpDNA). One species, *L. castellanum* **sp. nov.**, is endemic to the Kermadec Islands where it is sympatric with *L. oleraceum*. The North Island of New Zealand supports four species, with two of them, *L. amisum* **sp. nov.** and *L. obtusatum*, now extinct. The South Island supports six species, that, aside from *L. banksii*, *L. flexicaule* and *L. oleraceum*, are all confined to the south-eastern half of the island (*L. aegrum* **sp. nov.**, *L. crassum* **sp. nov.** and *L. juvenicum* **sp. nov.**). One of these, *L. juvenicum* **sp. nov.**, extends to Stewart Island. The Chatham Islands support six species (*L. flexicaule*, *L. oblitum* **sp. nov.**, *L. oleraceum*, *L. oligodontum* **sp. nov.**, *L. panniforme* **sp. nov.**, and *L. rekohuense* **sp. nov.**), one of which, *L. oligodontum* **sp. nov.**, extends to the Antipodes Islands group. The remote, subantarctic Bounty Islands group supports one endemic, *L. seditiosum* **sp. nov.**, which is the only vascular plant to be recorded from there. *Lepidium limenophylax* **sp. nov.** is known from islands off the south-western side of Stewart Island/Rakiura, The Snares and Auckland islands. *Lepidium naufragorum*, although not related to *L. oleraceum* and its allies, is also treated because populations with entire leaves are now known. Typification is undertaken for *L. banksii*, *L. oleraceum*, *L. oleraceum* var. *acutidentatum*, var. *frondosum* and var. *serrulatum*.

Introduction

As currently circumscribed, the New Zealand members of the cosmopolitan genus *Lepidium* comprise 10 indigenous species (Garnock-Jones 1988; Garnock-Jones and Norton 1995; Heenan et al. 2007). Recently, the New Zealand species have been the subject of ongoing research that has resulted in new circumscriptions of the inland species *L. sisymbrioides* Hook.f. and *L. solandri* Kirk (Heenan et al. 2007), as well as the publication of phylogenetic (Mitchell and Heenan 2000; Mummenhoff et al. 2004) and evolutionary studies (Dierschke et al. 2009). There are an additional 16 species naturalised in New Zealand (Garnock-Jones 1988; Webb et al. 1995; Howell and Sawyer 2006; Heenan and de Lange 2011), including species that have previously been assigned to *Coronopus* Zinn and *Cardaria* Desv. (Al-Shehbaz et al. 2002).

It has long been recognised that *Lepidium oleraceum* G.Forst ex Sparrm. is a widely distributed and rather variable coastal species (Kirk 1899; Cheeseman 1906, 1925; Allan 1961; Garnock-Jones 1988; Garnock-Jones and Norton 1995; de Lange et al. 2010a). As currently circumscribed, *L. oleraceum sensu lato* (s.l.) has a range encompassing the subtropical Kermadec Islands, the main islands of New Zealand (North, South and Stewart islands), Chatham Islands, and the subantarctic Antipodes, Snares and Auckland islands. Although the most recent treatment by Allan (1961) accepted one variable species, three additional named varieties of *L. oleraceum* were discussed: var. *acutidentatum* Kirk, var. *frondosum* Kirk, and var. *serrulatum* Thell. As Allan (1961) noted, the taxonomic status of these varieties has never been particularly clear, though it would seem that the large, bushy, broad-leaved form occurring on the Three Kings Islands and the northern part of North Island is referable to Kirk's var. *frondosum*, while plants with coarsely serrate and lanceolate leaves comprise his var. *acutidentatum*. *Lepidium oleraceum* var. *serrulatum* is known only from the type at the Paris Herbarium (P¹, Fig. 1), described by Thellung (1906) from a single collection made from 'New River, New Zealand' a place equated by Allan (1961) with the Riverton Estuary, Southland. The type is a plant with narrow and deeply serrated leaves; comparable forms have been occasionally gathered from the North and South islands.

Various authors have suggested that *L. oleraceum* s.l. requires further taxonomic study to resolve the variation that had been observed throughout its distributional range. In reference to the three varieties, Allan (1961, p. 177) concluded that they, along with *L. oleraceum*, "need much further study". Later, Given (1981) observed that such a study may now be impossible as *L. oleraceum* was in his view close to extinction and, because of this, many critical populations had by then been lost. In their paper describing *L. naufragorum* Garn.-Jones et D.A.Norton, Garnock-Jones and Norton (1995) discussed the variation of *L. oleraceum*, of which they felt that 'forms matching

named varieties can be recognised, [though] there is considerable variation (possibly clinal) present within *L. oleraceum*. A critical investigation of the whole complex, based on genetic as well as morphological analyses, is required before any taxonomic changes within this species are formalised'.

In this paper we present a taxonomic revision of *L. oleraceum* s.l. (hereafter referred to as the *Lepidium oleraceum* group), along with the allied species *L. banksii* Kirk, *L. flexicaule* Kirk, and the extinct *L. obtusatum* Kirk. This revision began in 1990 (de Lange 2010) and has involved the critical study of type specimens and herbarium material, extensive field work to examine natural variation of wild populations throughout their geographic range, supplemented with the use of DNA sequence data and, where possible, cultivating plants under uniform conditions. Although the current natural distribution of *L. oleraceum* group and its allies comprises small, highly fragmented populations that most probably represent only a small remnant of the original distribution, abundance, and morphological and genetic diversity of the species, sufficient populations remain to enable the taxonomic revision offered here.

In addition to revising the *L. oleraceum* group, we also treat *Lepidium naufragorum*. At the time of its formal naming *L. naufragorum* was regarded as having a relationship to *L. flexicaule* and the *L. oleraceum* group (Garnock-Jones and Norton 1995). It is now known to have no close relationship to these species (Mitchell and Heenan 2000; Heenan et al. 2007). Nevertheless we treat it here because of the recent discovery of some populations that have entire rather than pinnatifid rosette leaves, so necessitating a slight revision of the description provided by Garnock-Jones and Norton (1995).

Materials and methods

Plant collections and specimens

The taxonomic revision presented in this paper is based on the critical study of specimens and type material of *Lepidium banksii*, *L. flexicaule*, *L. obtusatum*, *L. oleraceum* group, and *L. naufragorum* held at the following herbaria AK, BM, CANU, CHR, HO, K, MEL, MPN, NSW, OTA, P, UNITEC, WAIK, WELT, and WELTU. Herbarium acronyms follow Thiers (2012). Live specimens of the northern South Island endemic *L. banksii* were studied in the field at Waimea Estuary (41°15'49.96"S, 173°6'5.09"E), Totaranui (40°48'53.32"S, 173°00'53.91"E) and Separation Point (40°46'57"S, 172°59'54.30"E). Plants of the indigenous *L. flexicaule* were examined in the wild in the North Island at Stent Road (39°9'46.72"S, 173°50'15.89"E), in the north-western South Island at Scott's Beach (41°5'27.95"S, 172°6'14.17"E), Punakaiki (42°5'19.95"S, 171°20'20.30"E) and, on Chatham Island (hereafter referred to as Rekohu) at Point Somes (43°50'18.73"S, 176°52'53.44"W). Plants of *Lepidium oleraceum* group were examined in the field on two islets of the Herald Islets (29°14'43.8"S, 177°51'25.9"W) in the northern group of the Kermadec Islands, and on Cheeseman Island (30°32'16.8"S, 178°34'1"W) and L'Esperance Rock (30°26'1"S, 178°54'W) in the southern Kermadec Islands group; on the Three Kings Islands (34°10'5.63"S, 172°5'40.94"E), Poor

Knights Islands (35°28'35.98"S, 174°44'22.27"E), Mokohinau Islands (35°54'23.93"S, 175°7'47.57"E), Ngatutura Point (Waikato) (37°31'5.31"S, 174°44'38.20"E), an unnamed islet near Banks Peninsula (43°53'46.26"S, 172°52'2.54"E), coastal Otago and Otago Peninsula (45°52'47.00"S, 170°37'56.97"E), islands off the coast of Stewart Island (46°51'38.92"S, 168°13'45.79"E), and throughout the Chatham Island group (43°55'58.38"S, 176°29'18.99"W). Additional observations, live plants and specimens of *L. oleraceum* group were also provided by J.W. Barkla and T.C. Greene from Macauley Island, Haszard Islet and Cheeseman Island in the Southern Kermadec Islands group; E.K. Cameron from West Island (part of the Three Kings Islands); by P. Sagar from North East Island, Snares Island group (47°59'49.23"S, 166°33'35.49"E); and J.W. Barkla and G. Loh from various sites around Otago. The late P.I. Knightbridge provided fresh material of *L. naufragorum* from Taumaka, Open Bay Islands (47°59'49.23"S, 166°33'35.49"E), and S. Walls provided live plants of *L. banksii* from Totaranui headland (40°48'53.32"S, 173°00'53.91"E) and Moutere Island (41°10'14.18"S, 173°2'11.28"E).

To this sampling were added further plants of *L. banksii*, *L. flexicaule*, *L. oleraceum* group and *L. naufragorum* collected by New Zealand botanists from a wide range of sites, and held by the Auckland Botanic Gardens, University of Auckland, Oratia Native Plant Nurseries, Motukarara Conservation Nursery and Landcare Research (Lincoln campus) to meet the *ex-situ* objectives of the Department of Conservation Coastal Cress Recovery Plan (Norton and de Lange 1999).

Molecular phylogenetics

In conjunction with the taxonomic revision of the *L. oleraceum* group and allied species, phylogenetic studies were carried out to determine relationships among the taxa, as well as to gain a better understanding of the population variation in extant populations of *Lepidium* species. For simplicity and clarity we use the new taxonomic names described here throughout the manuscript.

All taxa accepted in the revision presented here were included in the phylogenetic analyses as well as other closely related New Zealand and Australian taxa (Table 1) (Mummenhoff et al. 2004; Heenan et al. 2007). DNA sequence data (nrDNA (ITS1-5.8S-ITS2 and ETS), cpDNA (*trnL*-F spacer regions)) was obtained from 65 representatives of the *L. oleraceum* group and seven from the *L. sisymbrioides* group, which were used as outgroups (Mummenhoff et al. 2004). Not all DNA regions were amplified for each sample because it was difficult to access material. Only one species, the endemic and extinct *Lepidium amissum* de Lange & Heenan, described in this paper, was not included because three attempts failed to amplify DNA from the limited material available (three herbarium sheets > 100 years old). The phylogenetic relationship of both the *L. oleraceum* and *L. sisymbrioides* groups, and so the validity of using taxa from the *L. sisymbrioides* as outgroups, had already been established by Mummenhoff et al. (2004). Our sampling of the *L. oleraceum* group was intended to encompass the entire known range and extant variation within the species.

Total genomic DNA was extracted from 0.1–1.0 g of leaf tissue using a QIAGEN DNeasy® Plant Mini Kit or an INTRON Plant DNA kit using fresh material, fresh material stored in Silica Gel, and from herbarium specimens. DNA sequencing of nrDNA (ITS1-5.8S-ITS2 and ETS), and plastid DNA (*trnL*-F spacer regions) were carried out following the methods of White et al. (1990) and Mitchell and Heenan (2000) respectively.

PCR products were purified using either the Perfectprep PCR cleanup kits (Eppendorf), or diluted to approximately 1:4 with ultrapure water. Each sample was sequenced in the sense and antisense direction by the Centre for Gene Technology (University of Auckland), the Allan Wilson Centre Genome Service, (Massey University, Albany), or the Landcare Research Ecological Genetics Laboratory (Tamaki). Sequencing reactions were performed with the same primers as the PCR amplifications and the 3.1 ABI Prism™ Big Dye Terminator Sequencing Kit (Applied Biosystems, Scoresby, Vic.). Sequences obtained in this study have been assigned GenBank accession numbers (Table 1).

Matrix preparation

Sequence alignment was performed using ClustalX vers. 1.81 (Thompson et al. 1997). Multiple alignment parameters were set to 12 for gap opening penalty and 6.0 for gap extension penalty. No further alignment was required.

Maximum likelihood (ML) analyses were conducted using RaXML (Stamatakis 2006) employing the full search algorithm with Gamma Distribution and General time reversible (GTR) model. In each of the datasets support for nodes was assessed by non-parametric bootstrapping (Felsenstein 1985) using 1000 replicates. Because of the simple nature of the dataset, no further phylogenetic reconstruction was attempted. Bayesian reconstruction in Mr Bayes (Huelsenbeck and Ronquist 2001), and parsimony analysis (Swofford 2006) in Paup* were undertaken, but preliminary analyses yielded similar results (not shown).

Trees were drawn in Figtree version 1.3.1. (Rambault 2008) and labels follow those in Table 1.

Results

DNA sequence data

Phylogenetic analyses provided some resolution of relationships, with ETS the most informative (Fig. 2), resolving the *L. oleraceum* and *L. sisymbrioides* groups. Within the *L. oleraceum* group there is a strong north-south dichotomy, with another group present on the Chatham Islands and sub-Antarctic islands. The samples from the North Island comprised only *L. oleraceum sensu stricto* (*s.s.*), and the southern group included *L. aegrum* Heenan et de Lange from Banks Peninsula, *L. crassum* Heenan et de Lange from the Otago coast, *L. juvencum* Heenan et de Lange from Green Island and Long Beach Otago, *L. limenophylax* de Lange, B.D.Rance et D.A.Norton from the Snares Islands,

Table 1. Herbarium vouchers and GenBank numbers of *Lepidium* study group and outgroup samples used in the present investigation.

et Heenan from the Chatham Islands and *L. seditiosum* de Lange, Heenan & J.Rolfe from Bounty Island. ITS also resolved the *L. oleraceum* and *L. sisymbrioides* groups, but within ITS, there was no resolution within the *L. oleraceum* group including *L. banksii* (Fig. 3). The pattern for *trnL*-F was more complex (Fig. 4), and is discussed below, although it again provided no resolution within the *L. oleraceum* group and *L. banksii*.

ETS Sequence Characteristics and Phylogeny

Eighteen unique ETS sequences were present among the 65 *Lepidium* samples that were amplified for this region (58 from the *L. oleraceum* group and seven from the *L. sisymbrioides* group) (Fig. 2). Within the *L. sisymbrioides* group, the four samples of *L. sisymbrioides* all had different ETS ribotypes, and *L. naufragorum*, and *L. tenuicaule* Kirk also contained more than one ribotype. Within the *L. oleraceum* group, one described species, *L. flexicaule*, was found to contain more than one ETS ribotype, with the New Zealand and Tasmanian examples of this species differing by two base substitutions.

Two pairs of species (*L. rekohuense* and *L. seditiosum*; *L. oleraceum* and *L. banksii*) shared the same ETS type (Fig. 2). *Lepidium flexicaule* (Tasmanian sample), *L. foliosum* Desv. (Australian endemic) and *L. desvauxii* Thell. (Australia and New Zealand samples) also share identical ETS sequences, however New Zealand *L. flexicaule* have a different ETS type (Fig. 2). The three most southern / central South Island species, *L. crassum*, *L. aegrum* and *L. juvenum*, share an identical ETS type with *L. seditiosum* from the Bounty Islands, while *L. castellanum* from Macauley Island (Kermadec Islands group) is also similar, differing by only one base pair (Fig. 2).

There were three different ribotypes in *L. oleraceum* s.s., with a single sample from Mangere Island differing by a single base pair to the other *L. oleraceum* s.s. samples.

The extinct *Lepidium obtusatum* and morphologically rather different Chatham Islands endemic *L. panniforme* also share an ETS sequence type, which is almost identical to that of another Chatham Islands endemic, *L. oblitum* (Fig. 2). Notably, these three species also differ from the other Chatham Islands endemic, *L. rekohuense*, and the Chatham /Antipodes islands endemic, *L. oligodontum* (Fig. 2). *Lepidium limenophylax*, known from the southern Titi Island of the south-western coastline of Stewart Island, the Snares and Auckland Islands, is sister to these Chatham / Antipodes islands species (i.e., *L. oblitum*, *L. oligodontum*, *L. panniforme*, and *L. rekohuense*) (Fig. 2).

This study also confirms the taxonomic status of the Lord Howe Island endemic, *L. nesophilum* Hewson, which is a species that had previously been treated as *L. oleraceum* (see Green 1990).

ITS sequence characteristics and phylogeny

The 56 samples of *Lepidium* from which ITS data were collated (48 *L. oleraceum* group, 6 *L. sisymbrioides* group) are shown in Fig. 3. With the exception of *L. limenophylax*, all of the other species within the *L. oleraceum* group, including *L. banksii* and the Chatham Island sample of *L. flexicaule*, shared the same ITS sequence (Fig. 3).

The New Zealand (Karamea) sample of *L. flexicaule* grouped with Australian samples from which it differed by a single base pair (Fig. 3). In addition, the two Lord Howe samples of *L. nesophilum*, had markedly different ITS sequences, though, notably, they clustered with other Australian species and shared an identical ETS sequence.

trnL-F sequence characteristics and phylogeny

The plastid data (*trnL-F* spacer region, 30 *L. oleraceum* group, 7 *L. sisymbrioides* group included) is interesting for the lack of strong divergence between the *oleraceum* and *sisymbrioides* groups, with two species (*L. sisymbrioides* and *L. naufragorum*) being found in both clades (Fig. 4); see Heenan et al. (2007) for discussion on sequence variation in *L. naufragorum* and *L. sisymbrioides*. This conflict could be explained by hybridisation between representatives of each of the two groups. With the exception of *L. limenophyllax* (which differed by one base pair), all of the species previously described in the *L. oleraceum* group shared the same *trnL-F* sequence (Fig. 4).

Although the *trnL-F* spacer region showed only low sequence variation, several patterns were evident. For example, the morphologically distinctive species *L. nau-*

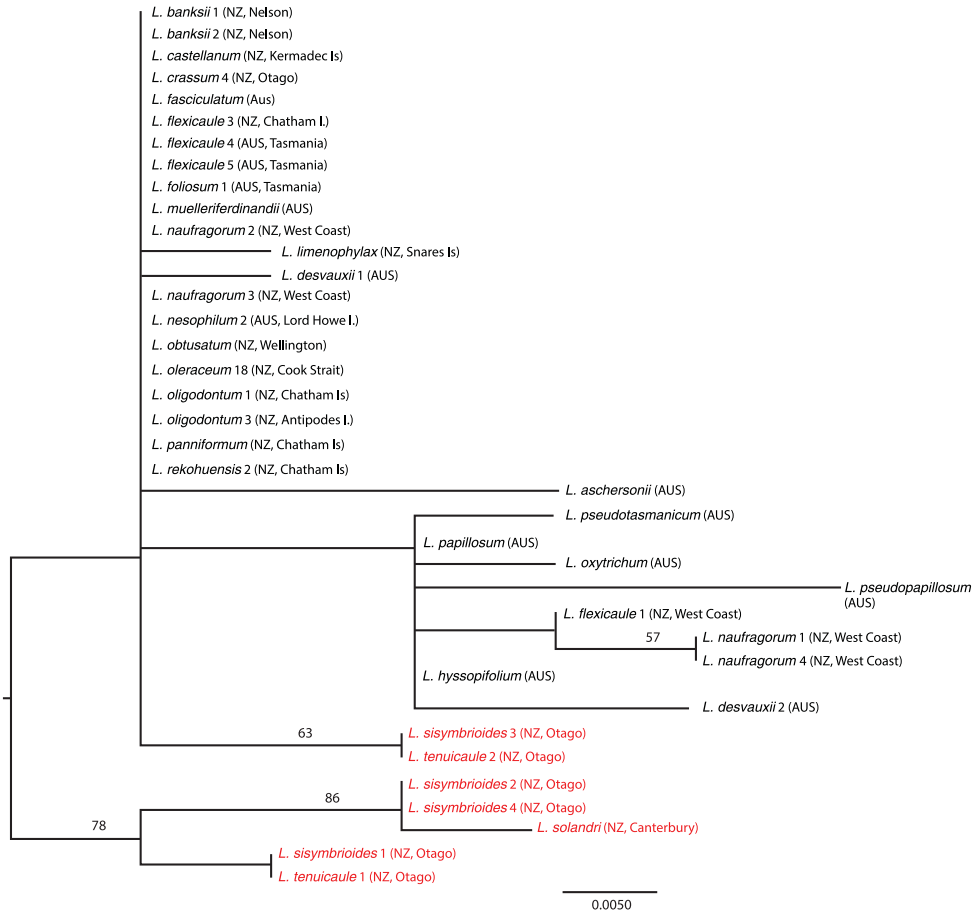

Figure 4. Maximum likelihood phylogeny of *trnL-F* as calculated in RaXML, showing the *Lepidium oleraceum* (black text) and *L. sisymbrioides* (red text) groups, including the newly described taxa. Bootstrap support from 1000 replicates is shown for branches where it is greater than 50. Codes for each individual in the phylogeny are shown in Table 1.

fragorum (New Zealand), *L. flexicaule* (Australia + New Zealand), *L. muelleri-ferdinandi* Thell. (Australia), *L. fasciculatum* Thell. (Australia) and *L. oleraceum* (Kermadec Islands and New Zealand) had identical sequences (Fig. 4), a pattern that suggests a recent origin for these taxa. Further, the two New Zealand samples of *L. flexicaule* (South Island (Karamea) and Chatham Islands) have distinct *trnL-F* sequences (Fig. 4). Morphologically, the Chatham Island race of *L. flexicaule* differs from the majority of New Zealand (North Island and South Island) *L. flexicaule* plants in that they lack the marginal leaf, pedicel and stem denticles that are diagnostic of the species on mainland New Zealand (see Garnock-Jones 1988). Interestingly, the Australian (Tasmanian) samples of *L. flexicaule* had the same *trnL-F* sequence as the Chatham Islands, and they too lack denticles. However, our study has found that, while denticles are usual for New Zealand (North Island, South Island) examples of this species, not all plants from western South Island have them, and, as we have not sequenced examples of these “non-denticulate” plants, further study into this pattern is warranted. The pattern is reversed for the ITS data set, in which the South Island (Karamea) sample of *L. flexicaule* clusters with Australian *L. flexicaule* (Fig. 3).

Phylogenetic implications

Bootstrap support for the trees was low to moderate, as would be expected for recently diverged taxa where resolution and divergence is low and where there has possibly been recent reticulation. An earlier study has indicated that hybridisation, and biocontinental origin for the New Zealand / Australian *Lepidium* is likely, although the age of this event and whether it is related to the divergence from the rest of the *Lepidium* group is unclear (Mummenhoff et al. 2004). Estimates for times of divergence vary between the *L. oleraceum* and *L. sisymbrioides* groups (0.7–1.3 Myr and 0.3–0.55 Myr respectively; Mummenhoff et al. 2004), although further hybridisation events and potential multiple dispersal events make accurate inference difficult. However, as noted by Mitchell and Heenan (2000), there was good support in the rDNA data for the *L. oleraceum* and *L. sisymbrioides* groups, though this was not found in the cpDNA dataset.

Lepidium naufragorum was found in the *L. oleraceum* clade for the plastid data, but is a member of the *L. sisymbrioides* group for both nuclear regions. This incongruence suggests that *L. naufragorum* could have had a hybrid origin, with a parent from each of these groups (see in this respect also Mummenhoff et al. 2004). Although further study is required to address this issue, shared DNA sequences are common within New Zealand taxa. They have usually been interpreted as evidence of genera that have undergone a recent and rapid species radiation (e.g. Wagstaff et al. 1999 (for *Carmichaelia* R.Br.), Wagstaff et al. 2004 (for *Brachyglottis* J.R.Forst. et G.Forst.), Mitchell and Heenan 2002 (for *Sophora* L.), de Lange et al. 2008 (for *Crassula* L.), de Lange et al. 2010b (for *Kunzea* Rchb.), Smissen et al. 2011 (for *Simplicia* Kirk), Prebble et al. 2012 (for *Wahlenbergia* Schrad.)). This explanation is also most likely for the shared ETS

ribotypes between *L. rekohuense* and *L. seditiosum*; and *L. oleraceum* and *L. banksii*, which also show this pattern.

In general, the *L. oleraceum* and *L. sisymbrioides* groups formed two distinct clades in both nuclear datasets, but was not strongly supported by the plastid data, as was found by Mummenhoff et al. (2004). Significantly for this study, the three DNA data sets confirm that those informally recognised morphological units within the *L. oleraceum* group (see de Lange 2010; de Lange et al. 2010a) warrant formal taxonomic recognition. This is especially evident when, in our study, such morphologically discrete taxa as *L. banksii* (Garnock-Jones 1988) proved indistinguishable from the very different *L. oleraceum* s.s based on the rDNA and cpDNA sequences used here. That such a distinct species is not distinguished using this data also further supports the idea that much of the New Zealand Flora is in a state of rapid speciation (see above references), and that the reliance of DNA data sets, in isolation, to resolve taxonomic uncertainty is fraught with difficulty. In the case of the sequence data presented here. We conclude that the retention of a single morphologically divergent species, *L. oleraceum* is unacceptable, and that formal taxonomic segregation within the group, at species level is warranted.

Characters

Growth habit

Lepidium oleraceum s.s., its allied species, and the unrelated *L. naufragorum* are all perennial herbs that can be distinguished by their growth habit. This includes plants with an upright, spreading or sprawling, shrubby growth habit (*L. castellanum*, *L. aegrum*, *L. banksii*, *L. crassum*, *L. juvencum*, *L. oleraceum*, *L. panniforme* and *L. seditiosum*) and those with a prostrate or decumbent growth habit (*L. amissum*, *L. flexicaule*, *L. limenophylax*, *L. oblitum*, *L. obtusatum*, *L. oligodontum*, and *L. rekohuense*). *Lepidium obtusatum* is, as discussed by Cockayne (1921), further distinguished from all other members of the *L. oleraceum* group by its uniquely suckering habit. A further separation, based on seasonal growth patterns, is also evident, i.e., whether plants die back to the rootstock or not during winter. Of the extant species, *L. castellanum*, *L. aegrum*, *L. juvencum*, and *L. oleraceum* have persistent stems that do not die back to a rootstock; *L. oblitum* and *L. panniforme* stems are usually long-persistent, though sometimes they die back to a basal rootstock. The remaining extant species all have stems that die back to their rootstock. Herbarium evidence indicates that the extinct *L. obtusatum* also died back in winter but there are insufficient herbarium specimens and no written accounts to enable us to determine whether the extinct segregate *L. amissum* did so as well. Unique amongst the *L. oleraceum* group, well-developed plants of *L. limenophylax* may develop prominent “swellings” around branch nodes; these may also be a point of seasonal die back and vegetative growth and they sometimes produce adventitious roots.

Leaf characters

The leaves of *Lepidium oleraceum* and allied species show a diversity of shape and degree of dentition that has been the basis for the recognition of a number of species and varieties (see Kirk 1899; Thellung 1906). Lamina-shape immediately distinguishes the pinnatifid *Lepidium flexicaule* from the other members of the *L. oleraceum* group but not from the pinnatifid-leaved forms of the unrelated *L. naufragorum*. Among the remaining members of the *L. oleraceum* group, lamina size, shape, and degree of dentition provide important differences between the species (Figs 5, 6).

Floral and fruit characters

The inflorescences, flowers and fruits of the *Lepidium oleraceum* group provide a number of characters enabling species recognition. The inflorescences of the species in the group are usually leaf-opposed. While in some species (*L. flexicaule* and *L. obtusatum*) the inflorescences tend to be obscured by foliage, they are held well above the surrounding foliage in the majority of species. In most species the inflorescence rachises and pedicels are glabrous, but in *L. castellanum*, *L. banksii*, *L. rekohuense*, *L. seditiosum*, (and very rarely *L. oblitum*), minute, usually sparse, eglandular, clavate hairs are present. The sepals and petals show little variation with respect to size, shape, and degree of investiture. The size, shape and degree of notching of the silicles, and the length and shape of the stigma remnant are also critical characters (see Garnock-Jones 1988).

Stamen number of the *Lepidium oleraceum* group varies between species with two (*L. flexicaule*, *L. limenophylax* and *L. rekohuense*), those with four (*L. castellanum*, *L. aegrum*, *L. amissum*, *L. juvenum*, *L. banksii*, *L. crassum*, *L. juvenum*, *L. naufragorum*, *L. obtusatum*, *L. oleraceum*, and *L. seditiosum*), to those with variable stamen numbers (*L. oblitum*, *L. panniforme*, and *L. oligodontum*). In these three species, stamen numbers may vary from two to four (*L. oblitum*, *L. panniforme*) to a maximum of six in *L. oligodontum*, often within the same inflorescence, or on different individuals of the same species.

Silicle shape (Table 1, Figs 7, 8) varies and comprises four main shapes: 1. Silicles mostly elliptic to elliptic-rhomboid (rarely orbicular-rhomboid) (*L. castellanum*, *L. aegrum*, *L. juvenum*, *L. limenophylax*, *L. naufragorum*, *L. oleraceum*); 2. Silicles orbicular-rhomboid only (*L. crassum*, *L. juvenum*); 3. Silicles mostly ovate (ovoid), oval to obovate (*L. amissum*, *L. banksii*, *L. oblitum*, *L. obtusatum*, *L. panniforme*); and, 4. Silicles mostly orbicular (rarely ovoid, obovate) (*L. flexicaule*, *L. oligodontum*, *L. rekohuense*). The silicles of *L. panniforme* can vary from ovate (the usual state) through to elliptic-rhomboid. With respect to silicle size, *L. obtusatum* has the largest silicles (up to 6.4 × 4.9 mm) and both *L. limenophylax* and *L. panniforme* the smallest (up to 3.5 × 3.3 mm) (Table 1). Although silicle characters are unavailable for *L. seditiosum*, of which we have only

Figure 5. Cauline leaves of (A) *L. aegrum*, (B) *L. banksii*, (C) *L. castellanum*, (D) *L. crassum*, (E) *L. juvenicum*, (F) *L. oblitum*, (G) *L. obtusatum*, (H) *L. oleraceum*. Scale bars = 20 mm.

a single immature fruiting specimen, the few immature silicles present indicate that, as with all the other members of the *L. oleraceum* group, the two valves are dehiscent (see *Lepidium* key).

Figure 6. Cauline leaves of (A) *L. oligodontum*—variation within a single plant, (B) *L. oligodontum* - variation amongst plants from different locations: (left to right) The Sisters, Western Reef, Point Somes, Moriori Creek, Star Keys, Rangatira Island, Antipodes Island. (C) *L. panniforme*, (D) *L. rekohuense*. Scale bars = 20 mm.

The presence or absence of an apical notch to the silicle in the New Zealand species was an important character emphasised by Kirk (1899), Cheeseman (1906, 1925), Allan (1961), and Garnock-Jones (1988). In all these treatments the lack of a notch in *Lepidium oleraceum* is noted, and a silicle of that species showing this is clearly illustrated by Garnock-Jones (1988). This is a significant observation, because, of the new species segregated here from *L. oleraceum* s.s. a shallow apical notch is present in eight species (though minute and so scarcely evident in *L. aegrum*, *L. limenophylax*, *L. juvencum* and *L. rekohuense*), absent in two (*L. castellanum* and *L. oleraceum*), and unknown for *L. seditiosum* (see above comments). We also stress that care is needed to observe the presence or absence of a notch. It is best seen in freshly matured silicles because, in older, over mature silicles, the apically initiated disarticulation of the valves can be misleading as it gives the false impression of a notch. Notching was noted by past workers (Kirk 1899; Cheeseman 1906, 1925; Allan 1961; Garnock-Jones 1988) as being especially prominent in *L. banksii* and *L. obtusatum*, as it also is in the new species *L. amissum* (which is segregated here from *L. obtusatum*) and *L. oblitum*. It is odd, therefore, that despite the prominence of the notch in *L. banksii*, Kirk (1899) in his dichotomous key emphasised the cordate silicle base rather than apical notch as diagnostic of *L. banksii* and he did not mention it in his key for *L. obtusatum*. In fact cordate silicle bases are not

Figure 7. Silicles of (A) *L. aegrum*, (B) *L. amissum*, (C) *L. banksii*, (D) *L. castellanum*, (E) *L. crassum*, (F) *L. flexicaule*, (G) *L. juvenum*, (H) *L. limenophylax*. Scale bars = 1 mm.

unique to *L. banksii* as they are also present in *L. oligodontum*. Silicle wings that occur around the margin of the silicle are also important. Of the 16 species for which mature silicles are available, ten have slightly winged silicles and six species (*L. castellanum*, *L. aegrum*, *L. juvenum*, *L. crassum*, *L. juvenum*, *L. oleraceum*) do not.

BRASSICACEAE

Figure 9. Holotype of *Lepidium aegrum* Heenan & de Lange.

Figure 10. *Lepidium aegrum* plant in the wild showing usual growth habit (*Lepidium aegrum* growing in association with *Disphyma australe* subsp. *australe*) amongst petrel burrows).

Etymology. The specific epithet ‘*aegrum*’ is derived from Latin, meaning ‘diseased and/or sick body’ and refers to the condition of the plants in the single known extant wild population on the unnamed rock stack near Island Bay, many of which are infected with turnip mosaic virus (Fletcher et al. 2009).

Description (Figs 10–14). Tap-rooted, strongly pungent smelling, perennial herb. Growth habit open, up to 50 cm tall, stems arising from basal woody stems. Stems upright, slender, flexible; mature stems woody, 100–500 × 10–12 mm, often devoid of foliage on middle and lower parts of stems; new stems 80–200 × 3–4 mm, leafy, glabrous. Leaves glabrous, membranous, light green, planar, pellucid glands sometimes scattered on abaxial surface, rosette and stem leaves usually withering, variable in size and shape. Leaves of young and vigorous plants and stems: lamina 35–80 × 10–20 mm, lanceolate, elliptic-lanceolate, narrowly elliptic; apex subacute, with a single prominent tooth; margin singly serrate, with 8–12 pairs of teeth; teeth up to 3.5 mm deep, not overlapping; base attenuate, tapering to distinct petiole. Leaves of mature plants and cauline stems: lamina 30–65 × 4–11 mm, narrowly lanceolate, elliptic-lanceolate, narrowly elliptic; apex acute to subacute, with a single prominent tooth; margin singly serrate in upper and/or lower half, with 2–10 pairs of teeth; teeth up to 1.2 mm deep, not overlapping; base attenuate, tapering to petiole. Inflorescence terminal and lateral, racemose, often branched, up to 95 mm long, rachis up to 2.1 mm diam., glabrous;

Figure 11. *Lepidium aegrum* stem showing four inflorescences. Scale bar = 20 mm.

Figure 12. *Lepidium aegrum* leafy stems showing mid-stem and apical foliage. Scale bar = 20 mm.

pedicels 4–10 mm long, erecto-patent, glabrous. Flowers 4.0–4.5 mm diam. Sepals 4, 1.0–1.5 mm long, saccate, green, apex obtuse, margin white, shape dimorphic; lateral sepals broad, 1.0–1.1 mm diam., orbicular, abaxial surface often hairy, hairs entirely eglandular or with glandular tip, 0.2–0.3 mm long; median sepals narrow, 0.8–0.9 mm diam., broadly elliptic, glabrous. Petals white, 2.3–2.5 × 1.2–1.4 mm, spreading, claw 0.7–0.9 mm long; limb broadly elliptic to orbicular, apex obtuse to rounded. Stamens 4; filaments 1.7–2.0 mm long, base 0.3–0.4 mm diam., equal; anthers 0.4–0.5 mm long. Ovary 0.9–1.0 × 0.9–1.0 mm, broadly ovate to broadly elliptic, green, apex usually with shoulders; style 0.3–0.4 mm long, cylindrical; stigma 0.3–0.4 mm diam. Nectaries 4, 0.2–0.3 × c. 0.1 mm, oblong, green. Silicles cartilaginous when fresh, coriaceous when dry, 4.0–4.7 × 3.2–3.5 mm, elliptic-rhomboid to orbicular-rhomboid, apex shallowly notched, valves pale brown, glabrous, not winged; style 0.3–0.4 mm long, exserted. Seeds 1.6–1.7 × 0.9–1.0 mm, narrowly ovoid, brown to orange-brown, not winged. FL Mar. FR Mar.

Representative Specimens. New Zealand (South Island): Banks Peninsula, Waikerikeri, n.d., R. M. Laing s.n., (AK 4463); Banks Peninsula, Akaroa, Akaroa Head, Island Bay, Unnamed Islet, July 2002, N. Head s.n., AK 283510. **Cultivated (New Zealand):** Landcare Research experimental nursery, Lincoln, ex Akaroa, Akaroa Head, Island Bay, Unnamed Islet, 5 September 2008, P. J. de Lange 7363 & G. Houliston, (AK 303515); Landcare Research experimental nursery, Lincoln, ex Island Bay, Banks Peninsula, 13 January 2010, P. B. Distribution (Fig. 15). Endemic. New Zealand, South Island, Canterbury, Banks Peninsula, Island Bay, unnamed rock stack.

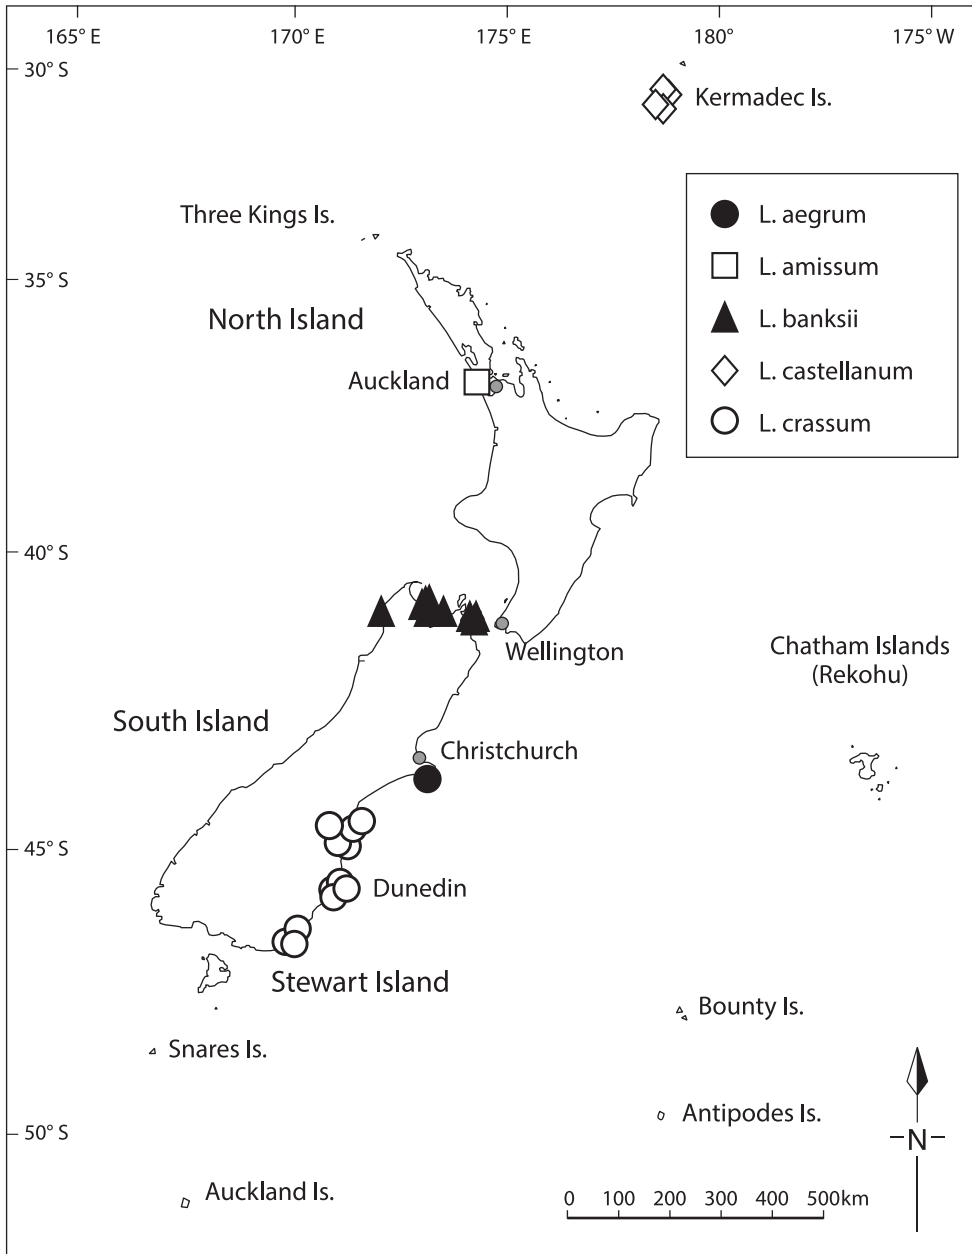

Figure 15. Distribution of *Lepidium aegrum*, *L. amisum*, *L. castellanum* (Kermadec Islands only), *L. banksii*, and *L. crassum*.

Ecology. Known from a single wild population on a small and unnamed island near Island Bay. Here it grows in open and disturbed areas among petrel burrows and *Disphyma australe* (W.I.Aiton) N.E.Br. subsp. *australe* (Fig. 6). Additional populations of *L. aegrum* have been established in Canterbury on

Motunau Island (Pegasus Bay), Quail Island (Lyttleton Harbour), and at Stony Bay (Banks Peninsula).

Recognition. *Lepidium aegrum* is distinguished by its slender flexible stems (Figs 11, 12), light green membranous leaves that are lanceolate, elliptic-lanceolate or narrowly elliptic with a prominent acute to subacute apex, and margins that are serrate with prominent and deep teeth (Fig. 13).

Conservation Status. *Lepidium aegrum* is known from a single wild population and three additional populations that have been established with nursery-raised plants. The single wild population and unknown recruitment patterns means that this species is especially vulnerable to stochastic events. Furthermore, turnip mosaic virus, which deforms and retards growth, is common in plants at the wild population, and this will likely reduce reproductive success (Fletcher et al. 2009). Using the New Zealand Threat Classification System (Townsend et al. 2008), *L. aegrum* qualifies as Threatened/Nationally Critical. We recommend appending the qualifiers 'CD' (Conservation Dependent – as it has been established and is being managed at Motunau and Quail islands, and at Stony Bay), 'DP' (Data Poor – to reflect uncertainty over plant numbers and population trends), 'OL' (One location – since it is known from a single wild population).

***Lepidium amissum* de Lange & Heenan, sp. nov.**

urn:lsid:ipni.org:names:77129254-1

http://species-id.net/wiki/Lepidium_amissum

A L. obtusato habitu suberecto parce ramoso et sine rhizome, caulibus arcutis potius quam flexuosis, foliis rosulae et caulis inferi profunde denticutis persistente oblanceolato-spathulatis ad obovato-spathulatis, foliis caulis superi sparsis lanceolatis ad anguste oblanceolatis vel obdetoideis truncatis et profunde dentatis (raro integris) paribus dentorum usque ad 6 profunde incisae et sparsim foliaceis, racemis longioribus quibus non obscuris caulibus vegetativis silicisque parvioribus et angustioribus differt.

Holotype. New Zealand (Fig. 16): Cliffs between Karekare and Manukau Heads, January 1917, T. F. Cheeseman s.n., AK 4474! Isotypes: AK 206570!, WELT SP030095!

Etymology. The epithet '*amissum*' is derived from the Latin '*amissus*' meaning 'lost' and is used here to refer to the loss through extinction, of this plant from the New Zealand flora.

Description (Figs 17–20). Glabrous, suberect, sparingly branched, succulent, perennial, herb forming open patches up to c. 1 m diam. Rootstock stout, woody, exposed portion rough, covered in old dead stem and rosette-leaf remnants admixed with actively growing stems. Stems arching, widely spreading, possibly with apices weakly ascendent, succulent, mature stems woody, 200–300 × 3–6 mm, densely leafy near base, leaves more widely spaced along upper stems. Leaves glabrous, coriaceous, probably succulent, dark green, planar, variable size and shape. Rosette leaves persistent at fruiting 71.7–95.2 × 12.4–23.2 mm, oblanceolate-spathulate to obovate-

Figure 16. Holotype of *Lepidium amissum* de Lange & Heenan.

Figure 17. Basal stem leaves of *Lepidium amissum*. AK 4473

spathulate; apex, truncate, praemorse, with 3–8 deeply incised teeth; margin coarsely and often irregularly incised or dentate, often weakly bidentate, with 24–36 pairs of teeth; teeth up to 4.8 mm deep, irregular in size, protruding beyond leaf outline; base narrowly attenuate to cuneate, \pm decurrent, petiole distinct, $43.4\text{--}55.2 \times 1.4\text{--}2.3$ mm long, slightly winged, or not, channelled. Lower stem leaves similar to rosette leaves, apparently persistent, widely spaced, gradually decreasing in size toward inflorescence; petioles distinct, slightly winged or not. Upper stem leaves much reduced; lamina $10.3\text{--}27.5 \times 3.4\text{--}7.6$ mm, lanceolate, narrowly oblanceolate, lanceolate to narrowly

obdeltoid, apex truncate, with 3–4 prominent teeth, margins prominently toothed in upper $\frac{1}{3}$ of lamina with 4–6 deeply incised pairs of teeth (rarely entire except for apex), base cuneate to broadly cuneate; petiole distinct or indistinct, up to 6 mm long when present, channelled. Inflorescence racemose, terminal and lateral, conspicuous, sparingly leafy and unfettered by associated vegetative leafy stems; racemes 22–68 mm long, rachis 0.9–1.6 mm diam., glabrous; pedicels 2.8–3.2 mm long at flowering, erecto-patent, elongating somewhat after anthesis, glabrous. Flowers 4.3–4.6 mm diam. Sepals 4, saccate, overlapping at base, green, apex obtuse, margin white, shape and size dimorphic; lateral sepals 2.2–2.9 \times 2.1–3.0 mm, suborbicular, mostly glabrous, sometimes sparsely hairy, hairs 0.2–0.4 mm long, caducous; median sepals 1.9–2.9 \times 1.5–1.7 mm, broadly elliptic to obovate, abaxial surface glabrescent, sparsely hairy, hairs 0.2–0.4 mm long, caducous. Petals white, 1.3–1.8 \times 1.3–1.8 mm, erect, claw minute, 0.2–0.3 mm; limb orbicular, apex obtuse. Stamens 4, \pm equal lengths, 1.2–1.8 mm long, base 0.6–1.0 mm wide; anthers 0.6–0.8 mm long, yellow, pollen yellow. Ovary 1.3–1.8 \times 1.3–1.7 mm, broadly ovate to suborbicular green, apex distinctly notched; style 0.3–0.5 mm long, cylindrical below, spreading at apex; stigma 0.5–0.6 mm diam. Nectaries 4, green, 0.12–0.14 \times c. 0.09 mm, narrow oblong, apex obtuse. Silicles 3.4–4.5 \times 2.9–3.9 mm, broadly ovate, oval to obovate, apex prominently notched, valves yellow-green (in dried specimens), glabrous, slightly winged; style 0.2–0.5 mm long, not or only slightly exerted. Seeds 2.0–2.7 \times 1.8–2.0 mm, obovate, broadly obovate, brown to orange-brown, not winged. FL: Dec–Jan. FR: Dec–Jan.

Representative Specimen. New Zealand (North Island): North Auckland, Cliffs north of the Manukau heads, December 1870, T. F. Cheeseman s.n., (AK 4473).

Distribution (Fig. 15). Endemic. New Zealand, North Island, where it was recorded from ‘between Manukau Heads and Karekare’ (Cheeseman 1906, 1925), not

Figure 18. Basal stem leaf of *Lepidium amissum*. AK 4473.

the ‘Titirangi’ noted by Kirk (1899). *Lepidium amissum* was last collected from the west Auckland coastline in 1917 and is presumed to be extinct.

Recognition. *Lepidium amissum* had previously been included in *L. obtusatum*, perhaps because the species have no obvious floral differences and both have deeply notched and winged silicles with tapering bases. However, from *Lepidium obtusatum*, *L. amissum* differs by the non-rhizomatous, suberect growth habit; arching, sparingly leafy stems (Fig. 16); long persistent, deeply, and sharply incised rosette and lower stem leaves (Figs 17, 18); upper stem leaves which are lanceolate, narrowly oblanceolate, to narrowly obdeltoid and mostly prominently toothed, with up to 6 pairs of deeply incised teeth, and with a truncate apex bearing 3–4 prominent teeth. The inflorescences of *L. amissum* are larger, only sparsely leafy when mature, and without associated vegetative stems (Fig. 19). The silicles are smaller than those of *L. obtusatum* (Fig. 20).

Figure 19. Upper-stem leaves and inflorescences of *Lepidium amissum*. AK 4473.

Figure 20. Mature silicle of *Lepidium amissum*. AK 4473. Scale bar = 1 mm.

Ecology. Little is known about the habitat preferences and ecology of *L. amissum*, beyond that it grew on sea cliffs (Cheeseman 1906, 1925).

Conservation Status. *Lepidium amissum* is considered to be extinct. There have been repeated unsuccessful surveys for this species over the last fifty years by various botanists. Aside from the type the species is known from only one collection made in 1917. This collection and the type came from an ill defined area of coastline stretching for some 6 km from the Manukau Heads to Karekare. Today this coastline is protected within the Centennial Park, Waitakere Ranges. However, during the period when this species was gathered, all of the coastline was being modified as a result of kauri (*Agathis australis* (D. Don) Lindl.) logging (see Harvey 2001, 2006; MacDonald and Kerr 2009), and this may have contributed to its eventual extirpation. It does seem that *L. amissum* was already uncommon at the time of its discovery and it is possible that the gatherings made by Thomas Cheeseman were sufficient to cause its extinction as they are copious and comprise many stems.

***Lepidium banksii* Kirk, *Stud. Fl. N. Z.*, 35 (1899)**

http://species-id.net/wiki/Lepidium_banksii

Type Collection: “SOUTH Island: Queen Charlotte Sound and Astrolabe Harbour, A. Richard, l.c.”

Lectotype (Fig. 21, designated here): Herbarium Richard, Paris!

Etymology. Although Kirk (1899) did not explain his choice of epithet, ‘*banksii*’ commemorates Sir Joseph Banks FLS, FRS (1743–1820) who together with Dr Daniel Solander made the first gatherings of New Zealand plants to be described by European botanists during the Endeavour voyage of discovery (1768–1771).

= *Lepidium banksii* var. *ovatum* Kirk, *Stud. Fl. N. Z.*, 35 (1899)

Lectotype (*vide* Allan 1961): Northwest Bay, Pelorus Sound, J. Rutland s.n., n.d., WELT SP079012!

Etymology. Although Kirk (1899) did not explain his choice of epithet, the protologue makes it clear that “*ovatum*” was chosen to refer to the shape of the mature silicles.

Note: The key provided by Kirk (1899, p. 34) used the name “*L. forsteri*” instead of *L. banksii*. This is considered to be a nomen nudum.

Description (Figs 22–25). Tap-rooted, strongly pungent smelling, perennial herb. Growth habit dense, stems closely placed, 20–50 cm tall. Stems upright to spreading, stout, barely flexuous; mature stems woody, 100–500 × 3–8 mm, often devoid of foliage on middle and lower parts of stems. Leaves glabrous, coriaceous, green, planar, rosette and stem leaves usually withering, variable in size and shape. Leaves of young and vigorous plants and stems: lamina 20–40 × 6–15 mm, oblanceolate-spathulate, obovate; apex obtuse, often with up to 3 or 4 teeth; margin coarsely serrate, with 15–21 pairs of teeth; teeth up to 2.0 mm deep, irregular in size, protruding beyond leaf outline; base attenuate to cuneate, petiole distinct; petiole up to 35.0 × 1.3–2.8 mm, channelled. Leaves of mature plants and cauline stems: lamina 8–25 × 3–6 mm, linear-oblanceolate, obovate; apex obtuse to truncate, often with up to 3 or 4 teeth; margin serrate in upper half, up to 7 pairs of teeth; not overlapping, up to 1.5 mm deep, often protruding beyond leaf outline; base attenuate to cuneate, usually tapering to ± distinct petiole, sometimes appearing sessile; petiole up to 8.0 × 1.0–1.8 mm, channelled. Inflorescences terminal and lateral, racemose, 20–80 mm long, rachis 0.6–1.4 mm diam., glabrous or sometimes with pale clavate hairs; pedicels 5–8 mm long, erectopatent, with pale clavate hairs on adaxial surface, hairs 0.1–0.15 mm long. Flowers 4.0–4.5 mm diam. Sepals 4, saccate, overlapping at base, green, apex obtuse, margin white, shape and size dimorphic; lateral sepals 1.6–2.1 × 1.1–1.5 mm, orbicular, glabrous; median sepals 1.5–1.9 × 0.9–1.1 mm, broadly elliptic, abaxial surface glabrous or sparsely hairy, hairs 0.2–0.4 mm long. Petals white, 1.8–2.0 × 0.1–0.9 mm, erect, claw indistinct; limb narrowly obovate, elliptic or filiform, often irregular in shape, apex obtuse to subacute. Stamens 4, ± equal lengths, 1.2–1.7 mm long, base 0.6–0.9 mm wide; anthers 0.4–0.7 mm long, yellow or sometimes violet. Ovary 1.4–1.6 × 1.0–1.6 mm, broadly ovate, green, apex round or sometimes weakly shouldered; style 0.2–0.3 mm long, cylindrical below, spreading at apex; stigma 0.45–0.5 mm diam. Nectaries 4, 0.2–0.4 × c. 0.1 mm, oblong, green. Silicles cartilaginous when fresh, coriaceous when dry, 4.5–5.5 × 4.0–5.0 mm, broadly ovate, apex notched, base cordate, valves green maturing yellow-green, glabrous, slightly winged; style 0.2–0.3 mm long, exserted. Seeds 1.8–2.3 × 1.0–1.2 mm, obovate or obovate-elliptic, brown to orange-brown, not winged. FL Nov–Jan. FR Nov–Jan.

J. de Lange 3249 & G. M. Crowcroft, (AK 231008); Karamea, 28 January 1985, P. Wardle s.n., (CHR 446772); Bird Island, Waimea Estuary, 1946, C. Baas s.n., (CHR 278958). **Cultivated (New Zealand).** Landcare Research experimental nursery, Lincoln, ex Totaranui, Nelson, 17 November 2005, P. B. Heenan s.n., (CHR 504666); Landcare Research experimental nursery, Lincoln, ex Abel Tasman National Park, 6 August 2006, P. B. Heenan s.n., (CHR 609830).

Distribution (Fig. 15). Endemic. New Zealand, South Island, Marlborough Sounds (Queen Charlotte, Kenepuru and Pelorus Sounds), Nelson (Waimea Estuary, Totaranui, Separation Point, Wainui Inlet), north-west Nelson (Karamea).

Recognition. *Lepidium banksii* is recognised by the clavate hairs on the pedicels (Fig. 24A), mostly filiform petals, styles that spread at the apex into a broad plate (Fig. 24B), and silicles that have a prominent apical notch (Fig. 25). In comparison, the styles of the other *Lepidium* species except for *L. seditiosum*, are cylindrical for their whole length.

Ecology. *Lepidium banksii* is a strictly coastal species favouring rubble slopes, boulder beaches, exposed rocky headlands (Fig. 22), and sparsely vegetated cliff faces

usually near penguin colonies or low lying, estuarine shell banks and sand and shell barrier islands used as high tide roosts by wading birds.

Conservation Status. *Lepidium banksii* is currently listed as ‘Threatened/Nationally Critical_{CD, EF}’ by de Lange et al. (2009). Both de Lange (2006) and Courtney (2009) describe the conservation management of this species, noting that there are probably no naturally occurring plants of *L. banksii* left in the wild, with all those known the result of deliberate plantings and sowing of seed. As such, the qualifier ‘EW’ (Extinct in Wild) should be added to the current threat listing. The most recent census of the numbers of *L. banksii* present in the ‘wild’ records 113 plants (Courtney 2009). Survival of this species is now completely dependent on direct hands-on management (de Lange 2006; Courtney 2009).

***Lepidium castellanum* de Lange & Heenan, sp. nov.**

urn:lsid:ipni.org:names:77129255-1

http://species-id.net/wiki/Lepidium_castellanum

A Lepidio oleraceo sympatrico sed foliis in caule medio ad supero anguste lanceolatis ad linearo-lanceolatis dentibus acicularibus, apicibus foliorum decrescento-acuminatis, et pedicellis minutis et sparsim puberuli differt, et sequentia nucleotidorum DNA distinguenda.

Holotype. Kermadec Islands (Fig. 26): Macauley Island, north-east coast, 3 July 2006, J. W. Barkla M29 & T. C. Greene, AK 297694! Isotype: CHR 552474!

Etymology. The epithet ‘*castellanum*’ from the Latin ‘associated with a fort, fortress or castle’ refers to the remote, craggy, castle-like habitats of this species in the southern Kermadec Islands group on which islands it is endemic.

Description (Figs 27–32). Tap-rooted, strongly pungent smelling, much-branched, leafy perennial shrub, up to 1.8 × 2.0 m. Tap-root up to 800 mm long, ± napiform and/or scarcely branched. Rootstock 6–10 mm diam., woody, exposed portion smooth. Stems persistent, arising from rootstock base and basal portion of main central stem, closely packed, woody, erect, weakly angled to ± terete, glabrous; mature stems 3.8–8.2 mm diam., 0.3–1.8 m long; red-green to yellow-green, brittle, bases bearing numerous leaf abscission scars otherwise mostly leafy from mid-stem to apex at flowering; middle stems dark green to red-green, fleshy and pliant, initially ± square, prominently angled, becoming ± terete with age. Leaves coriaceous, fleshy, green to dark green, rosette-leaves absent, stem leaves withering with age; basal stem leaves 88.5–120.0 × 14.5–30.0 mm, lamina broadly lanceolate to lanceolate, margin ± deeply and ± evenly incised, teeth in 50–90 ± equal pairs, 0.5–2.9 mm long, protruding beyond leaf line, narrowly deltoid, to deltoid, leaf apex truncate-praemorse often deeply lacerate, teeth 3–5, cut 2.4–4.2 mm to lamina, narrowly deltoid, to deltoid, often bidentate, leaf base attenuate extending into a broad petiole wing; petiole distinct, 23.6–31.0 × 3.1–3.3 mm, decurrent, channelled, often with a broadly sheathing base; upper stem leaves 50.0–68.0 × 4.4–12.2 mm, decreasing in size toward inflorescences, lamina narrowly lanceolate to linear-lanceolate, margin ±

Figure 25. Mature silicle of *Lepidium banksii*. CHR 509034. Scale bar = 1 mm.

deeply and \pm evenly incised, teeth in 6–14 widely and evenly spaced \pm pairs, 1.5–7.2 mm long, protruding beyond leaf line, narrowly deltoid, tapering, acerose, \pm acicular to acicular-falcate; lamina apex acute (rarely truncate-praemorse), acuminate, acumen 5.8–11.0 mm long, margins of acumen toothed, teeth often bidentate, 8–10 mm long, acerose, often acicular, or acicular-falcate, leaf base attenuate extending into a narrow petiole wing; petiole distinct, $2.9\text{--}8.2 \times 1.2\text{--}3.3$ mm, decurrent, channelled, often with a broadly sheathing base. Inflorescences racemose, 50–100 mm long at fruiting; rachis 0.5–2.25 mm diam., terminal and lateral, leaf-opposed, often long-persistent, sparsely to densely covered in pale, patent, \pm clavate hairs or rarely glabrous, hairs 0.1–0.14 mm long; pedicels 5.6–7.2 mm long at fruiting, erectopatent, with sparse, pale, patent, clavate hairs on adaxial surface, hairs 0.1–0.12 mm long. Flowers 3.0–4.5 mm diam., fragrant. Sepals 4, saccate, \pm overlapping at base, lateral sepals broad, 0.5–1.5 mm diam., orbicular, pale to dark green with a broad white, \pm undulose margin, apex rounded to obtuse, abaxial surface often hairy, hairs 0.2–0.4 mm long, eglandular or with glandular tip, mostly shedding at anthesis except near base, median sepals 0.5–0.9 mm diam., broadly elliptic, pale to dark green with a broad white, \pm undulose margin, apex rounded to obtuse, abaxial surface glabrous. Petals white, $1.1\text{--}2.0 \times 1.0\text{--}1.6$ mm, spreading, claw 0.4–0.8 mm long; limb obovate, obovate-spathulate to orbicular, apex obtuse to rounded often slightly emarginate, margins smooth, sometimes weakly undulose. Stamens 4, filaments 1.2–2.0 mm long, white; anthers 0.3–0.5 mm long, yellow. Ovary 1.1–1.8 \times 0.6–1.3 mm, ovate, broadly ovate to elliptic, green-brown, apex subacute; style 0.11–0.4 mm long, cylindrical; stigma 0.2–0.5 mm diam. Nectaries 4, 0.2–0.3 \times 0.1–0.15 mm, narrow-oblong to deltoid, pale translucent green. Silicles cartilaginous when fresh, coriaceous when dry, 2.4–3.6 \times 1.8–2.5 mm, elliptic to rhomboid, apex acute and

Figure 29. (From leaf to right) basal-, mid- and upper-stem leaves of *Lepidium castellanum*. Scale bar = 20 mm.

Figure 30. Close up of basal-stem leaf of *Lepidium castellanum* on Cheeseman Island (image: W. Chinn).

Distribution (Fig. 15). Endemic. Kermadec Islands (Macauley Island, Curtis Island, Haszard Islet and Cheeseman Island).

Recognition. *Lepidium castellanum* is distinguished by its very robust, shrubby growth habit (Fig. 27), sometimes up to 1.8 × 2.0 m, erect, often closely packed, usually leafy stems, narrowly lanceolate to linear-lanceolate upper stem leaves, and by the very long, needle-shaped teeth of the leaves which reach well beyond the leaf margin (Figs 28–30). In this species, the pedicels (and often the inflorescence rachises) are minutely hairy (Fig. 31), whilst those of *L. oleraceum* are glabrous. *Lepidium castellanum* is sympatric with *Lepidium oleraceum* on Curtis Island. Elsewhere, in northern New Zealand, especially on the Poor Knights and Hen (Taranga) islands, narrow-leaved forms of *L. oleraceum* are also common. However, these plants have a much smaller growth habit, their leaves lack the distinctive long needle-shaped teeth and long-acuminate leaf apices of *L. castellanum*, and, as with *L. oleraceum* populations elsewhere, their pedicels are glabrous.

Ecology. *Lepidium castellanum* is a sparse associate of the vegetation that has colonised the soft, erosion-prone cliff tops of Macauley Island, the less geothermally active summit slopes of Curtis Island, and the rocky tops of Haszard Islet and Cheeseman Island. On Macauley Island, *Lepidium castellanum* was recorded from open or sparsely vegetated, petrel-burrowed ground where it formed windswept shrubs in association with the creeping *Scaevola gracilis* Hook.f., tangles of *Ipomoea cairica* (L.) Sweet., *Disphyma australe* subsp. *stricticaule* Chinnock and *Polycarpon tetraphyllum* (L.) L. (Barkla et al. 2008; J. W. Barkla and T. C. Greene pers. comm.). On Curtis Island, it has been recorded growing amongst *Disphyma australe* subsp. *stricticaule*, while on the extensively seabird-burrowed Haszard Islet, it is one of the main shrub species, growing there

Figure 31. Pedicel hairs of *Lepidium castellanum*. Scale bar = 1 mm.

in association with *Myoporum rapense* subsp. *kermadecense* (Sykes) Chinnock, *Cyperus insularis* Heenan et de Lange, *Tetragonia tetragonioides* (Pall.) Kuntze, and *Parietaria debilis* G.Forst. On Cheeseman Island, numerous seedlings and a few adults were seen in 2011 growing on heavily petrel-burrowed soil covered ledges amongst *Disphyma australe* subsp. *stricticaule*, and also as a few sub-adults within an active petrel colony in a narrow gully, growing in association with *Cyperus insularis*, *Tetragonia tetragonioides*, and *Parietaria debilis*.

Conservation Status. *Lepidium castellanum* is confined to the Southern Kermadec Island group (see de Lange et al. 2004), part of the Kermadec Islands Nature Reserve. Within the southern Kermadec Islands group it has been recorded from Macauley Island, Cheeseman Island, Curtis Island, and from Haszard Islet. On Macauley Island it was recorded twice, in 2002 and 2006 (Barkla et al. (2008); T. C. Greene pers. comm.), at that time numbering at best five or fewer individuals. However, it was not seen on Macauley Island in 2011 (de Lange 2012; de Lange in press). In 2002 and 2006, the summit of Haszard Islet (6 ha, of which c.2.1 ha is vegetated) was thoroughly explored during helicopter-assisted landings by ornithologists. During those visits, it was noted that *Lepidium castellanum* was one of the major shrub-forming species on the richly manured and petrel-turbated soils of that islet's summit slopes (T. C. Greene and K. Baird pers. comm.). While accurate counts of the number of plants present on Haszard Islet were not made, it would seem that on both visits the islet summit supported approximately 20–50 individuals (T. C. Greene and K. Baird pers. comm.). Further south, its status on Curtis Island remains unknown, as there have been no gatherings of *Lepidium* from there since 1969, and several visits during the 1980s and in 2002 did not see it there (G.A. Taylor and T. C. Greene pers. comm.). However, on nearby Cheeseman Island, a 7-ha island (of which c.5.6 ha is vegetated)

Figure 32. Mature silicle of *Lepidium castellanum*. From holotype (AK 297694). Scale bar = 1 mm).

two plants were recorded in 2002 during a brief helicopter assisted 40 minute visit (T. C. Greene pers. comm.). Later, in 2011, nine adults and an estimated 1000 seedlings were noted on Cheeseman Island during a thorough botanical investigation of that island (de Lange 2012). Therefore, to the best of our knowledge there are between 20 and 50 adults on Hazard Islet and nine mature plants on Cheeseman Island, while the status of this species on Curtis Island and Macauley Island is uncertain. Therefore *Lepidium castellanum* qualifies as ‘Threatened/Nationally Critical’ either because the total number of plants in the wild is < 250 (criterion A(1) of Townsend et al. (2008)) or because the combined area of occupancy is < 1 ha (criterion A(3) of Townsend et al. 2008). To that assessment we add the qualifiers ‘DP’ (Data Poor) and ‘IE’ (Island Endemic). Data Poor (‘DP’) is recommended because of the lack of accurate counts of wild plants from Haszard Islet, absence of any recent survey for the species on Curtis Island, and lack of any trend data.

***Lepidium crassum* Heenan & de Lange, sp. nov.**

urn:lsid:ipni.org:names:77129256-1

http://species-id.net/wiki/Lepidium_crassum

A L. oleraceo habitu temporalis, caulibus ad caudicem lignosum emorientibus, foliis crasse coriaceis, distincte petiolatis, late ellipticis, ellipticis vel obovatis, apicibus obtusis vel truncatis, marginibus saepe duplicato-serratis, siliculis orbiculatis vel orbiculato-rhomboides, et sequentia nucleotidorum DNA distinguenda.

Holotype. New Zealand (Fig. 33): Otago Land District, Otago Peninsula, Aramoana, Mole, open sites among stones and rocks at the edge of the road down mole and in car park, 26 November 2009, P. B. Heenan s.n., CHR 609777A! Isotype: CHR 609777B!

Etymology. The specific epithet ‘*crassum*’ from the Latin for ‘thick’ refers to the distinctly thick and fleshy leaves of this species.

Description (Figs 34–37). Tap-rooted, strongly pungent smelling, perennial herb. Growth habit dense, stems closely placed, up to 50 cm tall, arising from underground woody stems. Stems upright to spreading, stout, short, rigid; mature stems woody, 100–400 × 10–12 mm, often devoid of foliage on middle and lower parts of stems, new stems 50–200 × 4–5 mm, leafy, glabrous. Leaves glabrous, coriaceous, green, undulate, rosette and stem leaves usually withering, variable in size and shape. Leaves of young and vigorous plants and stems: lamina 50–90 × 17–35 mm, broadly elliptic, elliptic to obovate; apex obtuse to truncate, often with up to 3 or 4 teeth; margin singly or doubly crenate, with 15–32 pairs of teeth; teeth up to 3.5 mm deep, sometimes overlapping, often protruding beyond leaf outline; base cuneate, petiole usually distinct; petiole up to 35.0 × 3.0–6.0 mm, channelled. Leaves of mature plants and cauline stems: lamina 15–45 × 6–15 mm, broadly elliptic, elliptic-obovate to obovate-oblong; apex obtuse to truncate, often with up to 3 or 4 teeth; margin singly crenate in upper half, teeth often protruding from leaf outline, with 5–10 pairs of teeth; teeth up to 1.2 mm deep, not overlapping, often protruding beyond leaf outline; base cuneate, sometimes narrowly so, usually tapering to ± distinct petiole; petiole 5–12 × 1.6–2.3 mm, channelled. Inflorescence terminal and lateral, racemose, 15–60 mm long, rachis 0.7–1.2 mm diam., glabrous; pedicels 4–7 mm long, erecto-patent, glabrous. Flowers 4.0–5.0 mm diam. Sepals 4, 1.3–1.6 mm long, saccate, overlapping at base, green, apex obtuse, margin white, shape dimorphic; lateral sepals broad, 1.4–1.5 mm diam., orbicular, abaxial surface often hairy, hairs 0.2–0.5 mm long; median sepals narrow, 1.0–1.3 mm diam., broadly elliptic, glabrous. Petals white, 1.8–2.0 × 1.0–1.1 mm, spreading, claw 0.6–0.8 mm long; limb broadly elliptic to orbicular, apex obtuse to rounded. Stamens 4; filaments 1.2–1.6 mm long, base 0.4–0.5 mm diam., equal; anthers 0.4–0.6 mm long. Ovary 1.0–1.6 × 0.9–1.1 mm, broadly ovate to broadly elliptic, green to green-brown, apex round or sometimes weakly shouldered; style 0.15–0.3 mm long, cylindrical; stigma 0.2–0.4 mm diam. Nectaries 4, 0.2–0.3 × 0.1–0.15 mm, oblong to oblong-triangular, green. Silicles cartilaginous when fresh, coriaceous when dry, 3.0–3.7 × 2.6–3.1 mm, orbicular to orbicular-rhomboid, apex obtuse to shallowly notched, valves pale brown, glabrous, not winged; style 0.2–0.3 mm long, exserted. Seeds 1.6–1.7 × 0.9–1.1 mm, narrowly ovoid, brown to orange-brown, not winged. FL Dec–Mar. FR Jan–Jul.

Distribution (Fig. 15). Endemic. New Zealand, South Island, Otago and Southland. *Lepidium crassum* once ranged from the Waitaki Valley (an inland location) and coastal locations at Oamaru to North Head, Waikawa Harbour in the south Catlins. Today, *L. crassum* is most common on Otago Peninsula, but occurs in small populations from near Kakanui, North Otago to The Nuggets, South Otago.

Recognition. *Lepidium crassum* differs from the related *L. oleraceum* by its usually much smaller stature (Fig. 34) and seasonal growth habit (with plants dying back to a basal rosette overwinter). *Lepidium crassum* has distinctly petiolate, uniformly broadly elliptic,

Figure 35. Leafy stem of *Lepidium crassum* showing basal leaves.

Figure 36. (From left to right) basal-, mid- to upper-stem leaves of *Lepidium crassum*. Scale bar = 20 mm.

elliptic to obovate, thickly coriaceous, often doubly crenate leaves with obtuse to truncate apices (Figs 35, 36). Its silicles are usually orbicular, sometimes orbicular-rhomboid, and with obtuse to shallowly notched apices (Fig. 37) and by its rDNA ETS sequence.

Figure 37. Mature silicle of *Lepidium crassum*. CHR 439956. Scale bar = 1 mm.

Ecology. Known from scattered populations that usually comprise fewer than 50 plants in a small geographic area. *Lepidium crassum* usually occurs on coastal headlands and rocky outcrops where it grows in disturbed open areas and among coastal herbfield of *Disphyma australe* subsp. *australe* and *Samolus repens* (J.R.Forst. et G.Forst.) Pers. var. *repens*. This species has also colonised the man made ‘Mole’ at Aramoana (Fig. 34) where it is can be common amongst rubble, concrete blocks and landfill.

Conservation Status. *Lepidium crassum* is known from a small number of wild populations on the Otago coast. As most populations comprise few plants or occur on unstable coastal headlands and rocky outcrops, this species is vulnerable to stochastic events. We estimate there are between 250 and 1000 plants and the largest population comprises fewer than 300 plants. Using the New Zealand Threat Classification System (Townsend et al. 2008), *L. crassum* qualifies as ‘Threatened/Nationally Endangered’ (criterion B(1/1)). We recommend appending the qualifiers ‘CD’ (Conservation Dependent – because there have been several populations established by the Department of Conservation and these are being actively managed), ‘DP’ (Data Poor – to reflect uncertainty over plant numbers), ‘EF’ (Extreme Fluctuations – because the largest known monitored population, that on Wharekakahu Island, appears to naturally undergo huge and apparently natural population fluctuations (J. W. Barkla pers. comm.)), and ‘RR’ (Range Restricted – because it is naturally confined to a geographically small part of the New Zealand Botanical Region).

Lepidium flexicaule Kirk, *Trans. & Proc. New Zealand Inst.* 14, 380 (1882)
http://species-id.net/wiki/Lepidium_flexicaule

Lectotype. New Zealand (North Island) (*vide* Garnock-Jones and Norton 1995): Onehunga, n.d. T.Kirk 341 WELT SP030080! Isolectotypes: WELT SP030089!, WELT SP027620!

Figure 38. Wild plant of *Lepidium flexicaule* growing on cobble beach showing decumbent growth habit (image: C.C. Ogle).

Etymology. The exact meaning of the species ‘*flexicaule*’ was not given by Kirk (1899) but the translation ‘flexuous stems’ accurately characterises the plant.

= *Lepidium incisum* Banks et Sol. ex Hook.f., *Flora Novae-Zelandiae* 1, 15 (1853) *nom. illeg.*, non Roth, *Neue Beytr. Bot.* 1: 224 (1802), nec Edgew., *Trans. Linn. Soc.* 20, 33 (1851)

Lectotype. New Zealand (North Island) (*vide* Garnock-Jones and Norton 1995): Opuraga, on Beach, rare, n.d., Banks and Solander, BM! Isolectotypes: AK 100095!, WELT SP063696a, b!

Etymology. Banks and Solander evidently chose the epithet ‘*incisum*’ in allusion to the deeply incised leaves of their specimens.

Description (Figs 38–43). Tap-rooted, strongly pungent smelling, decumbent, summer-green, perennial herb forming densely leafy, patches up to 1.5 m diam., and arising from stout, semi-circular, whitish-grey (when exposed) rootstock 3–10 mm diam. when fresh. Tap root fleshy, yellow to yellow-white when fresh, up to 300 mm long, deeply descending. Plants dying down in winter or in times of adversity to rootstock (in well-grown individuals the new season’s branchlets may die back to the previous season’s stem nodes). Stems prostrate, weakly flexuous, divergent to widely spreading, 100–800 mm long, 0.8–5.2 mm diam., woody near base, initially spherical in cross-section, pale yellow-green to dark green, sometimes tinged maroon and finely

Figure 39. Mature plant of *Lepidium flexicaule* with exposed root stock showing persistent past season's stems and new season's growth (image: S. Walls).

puberulent with short papillate or tapered hairs; becoming glabrous and prominently ridged and/or grooved with age, and usually bearing numerous leaf scars and withered petioles; upper portion of stems sparingly and openly to heavily branched; branches and branchlets, usually very leafy. Leaves glabrous, firmly fleshy to succulent, glossy dark green to yellow-green, at senescence turning yellow. Rosette and lower stem leaves withering at fruiting; petioles distinct 10–50 × 1–3 mm, slightly concave in cross-section, fleshy; leaves glabrous above, with papillae or denticles along midrib beneath and margins in New Zealand plants, or without denticles (absent in Chatham Islands and most Australian plants); lamina 50–90 × 15–30 mm, pinnatifid, obovate to oblanceolate; pinnae in 1–3 pairs, bluntly toothed or crenate at apex and distal margins. Upper stem leaves glabrous above, usually with triangular denticles, dense on margins and sparse to dense beneath (although absent in Chatham Islands and most Australian plants); mostly apetiolate, petiole if present minute up to 1.5 mm long; lamina 5–30 × 3–10 mm, obovate, oblanceolate, or spatulate, apex bluntly toothed to crenate, base broadly to narrowly cuneate. Racemes 10–50 mm long, elongating up to 60 mm at fruiting, terminal and leaf-opposed; rachis and pedicels puberulent with short tapering hairs, and ± covered in triangular denticles (absent in Chatham Islands and most Australian plants) or glabrous; axillary; rachis and pedicels hairs if present, retrorse to patent, very short, 0.05–0.8 mm long, ± clavate, eglandular – glandular; pedicels, erecto-patent to patent, initially 1.04–1.27(–2.38) mm; elongating to 2.34–5.00(–6.02) mm long at fruiting. Flower buds dark green, apex bearing a conspicuous, caducous,

Figure 40. *Lepidium flexicaule* plant at rosette stage of growth (early in growing season) (image: S. Walls).

crest of white, eglandular, antrorse hairs up to 0.9 mm long. Flowers sweetly fragrant, 1.4–1.8(–2.3) mm diam. Sepals, broadly ovate to oval, apex broadly obtuse, centrally green with a white margin, deeply concave, adaxially weakly keeled, adaxial midrib invested in conspicuous, caducous, white, eglandular, antrorse, hispid hairs, hairs sometimes scattered across rest of adaxial surface; abaxial surface glabrous; lateral sepals broad, 0.6–1.0 × 0.6–1.2 mm, median sepals narrower 0.4–0.8 × 0.4–0.7 mm. Petals white, 0.3–0.8(–1.0) × 0.2–0.8 mm, erecto-patent or patent, clawed; limb broadly obovate, apex obtuse, retuse or distinctly emarginate. Stamens 2, equal. Anthers c.0.16 mm long. Pollen bright yellow. Nectaries 4, subulate, 0.40 mm long. Silicles cartilaginous when fresh, subcoriaceous when dry, (2.1–)3.3(–4.1) × (2.2–)3.3–3.4(–4.0) mm, orbicular, obovate, to ovate, slightly winged in upper $\frac{1}{4}$, apex scarcely or shallowly notched, valves green maturing yellow-green, glabrous; style 0.8 (–1.0) mm long, free from the narrow wing, equal to or slightly exceeding the notch; stigma 0.2–0.4 mm diam. Seeds 2, 1.20–1.38 × 0.80–1.10 mm, ovoid to suborbicular, red-brown, dark red-brown or brownish black, not winged. FL. Oct–Feb. FR. Dec–Apr.

CH395, (AK 294940, CANB, CHR, WAIK); Rekohu, Ocean Bay, Unnamed Point south west of Bay, 14 January 2006, P. J. de Lange CH440 & J. W. D. Sawyer, (AK 295121); Rekohu, Wharekauri Farm Station, Cape Young, 13 January 2006, P. J. de Lange CH425 & J. W. D. Sawyer, (AK 295154).

Distribution (Fig. 44). Indigenous. Australia (Tasmania) and New Zealand (North, South, Chatham islands). In the North Island of New Zealand, *Lepidium flexicaule* is now known from only two extant populations, one on Saddle Island off the west coast of Great Barrier Island (Aotea Island) (de Lange and Cameron 2011) and the other at Stent Road north of Cape Egmont, Taranaki (Peet et al. 2003). Historically *Lepidium flexicaule* was present on Rangitoto Island, along the Waitakere Coastline, near North Head, Waitemata Harbour and near Onehunga, Manukau Harbour (Kirk 1899; Cheeseman 1906, 1925; Garnock-Jones and Norton 1995). It was also recorded from the Firth of Thames, at Mercury Bay (Kirk 1899; Cheeseman 1906, 1925; Garnock-Jones and Norton 1995) and near Wellington (Garnock-Jones and Norton 1995). In the South Island, the species is confined to the western coast of North-West Nelson from near Kaihoka to about Point Elizabeth. *Lepidium flexicaule* was discovered on the northern portion of Rekohu in 2005 by Department of Conservation botanists.

Recognition. *Lepidium flexicaule* is easily distinguished from all other indigenous *Lepidium* species by the combination of having a decumbent growth habit, pinnatifid rosette and basal stem leaves (Figs 38–41), and flowers with two stamens. Most North Island and South Island populations are further distinguished by the presence of tri-

Figure 43. Mature silicle of *Lepidium flexicaule*. AK 294940. Scale bar = 1 mm.

angular denticles on branchlet stems, leaf margins and petioles, and on the rachis and pedicels of the inflorescences (Fig. 42, see also Garnock-Jones 1988). Denticles are, however, absent from the Chatham Islands, most Australian collections, and some South Island ones. The absence of denticles prompted the brief listing of Rekohu and Australian plants as an unnamed subspecies (see de Lange et al. 2009). However, as denticles are sometimes absent from South Island plants, formal taxonomic distinction may not be warranted. Nevertheless, it is worth noting that Rekohu plants are consistently larger than those seen from the rest of this species' range, with well-grown specimens reaching up to 1.5 m diam., and that cpDNA data separates Tasmanian and Rekohu *L. flexicaule* from New Zealand samples (Fig. 4). Further study, including obtaining sequences of non-denticulate South Island *L. flexicaule*, is warranted. Of the indigenous species, it is perhaps most similar to *L. naufragorum*, which differs by its upright bushy shrub-forming habit with ascending to erect stems (Fig. 55), more sharply serrated pinnae of the leaves; racemes that are not so clearly leaf-opposed and are much longer (up to 150 mm, cf. 50 mm long), flowers that have four rather than two stamens, and emarginate petals that are longer than the sepals (see Garnock-Jones and Norton (1995) for other distinctions).

Lepidium flexicaule is however, commonly confused in the field with the naturalised *L. didymum* L. and *L. coronopus* (L.) Al-Shehbaz, species with which it sometimes grows. Both *L. didymum* and *L. coronopus* have long been treated in New Zealand under the segregate genus *Coronopus* but Al-Shehbaz et al. (2002) reinstated both species within *Lepidium*. *Lepidium flexicaule* can be distinguished from *L. didymum* and *L. coronopus* by the valves of the silicles, which are smooth and which dehisce into 2 valves to leave a persistent replum. The silicles of *L. didymum* and *L. coronopus* have a reticulate-ridged or warty surface, and do not dehisce along the valves; in *L. didymum* they split into 1-seeded segments and in *L. coronopus* they are indehiscent.

Ecology. The ecology of *Lepidium flexicaule* was described in some detail by Garnock-Jones and Norton (1995). They concluded that it is a strictly coastal species of turf communities, rock crevices and the strandline of bouldery beaches. *Lepidium flexi-*

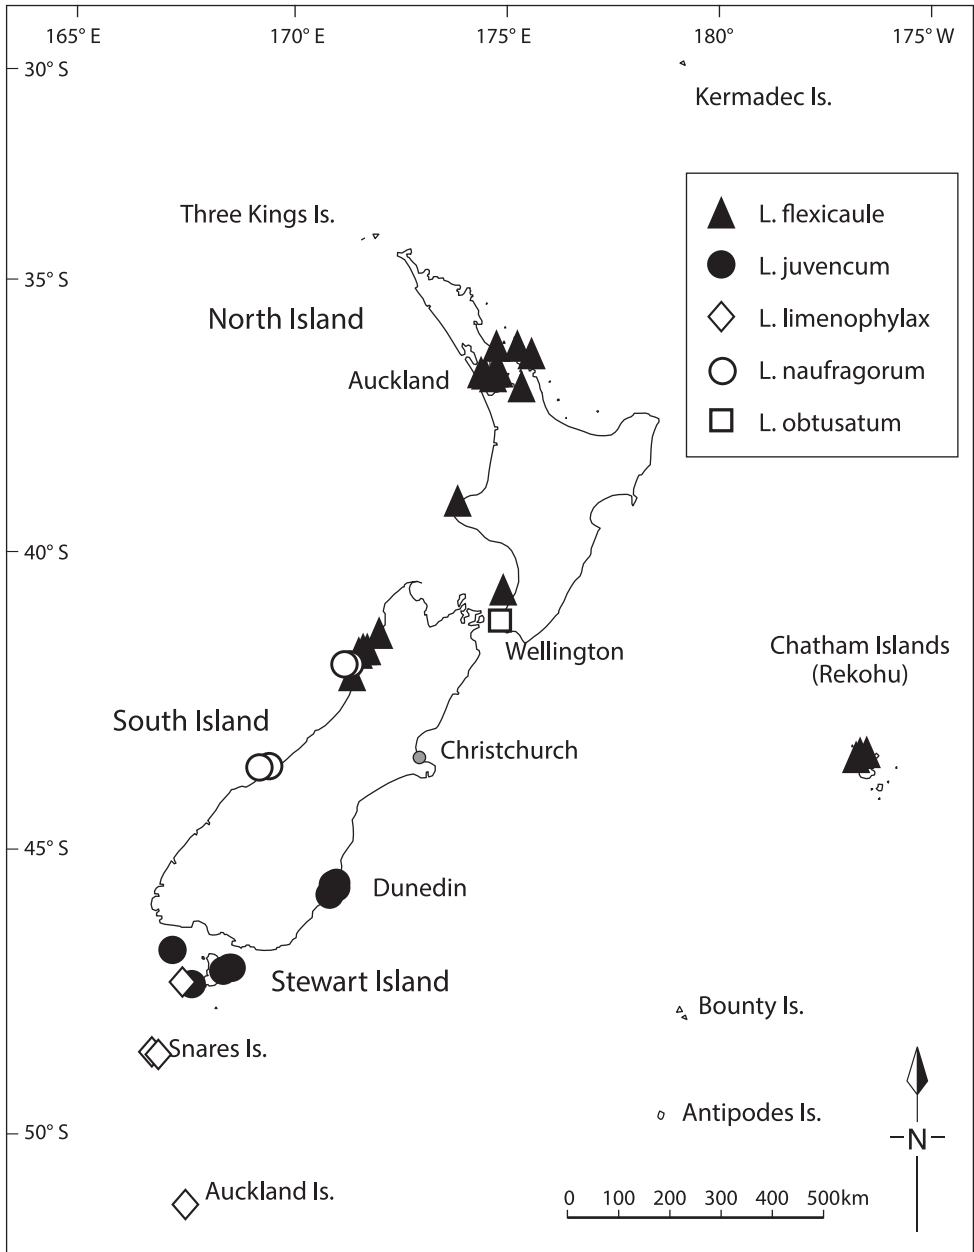

Figure 44. Distribution of *Lepidium flexicaule* (New Zealand distribution shown only), *L. juvenum*, *L. limenophylax*, *L. naufragorum* and *L. obtusatum*.

caule has also colonised tracksides, the compacted peaty ground of seal colonies, bird roosts, and even bird nests, where plants presumably arose from fruiting material that had been used for nest construction. In most locations, the species is found within the spray zone and always in sites prone to frequent disturbance.

Conservation Status. Previously *Lepidium flexicaule* had been assessed ‘Threatened / Nationally Vulnerable_{CD, EF}’ (de Lange et al. 2009). Based on current evidence, this ranking is no longer appropriate, as Rekohu populations of this species (treated in that paper as an unnamed entity *L. aff. flexicaule* but now included in *L. flexicaule* (see recognition above)) and all of the monitored New Zealand *L. flexicaule* populations are in decline, while the past total area of occupancy had been grossly underestimated. Based on current knowledge, *Lepidium flexicaule* is more appropriately assessed as ‘Threatened / Nationally Endangered’ (criterion A(3/1) of Townsend et al. (2008)) because the total area of occupancy of the sum of the populations is < 10 ha, and evidence obtained from monitoring indicates that there is an ongoing decline predicted to be up to 50% over the next ten years due to increased plant mortality (causes of which are as yet unknown) and loss of habitat caused by competition from weeds and coastal erosion. To this assessment we append the qualifiers ‘CD’ (Conservation Dependent – because virtually all known populations are being managed), ‘EF’ (Extreme Fluctuation – because monitoring also indicates that this is a species that, despite the decline, is naturally prone to seasonal population fluctuations) and ‘TO’ (Threatened Overseas – because, for the time being, we include Rekohu and Tasmanian plants within *L. flexicaule* (see recognition), and in Tasmania *L. flexicaule* is also seriously threatened (A. Buchanan pers. comm.)).

Hybridism. On the Chatham Islands, *Lepidium flexicaule* is occasionally found growing with *L. oligodontum* and *L. rekohuense*, and putative hybrids have been collected when these species occur together. There is good evidence for the hybrid *Lepidium flexicaule* × *L. oligodontum* (represented by AK 294939, *P. J. de Lange* CH391; AK 294942, *P. J. de Lange* CH394; AK 295119, *P. J. de Lange* CH442 & *J. W. D. Sawyer*). This hybrid is known from two sites on Chatham (Rekohu) Island where it is found in association with both parents. Like the parents, the hybrids have a decumbent growth habit. They share with *L. flexicaule* pinnatifid rosette leaves, but vegetative features of *L. oligodontum* are evident in the mid to upper stem leaves that are mostly spatulate to cuneiform (but with occasional deeply lobed margins to weakly pinnatifid leaves that are similar to *L. flexicaule*). The flowers of the hybrids have variable stamen numbers ranging from 1–5 per flower, compared to 2 in *L. flexicaule* and 2–4–6 in *L. oligodontum*, while pollen stainability varied from 80 to 85%. Seedlings raised from AK 295119 presented a bewildering array of foliage types grading into either parent. Unfortunately, through mishap these plants failed to reach maturity, so vouchers showing this are unavailable.

Evidence for *L. flexicaule* × *L. rekohuense* is less convincing. This putative hybrid is known from only one gathering (AK 295155, *P. J. de Lange* CH426 & *J. W. D. Sawyer*) which was collected in January 2006 from Cape Young, Rekohu, at a site where both parents grew. In the field, this specimen resembled *L. flexicaule* closely except that the plant was distinctly leafy and the upper stem foliage was more copious and larger than is usual for *L. flexicaule*. As with all Rekohu gatherings of *L. flexicaule*, this specimen lacked stem and marginal leaf denticles. Furthermore, as with both parents, there are two stamens per flower, and pollen stainability of this gathering was 98%. No fruiting material was present, and on a subsequent search of this site in 2007 the putative hybrid and its

parents had gone. This specimen may be a very well grown example of *L. flexicaule* but, as it appears anomalous alongside other Rekohu, New Zealand, and Australian gatherings of that species, we prefer to treat it as a putative *L. flexicaule* × *L. rekohuense* hybrid.

The putative hybrid *L. flexicaule* × *L. oleraceum* has also been recorded once, as a spontaneous plant arising in cultivation at the Auckland Regional Council Botanic Gardens (AK 228296 S. P. Benham s.n., AK 223492 S. P. Benham s.n.). The hybrid grew in a site where both parents (Scots Beach *L. flexicaule* and Stephens Island *L. oleraceum*) were planted together. The hybrid appeared from a seed lot gathered from the cultivated *L. flexicaule* plant. It initially appeared to be different because it was much larger and more vigorous than *L. flexicaule*, which it otherwise closely resembled (S. P. Benham pers. comm.). Over time, the hybrid developed weakly ascendant branches with rhomboid deeply serrated to pinnatifid mid and upper stem leaves, and flowers with 1–6 stamens. The hybrid appeared to be fully fertile, and seedlings raised from it showed clear segregation back to either parent (S. P. Benham pers. comm.). Again through mishap, these plants were lost before they reached maturity and specimens could be taken.

***Lepidium juvencum* Heenan & de Lange, sp. nov.**

urn:lsid:ipni.org:names:77129257-1

http://species-id.net/wiki/Lepidium_juvenum

A L. oleraceo habitu decumbente vel effuso patuloque, caulibus sparsis effusis gracilibus flexilibus, foliis subcoriaceis, apice obtuso vel truncato, plerumque 2–3 dentibus prominentibus ut videtur irregularibus, floribus fructibusque e plantis juvenibus prodientibus, et propria sequentia nucleotidorum DNA distinguenda.

Holotype. New Zealand (Fig. 45): Otago Land District, Otago Peninsula, Long Beach, Purakanui, on stabilised sand at base of cliff amongst introduced grasses, 26 November 2009, P. B. Heenan s.n., CHR 609785B! Isotype CHR 609785A!

Etymology. The specific epithet ‘*juvencum*’ from the Latin for ‘youthful’ refers to plants flowering and fruiting only a few months after germinating from seed.

Description (Figs 46–49). Tap-rooted, strongly pungent smelling, perennial herb. Growth habit open, straggly, up to 50 cm tall. Stems usually decumbent to sprawling, slender, flexible, sparse; mature stems woody, 100–1000 × 8–12 mm, often devoid of foliage on middle and lower parts of stems; new stems 100–400 × 3–4 mm, leafy, glabrous. Leaves glabrous, subcoriaceous, green, often undulate, rosette and stem leaves usually withering, variable in size and shape. Leaves of young and vigorous plants and stems: lamina 37–87 × 12–32 mm, elliptic, obovate or elliptic-oblancheolate; apex truncate to obtuse, usually with 2–3 prominent teeth and often appearing irregular; margin singly crenate, with 4–19 pairs of teeth; teeth up to 1.5 mm deep, not overlapping; base attenuate to cuneate, tapering to a distinct or indistinct petiole; petiole up to 23.0 × 2.0–5.0 mm, or sessile. Leaves of mature plants and cauline stems: lamina 10–60 × 3–21 mm, elliptic, elliptic-oblancheolate, obovate to elliptic-obovate; apex subacute, truncate or obtuse, usually with 2–3 prominent teeth and often appearing irregular;

Figure 45. Holotype of *Lepidium juvencum* Heenan et de Lange.

Figure 46. Young plant of *Lepidium juvencum* growing with *Poa astonii* near shearwater burrows.

margin singly crenate in upper and/or lower half, with 4–19 pairs of teeth; teeth up to 1.3 mm deep, not overlapping; base attenuate to cuneate, tapering to distinct or indistinct petiole, or sessile. Inflorescence terminal and lateral, racemose, 10–60 mm long, rachis 1.0–1.3 mm diam., glabrous; pedicels 4.0–6.0 mm long, erecto-patent, usually glabrous although lower pedicels occasionally sparsely hairy on adaxial surface. Flowers 4.0–5.0 mm diam. Sepals 4, 1.3–1.5 mm long, saccate, overlapping at base, green, apex obtuse, margin white, shape dimorphic; lateral sepals broad, 1.1–1.5 mm diam., orbicular, abaxial surface often hairy, hairs 0.1–0.5 mm long; median sepals narrow, 0.9–1.2 mm diam., broadly elliptic, glabrous. Petals white, 2.0–2.4 × 1.1–1.5 mm, spreading, claw 0.6–1.0 mm long; limb broadly elliptic to orbicular, apex obtuse to rounded. Stamens 4(–5); filaments 1.4–1.7 mm long, base 0.3–0.5 mm diam., equal; anthers 0.3–0.4 mm long. Ovary 1.0–1.5 × 0.9–1.4 mm, broadly ovate to broadly elliptic, green to green-brown, apex usually with shoulders; style 0.15–0.25 mm long, cylindrical; stigma 0.3–0.5 mm diam. Nectaries 4, 0.2–0.3 × c. 0.1 mm, oblong-obovate, green. Silicles cartilaginous when fresh, coriaceous when dry, 3.1–4.2 × 2.5–3.5 mm, elliptic-rhomboid to orbicular-rhomboid, valves light brown, glabrous, apex shallowly notched, not winged; style 0.2–0.3 mm long, exserted. Seeds 1.6–1.8 × 0.9–1.3 mm, narrowly ovoid, brown to orange-brown, not winged. FL Nov–May. FR Nov–Jun.

Representative Specimens. New Zealand (South Island): Otago, Long Beach, 30 December 1998, G. S. Stone s.n., (AK 239841); Otago, Long Beach, 25 Jun 1997, D. Nelson s.n. & J. Barkla, (CHR 518601); Otago, Long Beach, 13 July 2009, P. B. Heen-

Wilson 798-314, (CHR 368843); Lincoln, ex Long Beach, Landcare Research experimental nursery, 10 July 2008, P. B. Heenan s.n., (CHR 609803).

Distribution (Fig. 44). Endemic. New Zealand. South and Stewart Island/Rakiura. Known from Otago and islands off the coast of Stewart Island/Rakiura *Lepidium juvenicum* is currently known from just three locations: Long Beach and Green Island (Otago

Figure 48. (From left to right) basal-, mid- and upper-stem leaves of *Lepidium juvencum*. Scale bar = 20 mm.

Figure 49. (A) Mature silicle of *Lepidium juvencum*; (B) close up of silicle apex showing slight notch. AK 297694. Scale bars = 1 mm.

Peninsula) and Herekopare Island (east of Stewart Island/Rakiura). However, it is also probably present on some of the south-western Titi Island (south-west of Stewart Island/Rakiura) (B.D. Rance pers. comm.) and it is still likely to occur elsewhere, especially on rat free islands in the vicinity of Stewart Island, as is evidenced by specimens previously col-

lected from Womans (CHR 261892) and Solander (CHR 253066) islands in the 1960s and 1970s.

Recognition. *Lepidium juvencum* is distinguished by open, sprawling, straggling growth habit, and the stems are often trailing on the ground (Figs 46, 47). The leaves are elliptic, elliptic-oblancoelate, obovate to elliptic-obovate, and have attenuate bases; the marginal teeth are usually small and are mostly confined to the distal third of the leaf (Fig. 48). The silicles are most like *L. oleraceum* but differ by possessing a rounded, slightly notched apex (Fig. 49).

Ecology. *Lepidium juvencum* grows in open and often disturbed sites on sandy soil. At Long Beach it grows on stabilised sand at the base of a cliff immediately behind the beach, and at Herekopere Island it occurred on a steep coastal bank comprising sandy loam. On Kaimohu Island, in the south-western Titi group, what is probably *Lepidium juvencum* has been recorded growing with *L. limenophylax* on the margins of coastal scrub. *Lepidium juvencum* has also been established and is self-seeding at the Yellow-eyed Penguin Trust revegetation project at Tavora Reserve (near Palmerston, North Otago). Here it grows among *Euphorbia glauca* G.Forst. and *Ficinia spiralis* (A.Rich.) Muasya et de Lange on sand dunes at the back of the beach.

Conservation Status. *Lepidium juvencum* is presently known from three wild localities, and, while the number of plants at these localities is not known with certainty, it is estimated that there are < 100 in total. It is also acknowledged that *L. juvencum* is likely to be more widespread, especially in the vicinity of Stewart Island/Rakiura, and further field surveys are required. Recruitment is likely to be sporadic, and the small and sparse populations are especially vulnerable to stochastic events, such as storm surges, that could erode its habitat. Based on our current knowledge of this species and using the New Zealand Threat Classification System (Townsend et al. 2008), *L. juvencum* qualifies as ‘Threatened/Nationally Critical’ (either criterion A(1) or A(3) of Townsend et al. (2008) applies). We recommend appending the qualifiers, ‘CD’ (Conservation Dependent – because the species has been deliberately established at Tavora Reserve, where it is actively managed), ‘DP’ (Data Poor – to reflect uncertainty over its distribution), and ‘RR’ (Range Restricted – because it is naturally confined to a geographically small part of the New Zealand Botanical Region).

***Lepidium limenophylax* de Lange, B.D.Rance & D.A.Norton, sp. nov.**

urn:lsid:ipni.org:names:77129258-1

Holotype. New Zealand (Fig. 50): Snares Island, Snares Island Expedition 1969/72, University of Canterbury, December 1969, C. H. Hay s.n., WELT SP077578!

Etymology. The specific epithet ‘*limenophylax*’ derives from Greek (Ὁ λιμνοφυλαξ) and, though it strictly means ‘lake watcher’ (C. Blackford pers. comm.), it is used here in the sense of the alternative meaning of “harbour watcher or coast-guard”, which Green (1994; p. 535) states is the more appropriate derivation (see his comments on the etymology of the Norfolk Island endemic orchid *Phreatia limenophylax* (Endl.) Benth.). It is given in allusion to the preferred habitat of *L. limenophylax* on the Snares, i.e. the low turf confined to the exposed ends of rocky headlands jutting out into and overlooking the sea. Historically, it was on these exposed headlands that the World War II coastwatchers were posted to keep watch for signs of enemy shipping (Fleming 1948, McEwen 2005).

Description (Figs 51–54). Tap-rooted, strongly pungent smelling, summer-green, perennial herb, arising from stout rootstock 7.3–10.0 mm diam. Plants dying down to rootstock and previous season’s stem nodes during winter. Stems decumbent, bases often very stout, ± spherical, somewhat woody when mature 10–15 × 10–12 mm, composed of numerous old leaf and stem bases, sometimes producing roots, new season’s grow decumbent, spreading 10–300 × 3–10 mm, glabrous, sometimes with very sparse, appressed, caducous, silky 0.5–1.0 mm long, hairs near stem apices, at fruiting, often devoid of foliage from much of length. Leaves glabrous, firmly fleshy to succulent, usually dark green to green, sometimes yellow-green. Rosette and stem leaves usually withering at fruiting but sometimes with a few long persistent. Petiole distinct, 20–40 × 2–4 mm lamina 50–100 × 5–15 mm, lanceolate, narrowly lanceolate to linear lanceolate; distal $\frac{1}{3}$ – $\frac{2}{3}$ finely but sharply serrated or crenate, teeth in 10–20 pairs running to and including subacute, obtuse to rounded apex (teeth not extending beyond leaf outline), base cuneate to narrowly cuneate. Middle stems leaves with petiole indistinct, lamina narrowly linear lanceolate to linear, often recurved to falcate in the distal $\frac{1}{3}$ – $\frac{1}{2}$ of leaf length, 50–120 × 3–6 mm; upper $\frac{2}{3}$ or occasionally the entire leaf finely but sharply serrated; teeth in 12–30 pairs running to and including the apex, and not extending beyond leaf outline, lamina base tapered, very narrowly cuneate. Upper stem leaves with or without a distinct petiole, petiole if present 40–60 mm, linear to linear-spathulate, occasionally narrowly lanceolate, often recurved or falcate from $\frac{1}{2}$ of leaf length, 30–100 × 2.0–30.0 mm, margins finely but sharply serrated. Racemes 5–15 mm long, terminal and axillary; rachis glabrous; pedicels glabrous, erecto-patent, 2–8 mm long at fruiting. Flowers c. 0.4–1.0 mm diam. Sepals 4, saccate, overlapping at base, green with pale-green to white thickened margin, apex broadly obtuse, shape and size dimorphic; lateral sepals c. 0.6–1.0 × 0.6–1.2 mm, broadly ovate to oval, mostly glabrous, sometimes sparsely hairy, hairs 0.2–0.4 mm long, caducous; median sepals 0.9–1.2 × 0.5–1.2 mm, elliptic to obovate, abaxial surface sparsely hairy, hairs 0.2–0.4 mm long, caducous. Petals white to off-white, 1.5–2.0 × 0.3–1 mm, erecto-patent to somewhat spreading, clawed; limb narrowly obovate, apex obtuse, occasionally emarginated. Stamens 2, equal. Nectaries 2, subulate, 0.35 mm long. Silicles cartilaginous when fresh, coriaceous when dry, 2.5–3.5 × 1.5–3.3 mm, elliptic or rhomboid, not winged, apex usually notched (rarely truncate), valves green maturing yellow-green, glabrous; style 0.1–0.3 mm long, exceeding the shallow notch (if notch present); stig-

Kirk s.n., (WELT SP027634).

Distribution (Fig. 44). Endemic. New Zealand, South-western Titi (Muttonbird) Islands (Kaimohu Island), The Snares (North East, Broughton islands), and Auckland Islands. *Lepidium limenophylax* is possibly also present on Pohowaitai Island (B. A. Fineran, 4 Mar 1965, CANU 8723) another of the south-western Titi (Muttonbird) Islands, although this collection, comprising sterile specimens of a whole young plant and a branch are inadequate to be certain. There are also additional unconfirmed observations of what may be this species from many of the other south-western Titi (Muttonbird) Islands (B.A. Fineran and B.D. Rance pers. comm.).

Recognition. *Lepidium limenophylax* is recognised by the decumbent growth habit (Figs 51, 52), with plants developing a distinct woody network of branches. New season's growth arises from the nodes left from the previous season's growth. In this species, the leaves are consistently lanceolate, narrowly lanceolate, linear lanceolate or linear (Figs 50, 51B, 52), though slightly broader in seedlings and basal rosettes. The flowers have two stamens (Fig. 53). It is morphologically most similar to *L. rekohuense*, which also has a decumbent growth habit and flowers with two stamens. *Lepidium limenophylax* has lanceolate, narrowly lanceolate, linear lanceolate or linear leaves, rather than the spatulate to narrowly ovate or elliptic leaves of *L. rekohuense*. Furthermore, the silicles of *L. limenophylax* are elliptic, rhomboidal and unwinged (Fig. 54), rather than orbicular, obovate to ovoid and winged.

Ecology. On the Snares, *Lepidium limenophylax* has been described as an occasional component of cliff top vegetation where it is stated to grow in association with living or dead *Poa astonii* Petrie pedestals (and on occasion in association with *Poa tennantiana* Petrie and *Hebe elliptica* (G.Forst.) Pennell), often near the feeding sites of brown skuas (*Stercorarius lonnbergi* Mathews, 1912) and occasionally around the nests of Buller's mollymawk (*Thalassarche bulleri* (Rothschild, 1893)) or on dry peaty cliff tops (sometimes within the sandy quartz derived from the underlying granite) (Fineran 1969, Hay et al. 2004, Lake and Evans 2011). Further inland, it was also reported by Fineran (1969, p. 3) 'as uncommon... sometimes present on sites of old abandoned penguin rookeries, where it usually grew with great vigour'. Brian Rance (in litt.), on a visit to the islands in 2000, found that, as with Fineran (1969), *L. limenophylax* was virtually confined to the north-western cliffs. More recently, Lake and Evans (2011) failed to find it at any inland sites. All these authors and individuals noted *Lepidium limenophylax* as uncommon in other habitats, though a few plants have been noted near Boat Harbour growing in association with *Poa astonii*, *Asplenium obtusatum* G.Forst. and *Hebe elliptica* in semi-open situations caused by Hooker's sea lions (*Phocarctos hookeri* (Gray, 1844)) (Lake and Evans 2011; B. D. Rance pers. comm.). Very little is known about the associations of *Lepidium limenophylax* on Kaimohu Island, though herbarium notes suggest that it grew there in association with what is probably *Lepidium juvencum* (see comments under that species), and B. A. Fineran (pers. comm.) noted that this species was present mostly along ridge crests and above cliff faces, always in association with the feeding sites of skua. Brian Rance (in litt.) has also observed plants apparently matching *L. limenophylax* on several of the Titi (Muttonbird) islands south west of Stewart Island, usually growing along tracks in association with

a sparse ground cover of *Apium prostratum* subsp. *prostratum* var. *filiforme* (A.Rich.) Kirk, *Nertera depressa* Banks et Sol. ex Gaertn and *Poa astonii* under semi-open *Olearia angustifolia* Hook.f. / *O. lyallii* Hook.f. short forest.

Conservation Status. On the Snares *Lepidium limenophylax* occupies a very narrow habitat range scattered over four key areas and covering an area of 943 m² (Lake and Evans 2011). Lake and Evans (2011) were unable to count or estimate population size stating that ‘it was not possible to estimate the number of plants due to the tendency [of the species] to grow in patches and not [as] isolated plants’. Nevertheless, they reported ‘a good mix of mature and juvenile plants’. Outside these islands, the status of this species on the Auckland and south-western Titi (Muttonbird) Islands is unknown. Previously, *Lepidium limenophylax*, as *L. aff. oleraceum* (c) (CANU 5995; Snares), had been listed by de Lange et al. (2009, p. 89) under Appendix 2 Taxonomically Indeterminate Listings, as ‘Acutely Threatened/Nationally Critical’ with the qualifiers ‘IE’ (Island Endemic) and ‘RR’ (Range Restricted) appended. That assessment used data provided by B. D. Rance, on a visit to the Snares Islands in 2000. Lake and Evans (2011) provided a detailed update on the information obtained by Rance during a three week stay on the Snares between September and October 2010. They concluded that the species was in good health, and much more abundant than had been believed previously. While these observations suggest that this is probably a narrow-range species secure within its Snares stronghold, we recommend retention of the current threat listing of de Lange et al. (2009) as a precautionary measure because: 1. Accurate information about the status of this species outside the Snares is absent (i.e. it is not a Snares endemic), 2. The total area of occupancy on the Snares is < 1 ha (criterion A(3) in Townsend et al. (2008)) and 3. There is still no trend data available for the species. However, to reflect the observations of Lake and Evans (2011) and our ongoing uncertainty about population trend and the status of this species outside the Snares we recommend that the addition of the qualifier ‘DP’ (Data Poor) to the current threat listing. It should also be noted that because *L. limenophylax* is known from a number of islands and island groups it does not meet the definition of ‘IE’ in Townsend et al. (2008). *Lepidium limenophylax* also should be qualified ‘CD’ (Conservation Dependent) because the largest known population occurs within a Nature Reserve and World Heritage site (The Snares) where it is vulnerable to the spread of disease, weed and rat incursions, all of which would have a profound impact on its long-term security. Because of these threats, which put at risk not only the *Lepidium* but all other Snares terrestrial biota, access to the islands is strictly controlled by the New Zealand Department of Conservation, which also undertakes regular biosecurity inspections of the island group.

***Lepidium naufragorum* Garn.-Jones & D.A.Norton, *New Zealand J. Bot.* 33, 43 (1995)**

http://species-id.net/wiki/Lepidium_naufragorum

Holotype. New Zealand: Open Bay Islands, Taumaka, 15 February 1992, P. J. Garnock-Jones 2121, D. A. Norton & D. R. Given, CHR 470212!

Etymology. The epithet '*naufragorum*', the genitive plural form of '*naufragus*' meaning a 'castaway or ship wrecked person', was given by Garnock-Jones and Norton (1995) to commemorate a sealing gang that was set down on the type locality of the species, the Open Bay Islands, in 1810 where they were left for four years until they were rescued.

Description (Figs 55, 56). Tap-rooted, pungent-smelling, summer-green, perennial herb forming a densely leafy, shrub up to 680 mm tall, rootstock stout, 3–10 mm diam. when fresh semi-circular, whitish-grey (when exposed). Tap root fleshy, yellow to yellow-white when fresh, up to 300 mm long, deeply descending. Plants dying down in winter or in times of adversity to rootstock. Stems ascending to erect, 150–680 mm long, glabrous, 2–8 mm diam., woody near base, prominently ridged and/or grooved with age, and usually bearing numerous leaf scars and withered petioles, pale yellow-green to dark green, sometimes tinged maroon; mid to upper portion of stems much branched; branches and branchlets, usually very leafy. Leaves glabrous, fleshy to \pm subcoriaceous, glossy dark green to yellow-green, at senescence turning yellow. Rosette and lower stem leaves withering at fruiting; petioles distinct 40–80 \times 1–3 mm, slightly concave in cross-section, fleshy, winged; lamina 60–140 \times 15–25 mm, pinnatifid (rarely simple), narrow-oblong to narrow-oblongate; pinnae when present in 3–8 pairs, sharply toothed toothed at apex and distal margins, lamina of simple leaves, deeply and unevenly serrated, teeth 1.0–2.2(–5.1) mm long, usually not projecting beyond leaf outline. Middle stem leaves similar (rarely simple) or becoming shallowly pinnatifid, sharply serrate. Upper stem leaves 10–50 \times 2–10 mm, narrow-obovate to linear oblanceolate, pinnatifid to simple, sharply toothed at apex and at apex of pinnae if present, cuneate at base; petiole minute or absent. Racemes 10–120 mm long, elongating up to 140 mm at fruiting, terminal and axillary, \pm leaf-opposed; rachis glabrous or sparsely hairy; pedicels sparsely hairy, erecto-patent, initially 1.3–1.6 mm; elongating to 3–5 mm long at fruiting. Flower buds grass green to dark green, apex glabrous or sometimes bearing a conspicuous, caducous, crest of white, eglandular, antrorse hairs up to 0.9 mm long. Flowers sweetly fragrant, 2.8–3.2 mm diam. Sepals, ovate to oval, apex broadly obtuse, green with a white scarious margin, deeply concave, adaxially weakly keeled, abaxial midrib glabrous or invested in conspicuous, caducous, white, eglandular, antrorse, flexuous hairs, hairs sometimes scattered across rest of abaxial surface; adaxial surface glabrous; lateral sepals 0.8–1.2 \times 0.8–1.2 mm, median sepals narrower 0.7–1.0 \times 0.6–0.9 mm. Petals white, 0.9–1.4 \times 0.6–0.9 mm, erecto-patent, clawed; limb obovate, apex emarginate. Stamens 4, equal. Anthers c.0.12 mm long. Pollen bright yellow. Nectaries 4, subulate, 0.25 mm long. Silicles cartilaginous when fresh, subcoriaceous when dry 2.8–4.0 \times 2.3–3.2 mm, broadly elliptic, slightly winged, apex shallowly notched, valves green maturing pale green, glabrous; style 0.1–0.2 mm long, free from the narrow wing, equal to or slightly exceeding the notch; stigma 0.4 mm diam. Seeds 2, 1.6–2.0 \times 1.2–1.8 mm, obovoid, orange-brown, not winged, mucilaginous when wet. FL. Oct–Mar. FR. Nov–Apr.

Distribution (Fig. 44). Endemic. New Zealand, South Island, (Westland) where it is known from seven sites from Cape Foulwind south to the Open Bay Islands (Taumaka and Popotai). With the exception of the Open Bay Islands, *Lepidium nau-*

fragorum is scarce within the mainland part of its range. *Lepidium naufragorum* has also been collected once as a gutter weed in Auckland City, plants having established there from a nearby garden where the species was being cultivated. These naturalised plants persisted for about five years before they died out.

Recognition. *Lepidium naufragorum* is easily distinguished from all other *Lepidium* species in New Zealand by the upright bushy shrub habit (with plants dying down to a central root stock in winter), erect stems, mostly sharply serrated pinnatifid rosette and stem leaves (rarely entire) (Fig. 55), and by the emarginate silicles (Fig. 56). Of the New Zealand species, it is most similar to *L. flexicaule* in which it was included by Garnock-Jones (1988) before field work and further study recognised its distinctiveness. For differences between *L. naufragorum* and *L. flexicaule*, see under *L. flexicaule*.

Although most plants of *L. naufragorum* have pinnatifid foliage, occasional specimens with simple or weakly pinnatifid leaves are also known, and these can at times be locally common (Knightbridge and Newton 2006). It was plants such as these that were the basis for literature records (e.g. Burrows 1972) and collectors such as L. Cockayne and B.C. Aston (WELT!) referring this species to *Lepidium oleraceum* and *L. banksii* (as var. *ovatum*). From *Lepidium oleraceum* these forms can easily be distinguished by the seasonal growth habit (with plants dying back to the rootstock over winter), and by the distinctly emarginate silicles. So far, *Lepidium oleraceum* has not been found within the Westland range of *L. naufragorum*. The confusion with *Lepidium banksii* partly stems from these early collectors' uncertainty as to what this species is. In any case, non-pinnate leaved forms of *L. naufragorum* are readily distinguished from *L. banksii* by their much smaller ($2.8\text{--}4.0 \times 2.3\text{--}3.2$ mm) broadly elliptic and shallowly notched silicles. The silicles of *L. banksii* are much larger ($4.5\text{--}5.5 \times 4.0\text{--}5.0$ mm), broadly ovate and deeply notched (Fig. 25).

Ecology. The ecology of *Lepidium naufragorum* was described in some detail by Garnock-Jones and Norton (1995) who noted that it preferred sites frequented by seals and nesting sea birds or sea bird roosts. They concluded that the species required these species not only for nutrient enrichment but also because their disturbance kept the habitats of this species open. The authors also noted that *Lepidium naufragorum* was restricted to base-rich substrates.

Conservation Status. *Lepidium naufragorum* has a conservation status of "Threatened / Nationally Vulnerable_{CD, RR}" (de Lange et al. 2009). Based on current evidence this ranking is still appropriate.

***Lepidium oblitum* Houlston, Heenan & de Lange, sp. nov.**

Holotype. Chatham Islands (Fig. 57): Chatham Is., Mangere Island, Mangere Island Nature Reserve, South of Hut Landing, 14 February 2006, P.J. de Lange CH876 & P.B. Heenan, AK 300342! Isotypes: CHR 552303A-C!

Etymology. The epithet “*oblitum*” from the Latin meaning “forgotten, disregarded or neglected” refers to the circumstances in which this species was first discovered. At an early stage of this revision *L. oblitum* had been included within the range of *Lepidium panniforme*, with some plants treated as possible hybrids between *L. panniforme* and *L. oleraceum*. It was only following critical analysis of plants grown in New Zealand from samples collected from Mangere Island that the distinctive nature of this species was realized using DNA and morphological data.

Description (Figs 58–62). Tap-rooted, strongly pungent, sprawling, laxly though much-branched, leafy perennial shrub, forming patches up to 1.0 × 0.9 m. Tap-root up to 700 mm long, ± napiform, branched 1–2 or more times. Rootstock 6–14 mm diam., woody, exposed portion ± smooth, often covered in dried leaf remnants and withered branch stubs. Plants usually dying down to rootstock and/or previous seasons stem nodes, towards end of growing season. Stems mostly seasonal, a few ± persistent (i.e. lasting 2 or more years), arising from rootstock base and basal portion of main central stem, widely and unevenly spaced or closely packed, woody, lax and sprawling, sometimes arching and subscentent, weakly angled to ± terete, glabrous; mature stems 2.1–4.6 mm diam., 0.3–0.8 m long; green to yellow-green, brittle, bases bearing numerous leaf abscission scars, otherwise devoid of leaves for at least the first 2/3 with the final 1/3 distinctly leafy and often much branched when vegetative, with the leaves tending to fall at flowering and fruiting; upper stems similar, though distinctly leafy and pliant. Leaves coriaceous, fleshy, green to dark green, often glossy. Rosette leaves 5–14(–20), mostly present in autumn – early spring usually not persisting (very rarely so) at fruiting; petioles distinct, up to 40 × 2 mm, flat or slightly concave in cross-section, succulent; lamina oblanceolate, cuneiform, obovate-oblong to spatulate up to 60 × 22 mm, margins finely to deeply incised in upper 1/4–1/3, teeth in 3–6(–8) pairs running to praemorse apex, basal few teeth pair usually asymmetric, base narrowly attenuate. Middle stem leaves mostly persisting at fruiting; petiole up to 32 mm long, mostly flat in cross-section, sometimes slightly concave, usually winged; lamina narrowly oblanceolate, oblanceolate, spatulate, oblong, obdeltoid, 15.0–32.0(–56.2) × 12–16.8(–18.6) mm; margins finely to deeply incised in distal 1/4–1/3, teeth in 3–6(–8) pairs running to the usually praemorse apex, basal few teeth pairs usually asymmetric, lamina base narrowly attenuate, extending as a wing (0.8–1.2 mm wide) usually to petiole base. Upper stem leaves petiolate, petiole 12 mm long, flat or slightly concave, usually broadly winged; lamina narrowly oblanceolate, narrowly lanceolate, narrowly spatulate, to linear-cuneiform, 10.2–20.0(–29.0) × 2.4–3.5(–4.8) mm; margins entire or deeply dentate, if dentate then usually asymmetrically tridentate (rarely with 1–4 teeth), lamina base narrowly attenuate, extending as a wing (0.3–1.7 mm wide) almost to petiole base. Racemes (30–)50(–76) mm long, usually congested, elongating up to 100 mm at fruiting, terminal and axillary; rachis and pedicels glabrous (pedicels very rarely bearing a few minute, caducous, glandular hairs near base); pedicels, erecto-

Nature Reserve, Above Hut, 14 February 2006, P.J. de Lange CH874 & P.B. Heenan, (AK 300340; CHR 552373); Mangere Island, Mangere Island Nature Reserve, 'Top Plateau', 22 February 2011, B. Gibb s.n., (AK 331585).

Distribution (Fig. 63). Endemic. New Zealand, Chatham Is., Mangere and Rabbit Islands.

Recognition. *Lepidium oblitum* is recognised by its sprawling growth habit (Fig. 58); by the branches often widely spaced, trailing and mostly devoid of foliage except for the ends which are typically densely terminated by foliage (Fig. 57); and by the prominently notched silicles (Fig. 62). Of those species with which it grows (*L. oligodontum*, *L. oleraceum*, *L. panniforme* and *L. rekobuense*), it can be easily distinguished from *L. oleraceum* by its sprawling growth habit, flowers with 2–4 stamens, and distinctly notched silicles (Figs 58, 61, 62).

From *Lepidium oligodontum*, *L. oblitum* is easily distinguished by its more upright, though somewhat, untidy, sprawling growth habit (Fig. 58), and longer lived, persistently leafy branches. The foliage of *L. oblitum* (Figs 59, 60) has leaf margins that are consistently toothed (never sparingly-toothed or entire), while the flower-

Figure 60. Cultivated plant of *Lepidium oblitum* showing rosette leaves.

ing racemes are distinctly longer ((30–)50(–76) mm cf. (5.0)–9.7(–28.9) mm in *L. oligodontum*) and on fruiting they may elongate up to 100 mm (rather than 60 mm). In *L. oblitum* the flowers have 2–4 rather than 2–4–6 stamens (Fig. 61B, 61C), while the silicles are never fleshy or turgid, rather they are distinctly cartilaginous and prominently (rather than weakly) notched (Fig. 62). *Lepidium oblitum* also has consistently shorter styles ((0.1–0.2(–0.3) mm long) than *L. oligodontum* ((0.2–0.8(1.2) mm long)).

Lepidium oblitum and *L. panniforme* grow together on Mangere Island (Fig. 63). As they have similar silicles and flowers with 2–4 stamens but very different foliage, *L. oblitum* was initially thought to be hybrid between *L. panniforme* and *L. oleraceum*. At that time it was not realised how widespread *L. oblitum* is, nor that it comprised stable, true-breeding populations (G. Houlston unpubl. data). It was only following DNA-based investigations undertaken for this paper that the putative hybrid status was rejected and its status as a species recognised. Nevertheless, *L. oblitum* is still closely allied to *L. panniforme*, and both also share a relationship to the extinct *L. obtusatum*, a relationship evident by all three species sharing prominently notched silicles. *Lepidium oblitum* has widely spreading, lax (rather than erect to suberect), sprawling stems and rosette leaves that distinguish it from *L. panniforme* (Figs 82, 83). The leaves of *L. oblitum* are shallowly toothed but they are never as deeply serrated or lacerate as those of *L. panniforme* (Figs 81, 83, 84). DNA data suggests that gene flow between *L. oblitum* and *L. panniforme* has occurred at some sites on Mangere Island (G. Houlston unpubl. data).

Figure 61. **A** Upper stem leaves and inflorescence of *Lepidium oblitum* **B** flowers showing arrangement of sepals, petals, androecia and gynoecia **C** close-up of flower.

Lepidium oblitum also grows with *L. rekohuense* on Rabbit Island. From that species it is easily separated by its smaller growth habit; by the glabrous rather than sparsely papillate-hairy upper branch stems, and glabrous rather than finely hairy inflorescences (the pedicels of *L. oblitum* may, very rarely, bear a few caducous glandular hairs). Fur-

Figure 62. Mature silicle of the holotype of *Lepidium oblitum* (AK 300342). Scale bar = 1 mm.

thermore, the flowers of *L. oblitum* have 2–4 rather than 2 stamens, while the silicles of *L. rekohuense* are also mostly orbicular (rarely obovate) and slightly larger (up to 4.1 × 4.0 mm cf. 3.3 × 3.0 mm).

Ecology. *Lepidium oblitum* is one of three *Lepidium* species recorded from Mangere and Rabbit islands. On these islands, it is frequently found growing in association with petrel burrows, and on exposed, often wind eroded cliff faces, associated soil blowouts and ephemeral drainages and seepages. On Mangere Island, it is perhaps most common among the boulders and rocks forming the northern summit of the Top Plateau. In these habitats, *L. oblitum* commonly grows with *Asplenium obtusatum*, *Festuca coxii* (Petrie) Hack., *Disphyma papillatum* Chinnock, *Puccinellia chathamica* (Cheeseman) Allan et Jansen and *Senecio radiolatus* F.Muell. subsp. *radiolatus*. On Mangere Island, it is also associated with *Aciphylla dieffenbachii* (F.Muell.) Kirk, *Hebe chathamica* (Buchanan) Cockayne et Allan, *H. dieffenbachii* (Benth.) Cockayne et Allan (and hybrids between these two *Hebe*), *Myosotidium hortensium* (Decne.) Baill., and, on occasion, *Lepidium oleraceum* and *L. panniforme*. On Rabbit Island it is associated with *Atriplex australasica* Moq., *Critesion murinum* (L.) Á.Löve subsp. *murinum*, *Malva arborea* L., *Lepidium oligodontum* and *L. rekohuense*.

Conservation Status. *Lepidium oblitum* is so far known only from the Chatham Islands group where it has been collected from Mangere and Rabbit Islands (Fig. 63). On Mangere Island (a Nature Reserve, with strict permit controlled access) it is known from several populations, the largest of which occurs along the northern western cliff faces of ‘Top Plateau’. That population may number in the tens of plants; the only other ones known occur in steep runnels draining the western cliffs south of the main Landing area. When visited by PdL and PBH in 2006, there were fewer than 10 adults in total. Subsequent visits to Mangere Island by Department of Conservation rangers suggest that there has been little change in the population sizes on that island. However, hard data is unavailable and so it would inappropriate to infer from these observations that *L. oblitum* populations on Mangere are stable. On nearby privately owned Rabbit Island, two plants of *L. oblitum* were seen in 2006 and the island has not been visited by Department of Conservation staff since.

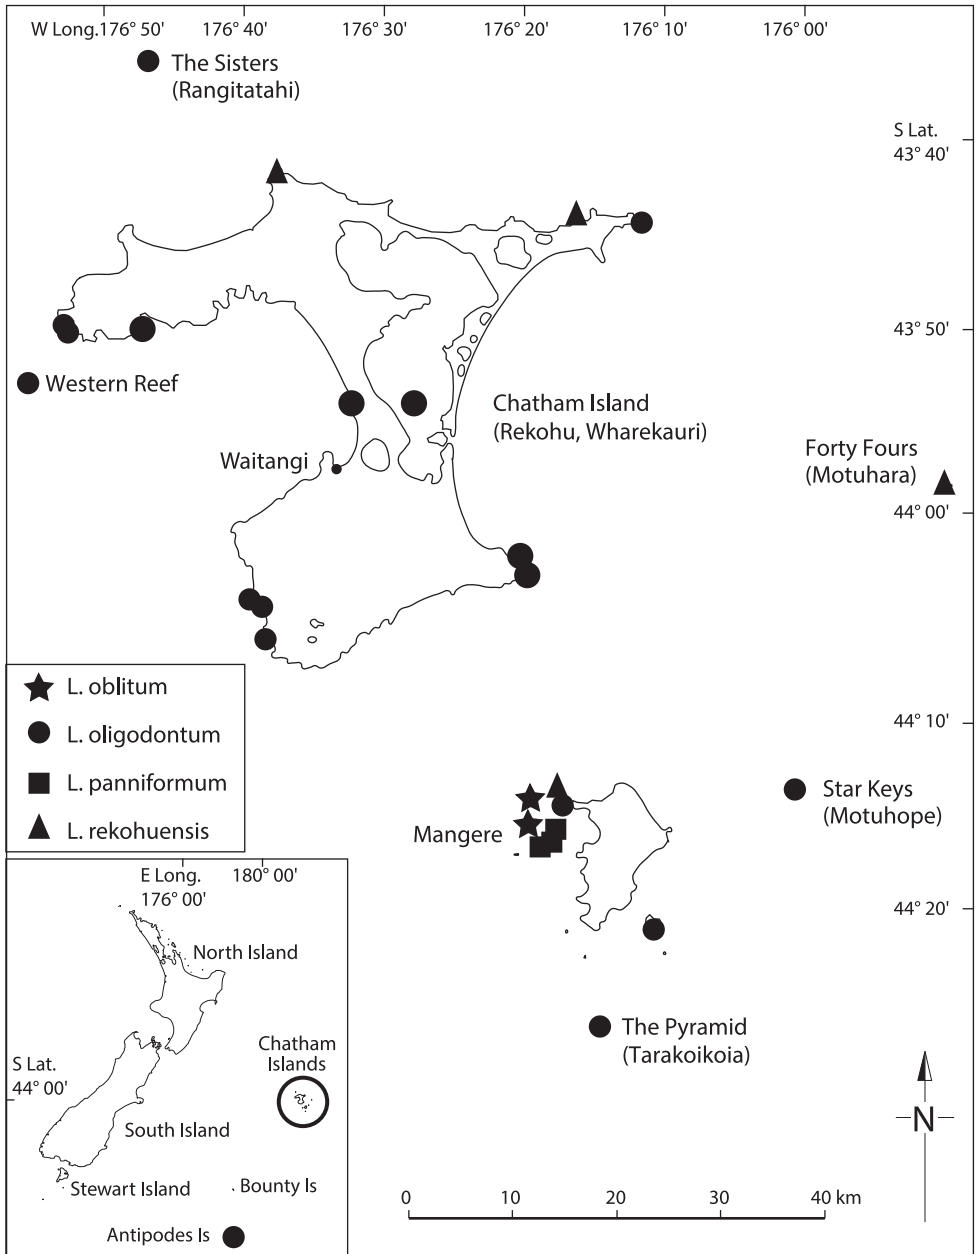

Figure 63. Distribution of *Lepidium oblitum*, *L. oligodontum*, *L. panniforme* and *L. rekohuense*.

Therefore, based on available information *Lepidium oblitum* is known from two sites, totalling 4 populations, which collectively are unlikely to exceed 100 mature individuals. Further, the total area of occupancy is considerably less than 1 ha. On the basis of that data, using Townsend et al. (2008), *Lepidium oblitum* qualifies as

“Nationally Critical” (using either criterion A(1) or A(3)) because there are fewer than 250 mature individuals known and the total area of occupancy is ≤ 1 ha. We favour criterion A(3) because a precise survey of the numbers of plants of *L. oblitum* has yet to be carried out, and available data (beyond that obtained by PdL and PBH) is unreliable because of understandable past confusion with *L. oleraceum* s.s. and *L. panniforme*.

This conservation assessment should also be qualified ‘CD’ (Conservation Dependent) because Mangere Island is subject to ecological restoration, and ongoing surveillance to ensure it remains predator-free. Should rodents establish on the island, they will affect that island’s *Lepidium* species, both directly through browse and indirectly through predation of the sea birds that maintain this species habitat. Other necessary qualifiers include ‘DP’ (Data Poor) because of the lack of precise information on population size and trend data, ‘IE’ (Island Endemic), and ‘RR’ (Range Restricted) because of its precise habitat requirements and geographically narrow-range.

***Lepidium obtusatum* Kirk, *Trans. & Proc. New Zealand Inst.* 24, 423, (1892)**
http://species-id.net/wiki/Lepidium_obtusatum

Holotype. New Zealand (Fig. 64): Port Nicholson, n.d., Miss Kirk, WELT SP030109!

Notes: Kirk’s protologue for *L. obtusatum* states “Hab. North Island: Maritime rocks at the entrance to Port Nicholson, Miss Kirk” (Kirk 1892). Only one herbarium sheet annotated ‘*Lepidium obtusatum* n.s., Port Nicholson, Miss Kirk’ and so matching the protologue as to name, collector (Miss [Lily] Kirk), type locality, and labelled in the naming authors hand could be located in the WELT (the main herbarium where Kirk material has come to be lodged) so this sheet is regarded here as the holotype.

Etymology. Although the exact meaning of the species “*obtusatum*” was not given by Kirk (1891) it seems that he took the name from the shape of the hypogynous glands (i.e. the nectaries) which he specifically noted (Kirk 1899) are “very short and obtuse”.

Description (Figs 65–68): Glabrous, prostrate, much-branched, succulent, rhizomatous, perennial herb, forming patches up to c. 1 m diam. Stems 200–300 × 3–6 mm, prostrate, succulent, flexuous, widely spreading, leafy along stems. Leaves glabrous, thick, succulent and very coriaceous, dark glossy green, variable in size and shape. Rosette leaves 50–80 × 15–20 mm, elliptic to elliptic ovate, oblong, oblong-spathulate; apex, obtuse or rounded, crenate-serrate with 3–4 blunt teeth; margin crenate, crenate-serrate, sometimes weakly bidentate, rarely entire, with 0–24 pairs of teeth; teeth up to 1.8 mm deep, mostly regular size, not protruding beyond leaf outline; base narrowly attenuate to cuneate, ± decurrent, petiole distinct, 32–40 × 1.6–2.9 mm, slightly winged, or not, channelled. Cauline leaves similar to rosette leaves but smaller (up to 42.3 × 13.3 mm), persistent; petioles distinct, and more consistently and conspicuously winged. Upper stem leaves much reduced; lamina 8.8–16.8 × 5.4–8.8 mm, broadly oblanceolate, spathulate, obdeltoid to suborbicular, apex obtuse, usually with 1 prominent and 2 smaller blunt teeth with rounded to obtuse apices (teeth not protruding beyond leaf outline); margin crenate to dentate or entire, if teeth present these in 2–6 pairs, usu-

Figure 64. Holotype of *Lepidium obtusatum* Kirk.

ally blunt ended sometimes subacute, up to 1.2 mm deep, base broadly cuneate to attenuate, petiole distinct, often appearing sessile, usually broadly winged, up to 6 mm long, channelled. Inflorescence terminal and lateral, usually obscured by associated leafy stems, racemose; racemes 9.9–45.6 mm long, rachis 0.6–0.9 mm; pedicels 2.8–3.2 mm long at flowering, erecto-patent, elongating somewhat after anthesis, glabrous. Flowers 4.3–5.0 mm diam. Sepals 4, saccate, overlapping at base, green, apex obtuse, margin white, shape and size dimorphic; lateral sepals 2.2–2.9 × 2.1–3.0 mm, orbicular, mostly glabrous, sometimes sparsely hairy, hairs 0.2–0.4 mm long, caducous; median sepals 1.9–2.9 × 1.5–1.7 mm, elliptic to obovate, abaxial surface glabrescent, sparsely hairy, hairs 0.2–0.4 mm long, caducous. Petals white, 1.3–1.8 × 1.3–1.8 mm, erect, claw minute, 0.2–0.3 mm; limb orbicular, apex obtuse. Stamens 4, ± equal lengths, 1.2–1.8 mm long, base 0.6–1.0 mm wide; anthers 0.6–0.8 mm long, yellow, pollen yellow. Ovary 1.3–1.8 × 1.3–1.7 mm, broadly ovate to suborbicular green, apex distinctly notched; style 0.3–0.5 mm long, cylindrical below, spreading at apex; stigma 0.5–0.6 mm diam. Nectaries 4, green, 0.12–0.14 × c. 0.09 mm, narrow oblong, apex obtuse. Silicles 4.9–6.4 × 4.2–4.9 mm, broadly ovate, oval-rhomboid to obovate, apex prominently notched, valves yellow-green in dried specimens, glabrous, slightly winged; style

Distribution (Fig. 44). Endemic. New Zealand, North Island, Wellington Harbour, Miramar Peninsula, in a small area of coastline between Worsler Bay and Breaker Bay.

Recognition. Kirk (1899), Allan (1961), Garnock-Jones (1988) and Garnock-Jones and Norton (1995) considered that *Lepidium obtusatum* was closely related to *L. banksii*. From that species, *L. obtusatum* is distinguished by the prostrate, rhizomatous (Figs 64, 65) growth habit, less deeply serrated (usually crenate to shallowly toothed) rosette and cauline leaves (Figs 64, 66), much smaller broadly oblanceolate, spatulate, obdeltoid to suborbicular, usually crenate margined upper stem leaves (Fig. 67), glabrous pedicles and emarginate shortly-winged silicles (Fig. 68). In this paper we have split west Auckland plants previously treated as *L. obtusatum* into a new species,

Figure 67. Upper stem leaves of *Lepidium obtusatum*. AK 4476.

L. amissum (Figs 16–20). From that species, *L. obtusatum* differs by its rhizomatous, prostrate growth habit, flexuose stems (Fig. 64), less deeply toothed (usually crenate-margined) rosette and cauline leaves (Figs 65, 66) which usually wither at flowering and fruiting, broadly oblanceolate, spatulate, obdeltoid to suborbicular, usually crenate margined upper stem leaves (Fig. 67), and inconspicuous inflorescences which are typically obscured by foliage and associated vegetative stems (Fig. 64). However, both species have similar shaped silicles (Figs 20, 68), though those of *L. amissum* are

Figure 68. Mature silicle of *Lepidium obtusatum*. CHR 464564. Scale bar = 1 mm.

slightly smaller and narrower. *Lepidium obtusatum* and *L. panniforme* have the same ETS sequence but are very different plants: from *L. obtusatum*, *Lepidium panniforme* differs by its non-rhizomatous, upright shrubby growth habit, much larger, deeply lobed to lacerate leaves, and much smaller, unwinged and only slightly notched fruit. Our rDNA ETS data also suggests that *Lepidium oblitum* is related to *L. obtusatum* though, again, they are very different plants (Figs 57–63 (*L. oblitum*) cf. Figs 64–68 (*L. obtusatum*)). *Lepidium oblitum* differs from *L. obtusatum* by its non-rhizomatous growth habit, much larger, prominently toothed (never crenate) leaves and much smaller silicles.

Ecology. Very little is known about the habitat preferences and ecology of this species. It apparently grew on rocky headlands, sea cliffs, coastal rocks and beaches (Kirk 1891, 1899; Cockayne 1921), and some herbarium specimens state that it also grew on sandy and gravel beaches at the high tide mark (e.g., WELT SP030104, SP030107). The species evidently had a most remarkable appearance when fresh, Cockayne (1921) noting that ‘in appearance *L. obtusatum* represents, even when in flower, a huge crusty saxifrage. Its leaves arranged in rosettes are very thick, glossy and rather dark green’. Its thick, fleshy leaves may have been the basis for a vernacular name ‘sea kale lepidium’ recorded by J. H. MacMahon (see WELT SP081926).

Conservation Status. It is a matter of some irony that when it was described, Kirk (1891) stated, ‘happily for *Lepidium obtusatum*, it grows in a few spots which are inaccessible to sheep, so that it will probably hold its ground for many years’. This prediction did not come to pass; the species was first treated as ‘Presumed Extinct’ by Williams and Given (1981), a status that has been maintained in all subsequent threatened indigenous vascular plant listings to the present (see Cameron et al. 1993; de Lange et al. 2009). The factors

leading to the demise of *Lepidium obtusatum* are well documented (Cockayne 1921; Norton et al. 1994; de Lange 2005). The species was a narrow-range endemic whose location on the margin of an actively expanding city meant that it was extremely vulnerable to habitat destruction (see de Lange 2005; de Lange et al. 2010a; de Lange et al. 2010c). Nevertheless it seems that, at least initially, it was very common within the small area it occupied, and Cockayne (1921) mentioned that the quarrying of rock from its cliff habitat, had, temporarily at least, caused an expansion in the population through the spread of 'underground stems'. Nevertheless, by 1951 it had gone extinct. From available evidence it seems that the biggest factor was not habitat loss but over collection (Norton et al. 1994). Herbarium specimens show that following its formal recognition by Kirk (1891), it was repeatedly gathered by botanists who made copious collections (often gathering whole plants). Most of these gatherings occurred between 1900 and 1939 (and they intensified between 1920 and 1939) ending with the last known collection in 1951 (de Lange 2005). During this period it is also likely that the modification of most of its habitat for housing and defense structures associated with military operations at Fort Dorset would have impacted on the population, as would the spread of weeds, especially those derived from nearby urban gardens. Today, all of the former range of *L. obtusatum* is now choked in a rank growth of weeds, most especially veldt grass (*Ehrharta erecta* Lam.).

Hybridism. A suite of specimens (WELT SP081927A, B, C, *J. H. MacMahon s.n.*, 1931, Seatoun) are tentatively identified here as a putative natural hybrid between *Lepidium obtusatum* and *L. oleraceum*. These specimens, which appear to be pieces split from the same plant seem to have had an erect, shrubby growth habit, with somewhat woody, flexuous branches, while the basal and upper cauline leaves are narrowly elliptic to lanceolate, deeply and sharply incised to weakly pinnatifid. The flowers, though in poor order, have four stamens (pollen stainability 0%). Only a few silicles in the specimens are mature and these measure up to 4.05×2.75 mm, are suborbicular to ovate, narrowly winged, with the apex weakly notched. Significantly, they contain no seeds. The putative parentage is based on the knowledge that both *L. obtusatum* (see collections cited above) and *L. oleraceum* were sympatric at Seatoun (WELT SP09712, *W. R. B. Oliver s.n.*) and that no other *Lepidium* species was known to be present in that area at that time. The erect, shrubby growth habit is a feature of *Lepidium oleraceum*, while morphologically the silicles are a close match for *L. obtusatum*. The shape of the cauline leaves fits within the range seen in *L. oleraceum*, though their degree of dentition also approaches that seen in *L. amissum*, *L. banksii* and *L. panniforme*.

Lepidium oleraceum G.Forst. ex Sparrm., *Nova Acta Soc. Sc. Upsal. iii*, 193 (1780)
http://species-id.net/wiki/Lepidium_oleraceum

Type Collection: From cultivated plants, originally collected from New Zealand (see below).

Neotype (Fig. 69, designated here): S, Sparrman, Nova Zelandia.

Figure 69. Neotype of *Lepidium oleraceum* G.Forst. ex Sparrm.

Notes: Nicolson and Fosberg (2004) were unsure about typification of *L. oleraceum* G.Forst. ex Sparrm., and the name has not been typified. They listed two Sparman specimens at S, but did not select a type specimen since neither of these appeared to have been gathered from cultivated plants. Given the revised taxonomic treatment presented here for the *L. oleraceum* complex, it is necessary to be certain of the application of *L. oleraceum* G.Forst. ex Sparrm. Therefore, we select one of the Sparman sheets as neotype.

When describing *L. oleraceum*, Sparman (1780) indicated that the description was based on cultivated plants: ‘*Prima vero, quam heic ex Forsterianis offerre licet, in praedi patrimoniali Sponga, seminibus ex Nova Zelandia allatis, culta per maximam partem aestatis floruit, Forsteroque Lepidium Oleraceum dicta, quippe qua, cum oleo & aceto, oleraceorum loco, ut & in jusclo cocta, deficientibus alius generis vegetabilibus, in itinere utebatur*’. Indeed, *L. oleraceum* was cultivated in Upsala (Sweden), where Sparman resided, as it is one of 11 species of *Lepidium* listed by Thunberg (1803) as having been grown there between 1780 and 1800.

It is unusual that this description was based on cultivated plants since it was the practice of A. Sparrman and G. Forster to prepare descriptions from freshly collected material during Captain Cook's second voyage (Forster and Forster 1776 (see Edgar (1969) for translation). Plant material of *L. oleraceum*, along with other edible, herbaceous coastal plants was frequently collected during the New Zealand part of the voyage to be utilised for their antiscorbutic properties (de Lange and Norton 1996). Therefore, there would have been ample opportunity to prepare the description from freshly collected material. Indeed, as noted by Nicolson and Fosberg (2004), the published description of the later homonym *L. oleraceum* G.Forst. differs from that of *L. oleraceum* G. Forst. ex Sparrm., and it is most likely that the description of the homonym was prepared on the voyage from fresh material.

The wild locality of the neotype of *L. oleraceum* is not known, except that it is from New Zealand. While anchored in Queen Charlotte Sound during May 1773, G. Forster noted 'the antiscorbutic plants grew on every beach' and 'we immediately gathered vast quantities... of a well-tasted scurvy-grass (*Lepidium*)' (Forster 1777, p. 126). They also collected it from Long Island (Hoare 1982, vol. II, p. 287), and saw it in the vicinity of Maori settlements: 'near all the places where the Indians have their huts, there grows a kind of Scurvy-Grass or *Lepidium*' (Hoare 1982, II, p. 297). Therefore, since J. R. Forster, G. Forster, and A. Sparrman would have had ample opportunity to collect *L. oleraceum* in Queen Charlotte Sound it is very likely that the neotype was collected from there. Dusky Sound, Fiordland, is the only other location where landfall was made in New Zealand during Cook's 1773 voyage, but the species is not known from the Fiordland coastline so is unlikely to have been collected from there.

Etymology. The exact meaning of the species '*oleraceum*' was not given by Sparrman (1780). However the epithet derives from the Latin '*oleraceus*' meaning 'used for herbs or vegetables' (Taylor 2002), a point that Sparrman had alluded to in a brief note he wrote in Latin on the backside of the neotype sheet.

= *Lepidium oleraceum* var. *acutidentatum* Kirk, *Stud. Fl. N.Z.*, 35 (1899)

Type Collection: NORTH and SOUTH Islands; STEWART Island; the SNARES; AUCKLAND Islands; CHATHAM Islands. In places near the sea.'

Neotype (Fig. 70, designated here): T. Kirk 367, March 1869, Taranga Islands – labelled as '*Lepidium oleraceum* var. *incisum*' in Kirk's hand. WELT SP027646!

Notes: Kirk (1899) described var. *acutidentatum* thus 'stems with slender leafy branches. Leaves 1in.–1½in. long, narrow, cuneate or oblong-spathulate, the upper portion acutely serrate or almost dentate'. Plants matching this vague description span large parts of the range of *L. oleraceum* s.l. Our searches of the herbaria where Kirk traditionally lodged specimens (see comments by de Lange 2007) have failed to find any specimens labelled by Kirk as var. *acutidentatum*. However, there are a range of specimens in WELT (WELT SP027646!, SP027647!, SP027648!, SP030087!) bearing in Kirk's hand the manuscript names 'var. *erectum*' and 'var. *incisum*', which, being unpublished, have no nomenclatural status whatsoever. These specimens, along with the generally confusing notes provided by Kirk (1899, p. 34–35) in his entry for *L. oleraceum*, suggest that *Lepidium* was a genus he was still working on close to his death

Figure 70. Neotype of *Lepidium oleraceum* var. *acutidentatum* Kirk.

on 8 March 1898 (Moore 1973, but see also comments by de Lange 2007 and de Lange and Gardner 2002). At the time of his death, Kirk was using these manuscript names on his herbarium specimens, but he was either undecided on his final choice of epithet or had yet to relabel his specimens as var. *acutidentatum*, a name which was then later published posthumously when his unfinished Flora manuscript was uplifted and published (Kirk 1899). Despite this confusion, Kirk's description of var. *acutidentatum* matches most closely those WELT specimens (*T. Kirk 367*, WELT SP027646, *T. Kirk 368*, WELT SP027647) that he had collected from Taranga Island, which is the largest of the Hen and Chicken Islands group and labelled 'var. incisum'. Notably, both specimens match his protologue as to the description of var. *acutidentatum*, e.g., 'slender leafy branches... Leaves 1in.–1½in. long, narrow, cuneate... upper portion acutely serrate'. Therefore, in the absence of any suitable material for a lectotype we designate *T. Kirk 367* (WELT SP027646) as the neotype of *L. oleraceum* var. *acutidentatum* Kirk.

Etymology. The meaning of the epithet '*acutidentatum*' was not given by Kirk (1899). However, the epithet as indicated by the protologue probably derives from the sharply toothed leaves.

= *Lepidium oleraceum* var. *frondosum* Kirk, *Stud. Fl. N.Z.*, 34 (1899)

Type Collection: 'Banks and Sol., MSS and Ic.'

Lectotype (Fig. 71, designated here): WELT SP063976/A! Isolectotype WELT SP063976/B!

Notes: Kirk (1899, p. 34) despite his rather confused and evidently incomplete treatment of *Lepidium oleraceum* nevertheless clearly described *Lepidium oleraceum* var. *frondosum* in the following manner: 'var. **frondosum**, (*sp.*), Banks and Sol. MSS. and Ic. Robust, leaves large, fleshy, broadly cuneate-oblong or oblong, sometimes 3in-5in. long and 1in. wide, sessile or narrowed into a broad petiole, serrate'. Although no specimens or locations were cited by Kirk in his protologue, his wording makes it clear that any specimens collected by Banks and Solander and labelled by them '*Lepidium frondosum*' and any accompanying illustrations made from these specimens constituted the type collections from which he formally recognised his *L. oleraceum* var. *frondosum*. Therefore, we have selected WELT SP063976/A as lectotype because this sheet, comprising two flowering and fruiting, leafy specimens, is labelled both by Kirk '*Lepidium oleraceum* Forster Prodr. N. 248 var. *frondosum*' and also in Solander's hand as '*Lepidium frondosum* Mscr'.

Etymology. The meaning of the epithet '*frondosum*' was not given by Kirk (1899) who took the name from the unpublished Banks and Solander manuscript. Nevertheless it seems reasonable to assume that the epithet refers to the large, much tooth, arched leaves typical of the robust forms of *L. oleraceum* that Kirk referred to this variety.

= *Lepidium oleraceum* var. *serrulatum* Thell., *Die Gatt. Lepidium*, 293, (1906)

Holotype (Fig. 1): P! '*Lepidium oleraceum* Forst. var. *serrulatum* Thell. n. var. 1905 3 VIII, New River, Godey' (label in A. Thellung's hand).

Notes: Thellung (1906, p. 293) described *L. oleraceum* var. *serrulatum* from a single undated gathering which, according to the specimen details, came from 'New River' where it was collected by Godey. Allan (1961, p. 177) equated this location

Figure 71. Lectotype of *Lepidium oleraceum* var. *frondosum* Kirk. © Museum of New Zealand Te Papa Tongarewa.

thus: 'S[outh Island]. New River estuary, Riverton, Southland'. The holotype bears two labels, one written in the hand of the naming author, Thellung, and the other in an unknown hand, presumably Godey, which reads '*Lepidium oleraceum* Forst var. New River, Nouv. Zélande, Godey'. We have been unable to find out who the collector Godey was.

Thellung distinguished his new variety from *L. oleraceum* s.s. thus: '*folia obovata, a medio ad apicem regulariter subtiliter et acute serrator*' meaning 'foliage obovate, regularly and acutely, finely serrated from middle of the leaf to the apex'.

Significantly the silicles of the holotype are acute rather than notched, a condition seen only in *L. castellanum* and *L. oleraceum*, neither of which are known from the southern South Island. For this reason, we suspect that the gathering was collected from the northern part of New Zealand, rather than the southern South Island, and that Allan's interpretation of location of 'New River' is incorrect. We also suspect that the exact location of the 'New River' will now never be known. In all probability this name may have simply been one used locally for some other part of New Zealand.

The obovate leaves of *Lepidium oleraceum* var. *serrulatum* place this variety within *L. oleraceum* (as treated here) rather than *L. castellanum*. Within *L. oleraceum* s.s., there are a few vegetatively similar, obovate-leaved plants with finely serrated leaf margins that approach the extreme condition seen in var. *serrulatum*. These gatherings all come from offshore islands in the northern part of the North Island (e.g., Three Kings Group, *A. E. Wright* 6072, AK 173005; Rock Stack north of Motuopao Island, *R. Parrish s.n.*, AK 196229; Motutakapu Island, *R. Parrish s.n.*, AK 209112). However none of those obovate-leaved plants have such prominently serrated leaf margins as the holotype of var. *serrulatum*. Based on these observations, we think that var. *serrulatum* was collected from somewhere in the northern part of the range of *L. oleraceum*, and that it represents nothing more than an extreme form of that species, which even following our treatment here remains a highly variable species.

Etymology. Thellung (1906) chose the epithet '*serrulatum*' to reflect the finely serrated / serrulate leaves of the holotype.

Description (Figs 72–75). Tap-rooted, glabrous, strongly pungent smelling, much-branched, erect, perennial, herb up to 1.2 × 1.3 m, usually less. Rootstock woody, exposed portion smooth, in old specimens usually retaining dead stem remnants admixed with actively growing stems. Stems sparse to closely packed depending on local growing conditions, persistent (only partially dying back in winter), erect to spreading; mature stems 0.2–1.5 m long, 3–15 mm diam. stout, woody near base, weakly angled to terete, devoid of foliage on lower and middle parts of stems; new stems 20.0–800.0 × 2.5–10.0 mm, fleshy, rigid, initially ± square, prominently angled, becoming ± terete with age, bases much covered in leaf abscission scars, middle and upper portion leafy. Leaves coriaceous, fleshy, green to dark green, rosette-leaves absent, stem leaves withering with age, variable in size and shape; petiole distinct, 2.0–50.0 × 1.2–5.3 mm, decurrent, weakly to prominently channelled, sometimes broadly winged, often with a broadly sheathing base; lamina variable 16.2–120.0 × 3.0–46.3 mm decreasing in size toward inflorescences, linear, linear-lanceolate, lanceolate, obovate, oblong, obdeltoid,

Figure 72. Growth habit of *Lepidium oleraceum* on North Brother Island (image E. Dale).

oblanceolate to broadly elliptic, rarely spatulate; apex acute, subacute to obtuse, usually tridentate, rarely praemorse; margin coarsely and regularly to irregularly dentate, dentate to biserrate, sometimes deeply incised, finely denticulate or subentire; teeth

Figure 73. (A) Inflorescences of *Lepidium oleraceum*; (B) close up of flowers.

usually protruding beyond leaf outline; in 10–60 pairs, up to 4 mm deep, increasing in size toward apex, sometimes with sporadic larger teeth randomly appearing from about the middle portion of lamina margin, or with teeth arranged \pm evenly along lamina margin; base broadly cuneate tapering, sometimes extending into a broad petiole wing. Inflorescences racemose, 20.4–90.5 mm long at fruiting, rachis 0.7–2.35 mm diam., terminal and lateral, usually leaf-opposed, often long-persistent, pedicels 3–10 mm

Figure 74. (From left to right) basal-, mid- to upper-stem leaves of *Lepidium oleraceum*. Scale bar = 20 mm.

long at fruiting, erecto-patent. Flowers 3.0–4.2 mm diam., fragrant. Sepals 4, saccate, pale to dark green with a broad white, \pm undulose margin; lateral sepals broad, 0.5–1.4 mm diam., orbicular, obovate to broadly obovate, \pm overlapping at base, apex rounded to obtuse, abaxial surface often hairy, hairs 0.1–0.4 mm long, eglandular or with glandular tip, mostly shedding at anthesis except near base, median sepals 0.5–0.9 mm diam., broadly elliptic, pale to dark green with a broad white, \pm undulose margin, apex rounded to obtuse, abaxial surface glabrous. Petals white, 1.3–2.2 \times 1.6–2.3 mm, spreading, claw 0.4–0.9 mm long; limb obovate, obovate-spathulate to orbicular, apex obtuse to rounded often slightly emarginate, margins smooth, sometimes weakly undulose. Stamens 4, filaments 1.2–2.0 mm long, white; anthers 0.3–0.5 mm long, yellow. Ovary 1.1–1.8 \times 0.6–1.3 mm, ovate, broadly ovate to elliptic, green-brown, apex round or subacute; style 0.11–0.4 mm long, cylindrical; stigma 0.2–0.5 mm diam. Nectaries 4, 0.2–0.3 \times 0.1–0.15 mm, narrow-oblong to deltoid, pale translucent green. Silicles cartilaginous when fresh, coriaceous when dry, 2.6–4.8 \times 1.7–3.4 mm, elliptic, rhomboid (rarely orbicular-rhomboid), apex acute to rounded, valves green maturing grey-green to straw-yellow, glabrous, not winged; style 0.3–0.6 mm long, exserted. Seeds 2, 1.2–1.9 \times 0.8–1.4 mm, narrowly to broadly ovoid, brown to orange-brown, not winged. FL Aug–Jun. FR Sep–Jul.

Distribution (Fig. 76). Endemic. Kermadec Island (Dayrell, Napier and Curtis islands). New Zealand, Three Kings, North, South (North-west Nelson and Marlborough Sounds and Chatham (Mangere Island) islands).

Recognition. Although extremely variable with respect to stature, leaf shape, size and dentition, *Lepidium oleraceum* is consistently recognised by the glabrous pedicels and by the mature silicles which are elliptic, rhomboid (very rarely orbicular-rhomboid) and with an acute to rounded apex that leaves the style remnant standing proud above the silicle apex (Fig. 75). Silicles often give the false impression of being notched, something that happens when the valves are over mature and so have started to dehisce at the apex. *Lepidium oleraceum* often forms a widely spreading but erect bushy plant whose stems are long persistent and, while slowing in growth over winter, do not die back to the rootstock as do all other New Zealand members of *L. oleraceum* complex except *L. castellanum* and, on occasion, *L. oblitum* and *L. panniforme*. *Lepidium oleraceum* also lacks the distinct rosette leaves seen in all other members of the *L. oleraceum* complex except *L. castellanum*.

Ecology. Much has been written about the ecology of *Lepidium oleraceum*, of which the summary provided by Norton et al. (1997) still applies despite our segregation here of 10 new species from it. *Lepidium oleraceum* is intimately associated with sea-bird trails, roosts and nesting grounds. Plants are dependent on these birds not only for the habitats they create through disturbance but also the nutrients they bring from the sea in the form of guano and discarded or regurgitated food, and because these birds assist with seed dispersal. Seed dispersal is most readily facilitated by birds because *Lepidium oleraceum*, as well as growing around bird nests and burrows, is often used for nesting material. In this way, the seeds, which are mucilaginous when wetted, can easily stick to the feathers and feet of birds.

Lepidium oleraceum tends to be short-lived, with individual plants rarely persisting for more than three years in the wild and up to five in cultivation. It has also been observed that some wild populations are prone to sudden crashes, and may even completely die out, only to reappear some years later. It is unknown whether the reappearance is from a residual seed bank or from seeds dispersed by birds from another site.

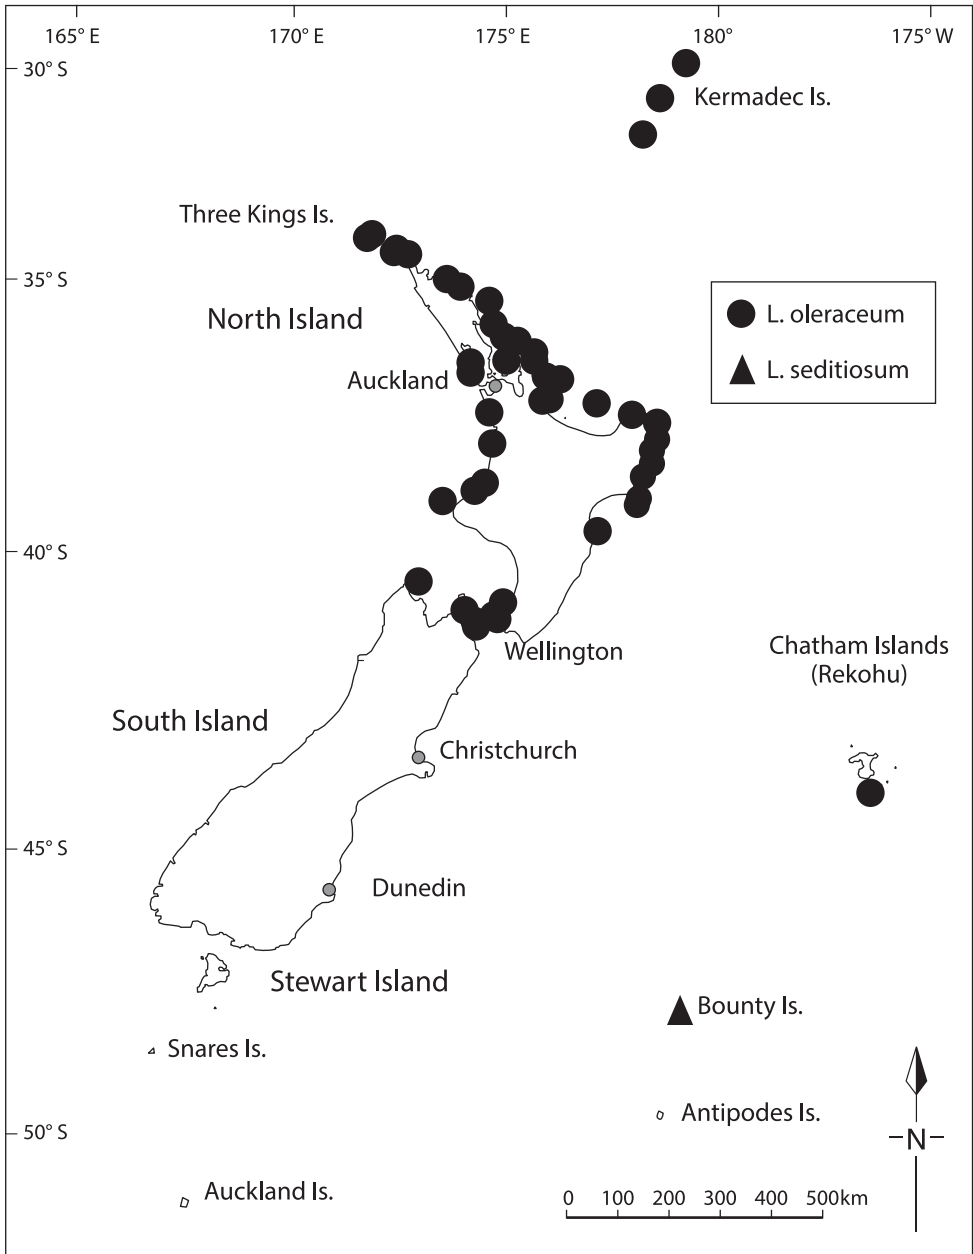

Figure 76. Distribution of *Lepidium oleraceum* and *L. seditiosum*.

Plants may even behave as annuals in some locations because, despite its predilection for open, drought-prone coastal habitats, *L. oleraceum* does not relish drought.

Norton et al. (1997) stressed the importance of sea birds in providing the nutrient regime necessary to sustain the species, arguing that the loss of sea bird breeding

grounds from large parts of the country best explains the rapid demise of *Lepidium oleraceum*. However, while that view is probably still valid, some anomalies remain to be explained. For example, *Lepidium oleraceum* appears to have always been scarce on the Three Kings Islands, which are naturally predator-free and harbour large sea bird breeding colonies. On those islands, *Lepidium* is confined to white-fronted tern (*Sterna striata* Gmelin, 1789) and red-billed gull (*Chroicocephalus scopulinus* (Forster, 1844)) nesting grounds, and is absent from all other sea bird colonies, including the heavily burrowed ground left by breeding black-winged petrel (*Pterodroma nigripennis* Rothschild, 1893). This requires further study, as on many Hauraki Gulf islands *Lepidium oleraceum* is usually absent from tern and gull nesting sites, and more usually associated with petrels such as grey-faced (*Pterodroma macroptera gouldi* (F.W.Hutton, 1869)), black-winged, and Pycroft's (*Pterodroma pycrofti* Falla, 1933), or with shearwaters (*Puffinus* spp.), white-faced storm petrels (*Pelagodroma marina* Latham, 1790) and common diving petrels (*Pelecanoides urinatrix* (Gmelin, 1789)). On some islands supporting these birds and gannets (*Morus serrator* Gray, 1843), *Lepidium oleraceum* is found only near gannet colonies. Interestingly, *Lepidium oleraceum* was regarded as one of the most common plants on the foreshore of Aorangi Island, Poor Knights until the removal of pigs in 1936 (Reynolds 1988; de Lange and Cameron 1999), yet now, despite the massive sea bird colonies covering that island, this species is scarce, being mostly confined to cliff habitats and recent slip scars (de Lange and Cameron 1999).

These patterns suggest that the overriding need for this species is a combination of nutrient rich soils and frequent habitat disturbance to keep sites free from competition. Yet why *Lepidium oleraceum* is so uncommon on some naturally predator free islands which appear to meet these criteria, and why it seems to show preferences for particular bird nesting associations that can vary from island to island remains to be elucidated.

It is also possible that *Lepidium oleraceum* was deliberately cultivated and utilised as a pot herb by Māori who knew the species (and probably those allied to it) as “nau” (see de Lange and Norton 1996). The early writings of Banks, Solander and Forster make frequent mention of its abundance near Māori dwellings and settlements and that these people often directed Cook's shore foraging crews to places where it could be collected (Beaglehole 1962, 1967, 1968; Forster 1777; Hoare 1982; de Lange and Norton 1996). While it could be argued that *Lepidium oleraceum* flourished around coastal human habitations because these were sites of frequent disturbance and nutrient enrichment, the fact that Māori had a specific name for the plant and knew that it was edible suggests that they may also have cultivated it, a possibility that needs further critical ethnobotanical investigation.

Conservation Status. Prior to this revision, *Lepidium oleraceum* was assessed as ‘Threatened/Nationally Vulnerable_{CD, EF, RR, Sp}’. Following the segregation of *Lepidium oleraceum* s.l. in this paper a new threat listing of *L. oleraceum* s.s. is now necessary. As circumscribed here, *Lepidium oleraceum* is now confined to the Kermadec Islands, North Island (and adjacent offshore islands), northern South Island and Chatham Islands (Mangere Island only). Within this area, *Lepidium oleraceum* is only “common” (i.e. occurring in numbers greater than 200 individuals) on a very few islands and is-

lets, notably Mahuki Island west of Great Barrier (Aotea Island), Karewa Island in the Bay of Plenty, Waioioi Reef off the west coast of Albatross Point, and on several islands (notably Stephens Island) within the Marlborough Sounds. It is now a very uncommon species elsewhere within this range, with most known populations comprising 50 or less mature individuals. At all known sites, populations are naturally prone to the sudden collapse and boom cycles briefly described by Norton et al. (1997) and Norton and de Lange (1999). Also, because there are few places where the *Lepidium oleraceum* s.s. is being closely monitored, available data on natural population fluctuations is insufficient from which to provide an overall general assessment of total population size and stability. Irrespective, the species is still very widespread in northern New Zealand and the Marlborough Sounds, and whilst most of the remaining populations are small (i.e. < 50 mature plants) this may reflect a natural state of affairs, as past accounts of this species' abundance do seem to have been exaggerated (see comments by de Lange and Norton 1996). Nevertheless, in the absence of key data on trend and rate of decline, it is difficult to provide a meaningful threat assessment, though the situation is not so difficult as to recommend a conservative assessment of 'Data Deficient'. Sufficient information exists to attempt a threat listing here, from which we recommend a conservation listing of 'Threatened/Nationally Vulnerable' applying criterion 'C' of Townsend et al. (2008, p. 20–21). This assessment is based on data collected and stored by the Department of Conservation-sponsored coastal cress recovery team (P. I. Knightbridge pers comm.), from which we estimate the total population for this species at c. 3000–3500, and a rate of decline of c.10% over the next 10 years. As few wild plants last longer than three years, we have opted for (as recommended by the manual (Townsend et al. 2010)) the rate of loss rather than generation time. To that assessment the qualifiers 'CD' (Conservation Dependent), 'EF' (Extreme Fluctuations), 'RR' (Range Restricted) and 'Sp' (Sparse) still apply but we recommend the addition of 'DP' (Data Poor) to reflect the overall absence of trend data.

Hybridism. Putative hybrids have between *L. oleraceum* and *L. flexicaule* and *L. obtusatum* are discussed under those species.

Figure 77. Holotype of *Lepidium oligodontum* de Lange et Heenan.

Figure 78. Wild plant of *Lepidium oligodontum* on Te Wakaru Island, showing decumbent growth habit.

Eymology. The name ‘*oligodontum*’ from the Latin meaning ‘few teeth’ refers to the leaves of this species which may be deeply toothed, sparingly toothed near the apex or entire, sometimes with all three conditions on the same plant. Plants with deeply toothed leaves are uncommon, whilst those with sparingly toothed leaves are more usual.

Description (Figs 78–80). Tap-rooted, decumbent, rather flaccid, pungent-smelling, summer-green, succulent, perennial herb forming sparse to densely leafy, circular ± flat masses up to 1 m diam., and arising from stout, semi-circular, greyish-white or reddish-grey (when exposed) rootstock 6.0–30.0 mm diam. Tap root woody, up to 0.2 m long, deeply descending. Plants dying down to rootstock and/or previous seasons stem nodes, at fruit set or soon thereafter. Stems decumbent, widely spreading, up to 0.8 m long and 3.20–4.56(–5.20) mm diam., ± woody throughout, ± square to somewhat angular-spheroidal in cross-section and prominently ridged on angles (this especially conspicuous when dry), dark reddish-green to dark green when fresh, drying dull grey; stems usually heavily branched from base, branches and branchlets numerous, prostrate, widely spreading, and usually very leafy; basal portion of stems, glabrous. Leaves glabrous, succulent, dark green, green to yellow-green at senescence turning yellow. Rosette leaves 5–10(–14), mostly present in autumn – early spring but not persisting (very rarely so) at fruiting; petioles distinct up to 70 × 2 mm, flat or slightly concave in cross-section, succulent; lamina narrowly spatulate, cuneiform, obdeltoid, obovate or rarely elliptic-lanceolate, up to 60 × 22 mm, margins entire, or sparingly

Figure 79. (A) (from left to right) variation in rosette and basal-stem leaves from a single plant of *Lepidium oligodontum*; (B) (from left to right) leaf variation within populations from The Sisters (Rangitatahi), Western Reef, Point Somes, (Rekohu), Moriori Creek (Rekohu), Star Keys (Motuhope), Rangitira and Antipodes Island. Scale bars = 20 mm.

dentate in upper $\frac{1}{3}$, if teeth present then in 1–3(–5) pairs running to and including the usually tridentate apex, basal teeth often asymmetric, base narrowly cuneate, cuneate to attenuate. Middle stem leaves persistent or not at fruiting; petiole usually distinct

Figure 80. Mature silicle of *Lepidium oligodontum*. AK 295634. Scale bar = 1 mm.

(rarely not) up to 14.0×1.13 mm, mostly flat in cross-section, sometimes slightly concave, succulent; lamina spatulate, cuneiform, linear-cuneiform, oblanceolate, narrowly ovate, to narrowly obovate, or rarely orbicular, $10.6\text{--}22.8(-33.2) \times 5.4\text{--}9.2(-17.5)$ mm; margins entire, or sparingly dentate with 1–2–3(–5) pairs of teeth in upper $\frac{1}{3}$ apex usually tridentate, basal teeth often asymmetric, lamina base narrowly attenuate, attenuate, cuneate or rarely acute. Upper stem leaves usually without a distinct petiole, petiole if present 1.0–3.6 mm, flat or slightly concave; lamina narrowly cuneiform, oblanceolate, or narrowly obdeltoid, $7.6\text{--}10.8(-11.9) \times 2.7\text{--}3.1(-3.5)$ mm; margins entire or weakly dentate to deeply incised, if dentate or incised then with 1(–2) often asymmetrical teeth present in the upper $\frac{1}{3}$, apex entire or tridentate, lamina base cuneate to narrowly cuneate. Racemes (5.0)–9.7(–28.9) mm long, usually congested, elongating up to 60 mm at fruiting, terminal and axillary; rachis and pedicels glabrous; pedicels, erecto-patent to patent, $0.82\text{--}1.00(-2.08)$ mm, $2.1\text{--}3.5(-6.1)$ mm long at fruiting. Flower buds dark green to green, apex glabrous. Flowers sweetly fragrant, $1.2\text{--}1.5(-2.2)$ mm diam. Sepals 4, saccate, pale to dark green with a broad white, \pm undulose margin, pale to dark green with a broad white, \pm undulose margin, deeply concave, adaxially weakly keeled or not; lateral sepals $0.9\text{--}1.4 \times 0.8\text{--}1.2$ mm, broadly ovate to oblong, \pm overlapping at base, apex rounded to obtuse, adaxial surface mostly glabrous sometimes diffusely papillate, abaxial surface often hairy, hairs patent, weakly flexuous, $0.1\text{--}0.4$ mm long, eglandular, mostly shedding at anthesis except near base; median sepals $1.0\text{--}1.4 \times 0.9\text{--}1.2$ mm, broadly ovate to oblong, apex rounded to obtuse, adaxial surface glabrous, abaxial surface usually glabrous, rarely sporting a small tuft of patent, eglandular, flexuous hairs $0.1\text{--}0.2$ mm long. Petals usually present (occasionally absent) usually equal to or slightly overtopping sepals (rarely > sepals), white, $0.8\text{--}1.6(-1.9) \times 0.6\text{--}1.2(-1.8)$ mm, patent, clawed; limb broadly obovate, apex obtuse, rarely retuse. Stamens 2–4(–6), equal. Anthers c.0.14 mm long. Pollen bright yellow. Nectaries 2, subulate, 0.32 mm long. Silicles somewhat fleshy and distinctly turgid when fresh, on drying collapsing to form a coarse reticulum, broadly orbicular

to orbicular, (3.0)–3.5(–3.8) × (2.8–)3.0–3.2(–3.8), margin slightly winged, sometimes more so toward apex, apex not or very slightly notched, base cordate (rarely truncate), valves green maturing yellow-green, glabrous; style 0.2–0.8(1.2) mm long, free from the narrow wing, equal to or slightly exceeding the notch; stigma 0.4–0.6 mm diam. Seeds 2, ovoid to suborbicular, light red-brown or red-brown, not winged, 0.84–0.98 × 0.80–1.00 mm. FL. Dec–Mar. FR. Dec–Apr.

Distribution (Fig. 63). Endemic. New Zealand, Chatham and Antipodes islands. On the Chatham Islands, it is known from Rekohu and South West (Rangatira) Island, and from all of the outlying islets and vegetated rock stacks except Mangere, Little Mangere and the Forty-fours. It is apparently absent from Rangiauria (Pitt Island). On the Antipodes Islands, *L. oligodontum* is known only from Antipodes Island, where it is has a very restricted occurrence at the northern end of that island (Godley 1989).

Recognition. *Lepidium oligodontum* is recognised by the combination of having a decumbent rather than erect growth habit (Fig. 78), glabrous stems, branchlets and pedicels, leaves which are either sparingly toothed or entire (Fig. 79), flowers with 2–4(–6) stamens, and silicles mostly broadly orbicular to orbicular, slightly winged, mostly cordate-based, and that are distinctly swollen (turgid) when fresh and whose apices are slightly notched (Fig. 80). Of the New Zealand species, *L. oligodontum* is unusual for the variability of stamen number. In some populations plants are found that have either two or four stamens, whilst others may show a range from two to four (rarely six). Some populations consistently have four stamens whilst others show a grade from two to six.

Ecology. *Lepidium oligodontum* is a strictly coastal, island endemic inhabiting richly manured, frequently disturbed habitats. On Rekohu it is extremely uncommon and now virtually confined to coastal cliffs, near-shore rock stacks, and, very occasionally, coastal turf communities, especially in places frequented by New Zealand fur seals (*Arctocephalus forsteri* Lesson 1828). In these habitats it is usually associated with *Disphyma papillatum*, *Apium prostratum* subsp. *denticulatum* P.S.Short, *Crassula moschata* G.Forst., *Dichondra* spp., *Hebe chathamica*, *Leptinella potentillina* F.Muell., and *Puccinellia chathamica*. In a few sites, such as at Point Somes and Ocean Bay, *Lepidium oligodontum* grows intermingled with *L. flexicaule* and hybrids between both species have occasionally been collected where they co-exist. Habitats occupied by *L. oligodontum* vary on the outer islands, islets and rock stacks of the Chatham archipelago. It is an occasional associate of coastal turf and cliff vegetation on islands such as South East (Rangitira). On the other outer islands (e.g., The Sisters (Rangitatahi), Star Keys), islets (e.g., The Pyramid (Tarakoikoia)), reefs and rock stacks *L. oligodontum* is a prominent species of the distinctive guano-dependent vegetation that has developed in the presence of New Zealand fur seals, and sea birds such as the albatrosses (*Diomedea sanfordi* Murphy, 1917, *Thalassarche eremita* (Murphy, 1930), *Thalassarche bulleri*), northern giant petrel (*Macronectes halli* (Mathews, 1912)), Chatham Island fumar prion (*Pachyptila crassirostris pyramidalis* C.A.Fleming, 1939), and white-fronted tern (*Sterna striata* Gmelin, 1789) (Aikman and Miskelly 2004). In these guano-enriched habitats, *L. oligodontum* is usually found growing in close association with the woody shrub, *Leptinella featherstonii* F.Muell., and herb, *Senecio radiolatus* subsp. *radiolatus* (see de Lange and Sawyer 2008). On Rabbit Island, *L. oligodontum* was found growing at the entrance to petrel (*Pterodroma* spp.) and shearwater (*Puffinus* spp.) burrows, sometimes in association with *L. oblitum* and *L. rekohuense*, and other coastal turf plants such as *Disphyma papillatum*. Detailed information on the habits of *L. oligodontum* on the Antipodes is lacking, although herbarium specimens and people's observations (G. A. Taylor and S. P. Courtney pers. comm.) note that it is seemingly restricted to a few coastal headlands where it grows at the top of steep cliffs in sites kept free of taller vegetation by wind and salt burn. Oddly, despite the abundance of sea birds and seals on the Antipodes, *L. oligodontum* was not observed growing anywhere near sites frequented by these animals, leading us to infer that the habitat is similar to that occupied along the southern coastal cliffs of Rekohu, e.g., Moriori Creek and Otawuae Point.

Lepidium oligodontum, more than any other member of the *L. oleraceum* complex, has a very seasonal growth pattern, with most vegetative growth occurring from late winter to summer. *Lepidium oligodontum* plants are scarcely visible during autumn and early winter because growth virtually ceases and most of the foliage, branches, branchlets and inflorescences wither away. During this time of 'dormancy', plants persist as minute leafy shoots clustered around the rootstock apex, or as a single leafy rosette.

It has also been observed that the annual growth cycle of *L. oligodontum* seems to be dictated, perhaps more than any other New Zealand *Lepidium*, by the onset and spread of the reproductive phase of the oomycete *Albugo candida* (Pers.) Kuntze. The spore-bearing pustules of *A. candida* appear on wild and cultivated plants within weeks

of the initiation of spring growth, and by late January/February have usually erupted across most of the stem leaves, flowers and fruits. Further vegetative growth from the host plant is either completely retarded or aborted. Observations of wild population of *Lepidium oligodontum* suggest that these seasonal eruptions of *Albugo candida* have a tremendous impact on this species' vigour, and we have found that the intensity of these *A. candida* infections make it impossible to maintain *L. oligodontum* in cultivation. It is not clear if the severity of these attacks in *L. oligodontum* populations is natural or a consequence of other, as yet undetermined, external factors, or even if the strain of *A. candida* infecting *L. oligodontum* is endemic to it (E. H. McKenzie pers. comm.). Whether indigenous, endemic or naturalized, this oomycete is now, at least, a critical constraint on the growing season, flowering and fruiting of this species, especially in what appear to be ecologically suboptimal sites. Field observations suggest that *Lepidium oligodontum* is more abundant and the plants clearly thriving in sites where nutrient levels remain high, such as on the guano-enriched Pyramid (Tarakoikoia), or within the seal colonies of the Star Keys and Western Reef (de Lange and Sawyer 2008). Despite the presence of *A. candida*, their growth season is longer and the plants more persistent than at any of the other Chatham Islands' *L. oligodontum* sites that we have been able to visit.

Conservation Status. *Lepidium oligodontum* as *L. aff. oleraceum* (b) (AK 208579; Antipodes – Chatham Islands) was listed in Appendix 2 of de Lange et al. (2009, p. 89) as “Threatened/Nationally Critical _{DR, EF, RR}”. With its formal description and recognition, a reassessment of that conservation listing is now appropriate.

Aside from a few, small, isolated islands, islets and rock stacks in the Chatham archipelago and possibly Antipodes Island, trend data gathered by the New Zealand Department of Conservation over the last 15 years confirm that *Lepidium oligodontum*, though naturally prone to extreme population fluctuations, is now in final stages of a major terminal decline on Rekohu (A. Baird unpubl. data).

Based on our knowledge of this species' ecology, its loss from Rekohu appears to be the result of an initial loss of habitat as key sea bird and seal populations on the larger islands of the group went extinct over the last 600 or so years (King 1989). Habitat loss has accelerated since the early 19th century following the settlement of Rekohu by Maori and Europeans whose impacts on the remaining seal and sea bird breeding grounds have been severe (Wills-Johnson 2008; King 2008). Land clearance and ongoing modification of the main Chatham Islands has also facilitated the spread of competing plants that were previously unknown there and which had been either deliberately or inadvertently introduced (de Lange et al. 2008; de Lange et al. 2011).

Another factor in the decline of this species is the oomycete *Albugo candida*, discussed above. It remains unclear whether *Albugo candida* truly poses a serious threat to indigenous New Zealand Brassicaceae, and in particular *Lepidium oleraceum* s.l. (Armstrong 2007). Nevertheless, our field observations and the remarks made by collectors on herbarium specimens note that *Albugo candida* strongly retards the growth of *Lepidium oligodontum* and that it continues to be a major factor in the decline and loss of many of the smaller populations on Rekohu. *Lepidium oligodontum* seems to

be buffered from the severity of *Albugo candida* outbreaks only on less modified outer islands, islets and rock stacks of the Chatham Island archipelago and, presumably, the Antipodes Islands, where there are intact, functional guano- and marine mammal-based ecosystems (de Lange and Sawyer 2008). Furthermore, *Albugo candida* has prevented *Lepidium oligodontum* from being successfully cultivated beyond a single season or translocated to new sites (A. Baird, S. Benham, G. Davidson, J. Santos, T. Silbery, and R. Smith pers. comm.).

Aside from *Albugo candida*, some of the Rekohu populations of *L. oligodontum* are also subjected to a diverse range of threats. These include browse by feral sheep (*Ovis aries* Linnaeus, 1758), cattle (*Bos primigenius taurus* (Linnaeus, 1758)) and possum (*Trichosurus vulpecula* (Kerr, 1792)). Possums, in particular, have been found avidly browsing *Lepidium oligodontum* plants growing on near-shore rock stacks at Point Somes and Te Koparuparu Bay on Rekohu.

Following extensive surveys of the Chatham Islands by the Department of Conservation during the summer of 2005/2006, 14 functional subpopulations were recognized, down from 28 known in 1996 (a decline rate of 50 % over 10 years). These gave a total population for that island group of 1321 adults, of which 748 (57%) were confined to one site, Western Reef. These figures exclude population data for The Sisters and The Pyramid (Tarakoikoia), which are privately owned and inaccessible to the Department of Conservation. To date, the few reports of *L. oligodontum* from these islands suggest that it is “common” (R. Emberson and P. Schofield pers. comm.). Monitoring at Te Wakaru Island, which has an intact guano and marine mammal-based ecosystem, shows that the population there fluctuates greatly from year to year. Therefore, trend data needs to be gathered over several years before any evidence of decline can be distinguished from natural population “boom/bust” cycles. Little is known about the species’ status on the Antipodes. In part because these remote islands are infrequently visited, and then usually by ornithologists at times when our data for the Chatham Islands suggests *L. oligodontum* was already undergoing its seasonal decline. For example, an ornithological party considered *L. oligodontum* to be very uncommon there in 1995, seeing perhaps only a few tens of plants (G. A. S. Taylor pers. comm.). These were restricted to one site at Reef Point, where, because of their close proximity to a former castaway hut and the unusual habitat they occupied, it was thought that the few plants seen may have been introduced there (G. A. S. Taylor pers. comm.). This contrasts somewhat to the observations published by Godley (1989) (a botanist) who visited the islands in 1969. Godley recorded *L. oligodontum* (as *L. oleraceum*) as being ‘common there [at Reef Point] on coastal rocks and occasionally on cliffs’, though he then went on to state that ‘it was not seen by any of the 1969 party at other possible localities’. Nevertheless, based on what we now know of the *Lepidium oleraceum* group, the possibility that *L. oligodontum* is introduced to the Antipodes seems unlikely, and based on the historical observations summarised by Godley (1989, p. 546) it would seem that, if anything, observers were witnessing different stages of the ‘boom/bust’ cycles observed elsewhere on the Chatham Islands. Nevertheless, as the Antipodes Islands are so infrequently visited, it is important that future visits focus

on gathering better data and setting up long-term monitoring of that island group's *Lepidium oligodontum* population.

In summary, we consider that *Lepidium oligodontum* is more appropriately assessed as 'Threatened/Nationally Vulnerable' (criteria B(1/1) of Townsend et al. (2008)). This is based on a population size that is likely to be between 1000 and 5000 mature individuals spread across the Chatham and Antipodes island groups (noting that our best available data (field season 2005/2006) recorded 1321 plants from those accessible locations on the Chatham Islands; that outside those areas on other islands in that group, such as The Sisters (Rangitatahi), Star Keys and The Pyramid (Tarakoikoia) there are likely to be at least as many individuals; and that there no reliable population data for the Antipodes Islands). Further, it would seem that, aside from the ongoing decline of what are effectively non-functional, residual populations on Rekohu, the species is secure on the outlying islands, islets and rock stacks of the Chatham Islands group where the ornithocoprophilous ecosystem remains intact and functional. Accepting the absence of hard data for the Antipodes Islands, observations by field parties suggests that *L. oligodontum*, while less abundant there, is probably also secure due to the intact nature of the ornithocoprophilous ecosystem there.

To this recommended threat listing we suggest appending the following qualifiers 'DP' (Data Poor – to reflect uncertainty over the status of the species on the Antipodes Islands), 'EF' (Extreme Fluctuations – to reflect the wide population fluctuations experienced throughout a normal growing season), and 'RR' (Range Restricted – because *L. oligodontum* is naturally confined to a geographically small part of the New Zealand Botanical Region).

Holotype. Chatham Islands (Fig. 81): Mangere Island, Mangere Island Nature Reserve, Mangere Island, 23 November 2000, M. Thorsen, AK 255607! Isotype: CHR!, K!

Etymology. The name "*panniforme*" from the Latin meaning "like a shredded rag" (N. G. Walsh pers. comm.) refers to the ragged appearance of the deeply lacerate, tattered basal and lower stem leaves characteristic of this species.

Description (Figs 82–85). Tap-rooted, pungent-smelling, summer-green, perennial herbarising from stock rootstock 7.3–8(–10) mm diam. Growth habit, erect to suberect, loose to densely branched plants up to 1 m across. Stems ± persistent, sometimes dying down to rootstock over winter or in times of adversity; upright to

Notes "New species allied to *L. oleraceum* but differing in suberect spreading growth habit; basal, mid and upper stem leaves that are deeply toothed and/or lacerate; flowers with 2-4 stamens, and by the orbicular notched silicula. Known only from Mangere and Little Mangere Islands. P. J. de Lange notes. DUPLICATE TO: CHR, K

Figure 81. Holotype of *Lepidium panniforme* de Lange et Heenan.

spreading, bases often very stout, \pm spherical, somewhat woody when mature 10–15 \times 10–12 mm, comprised of numerous old leaf and stem bases, sometimes producing roots, new seasons grow erect to suberect, glabrous, sometimes with very sparse, appressed, caducous, silky 0.5–1 mm long, hairs near stem apices; at fruiting stems often devoid of foliage for much of length. Leaves glabrous, firmly fleshy to succulent, usually dark green to green, sometimes yellow-green. Rosette and stem leaves usually withering at fruiting but sometimes with a few long persistent. Petiole distinct, 20–35(–40) \times 2–9 mm. Lamina oblanceolate, lanceolate, narrowly lanceolate (rarely spathulate), 50–100 \times 10–30 mm; either deeply toothed and/or lacerate or with distal $\frac{2}{3}$ to $\frac{1}{3}$ deeply toothed and/or deeply lacerate, teeth in 10–18(–20) pairs, blunt to sharp, running to and including apex and usually extending beyond leaf outline, base cuneate to narrowly cuneate. Middle stems leaves usually with indistinct petioles, these 10–30 mm long; lamina narrowly linear-lanceolate to linear, often recurved to falcate from or near $\frac{1}{2}$ to $\frac{1}{3}$ of leaf length, 50–80(–120) \times 3–6 mm; margins deeply lacerate and/or toothed, teeth usually prominent, often confined to the upper $\frac{2}{3}$, in 12–18(–30) pairs, these running to and including the apex; lamina base tapered, very narrowly cuneate. Upper stem leaves with or without a distinct petiole, petiole if present 40–60 mm, linear to linear-spathulate, occasionally narrowly lanceolate, usually toothed and/or lacerate, patent or recurved and/or falcate for upper $\frac{1}{2}$ of leaf length, 30–50(–100) \times 2.0–3.0(–30) mm. Racemes (5–)10–15 mm long, terminal and axillary; rachis glabrous; pedicels glabrous, erecto-patent, 2–5(–8) mm long at fruiting. Flowers c.0.4–0.8(–1.0) mm diam. Sepals glabrous or finely pubescent, or with both states within the one flower, green, broadly ovate to oval, c.0.6–1.0 \times 0.6–1.2 mm, with pale-green to white thickened margin, apex broadly obtuse. Petals white, 1.5–2.0 \times 0.3–0.8(–1) mm, erecto-patent to somewhat spreading, clawed; limb narrowly obovate, apex obtuse, occasionally emarginated. Stamens (2–)4, equal. Nectararies 2, subulate, 0.35 mm long. Silicles cartilaginous when fresh, coriaceous when dry, orbicular, orbicular-rhomboid (2.5–)3.0–3.5 \times (1.5–)1.8–2.5(–3.3), slightly winged in upper $\frac{1}{3}$, apex minutely notched, based obtuse to \pm cordate, valves glabrous, dried surface often distinctly reticulate; style 0.1–0.2(–0.3) mm long, free from the narrow wing, exceeding the shallow notch; stigma 0.2–0.3 mm diam., capitate. Seeds 2, narrowly ovoid, brown, red-brown to orange-brown, not winged, 1.25–1.3 \times 0.35–0.60 mm. FL. Nov–Feb. FR. Nov–Feb.

Distribution (Fig. 63). Endemic. New Zealand, Chatham Islands, where it is only known from Mangere and Little Mangere Island. In 2007, *L. panniforme* was collected once growing in the loose gravel of a car park near the Chatham Island Council Buildings, Waitangi, Rekohu. Those plants had probably established from seed that was accidentally discarded there by PdL and PBH while pressing freshly gathered fruiting specimens in 2006.

Recognition. *Lepidium panniforme* has an erect, suberect, or spreading growth habit (Figs 82, 83), which immediately separates it from the decumbent *L. oligodontum*, and *L. rekohuense*. It is further separated from these taxa by the long persistent, much larger, usually deeply toothed or lacerate and often rather tattered basal and lower stem leaves (Figs 81–84), and from *L. oligodontum* and *L. rekohuense* by the flowers which consist-

Figure 83. Vegetative stems and inflorescences of *Lepidium panniforme*.

ently have (2–)4 stamens. In growth habit, the species is most similar to *L. oblitum* and *L. oleraceum*, species with which it grows on Mangere Island. The key distinctions between *L. oblitum* and *L. panniforme* are described under *L. oblitum*, however; in brief, the deeply toothed and/or lacerate leaves of *L. panniforme* serve to readily distinguish it from *L. oblitum*. From *L. oleraceum* it is also easily separated, especially when fruiting when the notched rather than acute silicle apex can be seen, but also when vegetative, as the leaves of *L. panniforme* are diagnostically deeply toothed and/or lacerate. This is a condition seen otherwise only in the Bounty Islands endemic *L. seditiosum* which differs by having hairy inflorescences (Fig. 96) and distinct rDNA ETS sequence. *Lepidium panniforme* shares the same rDNA ETS sequence as the morphologically different *L.*

Figure 84. (From left to right) basal- and mid-stem leaves of *Lepidium panniforme*. Scale bar = 20 mm.

obtusatum. From that species it is recognised by its upright shrub-habit, deeply lobed to lacerate leaves and much smaller, minutely notched silicles.

Ecology. On the highly modified landscape that is Mangere Island, *Lepidium panniforme* is known only from a very few sites where it grows in coastal herbfield along cliff tops, in rough pasture, shrubland, regenerating forest and sites kept artificially open, such as track sides. Because Mangere Island is being actively restored to coastal forest, few of these habitats are natural, and as such it is difficult to determine what the real habitat preferences of *Lepidium panniforme* are. However, in less modified parts of the island, plants are mainly confined to the steeper, often heavily seabird burrowed slopes and cliff margins. Here, plants mostly grow amongst coxella (*Aciphylla dieffenbachii*), *Hebe chathamica*, Chatham Island forget-me-not (*Myosotidium hortensium*), Chatham Island sow thistle (*Embergeria grandifolia* (Kirk) Boulos) and, in places, *Lepidium oblitum*. Little is known about the habitat preferences of *L. panniforme* on Little Mangere Island. The only records of its presence there are a series of photographs taken by the late D.V. Merton in February 2006 which show it present on the forest floor within canopy gaps in the summit forest. One assumes that, as with nearby Mangere Island, it also grows on cliff faces, rock ledges are within other suitably open sites within the coastal shrubland and herbfield of that precipitous island.

Conservation Status. It is notable that while *L. oligodontum* and *L. rekohuense* are present in the earliest *Lepidium* collections made by Travers, Cockayne and Martin from the Chatham Islands, *Lepidium panniforme* is absent. The first records of it are

Figure 85. Mature silicle of *Lepidium panniforme* from holotype (AK 255607). Scale bar = 1 mm.

those gatherings and photographs taken by staff of the former Wildlife Service from Mangere and Little Mangere Island during the 1960s and 1970s. Based on these observations, *Lepidium panniforme* is naturally confined to Mangere and Little Mangere Island. On Mangere Island it is known with certainty only from the vicinity of the hut and along the track from there across to the isthmus. In 2006, c.60 individuals were seen in these areas.

Subsequent field work by Department of Conservation staff on Mangere Island indicates that *L. panniforme* is a very uncommon species, which is potentially further threatened by the re-vegetation of that island. This is in part a natural process, though it is one which has been augmented by deliberate plantings as part of that island's long term restoration management as a wildlife refuge for threatened endemic fauna (D. Houston pers. comm.). Nevertheless replanting within the *Lepidium panniforme* sites has been carefully managed to date, and the species remains locally abundant along the disturbed and open track margins from the hut to the isthmus. However, with such a small population *L. panniforme* remains vulnerable to any change in management, and, over time as the surrounding shrubland matures to forest, some decline through natural succession is to be expected. Therefore, this remarkable species will need to be closely monitored to ensure that it is not lost from the island. There is also a need to survey for the species on the almost inaccessible, closely adjacent Little Mangere Island, as the species is still known from there only from those few images taken by the late D.V. Merton.

Therefore, with < 250 mature plants known, and a total area of occupancy of < 1 ha, using the New Zealand Threat Classification System (see Townsend et al. 2008), *Lepidium panniforme* is rated as 'Threatened/Nationally Critical'. In this case criterion A(1) or A(3) equally apply. To that listing we recommend appending the qualifiers, 'CD' (Conservation Dependent – as the species is being actively managed), 'DP' (Data Poor – because accurate information about its status on Little Mangere Island is still needed), 'IE' (Island Endemic), 'OL' – because the species occurs on two closely associated islands such that it is at risk of elimination through catastrophe), and "RR"

(Range Restricted – because of the narrow geographic range this plant occupies in relation to the rest of the New Zealand Botanical Region).

Baird, Collection over three sheets comprising four pieces (one sterile) taken from the same plant. (AK 295129-AK 295131! Isotypes: BM!, CANB!, CHR!

Etymology. The epithet ‘*rekohuense*’ is derived from ‘Rekohu’, the Mori name for Chatham Island which is said to mean ‘land of misty skies’ (King 1989). This name was chosen to reflect the endemic status of this species on the Chatham Islands group.

Description (Figs 89–92): Tap-rooted, pungent-smelling, decumbent, summer-green, perennial herb forming densely leafy masses up to 2 m diam., and arising from stout, semi-circular, dark reddish-grey (when exposed) rootstock 100–500 mm diam. Tap root woody, up to 1.5 m long, deeply descending. Plants dying down to rootstock and/or previous seasons stem nodes, over winter or in times of adversity. Stems decumbent, widely spreading, up to 2 m long and 30 mm diam., woody, ± spherical in cross-section, prominently ridged and/or grooved (especially when dry), dark reddish-green to dark green, usually scarred throughout with numerous old leaf bases; stems heavily branched in upper 2/3, branches and branchlets numerous, prostrate, widely spreading, very leafy; basal portion of stems, ± glabrous, otherwise finely and sparsely papillate-hairy, especially along leaf decurrencies, and within stem grooves, hairs very short 0.01–0.3 mm long, white, glandular-pustulate, rather sticky when fresh. Leaves glabrous, firmly fleshy to succulent, dark green to green, at senescence turning yellow. Rosette leaves persistent at fruiting; petioles distinct up to 50 × 3 mm, slightly concave in cross-section, fleshy; lamina narrowly spatulate to spatulate-oblong, up to 30.0 × 13.3 mm, margins usually denticulate, crenulate, if denticulate then with 10–18(–26) pairs of blunt teeth running to and including apex, base broadly attenuate. Middle stems leaves persistent at fruiting; petiole distinct up to 15 × 2 mm, mostly flat in cross-section, sometimes slightly concave, fleshy; lamina elliptic, narrowly elliptic to oblong, 18.86–26.18(–35.00) × 9.64–16.20 (–18.00) mm; margins sharply and regularly serrate-dentate with 10–16(–22) pairs of teeth running to and including the apex, lamina base broadly cuneate to cuneate. Upper stem leaves with or without a distinct petiole, petiole if present 2.14–5.60 mm, flat; lamina 9.46–10.58

Bellingham s.n., (AK 290290). **Cultivated (New Zealand):** Lincoln, ex Kaiangaroa, Landcare Research experimental nursery, December 2008, P. B. Heenan s.n., (CHR 609795).

Distribution (Fig. 63). Endemic. Chatham Islands where it is known only from Rekohu and Rabbit Island, and the Forty Fours (Motuhara). *Lepidium rekobuense* has also been collected once as a casual in a car park in the main settlement of Waitangi. This occurrence of a single plant along with that of *Lepidium panniforme* collected in the same site probably accords with the use of nearby accommodation by PdL and PBH in 2006, during which time fruiting herbarium specimens of both species were processed in that general area.

Figure 92. Mature silicle of *Lepidium rekohuense* from holotype (AK 297694). Scale bar = 1 mm.

Recognition. Healthy specimens of *Lepidium rekohuense* can form patches up to 2 m in diameter, which is the largest of the New Zealand endemic *Lepidium* species (Fig. 89). Within the *L. oleraceum* group, *L. rekohuense* is morphologically most similar to *L. oblitum* and *L. oligodontum*. From these species it is easily separated by the flowers which consistently have two rather than 2–4 (*L. oblitum*) or 2–4–6 (*L. oligodontum*) stamens, by its much larger overall stature (up to 2 m diam.), by the sparsely papillate-hairy upper branch stems, and by the presence of retrorse to patent, very short, \pm clavate, eglandular–glandular hairs on the inflorescence rachis and pedicels. The silicles of *L. rekohuense* are orbicular (rarely obovate) and consistently, though minutely, notched (Fig. 92), while those of *L. oligodontum*, orbicular to suborbicular and not or scarcely notched.

Ecology. *Lepidium rekohuense* is currently known from salt-marsh and meadow at Kaiangaroa, from steep, eroded basaltic tuff erosion gullies and cliff faces at Cape Young and on Rabbit Island, and from the crevices and ledges of greywacke rock outcrops of the Forty Fours (Motuhara). At Kaiangaroa, *L. rekohuense* is a seasonally conspicuous member of the salt marsh and meadow vegetation that has developed behind the cobble beach and shallow shelving schist shore platform in and around Kaiangaroa Point. Here, plants grow in a variety of situations ranging from fully exposed and eroded habitats to low windswept thickets dominated by *Hebe chathamica*, and *H. chathamica* \times *H. dieffenbachii* hybrids. In the salt marsh plants are usually found growing within dense *Sarcocornia quinqueflora* (Bunge ex Unq.-Sternb.) A.J.Scott. subsp. *quinqueflora*, *Samolus repens* var. *repens*, and *Selliera radicans* Cav. turf. In this habitat, plants are often lost during storm surges or during the winter months, and it would seem, from the presence of seedlings and young plants along drainage channels and in and around eroded sections of salt marsh, that these storm events are necessary to exhume and disperse buried seed. At the back of the salt marsh, where the salt meadows are dominated by taller plants such as *Apodasmia* aff. *similis*, *Ficinia nodosa* (Rottb.) Goetgh. Muasya et D.A.Simpson, and occasional *Myosotidium hortensium*, *L. rekohuense* plants

are also present, and here they often grow intermixed with *Apium prostratum* subsp. *denticulatum*, *Selliera*, *Samolus*, and *Leptinella potentillina*. Higher up, where thickets of *Hebe chathamica* and hybrids form the dominant cover, *L. rekohuense* is less common, in part because they are often easily missed as they grow with *Apium prostratum* subsp. *denticulatum* threaded through *H. chathamica*. *Lepidium rekohuense* is also occasionally found growing on and around the small schist rock stacks around Kaiangaroa Point.

At Kaiangaroa the highly exposed and dynamic habitat means that many *L. rekohuense* plants, especially the younger plants are often lost through coastal erosion and from storm surges. However, in favourable sites, plants are remarkably resilient and long-lived once established. For example, mature plants first observed in 1996 are still present at the time of writing (2012) 16 years later, making this species easily the longest lived member of the *L. oleraceum* complex in New Zealand. The key to this species success at Kaiangaroa seems to be its remarkable tap root, which, once established, firmly anchors the plant into the substrate such that coastal erosion often leaves mature plants exposed, festooned in driftwood and kelp, while the surrounding salt-marsh turf has been destroyed.

The habitat occupied at Cape Young and on Rabbit Island is markedly different. Here the species grows at the apex of steeply descending, erosion gullies that have developed within the easily eroded basaltic tuff. In these sites it is often the only plant present though, in a few places on Cape Young, it grows with *Lepidium flexicaule*, with which it occasionally hybridises. On Rabbit Island, large plants grew at the head of an erosion gully under a sparse canopy of the introduced tree mallow (*Malva arborea*).

Little is known about its habitats on the remote Forty Fours (Motuhara). From the limited information available (P. N. Johnson pers. comm.) it seems that the species is very uncommon there, and that it grows mainly within crevices and on ledges on the cliff faces of those rock stacks.

Conservation status. The most recent census data that we have (July 2007) recorded 114 adult plants of *L. rekohuense* from just three accessible sites; two on Rekohu (Kaiangaroa and Cape Young) and one on Rabbit Island. The status is uncertain of the species on the Forty Fours, privately owned land from which the Department of Conservation has not been granted visiting rights. Nevertheless, observations made in 2005 by a private landing party of geologists, entomologists and ornithologists suggest that there are probably fewer than 10 plants on the larger of the two main islets making up the Forty Fours. Using the New Zealand Threat Classification System (Townsend et al. 2008), *L. rekohuense* is rated “Threatened/Nationally Critical” using criterion A(1) because there are < 250 adult plants known from the wild. To this threat rating we recommend appending the qualifiers ‘CD’ (Conservation Dependent – due to need for ongoing management of the Kaiangaroa population), ‘IE’ (Island Endemic – because *L. rekohuense* is naturally confined to the Chatham archipelago). It is worth noting that, without management, the largest population of *L. rekohuense* known to the Department of Conservation, that at Kaiangaroa, would probably now be extinct. There, intensive management has built the population up from an apparent low of six plants in 1996 to more than 100 in January 2006. At Cape Young the sole accessible

plant seen in January 2006 had disappeared by January 2007 but others observed further down the cliffs in sites inaccessible to human traffic are apparently still present (A. Baird pers. comm.). On Rabbit, eight plants were observed in February 2006 and these are assumed to be still present. Observations at Kaiangaroa suggest that, aside from the losses caused by the naturally dynamic conditions of that exposed coastal shore platform and wetland, predation from the caterpillars of the moth *Epyaxa rosearia* Doubleday, 1843 (identified by J. Dugdale *pers comm.*) is the main threat facing that population. Currently the caterpillars' of this moth are managed by regular applications of derris dust, without which most (sometimes all) adult *Lepidium rekohuense* plants can be severely damaged, affecting especially flowering and seed set, and killing seedlings and young plants. At Cape Young, *Lepidium rekohuense* may be threatened by hybridisation with *L. flexicaule* though this requires further study. So far only one putative and not completely convincing example of this hybrid has been observed (see *L. flexicaule* above).

***Lepidium seditiosum* de Lange, Heenan & J.Rolfe sp. nov.**

urn:lsid:ipni.org:names:77129263-1

http://species-id.net/wiki/Lepidium_seditiosum

A L. oleraceo rachidibus inflorescentiae et pedicellis hirsutus et a serie rDNA ETS differt. A L. panniformo floribus 4-staminatis praeterea differt.

Holotype. Bounty Islands (Fig. 93): Bounty Islands, Funnel Island, n.d. J. Amey s.n., OTA 59718!

Notes: *Lepidium seditiosum* is known only from the holotype collection, which was collected sometime in 2004 (Amey et al. 2007).

Etymology. The epithet '*seditiosum*' derived from the Latin '*seditio*' (meaning: dis-sension, insurrection, mutiny, rebellion), alludes to the mutiny of the majority of Lieutenant William Bligh's crew on the 28 April 1789. In 1788, some months before the rebellion, Bligh had discovered and named the Bounty Islands taking the name from his ill-fated ship The Bounty.

Description (Figs 94–96). Erect, perennial herb. Stems sparse, erect; mature stems long, 4.14–4.41 mm diam. stout, woody, rigid, ± square, prominently angled, bases much covered in leaf abscission scars, middle and upper portion leafy. Leaves fleshy, dark green, stem leaves evidently withering with age; petiole distinct, 14–22.0 × 1.9–2.6 mm, decurrent, prominently channelled, broadly winged, with a broadly sheathing base; lamina variable 32.4–45.4 × 21.2–26.4 mm decreasing in size toward inflorescences, broadly elliptic, elliptic to oblanceolate; apex praemorse or tridentate; margin coarsely and ± regularly dentate to deeply incised; teeth protruding beyond leaf outline; in 8–12 uneven pairs, up to 5.3 mm deep, increasing in size toward apex; base broadly attenuate tapering, extending into a broad petiole wing. Inflorescences immature but evidently racemose, rachis 1.3–1.5 mm diam., terminal and lateral, leaf-opposed, densely and mostly circumferentially covered in

Figure 93. Holotype of *Lepidium seditiosum* de Lange, Heenan & J. Rolfe.

Figure 94. *Lepidium seditiosum* growing in granite crevice on summit of Tunnel Island, Bounty Islands (image: J. Amey).

Figure 95. Inflorescence of holotype of *Lepidium seditiosum* (OTA 59718).

0.4–0.6 mm long, white, clavate hairs; pedicels 1.6–2.2 mm long at flowering, erecto-patent, densely and mostly circumferentially covered in 0.4–0.6 mm long, white, clavate hairs. Flowers 2.3–2.6 mm diam. Sepals 4, saccate, dark green usually with a narrow white, \pm undulose margin; lateral sepals broad, 0.8–1.2 mm diam., obovate to broadly obovate, \pm overlapping at base, apex rounded to obtuse, abaxial surface densely hairy, hairs 0.1–0.4 mm long, eglandular or glandular, mostly clavate, some setose, median sepals 0.8–1.0 mm diam., broadly obovate, dark green, usually with a narrow white, \pm undulose margin, apex rounded to obtuse, abaxial surface densely hairy, hairs 0.1–0.4 mm long, eglandular or glandular, mostly clavate, some setose. Petals white, 1.3–2.0 \times 1.0–2.3 mm, mostly recurved over stigma some spreading, claw 0.4–0.9 mm long; limb obovate, obovate-spathulate rarely orbicular, apex obtuse or slightly emarginate, margins smooth. Stamens 4, filaments 1.2–1.8 mm long, white; anthers 0.3–0.4 mm long, yellow. Ovary 1.1–1.8 \times 0.6–1.3 mm, broadly ovate to elliptic, dark green, apex round or weakly notched; style 0.11–0.4 mm long, cylindrical below, broadly spreading at apex; stigma 0.2–0.4 mm diam. Nectaries 4, 0.2–0.3 \times 0.1–0.15 mm, narrow-oblong, pale translucent green. Mature silicles not seen. FL Nov. FR unknown.

Distribution (Fig. 76). Endemic. Bounty Islands (Funnel Island, Molly Cap).

Recognition. Amey et al. (2007) initially reported the presence of *Lepidium oleraceum* s.l. from the remote Bounty Islands. In that paper they noted that unpublished rDNA ETS data from their gathering placed the Bounty Islands plant within a southern *L. oleraceum* clade of samples collected from Banks Peninsula south to Stewart

Figure 96. Close up of inflorescence of holotype of *Lepidium seditiosum* (OTA 59718) showing hairy rachises and pedicels, and immature silicles. Scale bar = 1 mm.

Island rather than plants from the nearby Antipodes Islands. On the basis of that information they suggested that the Bounty Islands plant was a recent arrival, probably coming from the Otago coastline of the southern South Island. Subsequently, the rDNA ETS phylogeny presented here confirms that *L. seditiosum* is related to the South Island species *L. aegrum*, *L. crassum*, and *L. juvencum* (Fig. 2). However none of these species are morphologically similar to *L. seditiosum*. Morphologically, the most similar species is the Chatham Islands endemic *Lepidium panniforme*, which also has deeply toothed (though also lacerate leaves) but whose stems and inflorescence rachis are glabrous (only very rarely furnished with sparse silky hairs), and whose rDNA ETS sequence places it as sister to *L. obtusatum*. The Bounty Islands plant differs from *L. panniforme* (and indeed all other members of the *Lepidium oleraceum* complex) by its distinctly clavate-hairy upper stems and inflorescence rachises.

While our material is inadequate to furnish a full species description, the absence of mature silicles and basal leaves should not preclude formal taxonomic recognition. The Bounty Islands are perhaps the most remote outlier of the New Zealand Archipelago, and are very rarely visited (Amey et al. 2007), so the alternative, of waiting for better fruiting material before describing what in our view is clearly a new species is, unacceptable. In the authors' opinion, there is sufficient data available to justify this plant's taxonomic recognition at species rank.

Ecology. Prior to the remarkable discovery of *Lepidium* on the Bounty Islands group, these islands had always been considered devoid of any form of terrestrial vegetation beyond a few lichens and algae (Amey et al. 2007). None of the 15 islands, islets

and rock stacks comprising the group reach any higher than 88 m a.s.l., and virtually all available dry land is occupied by some of the densest concentrations of nesting seabirds seen anywhere in the world (Amey et al. 2007). Amey et al. (2007) recorded *Lepidium seditiosum* (as *L. oleraceum* s.l.) as growing within rock crevices near the summits of one island (Funnel Island) and an inaccessible (by boat) rock stack (Molly Cap) within the Bounty Islands group. At the time of their discovery, on Funnel Island plants grew on the margins of a colony of nesting seabirds, in a site inaccessible to albatross and penguins but used by Fulmar prions (*Pachyptila crassirostris*) and possibly Cape pigeons (*Daption capense*). They noted that where the plants grew, a ‘rich friable soil’ had accumulated, and that the crevice walls provided some shelter from the most extreme winds. Because of the inaccessible nature of Molly Cap, no further observations on the plant they had seen from their boat could be made.

Conservation Status. Amey et al. (2007), during a November 2004 visit to the Bounty Islands group, recorded ‘at least 13’ plants at two sites (Funnel Island (12 plants) and Molly Cap (1 plant)). On this basis, *L. seditiosum* qualifies as ‘Threatened / Nationally Critical’ (either criterion A(1) or A(3) of Townsend et al. (2008)) as there are fewer than 250 mature plants known and the total area of occupancy is < 1 ha. To this assessment we add the qualifiers ‘CD’ (Conservation Dependent – as the Bounty Islands are a Nature Reserve and World Heritage Site with strict controls in place to regulate landings, and prevent the spread of diseases, weeds and foreign predators), ‘DP’ (Data Poor – because accurate data on the total number of individuals and trend data is not available), ‘IE’ (Island Endemic), and ‘OL’ (One Location – because, following the definition in Townsend et al. (2008), the species is confined to the Bounty Islands group, where it grows on an island and rock stack in close proximity, and so the chances of losing the species to a single event are greater than for a species found in one island group on several widely separated islands).

Revised key to *Lepidium* in New Zealand

* Denotes naturalised in New Zealand.

- 15 Silicles mostly orbicular or obovate (rarely with some broadly elliptic or broadly ovate)16
- Silicles ovate, elliptic or rhomboid18
- 16 Upper stem leaves pinnatifid, stem hairs spreading **L. bonariense* L.
- Upper stems leaves entire or toothed; stem hairs strongly recurved17
- 17 Silicles obovate, widest above middle; rachis of raceme with straight cylindrical or clavate hairs; petals absent or rudimentary and 0.3–0.9 mm; cotyledons incumbent **L. densiflorum* Schrad.
- Silicles orbicular, widest at middle; rachis of raceme with curved hairs; petals 1.0–2.5 mm, rarely rudimentary; cotyledons accumbent or rarely incumbent **L. virginicum* L.
- 18 Young stems and upper leaf margins with small triangular cartilaginous denticles, often paired from a common base; mid-stem leaves oblanceolate to cuneate, margins serrate to dentate; silicles 2.7–3.0 × 2.0–2.3 mm ovate
..... *L. desvauxii* Thell.²
- Young stems and leaf margins puberulent; mid-stem leaves linear, lanceolate to oblanceolate, entire with marginal hairs, silicles 1.8–5.0 × 1.5–2.5 mm, elliptic, ovate to rhomboid.....19
- 19 Lower and upper stem leaf bases auriculate-sagittate; upper stem leaves linear to lanceolate, usually with lateral 1–2 teeth in upper 1/3, apex acute; silicles 2.5–5.0 × 1.5–2.5 mm, ovate to narrowly rhomboid; petals minute
..... **L. hyssopifolium* Desv.
- Lower and upper stem leaf bases attenuate; upper stem leaves linear, entire, apex obtuse to subacute; silicles 1.5–3.0 × 1.5–2.3 mm, elliptic; petals absent..... **L. ruderale* L.³
- 20 Basal leaves simple, lanceolate to oblanceolate (very rarely with some leaves pinnatifid), margins serrate (sometimes deeply lacerate), occasionally with 1–2 lobes, lobes linear entire.....21
- Basal leaves pinnatifid or lyrate-pinnatifid, lobes linear, distal margins of lobes serrate or dentate (rarely entire)23
- 21 Flowers with (2–)4 stamens; silicles 2.5–3.5 × 1.5–3.3 mm, orbicular to orbicular-rhomboid, minutely notched*L. panniforme* de Lange et Heenan⁴
- Flowers with 2 stamens; silicles 2.0–3.5 × 1.8–2.5 mm, oblong, obovate or elliptic.....22
- 22 Stems ridged or grooved when dry, glabrous or sparsely puberulent; silicles 2.0–2.8 × 1.8–2.0 mm, obovate to elliptic..... **L. africanum* (Burm.f.) DC.
- Stems smooth when dry, glabrous near base otherwise puberulent; silicles 3.3–3.5 × 2.2–2.5 mm, oblong..... **L. divaricatum* W.T.Aiton
- 23 Cauline leaves mostly auriculate-sagittate at base; pedicels adaxially hairy; silicles 2.0–3.0 × 1.5–2.5 mm24

- Cauline leaves attenuate at base; pedicels glabrous (very rarely with scattered hairs); silicles 3.5×2.1 – 2.4 mm**L. pseudohyssopifolium* Hewson
- 24 Mid cauline leaves lanceolate with serrate / serrulate margins; rosette and lower cauline leaves lyrate-pinnatifid with a large broad terminal lobe; silicles 2.0 – 3.0×1.5 – 2.0 mm, ovate to elliptic**L. peregrinum* Thell.⁵
- Mid-cauline leaves oblanceolate to cuneate, the margins dentate with acute, \pm patent lobes, often with only a single pair below apex; rosette and lower cauline leaves not lyrate-pinnatifid; silicles 2.4 – 3.0×1.8 – 2.5 mm, ovate to rhomboid**L. pseudotasmanicum* Thell.
- 25 Young stems finely puberulent; hairs dense to sparse, shortly papillate or tapered.....26
- Young stems glabrous.....27
- 26 Rosette and lower stem leaves pinnatifid; racemes 10–50 mm long, leaf-opposed, obscured by surrounding foliage*L. flexicaule* Kirk
- Rosette and lower stem leaves spatulate, oblong or elliptic; racemes 10–90 mm long, not or scarcely leaf-opposed, overtopping surrounding foliage*L. rekohuense de Lange et Heenan*
- 27 Leaves narrowly spatulate, cuneate, obdeltoid, obovate (rarely elliptic-lanceolate), entire or sparingly dentate in upper $\frac{1}{3}$; teeth (if present) in 1–3(–) pairs; silicles broadly orbicular and turgid when fresh*L. oligodontum de Lange et Heenan*¹
- Leaves oblanceolate, cuneiform, oblong-obovate, obdeltoid to spatulate, margins finely to deeply incised in upper third to quarter; silicles orbicular, orbicular-ovate to \pm rhomboid, cartilaginous (never turgid)28
- 28 Plants prostrate; branches numerous, leafy for entire length; leaves finely serrated to crenate, teeth in 10–30 pairs, leaf apices subacute, obtuse to rounded; stamens 2; silicles 2.5 – 3.5×1.5 – 3.3 mm, elliptic, rhomboid, not winged*L. limenophylax de Lange, B.D.Rance et D.A.Norton*
- Plants decumbent to subsasendant, widely spreading; branches numerous, leafy only in upper third; leaves finely to deeply incised in upper third to quarter only, teeth in 3–8 pairs, leaf apices praemorse; stamens 2–4; silicles 2.8 – 3.3×2.4 – 3.0 mm, orbicular, orbicular-ovate to \pm rhomboid, winged....*L. oblitum Houlston, Heenan et de Lange*⁶
- 29 Rosette and/or basal leaves pinnatifid or pinnate.....30
- Rosette and/or basal leaves not pinnatifid or pinnate31
- 30 Plant forming compact, persistent leafy rosettes; flowering stems sparingly leafy, prostrate to ascending; silicles 1.5 – 2.0×1.5 – 1.8 mm, suborbicular, valves glabrous or sparsely hairy*L. tenuicaule* Kirk
- Plant erect, rosettes not compact, often withering at flowering; flower stems erect, leafy; silicles 2.8 – 4.0×2.3 – 3.2 mm, broadly elliptic, valves glabrous*L. naufragorum Garn.-Jones et D.A.Norton*⁷
- 31 Plants decumbent or prostrate32
- Plants ascending to erect38

- 32 Plants up to 150 mm diameter; stems filiform; leaves 3–6 mm wide, entire, basal leaves dark brown-green (rarely dark green); basal sheath broad, scarios, persistent; silicles 1.5–2.0 × 1.0–1.5 mm ***L. kirkii* Petrie**
- Plants 0.3–1.0 m diameter; stems stout; leaves 5–46 mm wide, serrate, dentate, crenate, lacerate or sometimes entire (*L. oligodontum* only), basal leaves green; basal sheath absent or if present, narrow, not scarios or persistent; silicles 2.1–6.4 × 1.5–5.0 mm **33**
- 33 Plants rhizomatous; stems flexuous; silicles 4.9–6.4 × 4.2–4.9 mm ***L. obtusatum* Kirk**
- Plants not rhizomatous; stems not flexuous; silicles 2.5–4.7 × 1.5–3.9 mm ... **34**
- 34 Rosette leaves persistent; silicles broadly ovate, ovate to obovate ***L. amissum* de Lange et Heenan**
- Rosette leaves absent, or withering at flowering; silicles broadly orbicular, orbicular, orbicular-rhomboid to elliptic-rhomboid **35**
- 35 Plants upright to spreading or decumbent or sprawling; leaves broadly elliptic, elliptic-oblancheolate, elliptic-obovate, oblanceolate to lanceolate, or obovate-oblong, margins crenate; silicles elliptic-rhomboid to orbicular rhomboid **36**
- Plants decumbent; leaves spatulate, cuneiform, linear-cuneiform, oblanceolate, narrowly ovate, to narrowly obovate (rarely orbicular), entire or margins sparingly, sometimes deeply toothed in upper 1/3; silicles broadly orbicular, orbicular (rarely ovate) ***L. oligodontum* de Lange et Heenan¹**
- 36 Plants upright to spreading; basal leaf margins deeply toothed and/or lacerate for entire length ***L. panniforme* de Lange et Heenan⁵**
- Plants decumbent to sprawling; basal leaf margins finely to sparingly deeply toothed, if deeply toothed then only in upper third of leaf **37**
- 37 Leaves elliptic, elliptic-oblancheolate, obovate to elliptic-obovate, apex subacute, truncate to obtuse, upper third of leaf margins mostly crenate, or shallowly serrated; stamens 4; silicles 3.1–4.2 × 2.5–3.5 mm, elliptic-rhomboid to orbicular-rhomboid, not winged ***L. juvenum* Heenan et de Lange**
- Leaves oblanceolate, cuneiform, oblong-obovate, obdeltoid to spatulate, apex praemorse margins finely to deeply incised in upper third or quarter, stamens 2–4; silicles 2.8–3.3 × 2.4–3.0 mm, orbicular, orbicular-ovate to ± rhomboid, margin winged ***L. oblitum* Houlston, Heenan et de Lange⁶**
- 38 Pedicels hairy **39**
- Pedicels glabrous **40**
- 39 Inflorescence rachises glabrous (sometimes with sparse, pale, clavate hairs); pedicels hairy on adaxial surfaces only; petals 1.8–2.0 × 0.1–0.9 mm, elliptic or filiform (rarely obovate); plant of northern South Island.. ***L. banksii* Kirk**
- Inflorescence rachises densely covered in white clavate hairs; pedicels densely and mostly circumferentially covered in white clavate hairs; petals 1.3–2.0 × 1.0–2.3 mm, obovate-spatulate (rarely orbicular); plant of Bounty Islands ... ***L. seditiosum* de Lange, Heenan & J.Rolfe⁸**

- 40 Plants with slender, upright stems; leaves thin, not fleshy, lanceolate, elliptic-lanceolate (rarely narrow elliptic), margin deeply serrate; silicles 4.0–4.7 × 3.2–3.5 mm, elliptic-rhomboid to orbicular-rhomboid, apex shallowly notched ***L. aegrum* Heenan et de Lange**
- Plants with stout, upright to spreading short, rigid, stems; leaves thick and fleshy, broadly elliptic, elliptic-obovate to obovate-oblong, margin crenate; silicles 3.0–3.7 × 2.6–3.1 mm, orbicular to orbicular-rhomboid, apex obtuse to shallowly notched ***L. crassum* Heenan et de Lange**
- ¹ *Lepidium oligodontum* plants may have 2, 4 or 6 stamens, though 4 is the usual number. On occasion plants with mostly 2 stamens are known. For this reason this species may key out in three areas depending on the number of stamens present.
- ² We follow de Lange et al. (2009) and de Lange and Rolfe (2010) in treating *Lepidium desvauxii* as indigenous within the southern part of its New Zealand range (including the Chatham Islands), and naturalised within the more modified parts of central and northern New Zealand.
- ³ *Lepidium ruderales* is accepted by Webb *et al.* (1995) as naturalised in New Zealand.
- ⁴ *Lepidium panniforme* usually has 4 stamens but occasional plants with 2 or 2–4 stamens occur, and for this reason this species may key out in two areas depending on the number of stamens present.
- ⁵ *Lepidium peregrinum* is regarded here as naturalised to New Zealand (see Heenan and de Lange 2011). It is as an uncommon naturalised plant of glauconite and glauconitic limestone rock stacks and islands along the southern shore line of the Kawhia Harbour. *Lepidium peregrinum* is a threatened species in Australia (Scarlett 1999).
- ⁶ *Lepidium oblitum* may have 2–4 stamens. For this reason this species may key out in two areas depending on the number of stamens present.
- ⁷ Occasional plants of *Lepidium naufragorum* with simple or weakly pinnatifid leaves are also known, and these could be confused with *L. oleraceum* from which they differ by the seasonal growth habit (with plants dying back to the rootstock over winter), and by the distinctly emarginate silicles
- ⁸ *Lepidium seditiosum* is known only from a single, imperfect gathering which lacks mature silicles. However, the shape of the ovary apex of immature silicles indicates that, in this species, they are notched.

Acknowledgements

This paper was started in 2005 naïvely with the intention of describing one species (*L. limenophylax*) as a precursor to a full revision of the *L. oleraceum* group. As they say the road to hell is paved with good intentions. This paper owes much to the initial drive of the late Phil Knightbridge (1969–2011) who during his short life expertly managed the New Zealand Department of Conservation coastal cress recovery plan (Norton & de Lange 1999) and associated team (1997–2006). To Phil it was essential that the taxonomy of *L. oleraceum* be revisited to allow for greater confidence in future conservation

management, and this paper is the result of his vision. Since 2005 the authors have had valued input from: Amanda Baird, Karen Baird, John Barkla, Steve Benham, Carolyn Blackford, Elizabeth Brown, Patrick Brownsey, Alex Buchanan, Ewen Cameron, Dave Clarke, Shannel Courtney, Gillian Crowcroft, Esther Dale, Geoff Davidson, Kenny Dix, Rowan Emberson, Richard Evans, Brian Fineran, Rhys Gardner, Paul Gasson, Bridget Gibb, Terry Greene, Dave Houston, Ken Hunt, Peter Johnson, Jeanette Keeling, Sue Lake, Graeme Loh, Janice Lord, Eric McKenzie, the late Don Merton (1939–2011), Colin Miskelly, Mei Nee Lee, David Norton, Leon Perrie, Dhahara Ranatanga, Brian Rance, Matt Renner, Paul Saegar, Jorge Santos, John Sawyer, Neville Scarlett, Paul Schofield, Ines Schönberger, Tony Silbery, Robyn Smith, Hawea Tomoana, Graeme Taylor, Mike Thorsen and Andrew Townsend. The senior author, Peter Heenan and Gary Houlston wish to especially acknowledge the staff of the Department of Conservation, Chatham Islands Area office who facilitated our field work on those islands in 2006, 2007 and 2008, and especially local fisherman Chippy Lanauze and Darcy Clarke, for assistance with visiting the outer islands of the Chatham group. Jeanette Keeling, Dilini Attanyake, Diana Prada, Dagmar Goeke, and Ana Ramon-Laca all assisted with DNA extraction, amplification and sequencing. The Latin diagnoses were prepared by Rhys Gardner, Hellmut Toelken, and Neville Walsh. We thank the curators and keepers of the following herbaria: AK, BM, CANU, CHR, HO, K, MEL, MPN, NSW, OTA, P, UNITEC, WAIK, WELT, and WELTU. We thank Museum of New Zealand Te Papa Tongarewa for permission to reproduce their image of the lectotype of *Lepidium oleraceum* var. *frondosum*. Field work on the Chatham Islands was made possible through funding by the New Zealand Department of Conservation's Conservation Management Units research fund. Funds to publish this paper were provided by the New Zealand Department of Conservation through the drive of Joseph Arand who saw a need to make this paper freely available online. Lastly the authors wish to acknowledge the detailed and thoughtful reviews received on this paper by three anonymous referees selected by PhytoKeys. This paper is all the better for their collective wisdom and input.
