Physiological roles and diseases of *tmem16*/*anoctamin* proteins: are they all chloride channels?

Charity DURAN, H Criss HARTZELL*

Emory University School of Medicine, Department of Cell Biology and Center for Neurodegenerative Disease Atlanta, GA 30322, USA

The *Tmem16* gene family was first identified by bioinformatic analysis in 2004. In 2008, it was shown independently by 3 laboratories that the first two members (*Tmem16A* and *Tmem16B*) of this 10-gene family are Ca^{2+} -activated Cl^- channels. Because these proteins are thought to have 8 transmembrane domains and be anion-selective channels, the alternative name, Anoctamin (anion and octa=8), has been proposed. However, it remains unclear whether all members of this family are, in fact, anion channels or have the same 8-transmembrane domain topology. Since 2008, there have been nearly 100 papers published on this gene family. The excitement about *Tmem16* proteins has been enhanced by the finding that *Ano1* has been linked to cancer, mutations in *Ano5* are linked to several forms of muscular dystrophy (*LGMDL2* and *MMD-3*), mutations in *Ano10* are linked to autosomal recessive spinocerebellar ataxia, and mutations in *Ano6* are linked to Scott syndrome, a rare bleeding disorder. Here we review some of the recent developments in understanding the physiology and structure-function of the *Tmem16* gene family.

Keywords: chloride channels; patch clamp; ion channels; channelopathies; ion transport; muscular dystrophy; ataxia; blood clotting

Acta Pharmacologica Sinica (2011) 32: 685–692; doi: 10.1038/aps.2011.48

Introduction

Ca^{2+} -activated Cl^- channels (CaCCs) play manifold roles in cell physiology^[1, 2] including epithelial secretion^[3, 4], sensory transduction and adaptation^[5–8], regulation of smooth muscle contraction^[9], control of neuronal and cardiac excitability^[10], and nociception^[11]. CaCCs were first described in *Xenopus* oocytes^[12, 13] and salamander rods^[14] in the early 1980's, but it was not until 3 years ago that the proteins responsible for these channels were identified. Prior to that, several other proteins were proposed as molecular candidates. These include *CIC-3*^[15], *CLCAs*^[16], and *bestrophins*^[17]. None of these proteins have properties that exactly fit those of classical CaCCs^[1]. Although *bestrophins* are indeed CaCCs, their expression profile is more restricted and their biophysical properties are different from classical CaCCs^[17]. So, in 2008, the announcements that three labs had cloned genes that encoded classical CaCCs generated considerable excitement^[18–20]. The two genes that have been shown definitively to encode CaCCs are called *Tmem16A* and *Tmem16B*. These are two members of a family that consists of 10 genes in mammals^[21]. Yang *et al*^[19] proposed the new name “*anoctamin*” or *Ano* (anion+octa=8) and this name is now the official HUGO nomenclature and

has replaced *Tmem16* in Genbank. *Tmem16A* is now *Ano1*, *Tmem16B* is *Ano2*, and so-on except that the letter I is skipped in the *Tmem16* nomenclature so that *Tmem16J* is *Ano 9* and *Tmem16K* is *Ano10*. There is some dissatisfaction in the field with the *Ano* nomenclature because, as discussed below, it is not certain that all the members of this family are anion channels or have the 8-transmembrane topology. Also, the term “*Ano*” has a potentially objectionable meaning in the Spanish language^[22]. For this reason, the *Tmem16* terminology still remains in use in parallel with *Ano*. This review summarizes some of the recent developments in this field. The reader should consult several other outstanding reviews on *Tmem16*/*Ano* proteins for more detail and different perspectives^[22–29].

Structure-function of *anoctamins*

Hydropathy analysis shows that all *anoctamins* have eight hydrophobic helices that are likely to be transmembrane domains with cytosolic N- and C-termini. This predicted topology has been confirmed experimentally for *Ano7*, whose topology has been determined using inserted HA epitope tag accessibility and endogenous N-glycosylation^[30]. Although this topology is appealing, the epitope tag accessibility methodology used to identify intracellular domains of *Ano7* does not clearly distinguish between intracellular domains and protein that is not efficiently trafficked to the plasma membrane. Because of this technical limitation and the fact that the topol-

ogy of other Anos has not been experimentally determined, more investigation is required to establish the topology of these proteins.

The quaternary structure of Ano1 was recently determined to be that of a homodimer using both migration in native gels as well as Förster resonance energy transfer (FRET)^[31, 32]. Ano1 subunits associate before they are trafficked to the plasma membrane. The association of Ano1 subunits is likely due to noncovalent interactions, as the Ano1 assembly cannot be separated into monomers by chemical reduction with DTT. The oligomeric state is not affected by changes in intracellular Ca²⁺, suggesting that the homodimeric structure of Ano1 is not a determinant of channel gating. The homodimeric structure of Ano1 is reminiscent of that of CLC chloride channels, although it is not known whether the channel functions as a dimer or a higher order oligomer that is not detected quantitatively by the techniques used to date. For example, it is possible that the dimer is a biochemically stable form, but that dimerization of the dimers is required to create a functional channel. Further, it is not known whether Ano1 can form heteromers with other Anos or whether it associates with other accessory subunits. It will be interesting to see if Ano1 subunits assemble to form a single functional pore, or if each subunit contains a separate Cl⁻ conduction pathway, similar to the double barrel structure of CLC channels.

Multiple isoforms

At least 4 splice variants have been identified for Ano1^[33] and two splice variants have been found for Ano7^[34]. Human Ano1 has 4 different alternatively-spliced segments, *a*, *b*, *c*, and *d* corresponding, respectively, to an alternative initiation site, exon-6b, exon-13, and exon-15^[33]. Segments *a* and *b* are located in the N-terminus and *c* and *d* are in the first intracellular loop. The variant with all 4 segments is designated as Ano1*abcd*; the variant lacking segments *b* and *d*, for example, is Ano1*ac*. Analysis of ESTs in Genbank predicts that several of the other Anos also have multiple splice variants. Some of these variants may not have channel functions because they are predicted to lack some or all of the transmembrane domains. For example, the short form of Ano7, which has been shown to be translationally expressed, is a short, soluble protein^[34]. The four splice variants of Ano1 exhibit different voltage-dependent and Ca²⁺-dependent gating properties^[33, 35]. Thus, alternative splicing is likely to contribute to the heterogeneity of CaCC currents observed in native tissues.

Gating mechanisms of Ano1

Ano1 is gated by both voltage and Ca²⁺ but examination of the sequence of Ano1 gives few clues about the sites that sense voltage or bind to Ca²⁺. Unlike voltage-gated channels that have amphipathic transmembrane helices with charged amino acids that serve to sense voltage, Ano1 has no such sequences. Furthermore, there are no obvious E-F hands that might serve as Ca²⁺ binding sites or definitive IQ domains for CaM binding. The first intracellular loop, between TMD2 and TMD3, has a large number of acidic amino acids including

a stretch of 5 consecutive glutamates (⁴⁴⁴EEEE₄₄₈) that have attracted attention as a possible Ca²⁺ sensor^[35]. The last glutamate in this sequence is the first residue of a 4-amino acid alternatively-spliced segment (⁴⁴⁸EAVK₄₅₁). Neutralization of the glutamates has little effect on Ca²⁺ sensitivity, although deletion of the alternatively-spliced segment (Δ EAVK) alters both voltage-dependent gating and Ca²⁺ sensitivity^[33, 35]. Thus, although the first intracellular loop plays an important role in coupling both voltage and Ca²⁺ binding to channel opening, it is unlikely to be the binding site for Ca²⁺.

If Ano1 has no Ca²⁺ binding site, perhaps the Ca²⁺ binding site is located on an accessory subunit, such as calmodulin (CaM). A recent paper reports that CaM binds to a 22-amino acid region that overlaps with the *b* segment in the N-terminus called CaM-BD1 and is "essential" for gating Ano1^[36]. This putative CaM binding site is not canonical, but resembles some other CaM binding sites. However, only the Ano1 splice variants containing the *b* segment (*eg*; Ano1*abc*) seems to require CaM. Ano1*ac*, which lacks the CaM-BD1, does not require CaM and is activated directly by Ca²⁺. It is curious that deletion of the *b* segment reveals a Ca²⁺ binding site that is suppressed in the variant having the CaM binding domain. Clearly, additional work is required to clarify the role of CaM in regulation of Ano1. Some endogenous CaCCs are regulated directly by Ca²⁺ and others by CaM-dependent pathways^[2, 37, 38] and this may be explained by expression of different splice variants or isoforms. For example, the Ca²⁺-sensitivity of the CaCC in olfactory receptor neurons, which is now thought to be Ano2, is decreased by a factor of ~2 by over-expression of dominant-negative inactive CaMs, but CaM is not essential for activation^[38].

Functions of Tmem16/Ano paralogs

Anoctamins display differential temporal and spatial expression in a variety of developing tissues, suggesting they may play an important role in development^[39-41]. In murine tissues, Anos 1, 6, 7, 8, 9, and 10 are expressed in a variety of epithelia, while Anos 2, 3, 4, and 5 are more restricted to neuronal and musculoskeletal tissues^[42]. Ano1 and Ano2 are the only two members of the family that have been shown conclusively to be CaCCs.

Ano1 is ubiquitously expressed

Ano1 is widely expressed in virtually every kind of secretory epithelium, for example, salivary gland, pancreas, gut, mammary gland, and airway epithelium^[18, 19, 43-46]. Ano1 knockout mice display defective Ca²⁺ dependent Cl⁻ secretion in a variety of epithelia^[44-46] and Ano1 has been implicated in rotovirus-induced diarrhea^[47]. In addition, Ano1 is expressed in a variety of other cell types including certain smooth muscles and sensory neurons.

Ano1 is a secondary Cl⁻ channel in airway

The major Cl⁻ channel in human airway is cystic fibrosis transmembrane conductance regulator (CFTR), the protein that is defective in cystic fibrosis. CaCCs have long been considered

as a potential target for therapy of cystic fibrosis based on the idea that upregulation or activation of CaCCs might compensate for loss of CFTR in airway fluid secretion^[48]. Two drugs that activate CaCCs by elevating intracellular Ca^{2+} are presently in clinical trials for treating cystic fibrosis^[49, 50]. Recently, however, Namkung *et al*^[51] showed that novel Ano1 inhibitors were rather ineffective in inhibiting CaCCs in airway epithelial cells despite their efficacy in inhibiting heterologously expressed Ano1 as well as native CaCCs in salivary gland. This result is puzzling in light of the reports by several groups that Ano1 is expressed in airway epithelium and that knock-out of Ano1 decreases airway secretion^[43, 44, 46]. One possible explanation is that that Ano1 in airway is a different splice variant or has other accessory proteins that alters its pharmacological profile. Cystic fibrosis affects other tissues in addition to airway – reproductive tract, pancreas, bile duct. Ano1 is expressed in all of these tissues and may be an alternate, non-CFTR Cl^- secretory pathway^[43, 44, 52]. Although Ano1 may represent a potential target for pharmacological treatment of cystic fibrosis, one serious concern is the fact that Ano1 is so widely expressed that systemically administered drugs are likely to have widespread side-effects. Thus, it seems that any therapy that targets Ano1 may require local delivery protocols. However, the differential sensitivity of airway and salivary gland CaCCs to novel Ano1 inhibitors raises the prospect that development of subtype-specific drugs may be feasible.

Ano1 is essential for gut motility

In addition to epithelia, Ano1 is robustly expressed in interstitial cells of Cajal which are responsible for generating pacemaker activity in smooth muscle of the gut^[43, 53, 54]. Mice homozygous for a null allele of Ano1 fail to develop slow wave activity in gastrointestinal smooth muscles. The resulting loss of gastrointestinal motility may be an important contributor to the early death of Ano1 knockout mice^[43] and decreased expression of Ano1 in interstitial cells of Cajal may contribute to gastroparesis common in diabetic patients^[55].

Ano1 is expressed in certain smooth muscle cells

Ano1 is also expressed robustly in various kinds of smooth muscle including vascular smooth muscle cells^[43, 56, 57]. Treatment of rat pulmonary aortic smooth muscle cells with siRNA against Ano1 results in a reduction of CaCCs^[56]. Ano1 is also strongly expressed in airway smooth muscle cells, suggesting the possibility that this channel might be involved in asthma. Asthma is characterized by disorders of smooth muscle Ca^{2+} signaling and remodeling of the airway smooth muscle^[58]. Considering that Ano1 is Ca^{2+} -regulated and implicated in tracheal development^[40], a role for Ano1 in asthma deserves attention.

Ano1 overexpression is associated with cancer

Ano1 originally attracted the interest of cancer biologists because it is upregulated in several cancers^[59-61]. Oncologists have recognized Ano1 by several other names including DOG1 (Discovered On GIST-1 tumor), ORAOV2 (Oral cancer

Overexpressed), and TAOS-2 (Tumor Amplified and Over-expressed). Ano1 may prove a useful tool for the diagnosis of certain cancers. Gene expression profiling identified *Ano1* as being highly expressed in gastrointestinal stromal tumors (GISTs). KIT immunoreactivity has traditionally been used to differentiate GISTs from other tumors that are morphologically similar^[62]. While KIT staining is highly specific for GISTs, not all GISTs display KIT immunoreactivity. Ano1 very specifically identifies a higher percentage of GIST tumors than does KIT, indicating that Ano1 may be a more robust and sensitive diagnostic biomarker for GISTs^[63, 64].

In both oral and head and neck squamous cell carcinomas, amplification of the Ano1 locus is correlated with a poor outcome^[61, 65]. Ano1 expression is significantly increased in patients with a propensity to develop metastases. Given the role that Cl^- channels play in cell proliferation and migration, it is possible that Ano1 overexpression provides a growth or metastatic advantage to cancer cells^[66]. Supporting the role of Ano1 in metastasis is that overexpression of Ano1 stimulates cell movement^[67]. In contrast, silencing of Ano1 decreases cell migration; treatment of cells with CaCC blockers has a similar effect. Overexpression of Ano1 has no marked effect on cell proliferation. Although evidence suggests Ano1 may have a role in metastases, it is still possible that the chromosomal region containing Ano1 (11q13) contains other genes involved in cancer progression.

Ano1 may be involved in nociception

Ano1 is expressed in small dorsal root ganglion neurons and is implicated in mediating nociceptive signals triggered by bradykinin^[11]. Bradykinin is a very potent inflammatory and pain-inducing substance that is released at sites of tissue damage or inflammation. Bradykinin acts on G_q -coupled B2 receptors to stimulate phospholipase-C, IP_3 production, and release of Ca^{2+} from intracellular stores. The elevation of intracellular Ca^{2+} opens CaCCs apparently encoded by Ano1. CaCC current, along with KCNQ channel activation, depolarizes and increases AP firing. Local injection of CaCC inhibitors attenuates the nociceptive effect of local injections of BK.

Ano2 plays a role in sensory transduction

In olfactory sensory neurons, odorants open cyclic nucleotide gated channels by binding to G-protein coupled olfactory receptors that elevate cAMP^[6]. Ca^{2+} influx through the cyclic nucleotide gated channels then activates CaCCs that amplify the receptor potential. From immunostaining studies, it was first suggested that Best2 might be the olfactory CaCC^[68], but electrophysiological recordings from Best2 knockout mice failed to confirm a role for Best2 in mediating the olfactory receptor potential^[69, 70]. It seems Ano2 is now the best candidate for the pore-forming subunit of CaCCs in olfactory sensory neurons^[5-7, 71]. Ano2 generates Ca^{2+} activated chloride currents when expressed in heterologous systems^[20, 72]. Ano2 is localized in the cilia and dendritic knobs of olfactory sensory neurons and displays electrophysiological properties similar to native olfactory CaCCs. Ano2 displays similar halide per-

meability, Ca^{2+} sensitivity, single-channel conductance, and rundown kinetics to native olfactory CaCCs^[5]. However, there are differences in channel inactivation kinetics, suggesting the possible presence of other regulatory subunits.

Release of the neurotransmitter glutamate at photoreceptor synapses is controlled by intracellular Ca^{2+} . Ca^{2+} -activated Cl^- channels located in photoreceptor nerve terminals^[14, 73] have been shown to provide a feedback control on transmitter release^[74]. Ano2 is highly expressed in photoreceptor synaptic terminals^[8]. Ano2 is localized to presynaptic membranes in ribbon synapses, where it co-localizes with the adapter proteins PSD95, MPP4, and VELI3. Ano2 contains a consensus C-terminal PDZ class I binding motif that interacts with the PDZ domains of PSD95. Through this interaction, Ano2 is tethered to membrane domains along photoreceptor terminals, and may serve to regulate synaptic output in these cells. Ano1 has also been shown to be expressed in photoreceptor terminals, suggesting there may be a contribution by both proteins to CaCCs in photoreceptors^[74].

Are Ano3-Ano10 chloride channels?

With the exception of Ano1 and Ano2, the status of other anoctamin family members as channels is unclear. In the hands of many investigators, including ourselves, many of the heterologously-expressed Anos 3–10 do not produce robust currents because they are not readily trafficked to the plasma membrane. This could indicate that they have intracellular functions or are simply missing the necessary chaperone subunits to help them to the surface. In a study by Scheiber *et al*^[42], it was concluded that in addition to Ano1 and Ano2, Anos 6, 7, and 10 were Cl^- channels. However, in iodide flux assays, the ATP- or ionomycin-stimulated flux reported for Anos 6, 7, and 10 were <10% of those for Ano1. Furthermore, the short form of Ano7 (Ano7S), which is a 179 amino acid protein with no predicted transmembrane domains and very unlikely to be an ion channel, produced approximately the same flux as the long form of Ano7. No patch clamp data were reported for Ano7. Over-expression of Ano10 produced a Cl^- current that was activated slowly over a time frame of 10 min. However, expression of Ano10 also suppressed maximal currents produced by Ano1. To date, no functional data have been published for Anos 3 and 4. Recently, Ano6 was reported by another lab to be a non-selective cation channel that is more permeable to Ca^{2+} than Na^{2+} ^[75]. It will be interesting to discover the functions of these proteins.

Ano5 mutations are linked to musculoskeletal disorders

Mutations in Ano5 result in a spectrum of musculoskeletal disorders. Ano5 was originally identified as GDD1, the gene product mutated in a rare autosomal dominant skeletal syndrome called gnathodiphyseal dysplasia (GDD)^[76]. Mutations in cysteine-356, a highly conserved cysteine in the first extracellular loop of Ano5, results in abnormal bone mineralization and bone fragility. Ano5 resides predominantly in intracellular membrane vesicles, but the nature of these compartments is still unknown^[77]. Although the function of Ano5 remains

to be determined, it clearly plays important roles in musculoskeletal development. Ano5 is expressed in growth-plate chondrocytes and osteoblasts at sites of active bone turnover, indicating an important role in bone formation. Ano5 is also expressed in somites and in developing skeletal muscle, and is upregulated during the skeletal muscle cell line C2C12 myogenic differentiation.

The importance of Ano5 in skeletal muscle physiology is further highlighted by the recent finding that mutations in Ano5 produce several recessive muscular dystrophies^[78–80]. Patients with a proximal limb-girdle muscular dystrophy (LGMD2L) and distal non-dysferlin Miyoshi myopathy (MMD3) carry mutations in Ano5. These mutations include a splice site and base pair duplication that result in premature stop codons, and two missense mutations, R758C and G231V. The phenotypes resulting from these mutations are reminiscent of dysferlinopathies, in which a deficiency in dysferlin causes defective skeletal muscle membrane repair. It has been suggested that chloride currents are important in membrane repair^[81] and Ano5 may be one of the channels involved in this process. Additional evidence implicating Ano5 in the maintenance of skeletal muscle is that Ano5 expression is increased in dystrophin-deficient mdx mice, a mouse model of Duchenne muscular dystrophy. In contrast to the Duchenne muscular dystrophy phenotype, dystrophin-deficient mdx mice maintain their ability to regenerate muscle fibers and have reduced endomysial fibrosis^[82]. The role of Ano5 in muscle membrane repair is still speculative, but determining if Ano5 functions as a chloride channel will be critical for elucidating its role in musculoskeletal pathologies (Figure 1).

Ano6 plays a role in blood clotting

Mutations in Ano6 have recently been implicated in Scott syndrome, a rare congenital bleeding disorder caused by a defect in blood coagulation^[83]. In platelets, like other cell types, phosphatidylserine is located on the inner leaflet of the plasma membrane. When platelets are activated they expose phosphatidylserine on the outer leaflet of the plasma membrane to promote clotting. This redistribution of phosphatidylserine is mediated by phospholipid scramblases that transport phospholipids bidirectionally from one leaflet to the other. In patients with Scott syndrome this mechanism is defective, resulting in impaired blood clotting. Ano6 was found to be critical for Ca^{2+} dependent exposure of phosphatidylserine on the cell surface in Ba/F3 platelet cells. Furthermore, a patient with Scott syndrome harbored a mutation at a splice-acceptor site of Ano6, resulting in premature termination of the protein. Cells derived from this patient did not expose phosphatidylserine in response to a Ca^{2+} ionophore, unlike cells derived from the patient's unaffected parents. These data imply that Ano6 is required for scramblase activity. However, the recent finding that Ano6 is a non-selective cation channel^[75] throws another wrinkle into the interpretation of these data.

Ano7 is highly expressed in prostate

Ano7, which is highly expressed in prostate, was discovered

Figure 1. Phylogenetic tree of vertebrate Anoctamins. Each branch is labeled with the Ano and Tmem16 nomenclature, followed by the known or suspected physiological function, and any diseases that have been associated with this protein. GDD: gnathodiphyseal dysplasia; LGMD2L: proximal limb girdle muscular dystrophy; MMD3: distal Miyoshi muscular dystrophy. The tree was computed using 103 vertebrate Anoctamins found in Genbank and Ensembl using nearest neighbor statistics.

in a search for genes whose expression patterns mimicked those of known prostate cancer genes^[34, 84]. Of 40 000 human genes examined, 8 novel genes, including Ano7, were identified as being the most closely linked to known prostate cancer genes. Ano7 is expressed on the apical and lateral membranes of normal prostate. In the prostate LNCaP cell line stably transfected with Ano7, the protein localizes to cell-cell contact regions. It has been suggested that Ano7 promotes cell association because cell association can be reduced with RNAi targeted to Ano7^[84]. The predominant expression in prostate and prostate cancers poise Ano7 as an attractive candidate for immunotherapy^[85, 86], although the role of Ano7 in the development of prostate cancer is uncertain.

Ano10 mutations are linked to ataxia

Mutations in Ano10 have been linked to autosomal-recessive cerebellar ataxias associated with moderate gait ataxia, down-beat nystagmus, and dysarthric speech^[87]. Affected individuals display severe cerebellar atrophy. Two of the mutations introduce premature stop codons, probably leading to null protein expression. The other mutation is a missense mutation, L510R, which is highly conserved among the Anos and lies in the sixth transmembrane domain within the DUF590 domain of unknown function. It remains especially uncertain whether Ano10 is an ion channel, because Ano10 and Ano8

constitute the most divergent branch of the anoctamin family. While there is little functional data for Ano10, a *Drosophila* ortholog of Ano8/10, called Axs, is necessary for normal spindle formation and cell cycle progression^[88]. Axs co-localizes with ER components, and is recruited to microtubules of assembling spindles during mitosis and meiosis. A dominant mutation in Axs causes abnormal segregation of homologous achiasmate chromosomes due to defects in spindle formation, and disrupts cell cycle progression. It remains to be seen if Ano10 plays a similar role in mammalian systems.

Summary

The Tmem16/Anoctamin family promises to reveal many exciting secrets over the next few years. We are impatient to know whether Anos3–10 are anion channels, other types of channel, or something else, such as a phospholipid scramblase. We would also like to know whether some of these proteins have functions in intracellular organelles. It is interesting that in just ~3 years since Ano1 and Ano2 were identified as CaCCs, Anos 5, 6, and 10 have been linked to several serious human diseases, but human diseases caused by mutations in Ano1 and Ano2 have not been found. Certainly in the case of Ano1, this may be because these mutations are lethal, just as the null allele is in mice^[40]. The location of the pore of the Ano1 channel still has not been clearly established. Although mutations between TMD5 and TMD6 point to the putative re-entrant loop here as being part of the pore^[18, 19], the remarkably high conservation in this region between Ano1, which is an anion channel, and Ano6, which is apparently a cation channel, argues against this region as a determinant of ion selectivity. Unravelling the mechanisms of Ano1 regulation by Ca²⁺ and voltage also remain areas that are certain to provide exciting insights.
