Received 7 October 2013, Accepted 4 December 2013, Published online 19 December 2013

**Abstract** – Many bucephalid species, mainly of the subfamily Prosorhynchinae, have been described from epinepheline serranids (groupers) throughout the World's Oceans. In this paper eight named prosorhynchine species are described and/or illustrated from epinepheline fishes from New Caledonia. *Neidhartia lochepintade* n. sp. in *Epinephelus chlorostigma* differs from other *Neidhartia* spp. in various combinations of distinct body-size, rhynchus size, previtelline and pre-mouth distance, post-testicular distance, cirrus-sac reach and egg-size. Other species are: *Neidhartia haywardi* Bott, Miller & Cribb, 2013 in *Plectropomus leopardus*; *Neidhartia tyleri* Bott, Miller & Cribb, 2013 in *Plectropomus leopardus* and *Plectropomus laevis*; *Prosorhynchus freitasi* Nagaty, 1937 in *Plectropomus leopardus* and *Plectropomus laevis*; *Prosorhynchus robertsthomsoni* Bott & Cribb, 2009 in *Cephalopholis argus*; *Prosorhynchus longisaccatus* Durio & Manter, 1968 in *Cephalopholis urodetata*, *Epinephelus areolatus*, *Epinephelus cyanopodus* and *Epinephelus maculatus*. *Prosorhynchus luzonicus* Velasquez, 1959 and *Prosorhynchus* sp. B. in *Epinephelus coioides*; *Prosorhynchus serrani* Durio & Manter, 1968 in *Variola albimarginata* and *Variola louti*; *Prosorhynchus* sp. A in *Epinephelus morrhua*; *Prosorhynchus* sp. immature in *Epinephelus coeruleopunctatus*. The new combination *Neidhartia longivesicula* (Bilquees, Khalil, Khan, Perveen & Muti-ur-Rehman, 2009) (Syn. *Prosorhynchus longivesicula*) is formed. Evidence from this paper and earlier molecular studies indicates that there are numerous morphologically similar prosorhynchine species in serranids, most of which show a high degree of host-specificity.

**Key words:** Bucephalidae, *Neidhartia*, *Prosorhynchus*, *Epinephelus*, *Cephalopholis*, *Variola*, New Caledonia.

**Résumé – Bucephalidae (Digenea) d'Epinephelinæ (Serranidae: Perciformes) en Nouvelle-Calédonie, y compris *Neidhartia lochepintade* n. sp.** De nombreuses espèces de Bucephalidae, principalement de la sous-famille Prosorhynchinae, ont été décrites de Serranidae Epinephelinæ (mérous) à travers les océans du monde. Dans cet article, huit espèces nommées de Prosorhynchinae sont décrites et / ou illustrées d'Epinephelinæ de Nouvelle-Calédonie. *Neidhartia lochepintade* n. sp., parasite d'*Epinephelus chlorostigma*, diffère des autres espèces de *Neidhartia* par des combinaisons variées de taille du corps, taille du rhynchus, distance pré-vitelline et pré-bouche, distance post-testiculaire, étendue du sac du cirre et taille des œufs. Les autres espèces sont : *Neidhartia haywardi* Bott, Miller & Cribb, 2013 chez *Plectropomus leopardus*; *Neidhartia tyleri* Bott, Miller & Cribb, 2013 chez *Plectropomus leopardus* et *Plectropomus laevis*; *Prosorhynchus freitasi* Nagaty, 1937 chez *Plectropomus leopardus* et *Plectropomus laevis*; *Prosorhynchus robertsthomsoni* Bott & Cribb, 2009 chez *Cephalopholis argus*; *Prosorhynchus longisaccatus* Durio & Manter, 1968 chez *Cephalopholis urodetata*, *Epinephelus areolatus*, *Epinephelus cyanopodus* et *Epinephelus maculatus*; *Prosorhynchus luzonicus* Velasquez, 1959 et *Prosorhynchus* sp. B. chez *Epinephelus coioides*; *Prosorhynchus serrani* Durio & Manter, 1968 chez *Variola albimarginata* et *Variola louti*; *Prosorhynchus* sp. A chez *Epinephelus morrhua*; *Prosorhynchus* sp. immature chez *Epinephelus coeruleopunctatus*. La nouvelle combinaison *Neidhartia longivesicula* (Bilquees, Khalil, Khan, Perveen & Muti-ur-Rehman, 2009) (Syn. *Prosorhynchus longivesicula*) est formée. Cet article et des études moléculaires antérieures indiquent qu'il existe de nombreuses espèces de Prosorhynchinae morphologiquement semblables chez les Serranidae, dont la plupart présentent un haut degré de spécificité à l'hôte.

## Introduction

Bucephalid digeneans are frequently found in fishes of the family Serranidae, in particular in members of the subfamily Epinepheliniae [8]. For example, Bray & Justine [5] listed 16 species of *Prosorhynchus* Odhner, 1905 from serranid fishes: *P. atlanticus* Manter, 1940, *P. bulbosus* Kohn, 1961, *P. caudovatus* Manter, 1940, *P. chorinemi* Yamaguti, 1952, *P. epinepheli* Yamaguti, 1939, *P. freitasi* Nagaty, 1937, *P. gonoderus* Manter, 1940, *P. jupe* (Kohn, 1967), *P. longisaccatus* Durio & Manter, 1968, *P. mcintoshii* (Velasquez, 1959) (this may belong to *Neidhartia*), *P. ozakii* Manter, 1934, *P. pacificus* Manter, 1940, *P. platycephali* (Yamaguti, 1934), *P. promicropsi* Manter, 1940, *P. serrani* Durio & Manter, 1968, and *P. thapari* Manter, 1953, and added a further species *P. maternus* Bray & Justine, 2006. Two were missed, namely *P. aguayoi* Vigueras, 1955 and *P. rarus* (Kohn, 1970). Later, Bott & Cribb [2] added a further five species, *P. jexi* Bott & Cribb, 2009, *P. lafii* Bott & Cribb, 2009, *P. robertsthomsoni* Bott & Cribb, 2009, *P. conorjonesi* Bott & Cribb, 2009 and *P. milleri* Bott & Cribb, 2009 and recently Bott et al. [3] added yet another five species, all from *Plectropomus* spp., *P. lesteri* Bott, Miller & Cribb, 2013, *P. wrightae* Bott, Miller & Cribb, 2013, *P. heronensis* Bott, Miller & Cribb, 2013, *P. munozae* Bott, Miller & Cribb, 2013 and *P. plectropomi* Bott, Miller & Cribb, 2013, making a total of 29 species. Other genera of bucephalids are also reported in serranids, e.g., *Neidhartia* Nagaty, 1937 (*N. neidharti* Nagaty, 1937, *N. ghardagae* Nagaty, 1937, *N. coronata* Durio & Manter, 1968, *N. epinepheli* Bott & Cribb, 2009, *N. tyleri* Bott, Miller & Cribb, 2013, *N. haywardi* Bott, Miller & Cribb, 2013, *N. plectropomi* Bott, Miller & Cribb, 2013), *Pseudoprosorhynchus* Yamaguti, 1938 (*P. hainanensis* Shen, 1990), *Rhipidocotyle* Diesing, 1858 (*R. angusticolle* Chandler, 1941, *R. clavivesiculum* Ku & Shen, 1975), *Bucephalus* Baer, 1827 (*B. heterotentaculatus* Bravo-Hollis & Lamothe-Arqumedo, 1956), *Myorhynchus* Durio & Manter, 1968 (*M. pritchardae* Durio & Manter, 1968), *Muraenicola* Nolan & Cribb, 2010 (syn: *Folliculovarium* Gu & Shen, 1983 pre-occupied) (*M. xishaensis* (Gu & Shen, 1983)), *Neoprosorhynchus* Dayal, 1948 (*N. purius* Dayal, 1948) and *Telorhynchus* Crowcroft, 1947 (*T. arripidis* Crowcroft, 1947).

Most of these species belong to the subfamily Prosorhynchinae Nicoll, 1914, but *Bucephalus* and *Rhipidocotyle* are in the Bucephalinae. These may be accidental records. The only bucephaline species originally described from a serranid is *R. clavivesiculus* which, according to the original description [22], has a recurved pars prostatica and sperm duct, a characteristic of the Prosorhynchinae [33].

This paper expands on the records made in Justine et al. [19], discussing the systematics of the reports in that paper, and adding new data obtained subsequently.

## Materials and methods

Digeneans were collected live, immediately fixed in nearly boiling saline and then transferred to 80% ethanol. Whole mounts were stained with Mayer's paracarmine, cleared in beechwood creosote and mounted in Canada balsam. Measurements were made through a drawing tube on an Olympus BH-2

microscope, using a Digicad Plus digitising tablet and Carl Zeiss KS100 software adapted by Imaging Associates, and are quoted in micrometres. The following abbreviations are used: BMNH, British Museum (Natural History) Collection at the Natural History Museum, London, UK; MNHN JNC, Muséum National d'Histoire Naturelle, Paris, France.

Use has been made of the visual key to *Prosorhynchus* developed by Bray & Palm [6]. (<http://www.nhm.ac.uk/bray2009>) and a similar key to the genus *Neidhartia* recently devised by us. We use the term "cirrus-sac reach" for the distance from the anterior-most extremity of the cirrus-sac to the posterior extremity of the body as a percentage of the body-length.

## Results

Family Bucephalidae Poche, 1907

Subfamily Prosorhynchinae Nicoll, 1914

Genus *Neidhartia* Nagaty, 1937

### *Neidhartia lochepintade* n. sp. (Figures 1, 2)

Syn. *Prosorhynchus* sp. in *Epinephelus chlorostigma* of Justine et al. (2010).

<urn:lsid:zoobank.org:act:A3A03B8A-A686-4168-AFE5-5F6A54C923BA>

Type-Host: *Epinephelus chlorostigma* (Valenciennes) brown-spotted grouper, Serranidae.

Site: Pyloric caeca.

Type-Locality: Off Récif Toombo, deep-sea (22°34'431S, 166°27'552E, 04/01/2008);

Other locality: Off Récif Toombo, deep-sea, 200–300m (22°34'187S, 166°26'292E, 01/12/2009).

Prevalence: 67% (2 of 3).

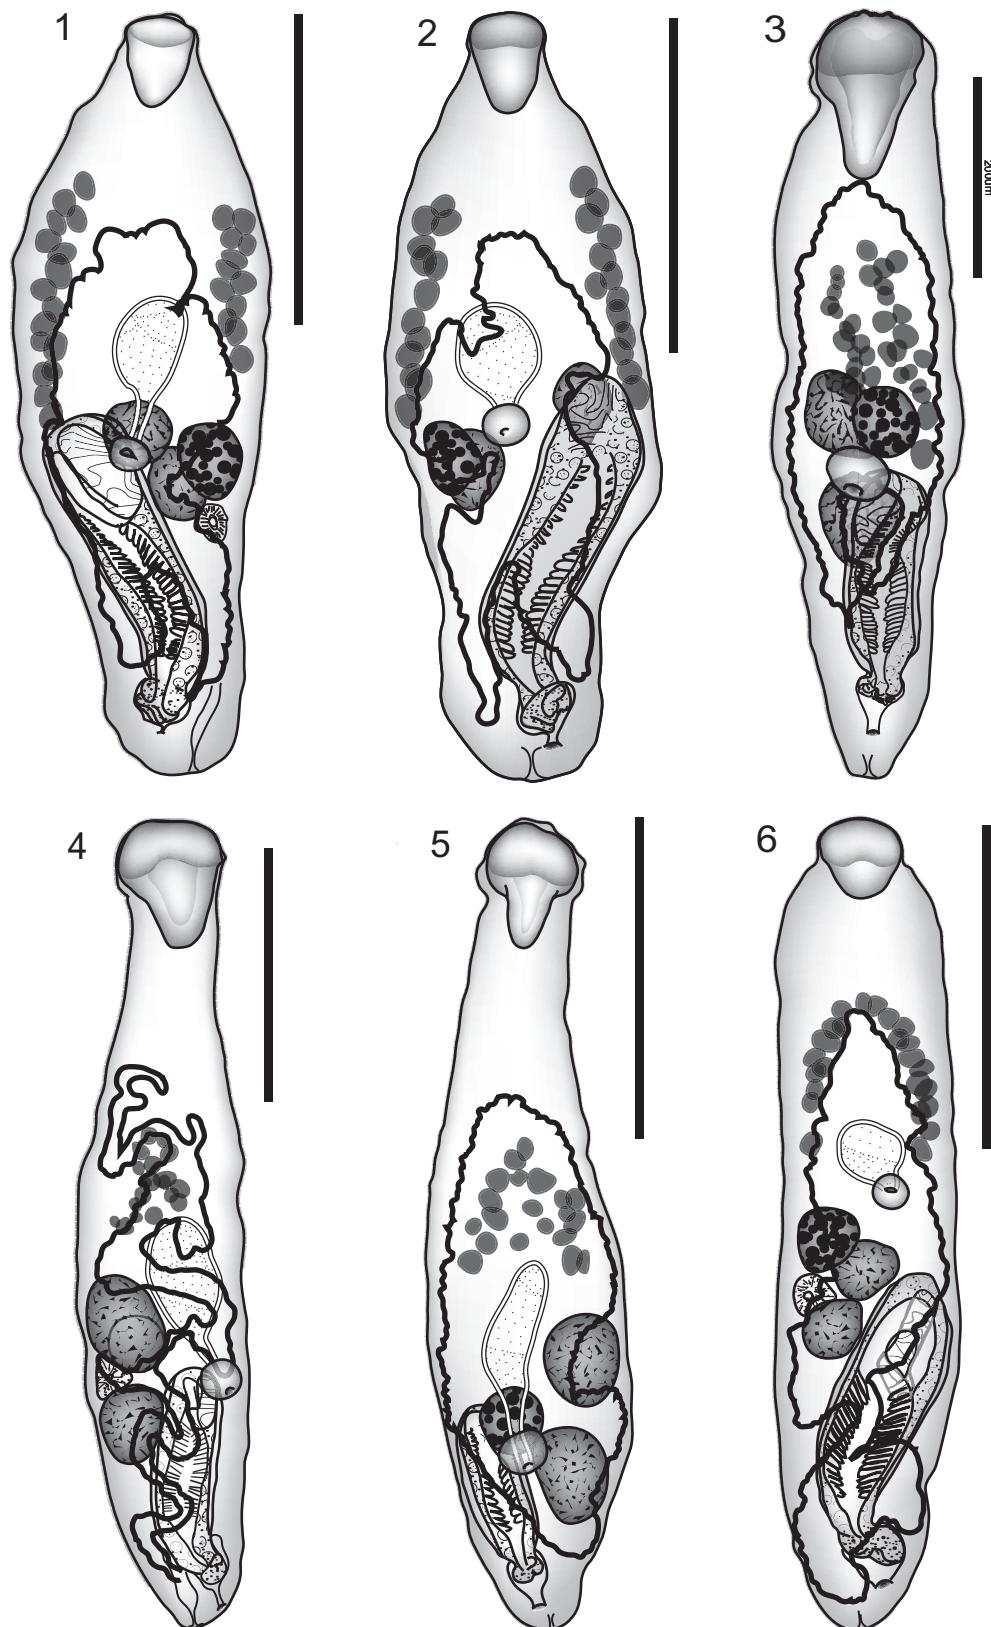

Type-specimens: Holotype MNHN JNC 2446d-1, Paratypes, MNHN JNC 2446d-2-5, JNC 3141, BMNH 2013.11.18.1.

Etymology: Loche Pintade is the New Caledonian name for the host species.

### Description

Based on 10 whole-mount preparations. Measurements and ratios in Table 1. Body fusiform, widest at about mid-body (Figures 1, 2). Tegument spinous; spines squamous, tiny, reach to posterior extremity. Rhynchus broad, relatively short and blunt. Mouth at about level of ovary, distinctly in post-equatorial half of body. Pharynx small, globular. Caecum oval, directed anteriorly.

Testes 2, irregularly oval, oblique, in about mid-body, usually well separated. Cirrus-sac elongate, more-or-less parallel sided, reaching anterior testis, anteriorly to pharynx. Seminal vesicle elongate-oval, in proximal cirrus-sac. Pars prostatica long, in two distinct parts; proximal part narrow, coiled over seminal vesicle; distal part wider, straighter, surrounded by

dense layer of gland-cells, lining of filaments in chevron arrangement. Ejaculatory duct narrow, opening on large, complex genital lobe inside genital atrium. Genital atrium large. Genital pore distinctly separated from posterior extremity.

Ovary oval, intertesticular, overlapping posterior testis. Mehlis' gland overlapping ovary and posterior testis. Details of proximal female system obscured by eggs. Uterus not reaching anteriorly to vitelline fields, fills most of available space to level of genital pore. Eggs numerous, tanned, operculate. Metratrem not detected, obscured by eggs. Vitellarium consists of two lateral fields of 12–15 follicles, more or less symmetrical, but with one field slightly longer than other, anterior extremity distinctly posterior to rhynchus and anterior to uterus, always anterior to caecum and gonads; posterior extremity at about level of ovary.

Excretory pore terminal; anterior extent of vesicle obscured by eggs.

## Discussion

The features that distinguish *N. lochepintade* from previously described *Neidhartia* species are discussed below; comparative metrical data in Table 2.

*Neidhartia coronata* Durio & Manter, 1968, based on “six somewhat macerated, extended specimens” from the intestine of a “Serranidae”, “probably *Epinephelus*”, from off New Caledonia [9], is narrower, with a larger rhynchus, longer pre-vitelline distance, longer pre-uterine distance, longer pre-mouth distance, shorter post-testicular distance, shorter cirrus-sac reach and greater egg-size. The host identifications in Durio & Manter [9] are often rather vague, and this case is no exception. In this particular case, Durio & Manter's “*Epinephelus*” could be any Serranidae, including any species of *Cephalopholis*, *Plectropomus*, *Variola* and even *Epinephelus*.

*Neidhartia epinepheli* Bott & Cribb, 2009, based on two specimens from the intestine of the highfin grouper *Epinephelus maculatus* (Bloch) (Serranidae) off Lizard Island on the Great Barrier Reef [2], has a relatively larger rhynchus and a longer previtelline distance. In *N. epinepheli* the uterus reaches anterior

to the vitellarium. Other probably differences are the pre-mouth distance, post-testicular region and cirrus-sac reach.

*Neidhartia ghardagae* Nagaty, 1937, based on 16 specimens from a “*Serranus* sp.” from off Ghardaga in the Red Sea [29], has a relative larger rhynchus, longer previtelline distance and longer pre-mouth distance and probably a shorter post-testicular region and a shorter cirrus-sac reach.

*Neidhartia haywardi* Bott, Miller & Cribb, 2013, based on 10 specimens and ITS2 sequence from *Plectropomus leopardus*, *P. laevis* and the spotted coralgrouper *P. maculatus* (Bloch), from Heron and Lizard Islands on the Great Barrier Reef [3] has a bigger rhynchus, longer previtelline distance and shorter post-testicular distance.

*Neidhartia longivesicula* (Bilqees, Khalil, Khan, Perveen & Muti-ur-Rehman, 2009) n. comb. (Syn. *Prosorhynchus longivesicula*) is based on seven specimens from the yellow-tail scad *Atule mate* (Cuvier) (as *Caranx affinis* Rüppell) (Carangidae) off Karachi in the northern Arabian Sea [1]. The ovary is described as “posterior to anterior testis and ventro-lateral to posterior testis”, indicating that the species belongs to *Neidhartia*. This species differs from *N. lochepintade* particularly in the more anterior mouth and greater body-size.

*Neidhartia mcintoshii* Velasquez, 1959, based on two mature and four immature specimens from the muscle, stomach and intestine of the duskytail grouper *Epinephelus bleekeri* (Vaillant) (Serranidae) off Malabon, Rizal, Luzon Island, Philippines [48], has a longer pre-uterine extent, and probably a relatively larger rhynchus, shorter pre-mouth distance and shorter cirrus-sac reach. In connection with unusual sites of infection given, Velasquez [48] stated that the “present species occurs as metacercaria and adult in the same host, showing evidence that infection of one fish is brought about possibly through the eating of the smaller fish by the larger”.

*Neidhartia microrhyncha* Chauhan, 1943, based on five non-ovigerous specimens from the alimentary canal of the Indian spiny turbot *Psettodes erumei* (Bloch & Schneider) (Psettodidae) off Bombay (now Mumbai), India [7], is narrower and has a shorter cirrus-sac reach. It is reported to grow much bigger.

**Table 2.** Comparisons of *Neidhartia* spp., blue shading shows major distinctions, green shading shows minor distinctions.

*Neidhartia neidharti* Nagaty, 1937, based on eight specimens from *Serranus* sp. locally called “Nagil”, from off Ghadaga in the Red Sea [29], has a relatively larger rhynchos and longer pre-mouth distance and probably a shorter post-testicular region and a shorter cirrus-sac reach. The vitellarium overlaps the rhynchos. According to Froese & Pauly [15] the common name “Nagil” refers to either the squaretail coralgrouper *Plectropomus areolatus* (Rüppell, 1830) or the roving coralgrouper *Plectropomus tessuliferus* (Fowler, 1904) (Serranidae).

*Neidhartia plectropomi* Bott, Miller & Cribb, 2013 based on 10 specimens and ITS2 sequence from *Plectropomus leopardus* and *P. laevis* from Heron and Lizard Islands on the Great Barrier Reef [3] has a bigger rhynchos and longer previtteline distance.

*Neidhartia polydactyli* Manter, 1953, based on a single specimen from the intestine of the striped threadfin *Polydactylus plebeius* (Broussonet) (Polynemidae) off Suva, Fiji [26], has a relatively larger rhynchos and longer previtteline and pre-mouth distances.

*Neidhartia tyleri* Bott, Miller & Cribb, 2013 based on 10 specimens and ITS2 sequence from the *Plectropomus leopardus*, *P. laevis* and *P. maculatus*, from Heron and Lizard Islands on the Great Barrier Reef [3] is narrower, with longer previtteline and pre-mouth distances, shorter post-testicular distance and cirrus-sac reach, and larger eggs.

*Pseudoprosorhynchus hainanensis* Shen, 1990, based on two specimens from the intestine of the *Plectropomus leopardus* off Hainan Island, southern China [41] is similar to *Neidhartia locheptintade* (and indeed the whole genus) in that the ovary is between the testes, but the rhynchos is disc-like, and the worm is long and narrow. It also appears to have a short cirrus-sac reach and smaller eggs.

These data, and the record from this deep-water serranid, indicate to us that the specimens described here belong to a new species. *Prosorhynchus epinepheli* Yamaguti, 1939 has been reported twice from this host, from off Tuticorin, India [18] and from the Arabian Gulf [40]. The illustrations in both papers show that the ovary lies partly anterior to and partly overlapping the anterior testis, and thus do not indicate that the worm in question is a *Neidhartia*. The Indian record [18] is from several host species and it is not stated from which the illustrated worm was collected. *E. chlorostigma* has also been listed as a host for unnamed *Prosorhynchus* spp. in the Arabian Gulf [11, 39].

As discussed below, the generic status of *Prosorhynchus epinepheli* and *P. longisaccatus* is ambiguous as often the ovary does not lie distinctly anteriorly to the testes, suggesting that they may be *Neidhartia* spp. Comparison of data in Tables 2 and 6 indicates that the rhynchos is relatively much larger in *P. epinepheli* and *P. longisaccatus*. The pre-uterine distance tends to be larger in *P. longisaccatus*, but overlaps considerably.

Host: *Plectropomus leopardus* (Lacepède) (Perciformes: Serranidae), leopard coralgrouper.

Site: digestive tract

Localities: Grande Rade, Nouméa 22°15'S 166°24'E, 23/10/2007 and 24/10/2007; Between Larégnière and Récif Crouy, 22°20'70S, 166°19'295E, 05/05/2008.

Prevalence: 57% (4 of 7).

Vouchers: MNHN JNC2333B, JNC2333C, JNC2334, JNC2513; BMNH 2013.11.18.5-6.

### Description

Based on five whole-mount preparations. Measurements and ratios in [Table 1](#). Body widest at about mid-body ([Figure 3](#)). Tegument spinous; spines squamous, tiny, reach to posterior extremity. Rhynchus broad, conical or bluntly conical. Mouth just posterior to ovary, well into post-equatorial half of body. Pharynx small, globular. Caecum oval, directed anteriorly.

Testes 2, irregularly oval, oblique, in about mid-body, usually well separated. Cirrus-sac elongate, more-or-less parallel sided, reaching to or almost to anterior testis, anteriorly to pharynx. Seminal vesicle elongate-oval, in proximal cirrus-sac. Pars prostatica long, in two distinct parts; proximal part narrow, coiled over seminal vesicle; distal part, wider, straighter, surrounded by dense layer of gland-cells, lining of filaments in chevron arrangement. Ejaculatory duct narrow, opening on large, complex genital lobe inside genital atrium. Genital atrium large. Genital pore distinctly separated from posterior extremity.

Ovary oval, intertesticular, overlapping testes. Mehlis' gland overlapping ovary and posterior testis. Details of proximal female system obscured by eggs. Uterus reaches anteriorly to vitelline fields, occasionally to level of vitellarium, fills much of available space to level of genital pore. Eggs numerous, tanned, operculate. Metratrem not detected, obscured by eggs. Vitellarium consists of two lateral fields of 12–15 follicles, more or less symmetrical, but with one field slightly longer than other, anterior extremity posterior to rhynchus and anterior extent of uterus, reaches anterior to caecum and gonads; posterior extremity at about level of ovary.

Excretory pore terminal; anterior extent of vesicle obscured by eggs.

### Discussion

This form appears to be *N. haywardi* or *N. plectropomi* differing only in the previtelline distance, as calculated from the illustration [[3](#), Figure 3], but it should be noted that in both species Bott et al. [[3](#)] found that the extent of the vitellarium was obscured by the uterus. *N. haywardi* and *N. plectropomi* are sister species according to the molecular study of Bott et al. [[3](#)]. We consider our specimens to be *P. haywardi* as the egg-sizes more nearly coincide ([Table 2](#)), but the cirrus-sac reach of our specimens tends to be greater than is apparent in either species. Both *P. haywardi* and *P. plectropomi* are reported from *P. leopardus* and *P. laevis*, and from Heron and Lizard Islands on the Great Barrier Reef.

The features distinguishing this species from its congeners can be seen in [Table 2](#), and two further species are not easily distinguished, namely *N. neidharti* Nagaty, 1937 and *N. epinepheli* Bott & Cribb, 2009.

*N. neidharti* was first reported in *Serranus* sp. locally known as "Nagil" from the Red Sea [[29](#)]. According to Froese & Pauly [[15](#)] this common name refers to the squaretail coral-grouper *Plectropomus areolatus* (Rüppell) or the roving coral-grouper *P. tesselliferus* (Fowler). It seems clear, therefore, that it is a parasite of *Plectropomus*. Chauhan [[7](#)] recorded, but did not describe, this species in *Belone* sp. (Beloniformes: Belonidae) from Mumbai (Bombay), India. As unlikely as this combination of hosts is, its putative hosts associations become even more puzzling when the record by Maurya et al. [[27](#)] in the freshwater long-whiskered catfish *Sperata* (= *Mystus*) *aor* (Hamilton) (Siluriformes: Bagridae) from Uttar Pradesh, India is considered. We are discounting the Indian records of this species. *N. neidharti* apparently grows to a much greater size than *N. plectropomi*, although there is room for confusion. In Nagaty's [[29](#)] description (p. 119) the length range is given as 561–908, whereas in the table of measurements (p. 166) the length is given as 842–2,112 (vs. 658–744 (715) for *P. haywardi*). This confusion also applies to width where, using the data from the description, the range is 24–27% and in the table it is 11–29% of body-length (vs. 20–24%). The body-width in Nagaty's Figure 56 is about 24% of the body-length. The pre-mouth distance may be greater than in *N. haywardi*.

**Table 4.** Comparisons of *Prosthorhynchus robertshomsoni*, green shading shows minor distinctions.

Species	Length	Width %	Rhynchus L %	Previtelarium %	Pre-Uterine %	Mouth	Post-testicular %	Cirrus-sac reach %	Eggs	Reference
<i>P. robertshomsoni</i> Bott & Cribb, 2009	1,088–1,256	23–24	10–12	18–23	10–26	45–47	31–40	39–48	32–38 × 16–20	new data
<i>P. robertshomsoni</i> Bott & Cribb, 2009	1,072–1,408	18–23	10–11	27	24	48	31	35	29–30 × 16	[2]
<i>P. aguayoi</i> Vigueras, 1955	1,700	29	9	21	18	46	44	36	40 × 26	[47]
<i>P. jexi</i> Bott & Cribb, 2009	1,104–1,424	19–25	15	20	32	43	41	37	32–33 × 16	[2]
<i>P. serrani</i> Durio & Manter, 1968	<b>1,027–2,245</b>	22	<b>12–18</b>	20	17	<b>49</b>	<b>27</b>	<b>33</b>	24–29 × 15–21	[9]
<i>P. serrani</i> Durio & Manter, 1968	816–1,826	30–32	<b>15–16</b>	30–34	31	<b>53–62</b>	<b>24–31</b>	<b>31–36</b>	25–29 × 17–21	[27]
<i>P. tsengi</i> Tsin, 1933	1,500–1,800	24–25	7–9	22	19	47	34	41	<b>19–25 × 14–17</b>	[44]

*Neidhartia epinepheli*. Bott & Cribb stated that it “It bears a superficial resemblance to the type-species, *N. neidharti* Nagaty, 1937, in that its uterus extends past the posterior margin of the rhynchus. *N. epinepheli* differs by having a caecum that does not extend into the anterior third of the body and the eggs are smaller, 25–26 × 12–13, compared with 30 × 15 for *N. neidharti* (see Nagaty, 1937)”. The confusion in the egg-size as given by Nagaty [29] for *N. neidharti*, in that he gives the egg-size as 30 × 15 in the text, but 19–29 × 15–19 in the table may well invalidate one of Bott & Cribb’s [2] distinctions. The other distinction is rather minor and it may be found that these species are synonymous. The pre-uterine distance is shorter than in *N. haywardi* in that the uterus overlaps the rhynchus.

#### *Neidhartia tyleri* Bott, Miller & Cribb, 2013 (Figures 4, 5)

#### Description

Based on seven whole-mount preparations from *P. leopardus* and six from *P. laevis*. Measurements and ratios in Table 1. Body fusiform, widest in posterior third (Figures 4, 5). Tegument spinous; spines squamous, tiny, reach to posterior extremity. Rhynchus broad, with narrow conical posterior extension. Mouth at about level of ovary or just posterior, well into post-equatorial half of body. Pharynx small, globular. Cae-cum elongate-oval, directed anteriorly.

Testes 2, irregularly oval, oblique to tandem, in about mid-body, slightly separated or not. Cirrus-sac elongate, more-or-less parallel sided, reaching anterior testis, anteriorly to pharynx. Seminal vesicle elongate-oval, in proximal cirrus-sac. Pars prostatica long, in two distinct parts; proximal part narrow, coiled over seminal vesicle; distal part, wider, straighter, surrounded by dense layer of gland-cells, lining of filaments in chevron arrangement. Ejaculatory duct narrow, opening on large, complex genital lobe inside genital atrium. Genital atrium large. Genital pore distinctly separated from posterior extremity.

Ovary oval, intertesticular, overlapping testes. Mehlis’ gland overlapping ovary and posterior testis. Details of proximal female system obscured by eggs. Uterus not reaching anteriorly to vitelline fields, fills much of available space to level of genital pore. Eggs numerous, tanned, operculate. Me-traterm not detected, obscured by eggs. Vitellarium consists of two lateral fields of follicles, more or less symmetrical, but

with one field slightly longer than other, anterior extremity distinctly posterior to rhynchus and anterior to uterus, always reaches anterior to caecum and gonads; posterior extremity at or just posterior to level of ovary.

Excretory pore terminal; anterior extent of vesicle obscured by eggs.

## Discussion

We have identified the larger *Neidhartia* specimens as belonging to *N. tyleri*. Most morphological characters are similar (Table 2), but the eggs in our specimens from *P. leopardus* (the type-host of *N. tyleri*) are distinctly smaller than those described for this species [3] and our specimens from *P. laevis*. This species is readily distinguished from most described species (Table 2). *N. neidharti* is not distinguishable from the specimens from *P. laevis* in major features of the visual key and differs from the *P. leopardus* specimens only in rhynchus length (Table 2). This feature probably distinguishes this form from *N. neidharti* as the *P. laevis* specimens do not overlap in this feature. Comparison with *N. neidharti* as described by Nagaty [29] is problematical as the measurements given in the description and table do not coincide, but our specimens are very distinct from the illustrated specimen [28, Figure 56] in shape (relatively more elongate, although the measurements in the table do not bear this out), the previtelline distance and pre-uterine distance.

*N. coronata* Durio & Manter, 1968, described from “Serranidae, probably *Epinephelus* sp.” from off New Caledonia [9], differs from our specimens in the visual key in the pre-uterine distance and cirrus-sac reach. It should be borne in mind, however, that Durio & Manter [9] stated that their description was “based on six somewhat macerated, extended specimens”. The previtelline distance may also be a distinguishing feature.

Genus *Prosorhynchus* Odhner, 1905

urn:lsid:zoobank.org:act:21111289-7672-4028-830D-A37199B68E26

### *Prosorhynchus robertsthomsoni* Bott & Cribb, 2009 (Figure 6)

urn:lsid:zoobank.org:act:0EEE6ED7-01CE-45A0-A2B9-27F32EBC64CC

Host: *Cephalopholis argus* Bloch & Schneider (Perciformes: Serranidae), peacock hind.

Site: digestive tract

Locality: Near Récif Toombo (22°31'30"S, 166°26'40"E, 03/11/2006).

Prevalence: 50% (1 of 2).

Vouchers: MNHN JNC 2110; BMNH 2013.11.18.25.

## Discussion

Measurements and ratios are given in Table 3. This species is known only from *Cephalopholis argus*, the coral hind *Cephalopholis miniata* (Forsskål) and the bluespotted hind *C. cyanostigma* (Valenciennes) from off Heron and Lizard Islands on the Great Barrier Reef [2, 3]. Using the visual key our specimens align with four species, in addition to *P. robertsthomsoni*. Distinctions are tabulated in Table 4.

*Prosorhynchus aguayoi* Vigueras, 1955 from the greater soapfish *Rypticus saponaceus* (Bloch & Schneider) (Serranidae) from off Cuba, Curaçao and Jamaica [30, 31, 50] is a very similar species to *P. robertsthomsoni* but is probably wider and more fusiform, with a longer post-testicular region. The vitellarium reaches the testes in *P. aguayoi* and the cirrus-sac does not.

*Prosorhynchus jexi* (syn: *P. epinepheli* of Durio & Manter (1968)) from the longfin grouper *Epinephelus quoyanus* (Valenciennes) (Serranidae) from the Great Barrier Reef [2, 9] differs from *P. robertsthomsoni* in the more restricted uterus. Bott & Cribb [2] considered that the reach of the uterus anterior to the vitellarium is a distinctive feature of *P. robertsthomsoni* but our observations indicate that this does not always occur (Figure 6). The cirrus-sac does not reach the testes in *P. jexi*.

*Prosorhynchus serrani* Durio & Manter, 1968 (syn: *Prosorhynchus crucibulus* of Nagaty (1937)) from the yellow-edged lyretail *Variola louti* (Forsskål) (Serranidae) from the Red Sea and off New Caledonia [9, 29] is very similar to *P. robertsthomsoni* but apparently has a distinctly different shaped rhynchus, in that it has a distinct narrow elongate posterior extension in contrast to the blunt rounded posterior of the *P. robertsthomsoni* rhynchus. It may be that the vitellarium reaches slightly more posteriorly in *P. serrani* in that the follicles extend just posterior to the pharynx, rather than just to the pharynx (see below).

*Prosorhynchus tsengi* Tsin, 1933 is a parasite of the bartail flathead *Platycephalus indicus* (Linnaeus) (Platycephalidae) off China [42, 47]. Bray & Palm [6] pointed out that the “original illustration of *P. tsengi* by Tsin [47, Figure 8] shows a lobed rhynchus, apparently with an aperture, and a straight pars prostatica, indicating that the species may in fact belong to the genus

**Table 6.** Comparisons of *Prosorhynchus longisaccatus*, green shading shows minor distinctions.

	Length	Width %	Rhynchos L %	Pivitellarium %	Pre-Uterine %	Pre-mouth %	Post-testicular %	Cirrus-sac reach %	Eggs	Reference

Site: Intestine, pyloric caeca, stomach, digestive tract.

Locality : *C. urodetata*, Off Récif Kué, New Caledonia (07/10/2008); *E. areolatus*, Off Pointe Bovis (22°14'S, 166°20'E, 21/10/2008); Nouméa Fish Market (15/06/2007); *E. cyanopodus*, Passe de Dumbéa (22°20'00"S, 166°15'00"E, 25/11/2005 and 05/10/2006), Passe de Boulari (22°30'00"S, 166°24'00"E, 05/10/2006), Near îlot Mato (22°33'E, 166°47'E, 05/08/2007), Baie Maa (22°12'762S, 166°19'924E, 13/11/2007), Baie des Citrons, Nouméa (22°18'S, 166°26'E, 31/03/2009); *E. maculatus*, Phare Amédée (22°27'S, 166°26'E, 20/06/2006), Off Ever Prosperity, external slope, depth 60 m; (22°27'S, 166°21'E, 22/08/2006), Off Ever Prosperity, external slope, depth 60-80 m (22°27'S, 166°21'E, 17/04/2007), Récif Kué, External slope (22°34'892S, 166°29'673E, 19/06/2007), Off Récif Kué (22°36'S, 166°31'E, 07/10/2008), Shallow, Interior Lagoon near Récif Toombo (22°32'583S, 166°28'978E, 05/11/2008), Shallow, Interior Lagoon near Récif Toombo (22°32'536S, 166°29'069E, 20/11/2008), Baie des Citrons, Nouméa (22°18'S, 166°26'E, 09/04/2009), Interior Lagoon near Récif Toombo (22°32'536S, 166°29'069E, 30/04/2009).

Prevalence: *C. urodetata*, 33% (1 of 3); *E. areolatus*, 75% (3 of 4); *E. cyanopodus*, 87% (7 of 8); *E. maculatus*, 61% (16 of 26).

Voucher specimens: *C. urodetata*, MNHN JNC 2683; *E. areolatus*, JNC2690, JNC2691, JNC2175; BMNH 2013.11.18.15-16; *E. cyanopodus*, JNC2270a, JNC1659, JNC1998B, JNC1998C, JNC2000A, JNC2000B, JNC2270, JNC2395, JNC2891A, JNC2891B; BMNH 2006.4.27.1-10, 2013.11.18.22-23; *E. maculatus*, JNC1874, JNC1927, JNC2157D, JNC2187A, JNC 2680, JNC 2754, JNC 2759, JNC2894B, JNC2929, JNC3031, JNC3052, JNC3053, JNC3061, JNC3066, JNC3067; BMNH 2007.5.2.39-41, 2013.11.18.17-21.

### Description

See Tables 3 and 5 for measurements and ratios based on 52 specimens. Ovary in variable position relative to testes: pre-ovarian distance is greater than the pre-testicular distance in the specimen from *C. urodetata*, in 13 of 16 from *E. areolatus*, 8 of 13 from *E. cyanopodus* and 10 of 22 from *E. maculatus*.

### Discussion

Our study of this species is based on 52 measured specimens. In our visual key only four species showed no non-overlapping features with our specimens, namely *P. atlanticus*,

**Table 7.** Measurements and ratios of *Prostorhynchus serrani*. % refers to % of body-length.

*P. longisaccatus*, *P. epinepheli* and *P. lafii* (Table 6). We consider that our specimens conform to the species *P. longisaccatus*, a species originally reported from a “leche”, a serranid from off New Caledonia [9]. Later, we [5] considered our specimens from *E. cyanopodus* as this species and then [19] reported *E. areolatus*, and *E. maculatus* as hosts; all these reports are from New Caledonia. In the latter paper we reported the specimen from *C. urodetata* as *Prosorhynchus* sp.

*Prosorhynchus atlanticus* Manter, 1940 is an Atlantic species, originally described in the serranids, the black grouper *Mycteroperca bonaci* (Poey), the gag *Mycteroperca microlepis* (Goode & Bean) and the yellowfin grouper *Mycteroperca venenosa* (Linnaeus) off Florida [25]. The ovary is, apparently, always pre-testicular, the uterus almost never reaches anteriorly to ovary (only slightly in 1 of 29) and the cirrus-sac reach is generally smaller (Table 6).

*Prosorhynchus epinepheli* Yamaguti, 1939 was originally described from the Hong Kong grouper *Epinephelus akaara* (Temminck & Schlegel) (Serranidae) from the Inland Sea of Japan [52]. The name has been widely used subsequently for *Prosorhynchus* specimens from serranids [8], although some may be misidentified. *P. longisaccatus* is closely similar to *P. epinepheli*. We believe that either *P. epinepheli* or *P. longisaccatus* is the most appropriate identification, particularly as the variable position of the ovary, which is anterior to (and overlapping) the testes or between the testes in our specimens is similar to that described for both of these species. Yamaguti [52] described the position of the ovary in *P. epinepheli* as “overlapping right testis or entirely on its dorsal side (in the type it lies anterodorsal to the right testis, but may be dorsal, dorsolateral or posterodorsal to it)”. Durio & Manter [9] found that in *P. longisaccatus* the ovary is “to the right of, or partly posterior to, anterior testis”. This sheds some doubt on the generic classification of the worm, the variation of which includes a characteristic feature of the genus *Neidhartia* Nagatay, 1937, which according to Overstreet & Curran [33] is “Ovary at level between testes”. Durio & Manter [9] compared their new species to *P. epinepheli*, using Yamaguti’s [52] original description and new material reported from the honeycomb grouper *Epinephelus merra* Bloch, 1793 off Heron Island, southern Great Barrier Reef. It should be noted, however, that Bott & Cribb [2] examined one of Durio & Manter’s “*P. epinepheli*” specimens and considered that it belonged to their new species *P. jexi*, and that the host was most probably not *E. merra*, but the similar species, the longfin grouper *Epinephelus quoyanus* (Valenciennes), which is much commoner in the waters around

Heron Island (see also [20]). Durio & Manter [9] summarised the differences between *P. epinepheli* and *P. longisaccatus* as “(1) the uterus does not extend even to midatrial level, whereas in all specimens of *P. epinepheli* it extends postatrially; (2) the rhynchos is wider, and the arrangement of muscles at its anterior edge gives a distinctive appearance”. The first distinction probably relies just on the amount of eggs produced and the second is rather vague and difficult to assess. It seems quite possible that these species are synonymous. There appear to be no morphological criteria for separating these species and we are recognising this species based on the locality of collection, and expect the status of this worm to be elucidated or at least clarified by molecular studies at present in progress.

*Prosorhynchus lafii* Bott & Cribb, 2009 from the brown-marbled grouper *Epinephelus fuscoguttatus* (Forsskål) from off Heron Island, Great Barrier Reef [2] differs from *P. longisaccatus* in the vitelline fields which are “tight lateral clusters at level of caecum”. It is probably a more slender worm than *P. longisaccatus* (Table 6). The ovary is anterior to, but overlapping, the anterior testis.

Suriano & Martorelli [45] reported *P. longisaccatus* in the Remo flounder *Oncopterus darwinii* Steindachner (Pleuronectidae) off Buenos Aires Province, Argentina. It is larger than previously described for this species, with a shorter post-testicular region and cirrus-sac reach, and probably a shorter rhynchos (Table 6). In agreement with Etchegoin et al. [12] we believe that these worms are not conspecific with the worms from serranids in the Pacific Ocean.

### ***Prosorhynchus serrani* Durio & Manter, 1968 (Figures 11, 12)**

(syn. *Prosorhynchus crucibulus* (Rudolphi, 1819) from *Serranus louti* of Nagatay (1937))

## Description

It should be noted that the uterus reaches anteriorly beyond the ovary. Measurements and ratios are given in Table 7.

## Discussion

*Prosorhynchus serrani* is known previously only from the yellow-edged lyretail *Variola louti* (Forsskål) (Serranidae) from the Red Sea and off New Caledonia [9, 29]. Our specimens appear indistinguishable from those described by these authors.

This species is very similar to several other species and their relationships will probably only be resolved by molecular means. However, there seem to be minor morphological features which may allow the continued recognition of the *Variola* parasites as distinct (Table 8). Of those with no distinction in the parameters used in the visual key two can immediately be distinguished by other features.

*P. attenuatus* Siddiqi & Cable, 1960 from the Atlantic bumper *Chloroscombrus chrysurus* (Girard) (Carangidae) off Puerto Rico was described with a “spherical, suckerlike” rhynchus and it certainly looks like a sucker in the illustration. The pars prostatica is described as “tubular” and appears straight in the illustration [43], thus indicating that it may have been placed in the wrong subfamily.

*P. caudovatus* Manter, 1940 (syn. *P. crucibulus* of Eckmann (1932)) from serranids in the waters around Africa [4, 10, 13, 14, 46] has distinctive filamented eggs.

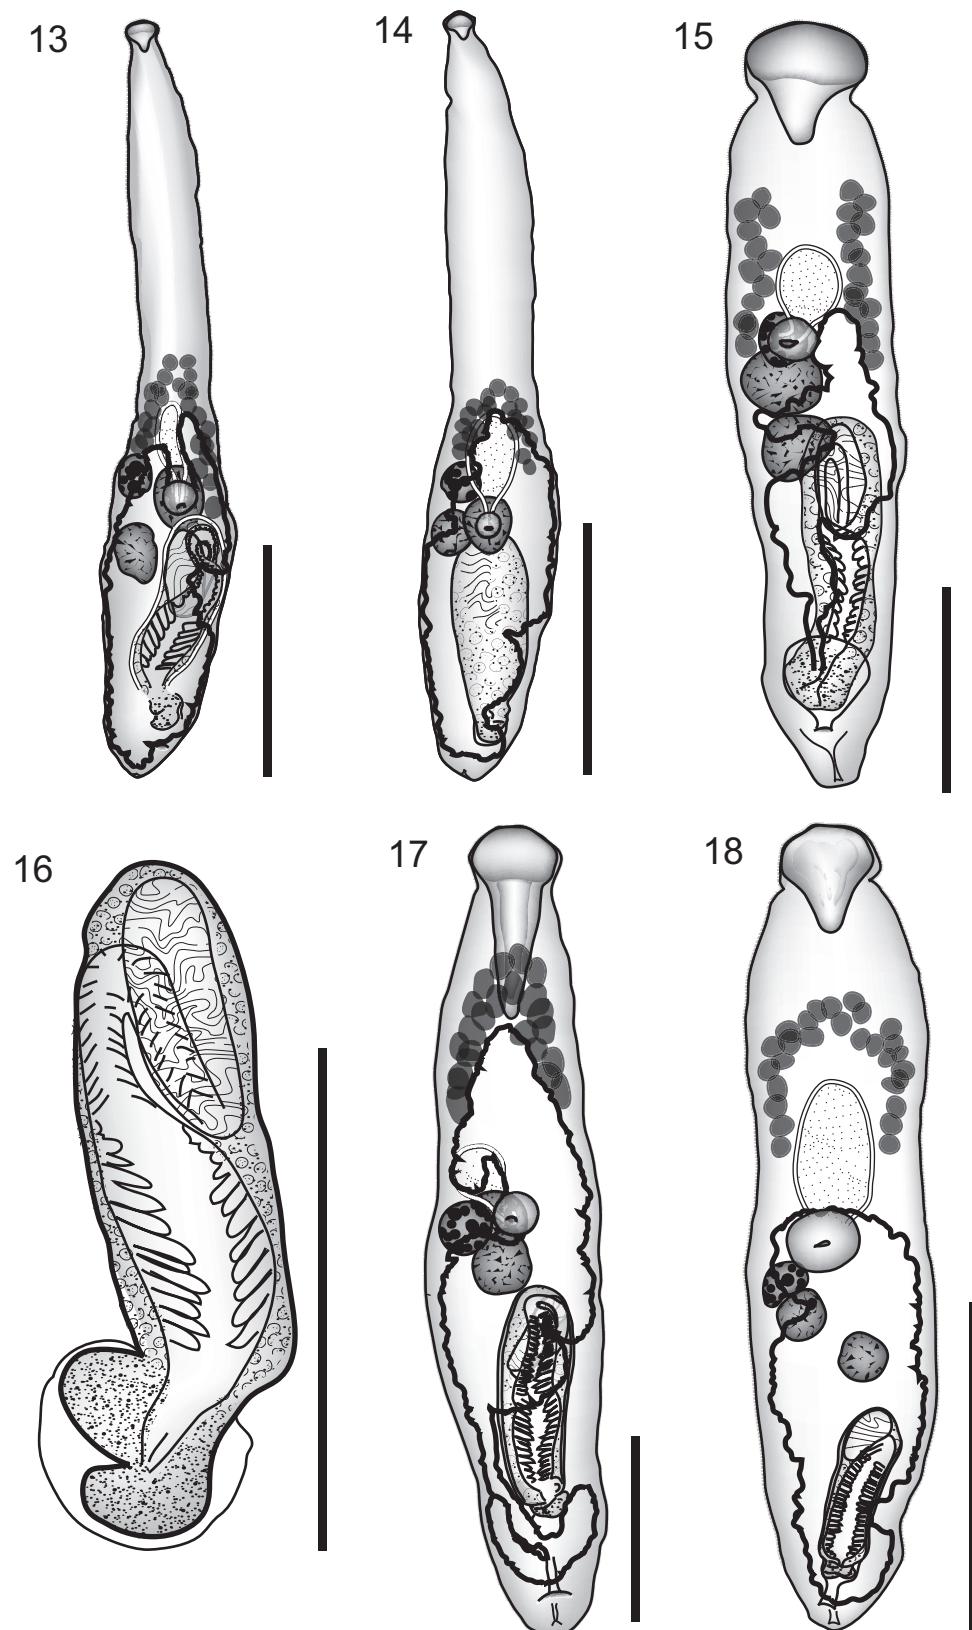

Other similar species are:

*Prosorhynchus caballeroi* Gupta & Ahmad, 1976 known from one specimen from the shrimp scad *Alepes djedaba* (Forsskål) (as *Caranx kalla* Cuvier) (Carangidae) in the Bay of Bengal [17] grows larger than *P. serrani*, with a smaller rhynchus and a longer previtellic distance.

*Prosorhynchus congorjonesi* Bott & Cribb 2009 from the barramundi cod *Cromileptes altivelis* (Valenciennes) (Serranidae) on the Great Barrier Reef [2] grows larger than *P. serrani*, is much narrower, with a more anterior mouth and a shorter cirrus-sac reach.

*Prosorhynchus jexi* has a more anterior mouth than *P. serrani* and a longer post-testicular region [2, 9].

*Prosorhynchus milleri* Bott & Cribb, 2009 based on two specimens from *Variola louti* from Lizard Island, Great Barrier Reef [2] is very similar to *P. serrani* and from one of the same host species. It is said to differ from *P. serrani* in that the latter has “a uterus that extends anterior to the vitelline follicles into the anterior quarter of the body”. Our results complicate things in that the anterior uterine extent varies considerably in our specimens from *V. louti*. Judging from the illustration of *P. milleri* in Bott & Cribb [2] the pre-uterine extent is about 51% of body-length and judging from Durio & Manter's [9] illustration of *P. serrani* this ratio is about 17%. Durio & Manter [9]

considered *P. crucibulum* from *V. louti* of Nagaty [29] a synonym of *P. serrani* and judging from Nagaty's illustration the pre-uterine distance is about 31% of body-length. This ratio in our worms varies between 26 and 52%, and without a distinct bimodal pattern (26, 29, 30, 32, 33, 38, 39, 40, 45, 49 and 52%). It may well be that there are two forms here, but we do not as yet have enough data to be certain where to draw the line.

*Prosorhynchus robertsthomsoni* Bott & Cribb, 2009 is very similar to *P. serrani* but apparently has a distinctly different shaped rhynchus, in that it has a blunt rounded posterior extension in contrast to the distinct narrow elongate posterior extension of the *P. serrani* rhynchus [2]. It may be that the vitellarium reaches slightly more posterior in *P. serrani* in that the follicles extend just posterior to the pharynx, rather than just to the pharynx.

*Prosorhynchus thapari* Manter, 1953 was based on 17 specimens from the spotted coralgrouper *Plectropomus maculatus* (Bloch) (Serranidae) from off Fiji [26]. We can detect no morphological distinctions from *P. serrani* and retain the species as separate based on host distinction, and the knowledge that as yet unpublished studies indicate some specificity and cryptic speciation in the genus. Nevertheless, it may well be that this is the oldest valid name for this species.

*Prosorhynchus truncatus* Verma, 1936 is based on two specimens, one ovigerous and lost and the other without eggs, from the intestine of the river catfish *Cephalocassis jatia* (Hamilton) (as *Arius j.*) (Ariidae) off Puri, Bay of Bengal [49]. It has a more posteriorly situated mouth and a shorter cirrus-sac reach.

#### *Prosorhynchus freitasi* Nagaty, 1937 (Figures 13, 14)

Host: *Plectropomus laevis* (Lacepède), Serranidae, black-saddled coralgrouper; *Plectropomus leopardus* (Lacepède), Serranidae, leopard coralgrouper.

Site: digestive tract.

Localities: *P. laevis* Off Ouano (21°49'430S, 166°44'278E, 25/10/2007); *P. leopardus* Grande Rade, Nouméa (22°15'S 166°24'E, 23/10/2007), Off Ouano (21°49'430S, 166°44'278E, 25/10/2007), Between Larégnière and Récif Crouy (22°20'702S, 166°19'295E, 05/05/2008).

Prevalence: *P. laevis* 1 of 2 (50%); *P. leopardus* 5 of 7 (71%).

Vouchers: *P. laevis* JNC2339; *P. leopardus* MNHN JNC233A, JNC 2334, JNC2340, JNC2513, JNC 2514; BMNH 2013.11.18.7-12.

#### Discussion

Table 9 measurements, Table 10 comparisons.

In terms of the parameters used in the visual key there are no differences between our specimens from *Plectropomus laevis* and *Prosorhynchus freitasi* as described from "Serranus guttatus" from the Red Sea [29]. According to Froese & Pauly [15] *S. guttatus* is now known as the peacock hind *Cephalopholis argus* (Bloch) (Serranidae). It has also been reported in *Epinephelus* sp. and the spotted coralgrouper *Plectropomus maculatus* (Bloch) (Serranidae) from off New Caledonia [9] and *Plectropomus leopardus* and *Plectropomus laevis* from the Great Barrier Reef [3]. It has an unusual morphology in that all the internal organs are restricted to the posterior half of the body and the rhynchus is relatively small.

Bott et al. [3] described six *Prosorhynchus* species from *Plectropomus* spp. on the Great Barrier Reef, five of which are new and one, *P. freitasi* already known. They are mostly distinguished by minor morphological characters and by analysis of ITS2 rDNA sequences. *P. lesteri* is distinguished by its distinctly larger rhynchus. *P. wrightae* differs in the pre-uterine extent, being the only one of these species where the uterus extends well beyond the vitellarium anteriorly. *P. heronensis* also has a larger rhynchus, although not as large as in *P. lesteri*, and a distinct U-shaped seminal vesicle. In *P. plectropomi* the uterus extends to, or just anterior to the anterior extent of the vitellarium, apparently forcing the anterior follicles apart, breaking up the continuous arc found in other related species. *P. munozae* is a rather small worm, but with larger eggs. Our specimens agree closely with Bott et al.'s [3] description of *P. freitasi*.

#### *Prosorhynchus luzonicus* Velasquez, 1959 (Figures 15, 16)

Prevalence: 1 of 1.

Vouchers: MNHN JNC3277; BMNH 2013.11.18.24.

## Discussion

See Table 9 for measurements and Table 11 for morphological comparisons. These specimens from *E. coioides* are clearly different from those from this host mentioned below as *Prosorhynchus* sp. B, particularly in pre-mouth distance (see Table 13) and vitelline distribution, but also in post-testicular distance and cirrus-sac reach. On the other hand they are very similar to *P. luzonicus* as originally described [48] from the barramundi *Lates calcarifer* (Bloch), (Latidae) from Malabon, Rizal, Luzon island, Philippines. It has been reported in *E. coioides* in Lampung Bay, southern Sumatra, Indonesia [34–36]. Rückert [35] described and illustrated this species from *Epinephelus fusco-guttatus*, also from Lampung Bay, and later reported it again in this host, both in culture and in the wild [38]. It is slightly disconcerting that Rückert et al. [37] failed to find this species in *L. calcarifer* in her study of Lampung Bay. Two useful, but not infallible, recognition features are the separated vitelline fields (occasionally they appear to form an arch), and the mainly postovarian uterus (but according to the figure and illustration by Rückert [35] this is not invariable). Our specimens differ slightly from Velasquez's [48] description in the greater extent of the cirrus-sac reach as a proportion of body-length (43–51% vs. about 38%). Rückert [35] shows a proportion of about 39%.

*Prosorhynchus jexi* is similar, but differs in cirrus-sac extent, in the arched vitelline fields and in the extension of the uterus anterior to the ovary (but note that these latter features appear to be variable in *P. luzonicus*) [2, 9].

*Prosorhynchus maternus* Bray & Justine, 2006 from the Malabar grouper *Epinephelus malabaricus* (Bloch & Schneider) off New Caledonia [5] differs in size, post-testicular region and cirrus-sac reach.

*Prosorhynchus pacificus* Manter, 1940 is an eastern Pacific form, having been reported originally from the serranids, the

sailfin grouper *Mycteroperca olfax* (Jenyns), the broomtail grouper *Mycteroperca xenarcha* Jordan and an unidentified grouper off the Galapagos [24]. Later records were summarised by Bray & Justine [5], who re-measured two type-specimens. Slight differences from our specimens can be detected in previtelline, pre-mouth and post-testicular distances, cirrus-sac reach and egg-size range. Some specimens from cultured *E. coioides* in Vietnam have been identified as this species, others as *P. epinepheli* [51].

*Prosorhynchus robertsthomsoni* (see above, including new data) differs slightly in pre-uterus, pre-mouth and post-testicular distances [2].

*Prosorhynchus squamatus* Odhner, 1905 is a Northern Hemisphere species, originally reported from the shorthorn sculpin *Myoxocephalus scorpius* (Linnaeus) (Cottidae) [32], but since reported in many cold-water hosts [16, 21]. It differs from *P. luzonicus* in width, previtelline, pre-uterine, pre-mouth and post-testicular distances, cirrus-sac reach and probably in its arched vitellarium and pre-ovarian uterine extent.

## *Prosorhynchus* sp. A (Figure 17)

*Epinephelus morrhua* (Valenciennes, 1833), Serranidae, comet grouper.

Site: digestive tract.

Locality: Off Récif Kué, deep-sea (22°35'511S, 166°9'893E, 23/01/2008).

Prevalence: 1 of 4 (25%).

Vouchers: MNHN JNC2453; BMNH 2013.11.18.26.

## Discussion

No species are identical to these two specimens according to the visual key (Tables 12, 13). As only one specimen is in good condition, the worms have not been described as new, but the very elongate rhynchus seems to be a distinguishing feature. Also note that the ovary lies beside the anterior testis.

One species, *Prosorhynchus epinepheli*, has one major distinguishing feature in the visual key, i.e., width (Table 13). Minor distinguishing features are the pre-mouth distance and the egg-size.

**Table 13.** Comparisons of *Prosorhynchus* spp. from *Epinephelus* spp., blue shading shows major distinctions, green shading minor distinctions.

***Prosorhynchus* sp. B. (Figure 18)**

Host: *Epinephelus coioides* (Hamilton, 1822) (Serranidae), orange-spotted grouper.

Site: Digestive tract.

Locality: Fish Market, Nouméa (27/11/2009).

Prevalence: 1 of 1.

Vouchers: MNHN JNC3140; BMNH 2013.11.18.27.

**Discussion**

Measurements of the three specimens are given in Table 12. Several species are very similar to *Prosorhynchus* sp. B, and show no differences in the visual key but may be distinguished by combinations of minor features (Table 13). More specimens are needed to describe this form as new as so many similar *Prosorhynchus* species are known.

*Prosorhynchus caudovatus* Manter, 1940 (syn. *P. crucibulus* of Eckmann (1932)) from serranids in the waters around Africa [4, 10, 13, 14, 46] has a distinctive filamented egg. It is also distinctly larger than *P. sp. B*, has a more anterior mouth and a longer post-testicular region.

*Prosorhynchus milleri* Bott & Cribb, 2009 based on two specimens from *Variola louti* from Lizard Island, Great Barrier Reef [2] is longer, narrower, with a smaller rhynchus, a longer previtelline region and a shorter post-testicular region. The vitelline fields reach to the pharynx (vs. distinctly anterior).

*Prosorhynchus pacificus* belongs to a group of *Prosorhynchus* spp. with the uterus restricted to the post-ovarian region. In this aspect it differs from *P. sp. B*. It also differs in previtelline distance, pre-mouth distance, post-testicular region and cirrus-sac reach. The vitelline fields reach the ovary (vs. well anterior to the pharynx).

*Prosorhynchus paracrucibulus* Velasquez, 1959 based on three non-ovigerous worms (presumably metacercariae) from the scales (!) of the Buru glass perchlet *Ambassis buruensis* Bleeker (Ambassidae) Manila Bay, Paranaque, Rizal, Luzon Island, Philippines [48]. It is a little wider, with symmetrical testes. The worm is not developed sufficiently enough to recognise, but conceivably it is the metacercaria of a serranid parasite.

*Prosorhynchus truncatus* Verma, 1936 is based on two specimens, one ovigerous and lost and the other without eggs, from the intestine of the river catfish *Cephalocassis jatia* (Hamilton) (as *Arius j.*) (Ariidae) off Puri, Bay of Bengal [49]. It is considerably longer than *P. sp. B*. It also differs in previtelline distance, pre-mouth distance, post-testicular region and cirrus-sac reach.

*Prosorhynchus* specimens from cultured *E. coioides* in Vietnam have been identified as *Prosorhynchus luzonicus* and *P. epinepheli* [51].

***Prosorhynchus* sp. immature**

Host: *Epinephelus coeruleopunctatus* (Bloch, 1790)

Site: Digestive tract.

Locality: Îlot Lebris, off Ouano (21°50'S, 166°45'E, 25/10/2007).

Prevalence: 1 of 3.

Vouchers: MNHN JNC2338.

## Discussion

A single unidentifiable immature specimen was recovered from this host species.

## Conclusions

The molecular evidence presented by Bott et al. [3] indicated that there are many distinct, but very similar species of prosorhynchines in serranids, especially *Epinephelus* and *Plectropomus*. The morphological similarity of these forms has led to many problems in identification, and some unlikely combinations of hosts in the literature, as for example the quoted hosts for *Neidhartia neidharti*, which in addition to serranids, includes a belonid and a freshwater siluriform. Recent molecular studies of a wide range of digeneans have indicated that most species exhibit oioxenous or stenoxenous specificity and “that no euryxenous host distribution should be accepted on the basis of morphology only” [28]. Although it is dangerous to identify parasites solely on the basis of their hosts, consideration should be taken of the relatedness of the hosts and the geographical distribution.

Cribb et al. [8] discussed the digenean fauna of epinepheline serranids and found that *Prosorhynchus* was the commonest parasite, both in the Atlantic/Eastern Pacific region and the Indo-West Pacific Region, and is the only bucephalid genus which has “apparently strongly radiated within the Epinephelinac”. Since that paper [8] our knowledge of epinepheline bucephalids has increased markedly [2, 3, 5] reinforcing that point, but suggesting that *Neidhartia* has also radiated, at least in the Indo-West Pacific region. The morphological distinctions between *Prosorhynchus* and *Neidhartia* are minor, but molecular evidence [3] indicates that these distinctions are reflected by the molecules. Those species of *Prosorhynchus* with a variable ovary configuration (e.g., *P. epinepheli*, *P. longisaccatus*) may invalidate this distinction, or may belong to either monophyletic genus.

**Acknowledgements.** Julie Mounier, Charles Beaufrère, Anaïs Guillou, Audrey Guérin, Damien Hinsinger, Éric Bureau, Chloé Journo, Violette Justine, Amandine Marie, Aude Sigura, Guilhem Rascalou, Géraldine Colli, Lenaïg Hemery, Pierpaolo Brena, Cyndie Dupoux, Isabelle Mary, Adeline Grugeaud, and Marine Briand, students, participated in the parasitological survey. Claude Chauvet (UNC, Nouméa) caught several fishes. Angelo di Matteo (IRD) provided technical help. Certain fishes were identified from photographs by Ronald Fricke (Staatliches Museum für Naturkunde, Stuttgart, Germany) or by Jack Randall (Bishop Museum, Hawaii). The authors wish to report that there are no competing interests.

An international open-access, peer-reviewed, online journal publishing high quality papers on all aspects of human and animal parasitology

Reviews, articles and short notes may be submitted. Fields include, but are not limited to: general, medical and veterinary parasitology; morphology, including ultrastructure; parasite systematics, including entomology, acarology, helminthology and protistology, and molecular analyses; molecular biology and biochemistry; immunology of parasitic diseases; host-parasite relationships; ecology and life history of parasites; epidemiology; therapeutics; new diagnostic tools.

All papers in Parasite are published in English. Manuscripts should have a broad interest and must not have been published or submitted elsewhere. No limit is imposed on the length of manuscripts.

**Parasite** (open-access) continues **Parasite** (print and online editions, 1994-2012) and **Annales de Parasitologie Humaine et Comparée** (1923-1993) and is the official journal of the Société Française de Parasitologie.

Editor-in-Chief:  
Jean-Lou Justine, Paris
