**Aim:** To elucidate the molecular mechanisms underlying the immunosuppressive effects of emodin isolated from *Rheum palmatum* L. **Methods:** Human T cells were isolated from the peripheral venous blood of 10 healthy adult donors. Cell viability was analyzed with MTT assay. AO/EB and Annexin V/PI staining and DNA damage assay were used to detect cell apoptosis. Fluorescence staining was used to detect the levels of ROS, the mitochondrial membrane potential and intracellular Ca<sup>2+</sup>. Colorimetry was used to detect the levels of MDA and total SOD and GSH/GSSG ratio. The expression and activity of caspase-3, -4, and -9 were detected with Western blotting and a fluorometric assay. Western blotting was also used to detect the expression of Bcl-2, Bax, cytochrome C, and endoplasmic reticulum (ER) markers.

**Results:** Emodin (1, 10, and 100 μmol/L) inhibited the growth of human T cells and induced apoptosis in dose- and time-dependent manners. Emodin triggered ER stress and significantly elevated intracellular free Ca<sup>2+</sup> in human T cells. It also disrupted mitochondrial membrane potential, and increased cytosolic level of cytochrome C, and the levels of activated cleavage fragments of caspase-3, -4, and -9 in human T cells. Furthermore, emodin significantly increased the levels of ROS and MDA, inhibited both SOD level and GSH/GSSG ratio in human T cells, whereas co-incubation with the ROS scavenger N-acetylcysteine (NAC, 20 μmol/L) almost completely blocked emodin-induced ER stress and mitochondrial dysfunction in human T cells, and decreased the caspase cascade-mediated apoptosis.

**Conclusion:** Emodin exerts immunosuppressive actions at least partly by inducing apoptosis of human T cells, which is triggered by ROS-mediated ER stress and mitochondrial dysfunction.

**Keywords:** emodin; immunosuppressant; T cell; apoptosis; caspase; intracellular Ca<sup>2+</sup>; reactive oxygen species; endoplasmic reticulum stress; mitochondrial dysfunction; N-acetylcysteine

## Introduction

An intense inflammatory process is a characteristic pathologic feature of transplant rejection. Therefore, an understanding of immune rejection mechanisms provides the basis for novel immunosuppressive therapies. There is now convincing evidence that T cells and their secreted cytokines are involved in the inflammatory process. The blockade of T cell activation and proliferation and consequential cytokine production is one of the main anti-immune rejection principles<sup>[1]</sup>. Molecules

such as FK 506<sup>[2]</sup>, cyclosporine A<sup>[3]</sup>, and rapamycin<sup>[4]</sup> have been shown to have immunosuppressive activity by mediating the apoptotic death of activated T cells. However, the quest to identify novel therapeutic compounds for immunosuppressive treatment is a never-ending venture. Plant-derived natural products occupy an important position in the area of immunosuppression.

Emodin (1,3,8-trihydroxy-6-methylanthraquinone) is an effective component isolated from the root and rhizome of the *Rheum palmatum* plant. It is well known for its physiological antipyretic and anti-inflammatory activities<sup>[5, 6]</sup>. Although it has been widely utilized in Chinese medicines to alleviate tissue inflammation<sup>[7]</sup>, there has been scarce evidence to prove its immunopharmacological activity.

In our previous study, we found that emodin prolonged the mean survival time of skin grafts and decreased the serum IL-2 level in a skin transplantation mouse model, suggesting the potential immunosuppressive activity of emodin<sup>[8]</sup>. Here, we report that in human T cells, emodin exhibited significant cytotoxicity that was associated with reactive oxygen species-mediated endoplasmic reticulum stress and mitochondrial dysfunction.

## Materials and methods

### Reagents and antibodies

Emodin (purity >99%, obtained from Sigma Chemical Co, St Louis, USA) was dissolved at a concentration of 1 mmol/L in 100% dimethylsulfoxide (DMSO) as a stock solution, stored at -20°C, and diluted with medium before each experiment. 5,5',6,6'-tetrachloro-1,1',3,3'-tetra-ethylbenzimidazolcarbocyanine iodide (JC-1) was purchased from Keygen Biotechnology (Nanjing, China). 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), 5-(and-6)-carboxy-2',7'-dichlorofluorescein diacetate (carboxy-DCFDA) and N-acetylcysteine (NAC) were obtained from Sigma (St Louis, MO, USA). Annexin V-FITC/PI was obtained from Beijing Biosea Biotechnology Co, Ltd (Beijing, China). Antibodies against Bcl-2, Bax, Cyt c, COX IV and  $\beta$ -actin were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Anti-caspase-3, -4, -8, and -9 antibodies were purchased from Cell Signaling Technology (Beverly, MA, USA). Detection kits for caspase-3, -4, and -9 activity and a malondialdehyde assay kit were obtained from Beyotime Institute of Biotechnology (Nantong, China). A human T cell enrichment column kit was purchased from R&D Systems (Minneapolis, MN, USA). All other chemicals were purchased from Sigma (St Louis, MO, USA).

### Human T cell purification and activation

Peripheral blood mononuclear cells (PBMCs) were isolated with Ficoll-Hypaque density gradients from the peripheral venous blood of ten healthy adult donors according to the manufacturer's instructions. Ethical approval was obtained from the ethics committee of the First Affiliated Hospital, Xi'an Jiaotong University. Cells were washed twice in phosphate-buffered solution (PBS), and the cellular concentration was adjusted to  $1.0 \times 10^6$ /mL. Cell viability was detected with the Trypan blue dye exclusion method. CD4<sup>+</sup> T cells were negatively isolated using magnetic beads (R&D Systems). T cells were then pre-coated with anti-CD3 (5  $\mu$ g/mL) and anti-CD28 (1  $\mu$ g/mL) in culture wells as previously described<sup>[9-11]</sup>. For activation, human T cells were treated with 1 mg/mL PHA for 24 h, washed, and subsequently cultured in RPMI-1640 medium (Gibco, Carlsbad, CA, USA). Supplemented with 10% fetal bovine serum (FBS, Hyclone, Logan, UT, USA).

### MTT assay for cell viability

Human T cells ( $5.0 \times 10^4$  cells/well) were seeded in 96-well plates and incubated with emodin at various concentrations (0, 1, 10, or 100  $\mu$ mol/L) for 24, 48, or 72 h at 37°C. Then, 20  $\mu$ L of MTT solution (5 g/L) was added to each well and incu-

bated for another 4 h. Supernatants were removed, and formazan crystals were dissolved in 200  $\mu$ L DMSO. Finally, the optical density was determined at 490 nm using a POLAR star OPTIMA microplate reader (BMG Lab Technologies, Ortenberg, Germany).

### AO/EB double staining

Cells were collected in 10-mL centrifuge tubes at a concentration of  $1 \times 10^6$ /mL and centrifuged at 1500 r/min for 15 min at room temperature. The cells were then washed with incubation buffer before centrifugation at 1500 r/min for another 10 min. The cells were resuspended in 100  $\mu$ L of labeling solution and incubated for 15 min at room temperature in the dark. Subsequently, the cells were centrifuged at 1500 r/min for 10 min at room temperature. Eventually, 25  $\mu$ L of the cell suspension ( $1 \times 10^6$  cells/mL) was incubated with 1  $\mu$ L of AO/EB solution and examined under a fluorescence microscope using a fluorescein filter and a 40 $\times$  objective.

### Annexin V/PI apoptosis assay

Pelleted cells were collected and incubated with 5  $\mu$ L Annexin V and 10  $\mu$ L PI solution at room temperature for 20 min in the dark. Cellular apoptosis was detected with flow cytometry at an excitation wavelength of 488 nm. FITC fluorescence was detected at a wavelength of 515 nm, and PI was detected at a wavelength of 560 nm.

### DNA damage assay

DNA damage was assessed using the alkaline single-cell gel electrophoresis assay (comet assay). After the emodin treatments mentioned above, cells were incubated in normal medium for 3 h, mixed with low-melting agarose and fixed onto slides. Subsequently, the cells were lysed, and DNA was denatured using an alkaline (pH > 14) solution at 4°C. Slides were then placed on a horizontal electrophoresis device, stained with ethidium bromide, and visualized by fluorescence microscopy. The results were analyzed with Komet 5 comet assay analysis software, which quantitatively determines the extent of DNA damage in each sample using the mean olive tail moment calculation, which was determined for 50 cells from each group.

### Caspase activity assay

Caspase-3, -4, and -9 activities were analyzed using a caspase apoptosis detection kit according to the manufacturer's instructions. In brief, cells ( $1 \times 10^6$ ) were pelleted by centrifugation, washed twice with PBS and incubated in 500  $\mu$ L lysis buffer on ice for 10 min. Then, 1 $\times$ reaction buffer and 10  $\mu$ L caspase-3 (DEVD-AFC), caspase-4 (LEVD-AFC), or caspase-9 (IEVD-AFC) substrate was added to lysis buffer. The reaction mixtures were incubated at 37°C for 60 min. The activities of caspase-3, -4, and -9 were measured with spectrofluorometry.

### Reactive oxygen species assay

2',7'-Dichlorodihydrofluorescein diacetate (DCFH-DA, Sigma) was used for ROS measurement. DCFH-DA is cleaved intrac-

cellularly with nonspecific esterases and converted into highly fluorescent 2',7'-dichlorofluorescein (DCF) upon oxidation by ROS. DCFH-DA working solution was added directly to the medium to reach 10  $\mu\text{mol/L}$  and incubated at 37°C for 15 min. The cells were then washed with PBS once and kept on ice for immediate DCF detection with flow cytometry.

#### Reduced and oxidized glutathione assay

Cells were trypsinized after drug treatment for 1 h and prepared according to the instructions of the GSH/GSSG Ratio Assay Kit (Calbiochem, San Diego, CA, USA). Briefly, for the GSSG sample, the thiol-scavenging reagent 1-methyl-2-vinylpyridinium trifluoromethanesulfonate was immediately mixed with the cell suspension to eliminate GSH. The cells were frozen and thawed and subsequently extracted with metaphosphoric acid. The cell lysates were added to GSSG or GSH assay buffer. The samples were mixed sequentially with the chromogen 5,5'-dithiobis-2-nitrobenzoic acid, glutathione reductase, and NADPH. The absorbance at 412 nm was recorded for 3 min, the reaction rate was determined, and the GSH/GSSG ratio was obtained [ratio=(GSH-2GSSG)/GSSG].

#### Malondialdehyde and total superoxide dismutase assay

The MDA concentration, a marker of lipid peroxidation, was measured with a colorimetric commercial kit (Malondialdehyde Assay kit). Briefly, treated T cells were harvested, and cellular extracts were prepared with sonication in ice-cold buffer. After centrifugation at 10000 $\times g$  for 20 min, the supernatant was measured spectrophotometrically at 532 nm. The MDA level was then normalized to milligram protein, as previously described<sup>[12]</sup>. SOD is one of the most important antioxidative enzymes<sup>[13]</sup> and its activity was measured with a colorimetric assay kit according to the manufacturer's protocol. Briefly, SOD activity was measured using 100  $\mu\text{g}$  of the total protein extract from the emodin-treated human T cells. Absorbance values were measured spectrophotometrically at 450 nm.

#### Intracellular calcium measurement

Human T cells were loaded with 5 mmol/L fluo-3-acetoxymethyl ester (Fluo-3-AM) at 37°C for 30 min. The cells were then resuspended in  $\text{Ca}^{2+}$ -free medium without phenol red to a concentration of 4 $\times 10^6$  cells/mL. In each experiment, 0.5 mL of cell suspension was equilibrated with an equal volume of 2 mmol/L  $\text{Ca}^{2+}$ -containing medium at 37°C. The cells were incubated with 2.0 mL of 0.1% DMSO or emodin (1, 10, or 100  $\mu\text{mol/L}$ ), and the fluorescent activity was recorded at Ex=488 nm and Em=515 nm using an MRC-1000 Laser Scanning Confocal Imaging System (Bio-Rad Laboratories, Berkeley, CA, USA).

#### Mitochondrial membrane potential assay

After being cultured for 48 h, T cells were collected in 0.5 mL medium and incubated with 0.5 mL JC-1 (Sigma) working solution. Cells were incubated at 37°C and 5%  $\text{CO}_2$  in a humidified incubator for 30 min. The cells were centrifuged at

1000 r/min for 3 min at 4°C and washed twice with JC-1 buffer solution. The mitochondrial membrane potential ( $\Delta\Psi\text{m}$ ) of cells was detected with flow cytometry.

#### Western blot analysis

Cells were exposed to various concentrations of emodin and lysed in RIPA buffer (Beyotime Inc, Nantong, China). The protein concentration was determined with the Bradford reagent (Beyotime Inc, haimen, China). Equal amounts of total proteins were separated and transferred to a polyvinylidene difluoride membrane (Millipore, Bedford, MA, USA). The membranes were subsequently immunoblotted with the appropriate primary and secondary antibody (Santa Cruz Biotechnology, Dallas, TX, USA) according to our previous report<sup>[14]</sup>. Signals were detected using an ECL Kit (Pierce, Rockford, IL, USA).

#### Statistical analysis

All data were expressed as the mean $\pm$ standard deviations and analyzed with SPSS (Statistical Package for the Social Sciences) 13.0 software (SPSS Inc, Chicago, IL, USA). The samples of each group were compared using an analysis of variance, and multiple comparisons between groups were performed using Student's *t*-test. Values of  $P < 0.05$  or  $P < 0.01$  were considered statistically significant.

## Results

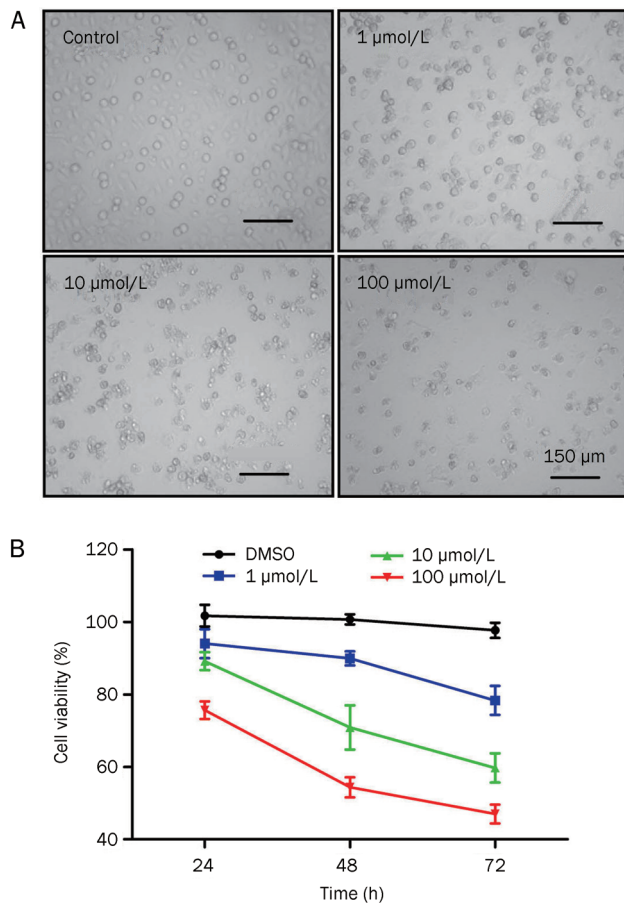

### Emodin inhibited the growth of human T cells in a dose- and time-dependent manner

Initially, the cytotoxicity of emodin at different doses (1, 10, and 100  $\mu\text{mol/L}$ ) was investigated in human T cells. Morphological changes, including cytoplasmic shrinkage and apoptotic bodies, were observed in T cells treated with emodin for 72 h (Figure 1A). The cell number was significantly decreased in 100  $\mu\text{mol/L}$  emodin-treated T cells. After treatment with different doses of emodin, the MTT assay was used to detect the growth of human T cells at the indicated times (24, 48, or 72 h). As shown in Figure 1B, emodin inhibited the viability of human T cells in a dose- and time-dependent manner.

### Emodin induced significant apoptosis and DNA damage in human T cells

To assess whether the cytotoxic effect of emodin was caused by apoptotic death, we evaluated the apoptosis of human T cells treated with emodin for 72 h using AO/EB staining. Compared with the control group, the percentage of apoptotic cells (yellow) was increased after emodin treatment, and necrotic cells were slightly increased (Figure 2A and 2B). These results were also supported by Annexin V/PI staining results (Figure 2C and 2D). Approximately 41.5% of the cells were in early apoptosis in the 100  $\mu\text{mol/L}$  emodin-treated group compared with other groups (Figure 2C). As illustrated in Figure 2D, emodin induced a dose-dependent increase in apoptotic T cells.

Apoptosis is a prominent route of cell inactivation and is triggered by DNA damage. We used the comet assay to assess

**Figure 1.** Effect of emodin treatment on the growth of human T cells. (A) Morphology changes of human T cells after treatment with emodin at different concentrations (1, 10, or 100 µmol/L). (B) The inhibition of T cell growth induced by Emodin was detected by MTT assay. Data are represented as mean±SD from three independent experiments.

DNA damage accumulation. The difference in the tail moment of T cells treated with different concentrations of emodin was significant, indicating that DNA damage was involved in emodin-induced apoptosis in human T cells (Figure 2E and 2F).

#### Emodin activated caspase cascades in human T cells

Because caspase cascade activation is a key event in apoptosis pathways, we next assessed the effects of emodin on caspase activation in human T cells by Western blotting. The results showed that the quantities of the activated cleavage fragments of caspase-9 and -4 increased after exposure to 100 µmol/L emodin for 72 h, whereas the activated cleavage fragment of caspase-8 was not detected (Figure 3A–3D). We hypothesized that endoplasmic reticulum stress or the mitochondria-mediated intrinsic apoptotic pathway might be involved in emodin-induced apoptosis, but the death receptor-mediated extrinsic apoptotic pathway might not be involved. In parallel with caspase-9 and -4 activation, cleavage of the effector caspase-3 was also increased (Figure 3A and 3E). Caspase-9, -4, and -3 activation was also detected with the caspase activity

assays, which supported the hypothesis that emodin activated caspase cascades via the intrinsic apoptosis pathway (Figure 3F, 3G, and 3H).

#### Emodin induced ER stress and intracellular free calcium elevation

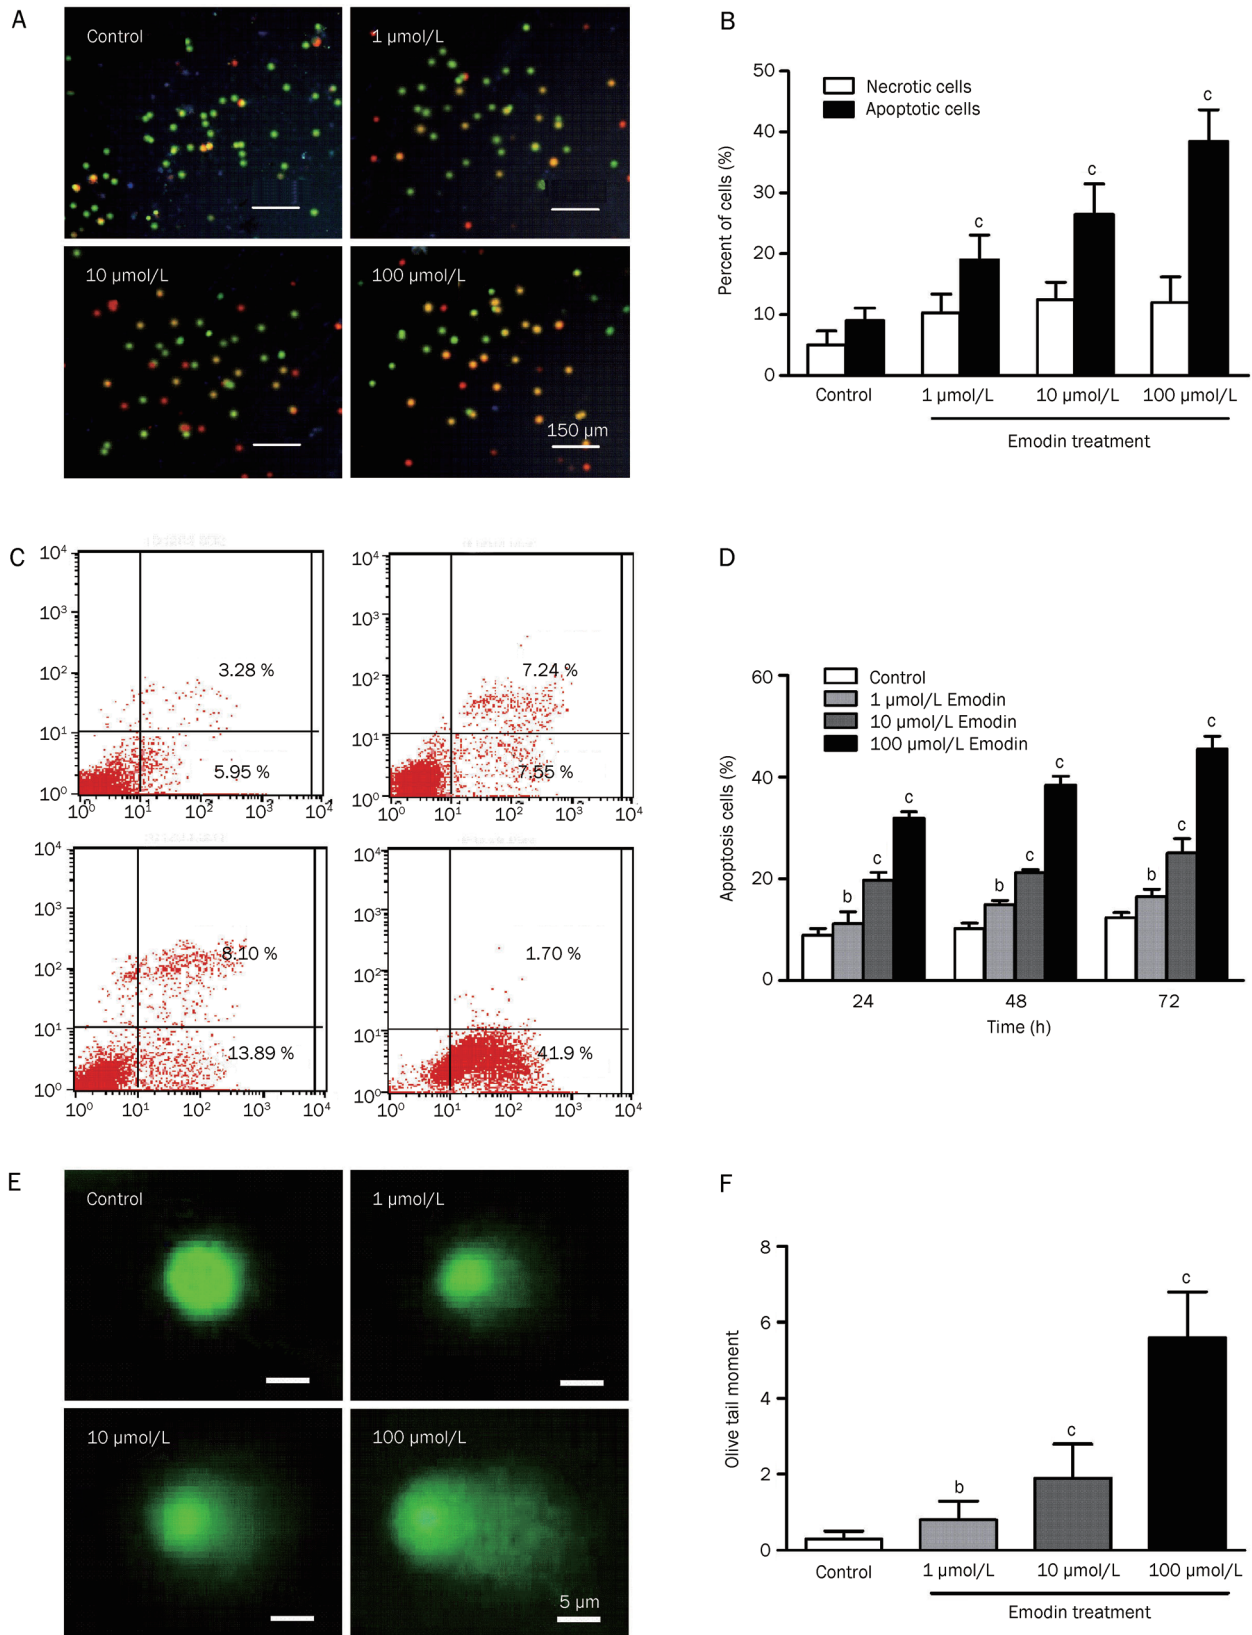

Several studies have previously reported that ER stress can lead to the proteolytic cleavage of caspase-4, which is localized to the cytoplasmic side of the ER membrane<sup>[15]</sup>. In our study, caspase-4 was also activated by emodin treatment, suggesting that ER stress might be induced by emodin and involved in the apoptosis pathway. To determine whether emodin could induce ER stress, we investigated several crucial ER stress markers, including GRP78, ATF-4, XBP-1s, and CHOP. The expression of these ER stress markers in T cells was time-dependently induced after 100 µmol/L emodin treatment for 72 h (Figure 4A and 4B). Because the ER plays an important role in maintaining intracellular Ca<sup>2+</sup> homeostasis, we speculated that emodin-induced ER stress might trigger Ca<sup>2+</sup> release. Changes in intracellular free calcium were measured using Fluo-3-AM staining. The results showed more positively stained cells in emodin-treated T cells than in the control (Figure 4C), indicating intracellular Ca<sup>2+</sup> overload after emodin treatment. The intracellular Ca<sup>2+</sup> level was significantly increased along with the concentration of emodin, with the highest intracellular Ca<sup>2+</sup> level in the 100 µmol/L emodin group (Figure 4D).

#### Emodin disrupted the mitochondrial membrane potential and triggered Cyt c release

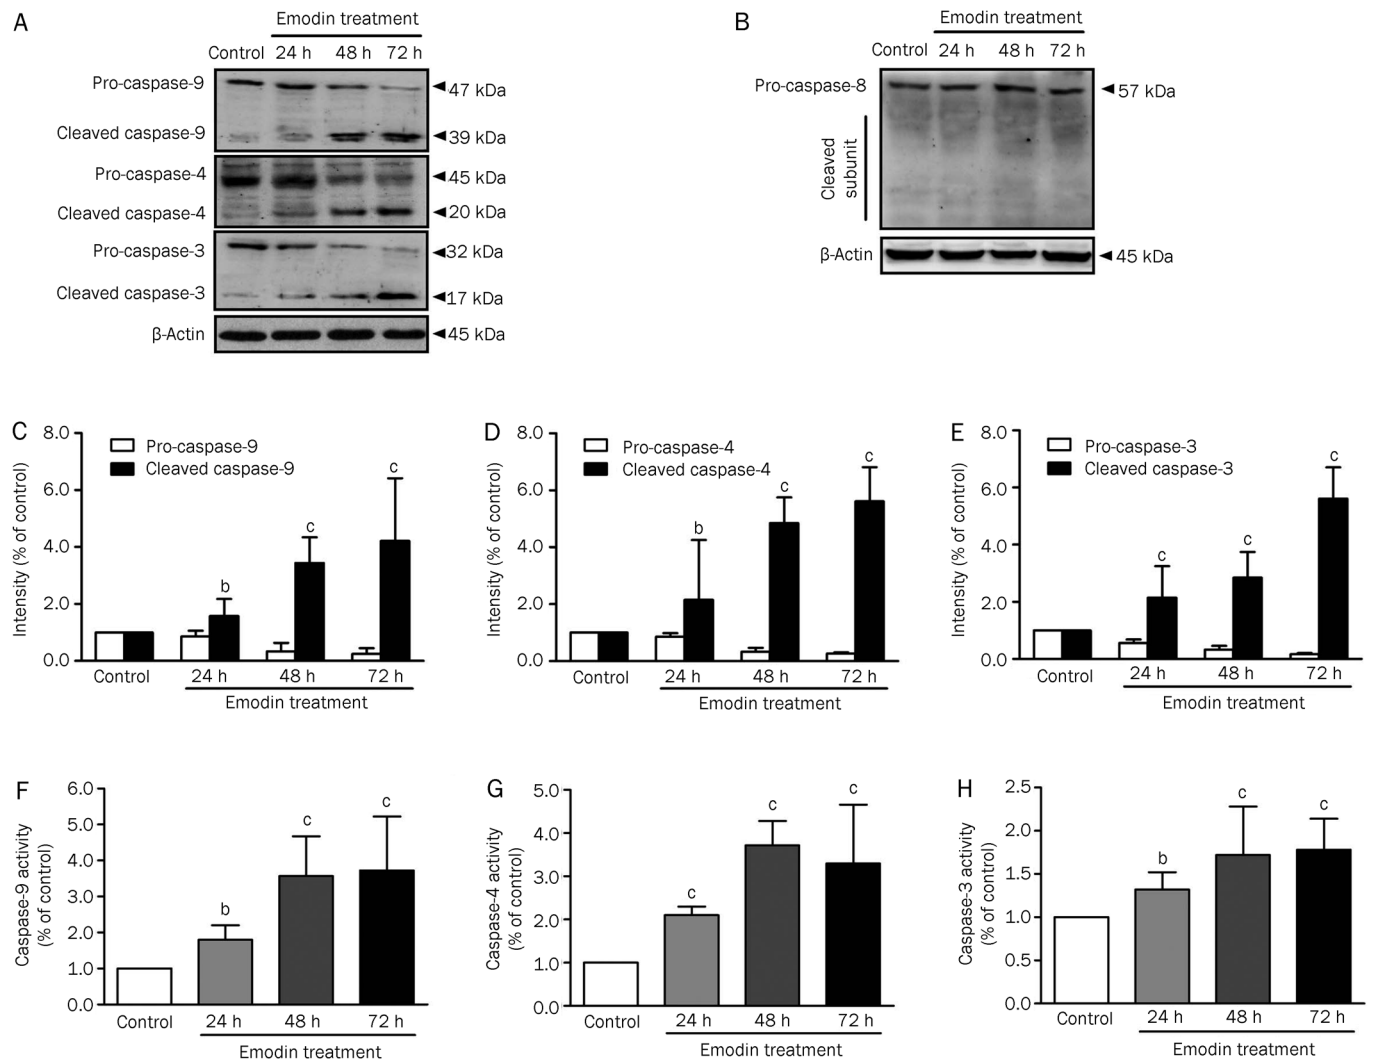

The uptake of JC-1, a lipophilic cationic fluorescent dye absorbed by mitochondria, is positively correlated with the mitochondrial membrane potential<sup>[16]</sup>. An increase in green JC-1 can reflect the collapse of  $\Delta\Psi_m$ . As shown in Figure 5A and 5B, a significant increase in green JC-1 was clearly observed in emodin-treated groups in a dose-dependent manner. In addition, the mitochondrial protein and cytosolic protein isolated from emodin-treated T cells were subjected to Western blotting. Equal protein loading was confirmed with COX IV immunodetection for mitochondrial protein and  $\beta$ -actin for cytosolic protein. The Western blotting results showed that the Bcl-2/Bax ratio in T cells, which reflects the maintenance of mitochondrial membrane stability, was significantly suppressed after 100 µmol/L emodin treatment for 72 h (Figure 5C and 5D). The release of Cyt c from mitochondria triggers the activation of caspase proteases and cell death by apoptosis. Our results also demonstrated that 100 µmol/L emodin increased cytosolic Cyt c and decreased mitochondrial Cyt c compared with the control group in a time-dependent manner (Figure 5E and 5F).

#### Emodin treatment induced ROS production and oxidative stress in human T cells

We explored the upstream mechanisms leading to emodin-induced ER stress and mitochondrial dysfunction using DCFH, which is an intracellular probe used to examine the

**Figure 2.** Emodin induced apoptosis and DNA damage of human T cells. cellular ROS level. There was a significant dose-dependent increase in intracellular ROS levels in human T cells treated with emodin at 72 h (Figure 6A and 6B). In addition, we detected several crucial indicators of the redox potential in T cells treated with emodin, including an oxidative product (MDA) and anti-oxidative factors (SOD and GSH/GSSG). MDA and SOD are important markers that indicate a pro- and anti-oxidative status, respectively, and our results showed that SOD activity was significantly downregulated in T cells after emodin treatment, whereas MDA activity was upregulated (Figure 6C and 6D). The redox cycling of glutathione is believed to be a major intracellular antioxidant system that prevents the toxic accumulation of hydroperoxide. As shown in Figure 6E–6G, the GSH/GSSG ratio was decreased in T cells after emodin treatment. Taken together, these results indicated that emodin had a marked oxidative impact on the cel-

lular redox status, which might be involved in ER stress and mitochondrial dysfunction-mediated apoptosis.

#### Removal of ROS with NAC attenuated emodin-induced ER stress, mitochondrial dysfunction and apoptosis in human T cells

To demonstrate the relationship between emodin-induced ROS production and ER stress, we coincubated T cells with 1 mmol/L exogenous NAC and 100 μmol/L emodin. After co-incubation with 1 mmol/L NAC for 72 h, changes in the ROS, MDA and SOD levels caused by emodin treatment were abrogated (Figure 7A–7C). NAC also significantly attenuated emodin-induced Ca<sup>2+</sup> overload (Figure 7D) and the activation of GRP78, ATF-4, XBP-1s, and CHOP (Figure 7G and 7H). In addition, we investigated the effect of ROS elimination with NAC on emodin-induced mitochondrial dysfunction. Exogenous NAC addition prevented the emodin-induced changes in

**Figure 4.** Endoplasmic reticulum stress and intracellular free calcium elevation of human T cells after emodin treatment. (A) Markers of ER stress including GRP78, ATF4, XBP1s and CHOP were detected by Western blotting. (B) The results of Western blotting were analyzed by Quantity One software. (C) Intracellular calcium measurement shown by Fluo-3-AM staining after emodin treatment for 72 h. (D) Positive rate of Fluo-3-AM staining in different emodin treatment groups. The results are given as mean $\pm$ SD from three experiments. <sup>b</sup> $P$ <0.05, <sup>c</sup> $P$ <0.01 vs control.

the mitochondrial membrane potential (Figure 7E, 7I and 7J). Furthermore, NAC simultaneously inhibited cell apoptosis (Figure 7F) and the activation of caspase-9, -4, and -3 (Figure 7K and 7L) induced by emodin. These results indicated that ROS played a significant role in emodin-induced ER stress and mitochondrial dysfunction in the T cell apoptosis process.

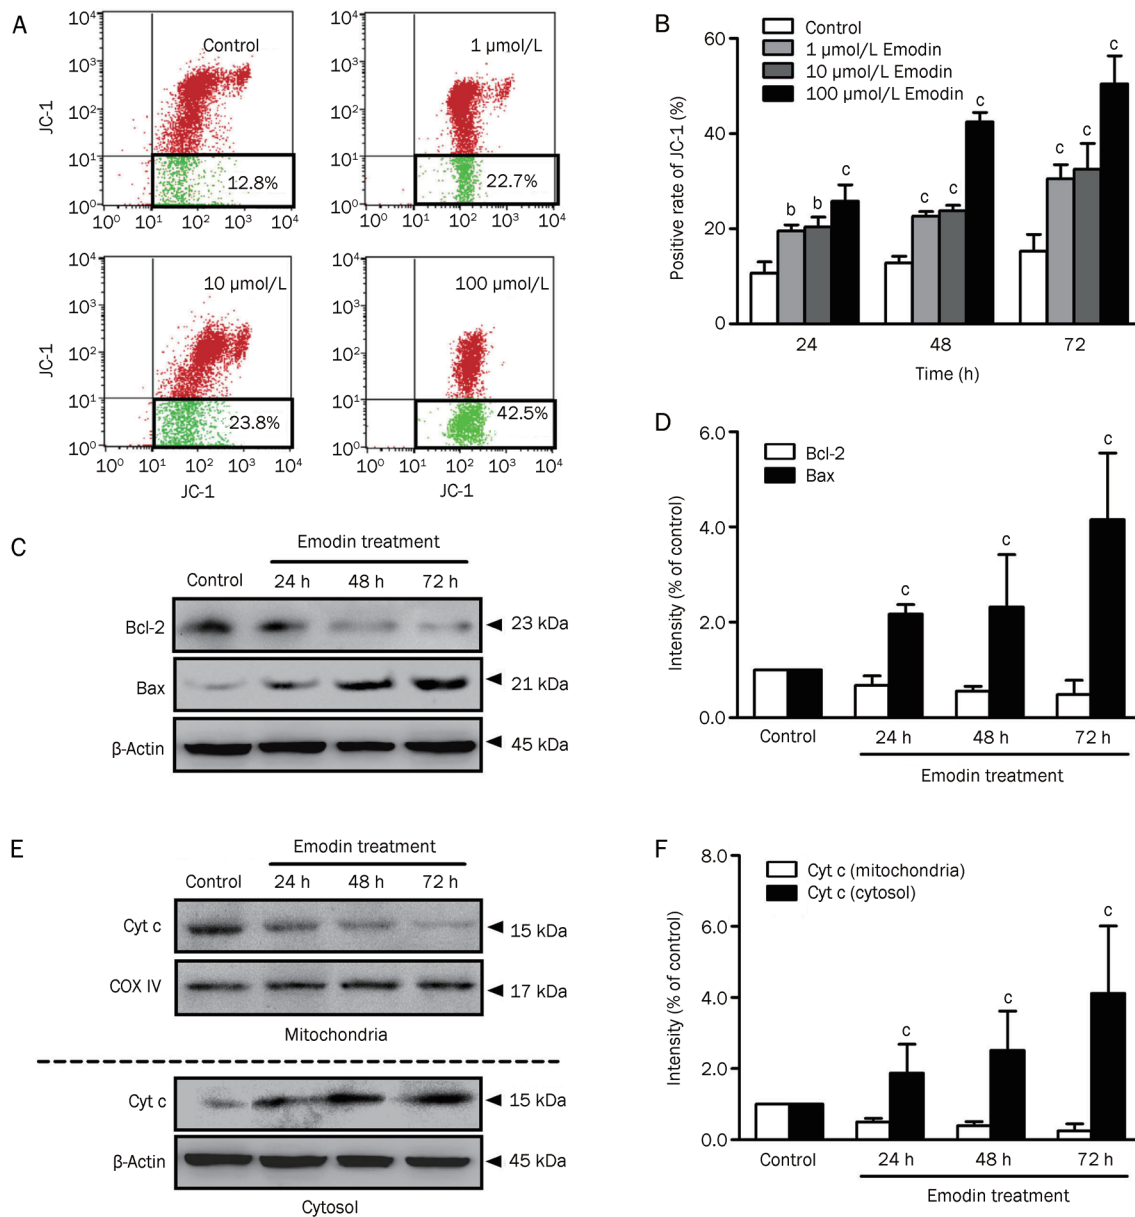

## Discussion

Emodin exhibits a wide range of pharmacological effects, including anti-tumor<sup>[17]</sup>, anti-inflammatory<sup>[6]</sup> and hepatic and renal protective activities<sup>[18]</sup>. Huang *et al*<sup>[19]</sup> was the first to demonstrate the immunosuppressive effects of emodin, and our previous study also confirmed that emodin treatment attenuated skin allograft rejection and prolonged skin graft survival via stimulating serum IL-2 levels in skin transplantation models<sup>[8]</sup>. Similarly, Kuo *et al* demonstrated that emodin inhibited T cell proliferation via repressing IL-2 and IL-2R expression<sup>[20]</sup>. However, the effect and molecular mechanism of emodin on cellular apoptosis in human T cells remain unknown.

ROS are mediators of intracellular signaling cascades and can induce the collapse of the mitochondrial membrane potential, which can trigger a series of mitochondria-associated

events, such as apoptosis<sup>[21]</sup>. Excessive ROS production may lead to oxidative stress, loss of cell function, and ultimately apoptosis or necrosis<sup>[22]</sup>. The molecular structure of emodin is similar to dimethyl naphthoquinone and mitochondrial ubiquinone, both of which have been reported to be able to induce ROS production<sup>[23, 24]</sup>, and thus, we hypothesized that emodin may have the potential to induce ROS generation in T cells. In the present study, we demonstrated that emodin-induced T cell apoptosis was associated with ROS generation, which triggered ER stress and mitochondrial damage in T cells and activated the apoptosis pathway.

The disruption of ER homeostasis by ROS triggers cellular stress responses, including the unfolded protein response (UPR), an ER-specific stress response. GRP78, ATF-4, XBP-1s and CHOP, which are found in the UPR signaling pathway, are important for the maintenance of normal cellular homeostasis<sup>[25-27]</sup>. The ER, as the major internal Ca<sup>2+</sup> storage organelle, acts as a Ca<sup>2+</sup> buffer that regulates Ca<sup>2+</sup>-dependent signaling in the cytosol. However, inappropriate activation of the UPR can lead to cellular dysfunction, and ultimately, cell death<sup>[28]</sup>. The results from our studies demonstrated that emodin-induced ROS can not only activate the ER stress markers GRP78, ATF-4, XBP-1s and CHOP but also disrupt the ER

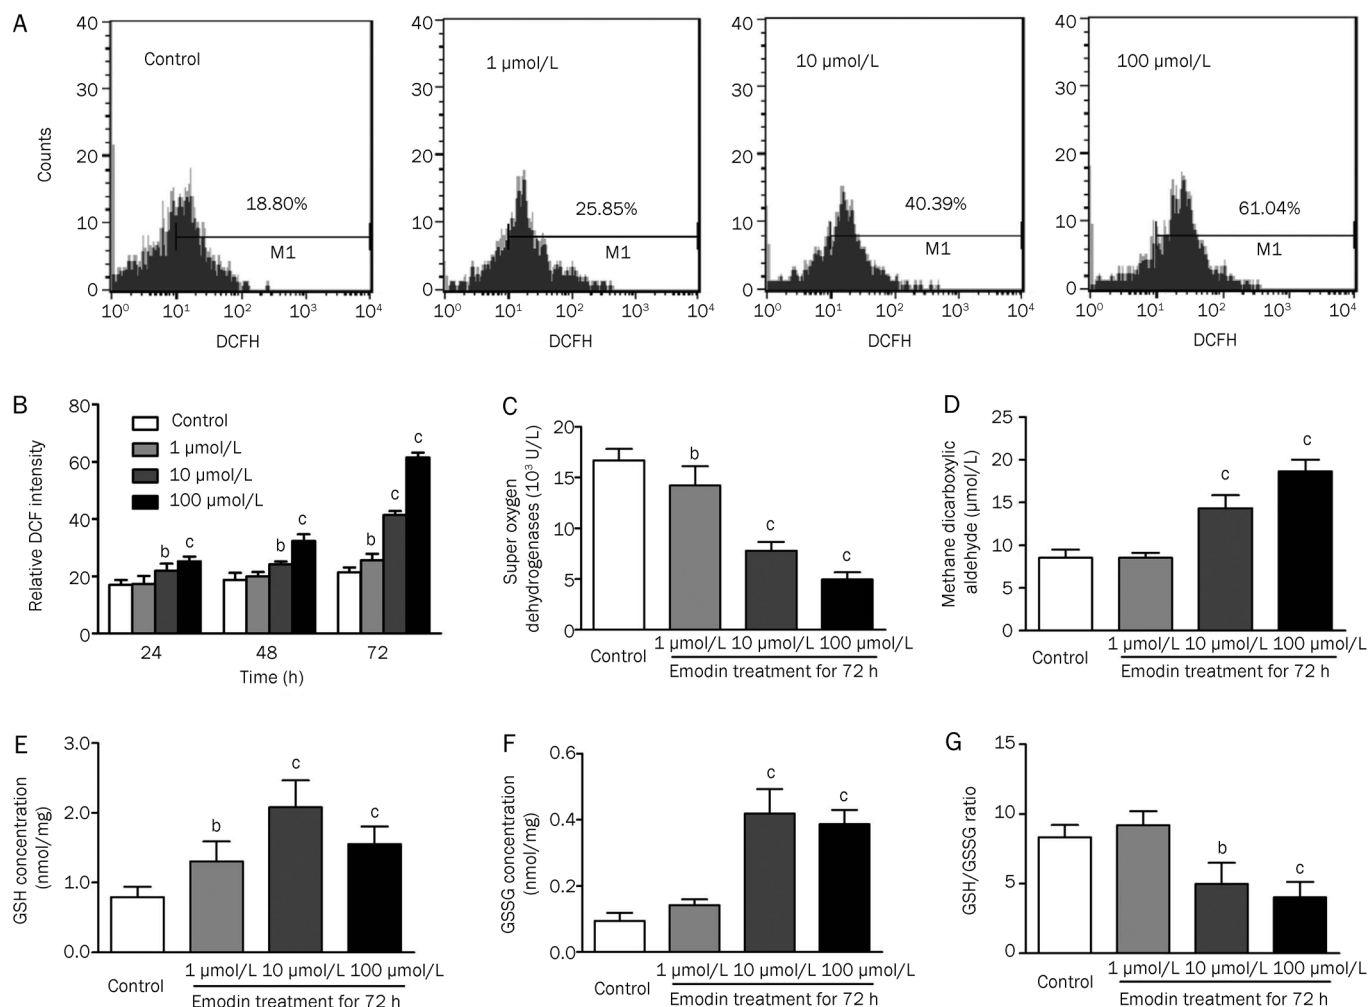

**Figure 5.** The disrupted mitochondrial membrane potential and Cyt c release of human T cells after emodin treatment. membrane and trigger  $\text{Ca}^{2+}$  release in human T cells (Figure 4). In contrast, the removal of ROS with the antioxidant NAC attenuated the emodin-induced activation of UPR and  $\text{Ca}^{2+}$  release.

Mitochondria and the ER constitute the endomembrane networks and interact with each other physically and functionally. Mitochondria and the ER are major internal  $\text{Ca}^{2+}$  storage organelles, and the transfer of  $\text{Ca}^{2+}$  from the ER to mitochondria through this connection is one of the critical pathways in regulating cell functions. Calcium uptake into the mitochondria is driven by the consumption of the mitochondrial mem-

brane potential. Several reports showed that emodin induced ER stress and mitochondrial dysfunction in cancer cells<sup>[15, 29, 30]</sup>. To investigate whether mitochondrial function was affected by emodin-induced ER stress in human T cells, we evaluated alterations in the mitochondrial membrane potential and several crucial proteins that maintain mitochondrial function. Our results confirmed that emodin significantly decreased the mitochondrial membrane potential. Furthermore, the ratio of Bcl-2 and Bax, which represents mitochondrial function, was also decreased in T cells after emodin treatment. As a result, the release of Cyt c and the activation of caspase proteases

**Figure 6.** Emodin significantly induced ROS generation in human T cells. (A) DCFH staining was used to detect ROS level in human T cells treated by 100 μmol/L emodin for 72 h. (B) Analysis of ROS changes in different emodin treated T cells. (C) Effect of emodin on intracellular SOD activity. (D) Effect of emodin on intracellular MDA activity. (E) Effect of emodin on intracellular GSH level. (F) Effect of emodin on intracellular GSSG level. (G) Analysis of the GSH/GSSG ratio. caused by mitochondrial dysfunction eventually trigger cellular apoptosis. As a ROS scavenger, the antioxidant NAC can suppress emodin-induced mitochondrial dysfunction and attenuate apoptosis.

In conclusion, our results demonstrate that emodin-induced apoptosis in human T cells is mediated by the activation of ER stress and the dysfunction of mitochondria and requires ROS generation (Figure 8). Our study thus provides a rationale for the development of emodin as an immunosuppressive agent against T cell-mediated autoimmune disease.

**Figure 7.** Effect of NAC-replenishing on emodin-induced ER stress, mitochondrial dysfunction and apoptosis in T cells. Replenishing of 20  $\mu\text{mol/L}$  exogenous NAC significantly reduced the ROS (A) and MDA (C) production induced by 100  $\mu\text{mol/L}$  emodin, and elevated antioxidant SOD level (B). NAC replenishing also rescued ER stress (G and H),  $\text{Ca}^{2+}$  release (D), disruption of  $\Delta\Psi\text{m}$  (E), mitochondrial dysfunction and cytochrome c release (I and J) induced by emodin, which finally inactivated caspases (K and L), and reduced apoptosis of T cells (F). The results are given as mean $\pm$ SD from three experiments. <sup>b</sup> $P<0.05$ , <sup>c</sup> $P<0.01$  vs control groups.

**Figure 8.** Overview of the ROS-mediated ER stress and mitochondrial dysfunction in emodin-induced apoptosis in human T cells. Treatment of T cells with emodin results in ER stress by upregulating GRP78, ATF-4, XBP-1s, and CHOP. As the key transcription factors induced by ER stress, they would trigger the  $\text{Ca}^{2+}$  release. Emodin also reduces the mitochondrial membrane potential and Bcl-2/Bax ratio, contributing to the activation of caspase-4, -9, and -3 and apoptosis progression. The emodin-induced ER stress and mitochondrial dysfunction require the ROS generation, and on the contrary, antioxidant NAC suppresses emodin-induced apoptosis in human T cells.
