# Abstract

**Background**—Pre-eclampsia is a relatively common complication of pregnancy. HELLP (hemolysis, elevated liver enzymes, low platelets) syndrome is a severe manifestation of preeclampsia with significant morbidity and mortality for pregnant women and their children. Corticosteroids are commonly used in the treatment of HELLP syndrome in the belief that they improve outcomes.

**Objectives**—To determine the effects of corticosteroids on women with HELLP syndrome and their children.

**Search methods**—We searched the Cochrane Pregnancy and Childbirth Group's Trials Register (30 June 2010).

**Selection criteria**—Randomized controlled trials comparing any corticosteroid with placebo, no treatment, or other drug; or comparing one corticosteroid with another corticosteroid or dosage in women with HELLP syndrome.

**Data collection and analysis**—Two review authors assessed trial quality and extracted data independently.

Publication status and date: New, published in Issue 9, 2010.

DECLARATIONS OF INTEREST None known.

Editorial group: Cochrane Pregnancy and Childbirth Group.

Review content assessed as up-to-date: 27 July 2010.

**CONTRIBUTIONS OF AUTHORS** Douglas Woudstra selected the review topic and designed and coordinated the review including writing the protocol and text of the review, extracting data, and assessing trials for bias. He serves as guarantor for this review. Sue Chandra wrote the background for the review, provided a clinical perspective, and secured funding for the review. Justus Hofmeyr provided initial motivation for this review, contributed to the protocol and text of the review, and provided a methodological perspective for the review. Therese Dowswell performed data extraction, assessed trials for bias, and contributed to the text of the review.

**Main results**—Eleven trials (550 women) compared corticosteroids with placebo or no treatment. There was no difference in the risk of maternal death (risk ratio (RR) 0.95, 95% confidence interval (CI) 0.28 to 3.21), maternal death or severe maternal morbidity (RR 0.27, 95% CI 0.03 to 2.12), or perinatal/infant death (RR 0.64, 95% CI 0.21 to 1.97). The only clear effect of treatment on individual outcomes was improved platelet count (standardized mean difference (SMD) 0.67, 95% CI 0.24 to 1.10). The effect on platelet count was strongest for women who commenced treatment antenatally (SMD 0.80, 95% CI 0.25 to 1.35).

Two trials (76 women) compared dexamethasone with betamethasone. There was no clear evidence of a difference between groups in respect to perinatal/infant death (RR 0.95, 95% CI 0.15 to 6.17) or severe perinatal/infant morbidity or death (RR 0.64, 95% CI 0.27 to 1.48). Maternal death and severe maternal morbidity were not reported. In respect to platelet count, dexamethasone was superior to betamethasone (MD 6.02, 95% CI 1.71 to 10.33), both when treatment was commenced antenatally (MD 8.10, 95% CI 6.23 to 9.97) and postnatally (MD 3.70, 95% CI 0.96 to 6.44).

**Authors' conclusions**—There was no clear evidence of any effect of corticosteroids on substantive clinical outcomes. Those receiving steroids showed significantly greater improvement in platelet counts which was greater for those receiving dexamethasone than those receiving betamethasone. There is to date insufficient evidence of benefits in terms of substantive clinical outcomes to support the routine use of steroids for the management of HELLP. The use of corticosteroids may be justified in clinical situations in which increased rate of recovery in platelet count is considered clinically worthwhile.

## Medical Subject Headings (MeSH)

Adrenal Cortex Hormones [\*therapeutic use]; Betamethasone [therapeutic use]; Dexamethasone [therapeutic use]; HELLP Syndrome [\*drug therapy; mortality]; Maternal Mortality; Perinatal Mortality; Platelet Count; Prednisolone [therapeutic use]; Randomized Controlled Trials as Topic

#### MeSH check words

Female; Humans; Pregnancy

# BACKGROUND

#### **Description of the condition**

Pre-eclampsia (also referred to as gestational hypertension with proteinuria, or proteinuric hypertension) is a serious complication of pregnancy characterised by increased blood pressure and protein in the urine. It develops in 5% to 7% of pregnancies and is associated with poor maternal and perinatal outcomes. Although the cause has not been definitively determined, the final common pathway is vascular endothelial dysfunction with activation of the clotting cascade (Roberts 2000).

The syndrome of hemolysis, elevated liver enzymes and low platelets (HELLP) is a severe manifestation of pre-eclampsia and complicates approximately 0.5% to 0.9% of all pregnancies and 10% to 20% of cases with severe pre-eclampsia (Haram 2009). For HELLP syndrome to be diagnosed, there must be microangiopathic hemolysis, thrombocytopenia,

and abnormalities of liver function. There is no consensus, however, on the specific thresholds of hematologic and biochemical values to use in establishing the diagnosis of HELLP syndrome. Sibai has used the following criteria: hemolysis as evidenced by an abnormal peripheral smear, lactate dehydrogenase (LDH) greater than 600 IU/L, or total bilirubin greater than 20.52 µmol/L; elevated liver enzymes as evidenced by an aspartate transaminase (AST) greater than 70 IU/L and platelets less than 100,000 cells/mm<sup>3</sup>. Those women who do not have all of these parameters are considered to have partial HELLP syndrome (Sibai 1993; Sibai 2004). Martin defines HELLP syndrome as hemolysis evidenced by an increased LDH level and progressive anemia; hepatic dysfunction as evidenced by an LDH level over 600 IU/L; elevated liver enzymes as evidenced by an AST greater than 40 IU/L, an alanine transaminase (ALT) greater than 40 IU/L, or both; and thrombocytopenia evidenced by a platelet nadir less than 150,000 cells/mm<sup>3</sup>. Further subclassification proposed by Martin and known as the Mississippi HELLP Classification System classifies women based on the lowest perinatal platelet count: class one HELLP syndrome - platelet nadir less than or equal to 50,000 cells/mm<sup>3</sup>, class two HELLP syndrome - platelet nadir less than or equal to 100,000 cells/mm<sup>3</sup>, class three HELLP syndrome - platelet nadir less than or equal to 150,000 cells/mm<sup>3</sup> (Martin 1991; Martin 1999).

We will consider trials for inclusion in this review if they specify a definition of HELLP syndrome which includes generally accepted diagnostic criteria for hemolysis, elevated liver enzymes and thrombocytopenia.

The presence of HELLP syndrome is associated with significant maternal mortality and morbidity including acute renal and liver failure, disseminated intravascular coagulopathy, pulmonary edema, cerebrovascular accident, and sepsis (Sibai 1993). Additionally, perinatal morbidity and mortality are also markedly high and are related primarily to the complications of prematurity and growth restriction (Visser 1995). Approximately 70% of pregnancies complicated by HELLP syndrome require preterm delivery, with 15% occurring at extremely preterm gestational age (before 27 completed weeks' gestation) (Abramovici 1999).

#### Description of the intervention

The intervention evaluated was the use of corticosteroids for the treatment of maternal HELLP syndrome. Various regimens have been reported using dexamethasone or betamethasone. The purpose of this review was to summarize the evidence from randomized controlled trials (RCTs) examining the maternal and perinatal effects of corticosteroid administration in women with HELLP syndrome.

## How the intervention might work

Since adverse perinatal outcomes are increased at preterm gestations, interventions that would allow the potential for pregnancy prolongation without negatively impacting the maternal condition could result in increased fetal maturity and subsequently decreased perinatal morbidity and mortality. Corticosteroids have been well established in controlled trials to decrease perinatal morbidity and mortality in the context of preterm birth,

specifically by decreasing the risk of respiratory complications (Roberts 2006). Although the goal of corticosteroid administration in this setting is to promote fetal pulmonary maturation, improvements in maternal platelet count have also been reported (Vigil-De Gracia 1997).

#### Why it is important to do this review

HELLP syndrome is a severe complication of pregnancy with considerable maternal and perinatal morbidity and mortality. There are suggestions from observational studies that steroid treatment in HELLP syndrome may improve disordered maternal hematological and biochemical features and perhaps perinatal mortality and morbidity (Clark 1986; Magann 1993; Yeast 1987).

The Cochrane review by Matchaba and Moodley was last updated in 2004 (search date 2003), and two of the seven trials identified were awaiting translation/more information (Matchaba 2004). The five studies reviewed showed improved biochemical profiles with steroid therapy, but were insufficient in numbers to address clinical outcomes adequately. Further research was called for as a matter of urgency.

For more information on eclampsia and HELLP syndrome, please refer to the 'Interventions for treating pre-eclampsia and its consequences: generic protocol' (Duley 2009).

# OBJECTIVES

To determine, from the best available evidence, the effects of corticosteroids on maternal and perinatal mortality and morbidity in women with HELLP syndrome.

# METHODS

#### Criteria for considering studies for this review

**Types of studies**—All published, unpublished, and ongoing RCTs. We excluded quasirandomized trials (e.g. those randomized by date of birth or hospital number) from the analysis due to a high potential for bias. We examined studies published only as abstracts and included them only if they contained enough information to meet the inclusion criteria.

**Types of participants**—Women with hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome, as determined clinically or based on biochemical markers, both during pregnancy and after delivery, and their babies.

**Types of interventions**—Any corticosteroid versus placebo, no treatment, or other drug; or corticosteroid versus other corticosteroid or other dosage.

**Types of outcome measures**—Only outcomes with available data appear in the analysis tables. To avoid losing valuable data, we also included trials that used acceptable variations of the definitions of primary and secondary outcomes specified below, along with those that did not state their definitions.

We noted outcome data that were not pre-specified by the review authors, but which were reported by the trial authors, as non pre-specified and did not include them in the analysis or use them for the conclusions.

#### **Primary outcomes**

#### For the mother:

1. Maternal death or severe maternal morbidity, defined as any one of the following: presence of liver hematoma, rupture or persistent liver failure; pulmonary edema; renal failure; abruptio placentae; eclampsia; or cerebrovascular accident.

#### For the child:

- 1. Perinatal death: stillbirths (death in utero at or after 20 weeks' gestation), perinatal deaths (stillbirths plus deaths in the first week of life), death before discharge from hospital, neonatal deaths (death in the first 28 days after birth).
- 2. Death or severe perinatal morbidity, defined as any one of the following: respiratory distress syndrome (RDS) with/without ventilatory support required; intracerebral hemorrhage; necrotizing enterocolitis; care in a special care nursery for seven days or more; or severe neonatal encephalopathy.

### Secondary outcomes

#### For the mother:

- 1. Presence of liver hematoma or rupture or liver failure.
- 2. Pulmonary oedema.
- 3. Renal failure.
- 4. Abruptio placenta.
- 5. Eclampsia.
- 6. Cerebrovascular accident.
- 7. Elective delivery: induction of labor or elective caesarean section.
- 8. Caesarean section and caesarean section performed under general anaesthesia.
- 9. Postpartum hemorrhage defined as blood loss of 500 mL or greater.
- 10. Change in platelet count.
- **11.** Side effects or adverse events: any side effects or adverse events related to the intervention or intervention stopped due to side effects.
- **12.** Use of hospital resources: admission to intensive care unit, length of stay, cost of care, use of mechanical ventilation, dialysis.
- **13.** Woman's experience and views of the interventions: childbirth experience, physical and psychological trauma, postnatal depression, breastfeeding, mother-infant interaction, and attachment.

## For the child:

- 1. Time from enrolment to birth.
- 2. RDS with/without ventilatory support required.
- **3.** Intracerebral hemorrhage.
- 4. Necrotizing enterocolitis.
- 5. Care in a special care nursery for seven days or more.
- 6. Preterm birth defined as birth before 37 completed weeks' gestation.
- 7. Very preterm birth defined as birth before 33 completed weeks' gestation.
- 8. Extremely preterm birth defined as birth before 27 completed weeks' gestation.
- 9. Infection.
- 10. Retinopathy of prematurity.
- 11. Apgar score at five minutes: low (seven or less) and very low (four or less).
- **12.** Use of hospital resources: admission to special care nursery, length of stay, cost of care, endotracheal intubation, use of mechanical ventilation.
- **13.** Long-term growth and development: blindness, deafness, seizures, poor growth, neurodevelopmental delay and cerebral palsy.

#### Search methods for identification of studies

**Electronic searches**—We contacted the Trials Search Co-ordinator to search the Cochrane Pregnancy and Childbirth Group's Trials Register (30 June 2010).

The Cochrane Pregnancy and Childbirth Group's Trials Register is maintained by the Trials Search Co-ordinator and contains trials identified from:

- quarterly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
- 2. weekly searches of MEDLINE;
- 3. handsearches of 30 journals and the proceedings of major conferences;
- **4.** weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Details of the search strategies for CENTRAL and MEDLINE, the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service can be found in the 'Specialized Register' section within the editorial information about the Cochrane Pregnancy and Childbirth Group.

Trials identified through the searching activities described above are each assigned to a review topic (or topics). The Trials Search Co-ordinator searches the register for each review using the topic list rather than keywords.

We did not apply any language restrictions.

## Data collection and analysis

**Selection of studies**—Two review authors independently assessed for inclusion all studies identified as a result of the search strategy. We resolved any disagreement through discussion or, if required, consulted a third person.

**Data extraction and management**—We designed a form to extract data. For eligible studies, at least two review authors extracted the data using the agreed form. We resolved discrepancies through discussion or, if required, consulted a third person. We entered data into Review Manager software (RevMan 2008) and checked for accuracy.

When information regarding any of the above was unclear, we attempted to contact authors of the original reports to provide further details.

**Assessment of risk of bias in included studies**—Two review authors independently assessed risk of bias for each study using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2009). We resolved any disagreement by discussion or by involving a third assessor.

(1) Sequence generation (checking for possible selection bias): We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

- adequate (any truly random process, e.g. random number table; computer random number generator);
- inadequate (any non-random process, e.g. odd or even date of birth; hospital or clinic record number); or
- unclear.

(2) Allocation concealment (checking for possible selection bias): We described for each included study the method used to conceal the allocation sequence in sufficient detail and determined whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- adequate (e.g. telephone or central randomization; consecutively numbered sealed opaque envelopes);
- inadequate (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear.

(3) Blinding (checking for possible performance bias): We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We judged studies at low risk of bias if they were blinded, or if we judged that the lack of blinding could not have affected the results. We assessed blinding separately for different outcomes or classes of outcomes.

We assessed the methods as:

- adequate, inadequate or unclear for participants;
- adequate, inadequate or unclear for personnel;
- adequate, inadequate or unclear for outcome assessors.

(4) Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations): We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomized participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or could be supplied by the trial authors, we re-included missing data in the analyses which we undertook. We assessed methods as:

- adequate;
- inadequate:
- unclear.

We considered adequate a level of missing data up to 20%. We judged studies missing more than 20% of outcome data as inadequate.

(5) Selective reporting bias: We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found. We assessed the methods as:

- adequate (where it was clear that all of the study's prespecified outcomes and all expected outcomes of interest to the review had been reported);
- inadequate (where not all the study's pre-specified outcomes had been reported; one or more reported primary outcomes were not pre-specified; outcomes of interest were reported incompletely and so could be used; study failed to include results of a key outcome that would have been expected to have been reported);
- unclear.

(6) Other sources of bias: We described for each included study any important concerns we had about other possible sources of bias.

We assessed whether each study was free of other problems that could put it at risk of bias:

- yes;
- no;
- unclear.

(7) Overall risk of bias: We made explicit judgements about whether studies were at high risk of bias, according to the criteria given in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2009). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it was likely to impact on the findings. We explored the impact of the level of bias through undertaking sensitivity analyses - see Sensitivity analysis.

## Measures of treatment effect

**Dichotomous data:** For dichotomous data, we have presented results as summary risk ratio with 95% confidence intervals.

<u>Continuous data:</u> For continuous data, we used the mean difference if outcomes were measured in the same way between trials. We used the standardized mean difference to combine trials that measured the same outcome, but used different methods. (The standardized mean difference is the difference between two means divided by an estimate of the within-group standard deviation which allows the standardized values to be combined since they have no units.)

Unit of analysis issues—We included only individually RCTs in this review.

For neonatal outcomes, we adjusted the results for multiple pregnancies for clustering if sufficient information was available. If not, we performed sensitivity analysis to assess the impact of assuming independence or non-independence of the multiple birth babies. For neonatal outcomes, the denominator was the number of individual babies randomized rather than the number of pregnancies. In the case of trials comparing more than one type or dose of drug with placebo, each drug was compared individually with the placebo group. Where more than one comparison was included in the same analysis, the numbers in the placebo group were divided by the number of comparisons to avoid double-counting of cases.

**Dealing with missing data**—For included studies, we noted levels of attrition. We explored the impact of including studies with high levels of missing data in the overall assessment of treatment effect by using sensitivity analysis. For all outcomes, we carried out analyses, as far as possible, on an intention-to-treat basis, i.e. we attempted to include all participants randomized to each group in the analyses. The denominator for each outcome in each trial was the number randomized minus any participants whose outcomes were known to be missing.

**Assessment of heterogeneity**—We used the  $I^2$ ,  $T^2$  and  $Chi^2$  statistics to examine heterogeneity among the trials in each analysis. If we identified substantial heterogeneity we explored it by pre-specified subgroup analysis. Heterogeneity greater than 50% as measured by the  $I^2$  statistic was considered substantial.

**Assessment of reporting biases**—Where we suspected reporting bias (*see* 'Selective reporting bias' above), we attempted to contact study authors asking them to provide missing outcome data. Where this was not possible, and the missing data were thought to introduce serious bias, we planned to explore the impact of including such studies in the overall assessment of results by a sensitivity analysis.

**Data synthesis**—We carried out statistical analysis using Review Manager software (RevMan 2008). We used fixed-effect inverse variance meta-analysis for combining data where trials examined the same intervention, and the trials' populations and methods were judged sufficiently similar. Where we suspected clinical or methodological heterogeneity between studies sufficient to suggest that treatment effects may differ between trials, we used random-effects meta-analysis.

If substantial heterogeneity was identified in a fixed-effect meta-analysis we noted this and repeated the analysis using a random-effects method. With random-effects analysis the point estimate represents the average treatment effect.

**Subgroup analysis and investigation of heterogeneity**—Where data were available we planned to carry out the following subgroup analyses.

- 1. Gestation at trial entry: greater than 37 completed weeks' gestation, between 33 and 37 completed weeks' gestation, between 27 and 33 completed weeks' gestation, and less than 27 completed weeks' gestation.
- 2. Type of intervention: type or class, dose, or duration of corticosteroid.
- 3. Corticosteroid versus no treatment, corticosteroid versus placebo.

We planned to use the following outcomes in subgroup analysis.

#### For the mother:

1. Maternal death (during pregnancy or up to 42 days after end of pregnancy) or severe maternal morbidity, defined as any one of the following: presence of liver hematoma, rupture or liver failure; pulmonary edema; renal failure; abruptio placentae; eclampsia; or cerebrovascular accident.

#### For the child:

- 1. Perinatal death: stillbirths (death in utero at or after 20 weeks' gestation), perinatal deaths (stillbirths plus deaths in the first week of life), death before discharge from hospital, neonatal deaths (death in the first 28 days after birth).
- 2. Death or severe perinatal morbidity, defined as any one of the following: RDS with/without ventilatory support required; intracerebral hemorrhage; necrotizing enterocolitis; care in a special care nursery for seven days or more; or severe neonatal encephalopathy.
- 3. Time from enrolment to birth.

4. Severity of preterm birth (gestational age at time of birth). For fixed-effect metaanalyses we planned to conduct subgroup analyses classifying whole trials by interaction tests as described by (Deeks 2001). For random-effects meta-analyses we planned to assess differences between subgroups by inspection of the subgroups' confidence intervals; non-overlapping confidence intervals indicating a statistically significant difference in treatment effect between the subgroups.

**Sensitivity analysis**—We used sensitivity analysis when any significant sources of bias were identified in the methods of this review or of included studies.

# RESULTS

## **Description of studies**

See: Characteristics of included studies; Characteristics of excluded studies; Characteristics of studies awaiting classification; Characteristics of ongoing studies.

**Results of the search**—The search of the Pregnancy and Childbirth Group's Trials Register found 24 reports representing 16 different studies (several studies resulted in more than one publication or report). After assessing eligibility we included 13 studies and excluded one (Barrilleaux 2005); we are seeking further information on one study before assessing eligibility (Morrison 1992); and awaiting translation of one study (Borekci 2008).

**Included studies**—All of the included studies recruited women with a diagnosis of hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome. Criteria for recruitment in eight of the studies was a diagnosis of HELLP class one or two on the Mississippi HELLP classification system as defined by Martin 1999 (hemolysis (lactate dehydrogenase (LDH) greater than 600 IU/L), hepatic dysfunction (alanine transaminase (ALT) or aspartate transaminase (AST) greater than 70 IU/L), thrombocytopenia (platelets below 100,000 cells/mm<sup>3</sup>)), (Bouchnak 2005; Fonseca 2005; Isler 2001; Isler 2003; Magann 1994; Magann 1994a; Van Runnard 2006; Yalcin 1998). In the study by Katz 2008 85.7% of the women recruited were diagnosed with HELLP class one or two, although the sample also included women with less severe symptoms and where women had abnormal findings for at least one of the laboratory parameters used for diagnosis (described as partial cases). Ozer 2009 and Vigil-De 1997 recruited women with HELLP classes one, two, and three (i.e. with platelets below 150,000 cells/mm<sup>3</sup>) and it was not clear how many women were included with less severe disease. In two studies the diagnostic criteria were less clear (Kadanali 1997; Mould 2006).

In five of the included studies pregnant women were recruited, and treatment commenced, in the antenatal period (Isler 2001; Kadanali 1997; Magann 1994; Ozer 2009; Van Runnard 2006). In the study by Fonseca 2005 women were recruited and treatment commenced both antenatally and postnatally. In the remaining studies corticosteroid treatment was commenced just after delivery or in the postnatal period (although the diagnoses of HELLP syndrome may have been made before delivery) (Bouchnak 2005; Isler 2003; Katz 2008; Magann 1994a; Mould 2006; Vigil-De 1997; Yalcin 1998).

In the studies by Isler 2001 and Isler 2003, two different corticosteroids were compared (dexamethasone versus betamethasone). In all of the remaining studies corticosteroid therapy (with dexamethasone, betamethasone or prednisolone) was compared with placebo or no treatment. The drugs used in trials, routes of administration, dosing regimens, duration of treatment and criteria for discontinuation of treatment are set out in the Characteristics of included studies tables.

In most of the studies it was stated that women also received other standard treatment as required including magnesium sulfate and anti-hypertensive drugs, as well as standard doses of corticosteroids antenatally for fetal lung maturation in some studies.

**Excluded studies**—We excluded one study identified in our search as it did not meet our inclusion criteria for participants. It assessed the effect of steroids in severely pre-eclamptic women *without* HELLP syndrome (Barrilleaux 2005).

## **Risk of bias in included studies**

The overall quality of these studies was very mixed, and this should be taken into account in the interpretation or results. We have set out details of the risk of bias assessment for each study in the Characteristics of included studies tables.

**Allocation**—Two of the included studies used random number tables to generate the allocation sequence (Isler 2001; Isler 2003) and four used computer-generated randomization sequences (Katz 2008; Magann 1994; Magann 1994a; Van Runnard 2006). Fonseca 2005 described using a block design (block size four) although it was not clear how the sequence was decided. In the remaining studies the method used to generate the randomization order was not described, or was not clear (Bouchnak 2005; Kadanali 1997; Mould 2006; Vigil-De 1997; Yalcin 1998).

In five of the included trials authors described using sealed opaque sequentially numbered envelopes to conceal the allocation sequence (Fonseca 2005; Isler 2001; Magann 1994; Magann 1994a; Ozer 2009) and Mould 2006 referred to the "sealed envelope system". In two studies randomization was carried out by pharmacy, and in these placebo controlled studies drugs were provided in coded containers to conceal treatment group allocation (Katz 2008; Van Runnard 2006). In the Isler 2003 trial, group allocation was also described as being concealed by the use of sealed opaque envelopes; however, a number of women (it was not clear how many) were not assigned to groups on a random basis, but rather according to the type of corticosteroid treatment they had previously received; this is a potentially serious source of bias in this study.

The methods used to describe allocation concealment were not described in the trials by Bouchnak 2005, Kadanali 1997, Vigil-De 1997 and Yalcin 1998.

**Blinding**—Four of the included studies were placebo controlled trials, and women and clinical staff were likely to have been unaware of treatment group (Bouchnak 2005; Fonseca 2005; Katz 2008; Van Runnard 2006).

Woudstra et al.

In the remaining studies, women in the two arms of the trials received either different types of corticosteroid treatment or women in control groups received no corticosteroid treatment, and treatment blinding was either not attempted or was not feasible (Isler 2001; Isler 2003; Kadanali 1997; Magann 1994; Magann 1994a; Mould 2006; Ozer 2009; Vigil-De 1997; Yalcin 1998). The lack of treatment blinding is a potentially serious source of bias in these trials as decisions about interventions (e.g. labor induction) may have been affected by knowledge of group allocation, and such clinical decisions may have had an impact on outcomes for mothers and babies.

**Incomplete outcome data**—Loss to follow up or missing data was not always well described in these studies, but in most trials all or most women appeared to be accounted for in the analysis. In the study by Magann 1994a, while all women were included in the analysis, for some outcomes (e.g. laboratory values) there were relatively high levels of missing data. In the study by Mould 2006 19% of the original sample were lost to follow up because of protocol violations or missing data, and there was no mention of an intention-to-treat analysis being carried out.

**Selective reporting**—We found it difficult to assess outcome reporting bias as study protocols were not available for most trials and study data were obtained directly from published reports; without access to original protocols it is difficult to determine whether results are reported for all study outcomes. Although most of the studies provided data on laboratory parameters it was surprising to us that morbidity (and even mortality) for mothers and babies were not reported in all of these trials.

We were not able to assess publication bias as there were too few studies contributing data to the analyses.

**Other potential sources of bias**—In two studies, data extraction and analysis was carried out from translation notes and our assessments of risk of bias are likely to be limited (Bouchnak 2005; Kadanali 1997).

In the studies by Isler 2003, Magann 1994, Magann 1994a and Vigil-De 1997 there appeared to be some baseline imbalance between groups at the commencement of treatment (either in disease severity or participant characteristics); it is difficult to assess the impact (if any) of such imbalance on results. For more details please see the full risk of bias assessments in the Characteristics of included studies tables.

#### Effects of interventions

We examined the effects of the interventions through two comparisons: the effect of corticosteroid versus placebo or no treatment, and the effect of one corticosteroid versus another corticosteroid. Within these comparisons we carried out subgroup analyses based on time of commencement of treatment - treatment commenced antenatally, treatment commenced postnatally, and treatment commencement mixed or uncertain. (The protocol of this review stated that we would perform subgroup analysis based on gestation at trial entry. However, methods of the identified trials varied considerably, and data were not available to allow for meaningful analysis based on gestation at trial entry. Therefore our analysis of

subgroups was solely based on whether treatment was commenced antenatally, postnatally, or mixed or uncertain.) There were no studies that compared different doses of the same corticosteroid. All outcomes relating to the child are from trials that commenced treatment in the mother antenatally.

We assessed 48 outcomes based on the data of the included studies. We performed metaanalysis on 21 of the 48 outcomes as many of the prespecified outcomes were only described in a single study.

## 1. Corticosteroid versus placebo or control

#### A. Pre-specified outcomes

*Maternal death:* For the four trials (362 women) reporting maternal death, the risk ratio (RR) was 0.95 (95% confidence intervals (CI) 0.28 to 3.21). This lack of evidence for any overall effect was consistent across all subgroups.

*Maternal death or severe maternal morbidity:* Three trials (278 women) reported maternal death and severe maternal morbidity as defined above as the presence of liver hematoma, rupture or persistent liver failure; pulmonary oedema; persistent renal failure; abruptio placentae; eclampsia; or cerebrovascular accident. These trials included Fonseca 2005, Katz 2008, and Van Runnard 2006. Only Van Runnard 2006 provided sufficient information to determine if the recorded maternal deaths and maternal morbidity were mutually exclusive. The data provided by Fonseca 2005 and Katz 2008 did not allow us to determine whether events were mutually exclusive, or if multiple events could have occurred in the same woman. Both Fonseca 2005 and Katz 2008 found no evidence of any difference between treatment groups in respect to maternal deaths or individual maternal complications considered in the above definition of severe maternal morbidity. The one remaining trial (31 women), found no overall difference in the risk of maternal death or severe maternal morbidity (RR 0.27, 95% CI 0.03 to 2.12) (Van Runnard 2006).

*Perinatal/infant death:* Two studies (58 participants) reported perinatal or infant death (Magann 1994; Van Runnard 2006). There was no clear difference in perinatal/infant death between the two groups when treatment was commenced antenatally (RR 0.64, 95% CI 0.21 to 1.97).

*Perinatal death or severe perinatal morbidity:* Two trials (77 infants), Magann 1994 and Van Runnard 2006, reported perinatal death and perinatal morbidity as defined above as RDS with/without ventilatory support required; intracerebral hemorrhage; necrotizing enterocolitis; care in a special care nursery for seven days or more; or severe neonatal encephalopathy. Both studies administered corticosteroids to the mother antenatally. In each trial there was insufficient information to determine if the recorded outcomes and deaths were mutually exclusive. It was therefore not possible to create a composite outcome from these data. Neither study, however, found evidence of a difference between treatment groups in respect to perinatal death or any individual infant outcomes included in the above definition of severe perinatal morbidity.

*Maternal liver hematoma, rupture, or failure:* For the two trials (91 women) reporting maternal liver hematoma, rupture or failure the RR was 0.22 (95% CI 0.03 to 1.83). This demonstrated a lack of evidence for corticosteroids administered antenatally for HELLP syndrome. There were no studies that examined maternal liver hematoma, rupture or failure when treatment with corticosteroids was commenced postnatally, or when treatment commencement was mixed or uncertain.

*Maternal pulmonary edema:* There was no overall difference in maternal pulmonary edema in the three trials (297 women) that reported this outcome (RR 0.77, 95% CI 0.24 to 2.48). This lack of evidence was consistent across subgroups.

*Maternal renal failure:* Three trials (297 women) reported maternal renal failure. The RR for renal failure was 0.69 (95% CI 0.39 to 1.22) and this apparent lack of effect was similar across subgroups.

*Eclampsia:* Only one study (132 women) with corticosteroid commencement both antenatally and postnatally assessed eclampsia. There was no clear evidence of any difference between groups (RR 0.80, 95% CI 0.34 to 1.90).

*Caesarean section or elective delivery including induction of labor:* No clear effect was seen in two trials (46 women) that assessed the number of caesarean sections or elective deliveries. Both trials administered corticosteroids antenatally and found a RR of 1.01 (95% CI 0.79 to 1.29) (random effects analysis; heterogeneity:  $I^2 = 56\%$ ,  $Tau^2 = 0.02$ , Chi<sup>2</sup> test for heterogeneity P = 0.13).

Length of stay in hospital or obstetrical delivery room for the mother: Five trials (354 women) assessed length of stay in hospital or in the obstetrical room. When meta-analysis was performed there was no effect shown overall (mean difference (MD) -1.15, 95% CI -2.77 to 0.46), (random effects analysis; heterogeneity;  $I^2 = 63\%$ , Tau<sup>2</sup> = 1.87, Chi<sup>2</sup> test for heterogeneity P = 0.03), and no effect in any subgroup individually. Sensitivity analysis showed only a single trial which demonstrated any effect (Yalcin 1998) but there was no indication to consider this trial alone in the subgroup of trials in which treatment was commenced postnatally. Two studies examined the effect of corticosteroids initiated postnatally (Katz 2008; Yalcin 1998) and the trial by Yalcin 1998 was a lower power trial and possibly affected by performance and selection bias as the randomization method was unclear as well as whether blinding was present. The Katz 2008 trial had a low risk of bias.

*Need for dialysis:* There was no evidence of effect in respect to need for dialysis in the one trial that assessed this outcome in women who received treatment antenatally (RR 3.00, 95% CI 0.13 to 70.83). There were no studies that examined need for dialysis when treatment with corticosteroids was commenced postnatally, or when treatment commencement was mixed or uncertain.

*Time from enrolment to birth (hours):* Three trials (118 women) that commenced treatment with corticosteroids antenatally assessed the time from enrolment to birth. There was a high level of heterogeneity for this outcome suggesting different standards of care or differing

treatment protocols and therefore we did not perform meta-analysis with data from these three trials. Each of the three trials (Magann 1994; Ozer 2009; Van Runnard 2006) assessed the effect of a different corticosteroid, (dexamethasone, betamethasone, and prednisolone respectively) commenced antenatally for HELLP syndrome. The Magann 1994 trial (25 women) was the only trial that assessed the effect of dexamethasone and while it did find a difference between groups (MD 26.00, 95% CI 17.17 to 34.83), this trial showed some baseline imbalance and was not blinded making it subject to performance bias. Additionally, this trial sample was too small (25 women) for any reliable conclusions about potential differential effects. No evidence of a treatment effect of betamethasone compared with placebo commenced antenatally and found no difference between treatment groups (MD 5.30, 95% CI -4.28 to 14.88) while the Van Runnard 2006 trial (33 women) assessed the effect of prednisolone compared with placebo commenced antenatally and found no evidence of effect (MD -26.40, 95% CI -135.61 to 82.81).

*Abruptio placenta:* There was no clear evidence of a difference between treatment groups in respect to frequency of abruptio placenta in women who had received corticosteroids antenatally in one trial (31 women). The RR was 1.07 (95% CI 0.07 to 15.57).

**RDS with/without ventilatory support:** There was no clear effect seen between treatment groups in regard to the frequency of RDS in two studies (58 infants) that assessed this outcome in infants of women who received treatment antenatally (RR 0.95, 95% CI 0.45 to 2.03).

*Intracerebral hemorrhage:* In two trials (58 infants) that measured the effect of corticosteroids on intracerebral hemorrhage the RR was 2.31 (95% CI 0.58 to 9.28). This lack of evidence was found in infants of women who commenced treatment antenatally.

*Necrotizing enterocolitis:* There was no clear evidence of any difference between groups in the one trial (33 infants) that reported necrotizing enterocolitis in infants of mothers who had received corticosteroids antenatally (RR 0.21, 95% CI 0.01 to 4.10).

*Gestational age at delivery:* One trial (33 infants) measured gestational age at delivery. There was no clear effect seen between the treatment groups in this trial (MD -0.30, 95% CI -1.30 to 0.70).

*Retinopathy of prematurity/retrolental fibroplasia:* In the one trial (25 infants) that measured retinopathy of prematurity/retrolental fibroplasia in infants of women who had received corticosteroids antenatally the RR was 0.36 (95% CI 0.02 to 8.05). This outcome does not indicate a clear difference between treatment groups.

*Apgar score at five minutes less than seven:* There was no differential effect seen in the two trials (58 infants) that measured Apgar scores at five minutes. The RR for an Apgar score less than seven was 0.89 (95% CI 0.27 to 2.95) in infants whose mothers had received corticosteroids antenatally.

*Length of stay in hospital or special care nursery/neonatal intensive care unit:* The MD in length of stay in hospital or special care nursery/neonatal intensive care unit in one trial (33 infants) was -3.80 (95% CI -19.60 to 12.00). This finding does not indicate a clear difference between treatment groups.

*Long-term growth and development - head circumference less than two SD at 24 months:* One trial (33 infants) measured the long-term effect of antenatal corticosteroids on growth and development of the infant at 24 months. No clear effect was seen in respect to head circumference less than two SD with a RR of 5.00 (95% CI 0.27 to 92.62).

*Long-term growth and development - abnormal Griffiths or BSID Scales at 24 months:* One trial (33 infants) measured the long-term effect of antenatal corticosteroids on growth and development of the infant at 24 months. No clear effect was seen in respect to abnormal Griffiths or BSID Scales with a RR of 0.75 (95% CI 0.22 to 2.52).

*Days of mechanical ventilation required:* No clear evidence of effect was seen between groups in respect to the number of days of mechanical ventilation required. In one trial (33 infants) the MD was 0.80 (95% CI –9.10 to 10.70).

*Platelet count, change in platelet count, or rate of change of platelet count:* Three trials (90 women) measured the effect of corticosteroids commenced both antenatally and postnatally on the absolute platelet count, change in platelet count, or rate of change of platelet count. As there were significant methodological differences between studies the effect on platelets was analysed using the standardized mean difference (SMD). There was clear evidence of an effect on platelets in women who received corticosteroids versus women who received placebo or no treatment. The overall effect demonstrated a SMD of 0.67 (95% CI 0.24 to 1.10). The strongest evidence is found in the group of women who commenced treatment antenatally; there was no clear evidence of an effect on platelet count at 72 hours postpartum 0.47, 95% CI –0.21 to 1.16). By contrast, in the group in which treatment was commenced antenatally, there was evidence of a treatment effect (SMD 0.80, 95% CI 0.25 to 1.35).

**B.** Non pre-specified outcomes: Several studies comparing the effect of corticosteroid against placebo or control also measured other hematologic outcomes that were not pre-specified in the protocol of this review but will be reported here. These include rates of change or serum levels of AST, ALT, and LDH as well as blood pressure and urinary output.

AST level or rate of change of AST: Two trials (56 women) measured the effect of corticosteroids commenced antenatally on AST level. Magann 1994 reported a rate of change of AST (units/hour) and Van Runnard 2006 reported AST levels (U/L) at nadirs following the start of trial medication. The combined data demonstrate a treatment effect with a SMD of -0.55 (95% CI -1.09 to -0.22).

*ALT level or rate of change of ALT:* Two trials (56 women) measured the effect of corticosteroids commenced antenatally on ALT level. Magann 1994 reported a rate of change of ALT (units/hour) and Van Runnard 2006 reported ALT levels (U/L) at nadirs following the start of trial medication. The combined data demonstrate a treatment effect with a SMD of -0.58 (95% CI -1.12 to -0.04).

*LDH level or rate of change of LDH:* Two trials (56 women) measured the effect of corticosteroids commenced antenatally on LDH level. Magann 1994 reported a rate of change of LDH (units/hour) and Van Runnard 2006 reported LDH levels (U/L) at nadirs following the start of trial medication. The combined data demonstrate a treatment effect with a SMD of -0.76 (95% CI -1.40 to -0.11).

*Diastolic blood pressure or rate of change of mean arterial pressure:* Two trials (56 women) measured the effect of corticosteroids commenced antenatally on blood pressure. Magann 1994 reported a rate of change of mean arterial pressure (units/hour) and Van Runnard 2006 reported mean diastolic blood pressure levels (mmHg). There was no clear difference demonstrated between groups with a SMD of -0.26 (95% CI -0.79 to 0.27).

*Rate of change of urinary output:* Only one trial (25 women) measured the effect of dexamethasone on the rate of change of urinary output in women with HELLP syndrome. Magann 1994 demonstrated a clear benefit in patients who received dexamethasone as compared to control with a MD of 3.49 (95% CI 1.83 to 5.15).

**Planned subgroup analysis:** For the review's primary outcomes we had planned to carry out subgroup analysis by gestation at trial entry, by the dose and duration of the intervention, and by corticosteroid versus no treatment and corticosteroid versus placebo. In this version of the review insufficient data were available to allow us to carry out some of these additional analyses. If more data become available, we will carry out the planned analyses in future updates.

## 2. Dexamthasone versus betamethasone

A. Pre-specified outcomes: There was only one trial (Isler 2001) with 40 women (43 infants) that compared the effects of dexamethasone with betamethasone with treatment commenced antenatally. A second trial (Isler 2003), with 36 women, compared dexamethasone with betamethasone but commenced treatment postnatally. Participants included women with class one or class two HELLP syndrome at more than 22 weeks' gestational age. Outcomes are therefore applicable to this group. The only pre-specified outcome that was examined by both studies was the adjusted time averaged change in platelet count. All other data are derived solely from the Isler 2001 trial which assessed treatment commenced antenatally.

*i. Treatment commenced antenatally (Isler 2001):* There was no clear difference found between treatment groups receiving dexamethasone versus betamethasone in all prespecified outcomes reported in this trial - details are listed below.

Woudstra et al.

*Maternal death:* No maternal deaths were reported in either the dexamethasone or betamethasone group.

*Severe maternal morbidity:* No maternal outcomes were reported that met the pre-specified definition of severe maternal morbidity.

*Perinatal/infant death:* No difference was found in the rates of perinatal/infant death (43 infants) (RR 0.95, 95% CI 0.15 to 6.17).

*Severe perinatal/infant morbidity or death:* No difference was found in the rates of severe perinatal/infant morbidity or death (43 infants) (RR 0.64, 95% CI 0.27 to 1.48). The only measured outcome that met the definition of severe perinatal/infant morbidity was infant RDS. In the dexamethasone group there were four infants with RDS, in the betamethasone groups there were seven infants with RDS. Additionally, there were two deaths in the dexamethasone group there were two deaths from extreme prematurity. In the betamethasone group there were two deaths from extreme prematurity. From the text of the paper it was understood that these events were mutually exclusive. In the case that some or all of these deaths occurred in infants who had also been recorded as having RDS, sensitivity analysis was undertaken which showed no change in treatment effect.

*Caesarean section:* No difference was found in the caesarean section rates: 40 women (RR 0.79, 95% CI 0.47 to 1.33).

*Length of stay in hospital or obstetrical delivery room for the mother:* No difference found: 40 women (MD –7.50, 95% CI –24.29 to 9.29).

*RDS with/without ventilatory support:* No difference found: 43 infants (RR 0.55, 95% CI 0.19 to 1.60).

*Gestational age at delivery:* No difference found: 43 infants (MD –0.60, 95% CI –3.35 to 2.15).

Fetal sepsis or infection: No difference found: 43 infants (RR 4.78, 95% CI 0.24 to 94.12).

*Apgar score at five minutes less than seven:* No difference found: 43 infants (RR 0.95, 95% CI 0.22 to 4.21).

*Length of stay in hospital or special care nursery/neonatal intensive care unit:* No difference found: 43 infants (MD –5.40, 95% CI –18.86 to 8.06).

*Use of mechanical ventilation:* No difference found: 43 infants (RR 0.55, 95% CI 0.19 to 1.60).

#### ii. Treatment commenced antenatally (Isler 2001) and postnatally (Isler 2003)

*Adjusted time averaged change in platelet count:* There was clear evidence of a difference in effect between groups comparing dexamethasone with betamethasone in respect to the adjusted time averaged change in platelet count. Dexamethasone was found to be superior compared with betamethasone although there were high levels of heterogeneity of this

Woudstra et al.

outcome (76 women) (MD 6.02, 95% CI 1.71 to 10.33), (random-effects analysis; heterogeneity:  $I^2 = 85\%$ ,  $Tau^2 = 8.25$ ,  $Chi^2$  test for heterogeneity P = 0.009). Subgroup analysis demonstrated this effect both when treatment was commenced antenatally, (MD 8.10, 95% CI 6.23 to 9.97) and when treatment was commenced postnatally (MD 3.70, 95% CI 0.96 to 6.44).

**B. Non pre-specified outcomes:** Isler 2001 (40 women) and Isler 2003 (36 women) also reported several other hematologic outcomes that were not pre-specified in the protocol of this review but will be reported here. These include adjusted time averaged change in AST level, LDH level, mean arterial pressure and urinary output. There were high levels of heterogeneity for several of these outcomes.

*Adjusted time averaged change in AST level:* There were differences in adjusted time averaged change in AST level between groups treated with dexamethasone and betamethasone although the overall difference between groups was not statistically significant (76 women) (MD –18.80, 95% CI –41.34 to 3.74), (random-effects analysis; heterogeneity:  $I^2 = 97\%$ , Tau<sup>2</sup> = 255.79, Chi<sup>2</sup> test for heterogeneity P < 0.00001).

*Adjusted time averaged change in LDH level:* Dexamethasone was found to be superior to betamethasone in respect to adjusted time averaged change in LDH level (76 women) (MD -73.40, 95% CI -113.13 to -33.67), (random-effects analysis; heterogeneity: I<sup>2</sup> = 58%, Tau<sup>2</sup> = 478.14, Chi<sup>2</sup> test for heterogeneity P = 0.12).

*Adjusted time averaged change in mean arterial pressure:* There was clear evidence of a superior effect of dexamethasone as compared to betamethasone in relation to adjusted time averaged change in mean arterial pressure (76 women) (MD –7.64, 95% CI –8.27 to –7.01).

Adjusted time averaged change in urinary output: Greater treatment effect was evidenced in patients receiving dexamethasone as compared to patients receiving betamethasone in respect to adjusted time averaged change in urinary output (76 women) (MD 16.73, 95% CI 0.47 to 32.99), (random-effects analysis; heterogeneity:  $I^2 = 92\%$ , Tau<sup>2</sup> = 126.89, Chi<sup>2</sup> test for heterogeneity P = 0.0004).

# DISCUSSION

#### Summary of main results

**Corticosteroid versus placebo or no treatment**—Pre-specified outcomes: there was no clear evidence of any treatment effect of corticosteroids on substantive clinical outcomes. Those receiving steroids showed significantly greater improvement in platelet counts.

Non pre-specified outcomes: there were also significantly greater improvements in aspartate transaminase, alanine transaminase (ALT), lactate dehydrogenase (LDH), and urinary output in women receiving corticosteroids.

**Dexamethasone versus betamethasone**—Pre-specified outcomes: there was no clear evidence of any difference between groups receiving dexamethasone versus betamethasone

in respect to substantive clinical outcomes. Those receiving dexamethasone showed significantly greater improvements in platelet count than those receiving betamethasone.

Non pre-specified outcomes: those receiving dexamethasone versus betamethasone showed significantly greater improvements in LDH level, blood pressure, and urinary output. No difference was found between steroids in respect to ALT level.

## Overall completeness and applicability of evidence

A limitation of the evidence was the limited number of outcomes reported in various trials, and different methods of measurement of continuous data.

#### Quality of the evidence

The trials were of varying quality; however, there was general consistency in the results.

#### Potential biases in the review process

The possibility of reporting bias could not be excluded, as not all trials reported all relevant outcomes.

#### Agreements and disagreements with other studies or reviews

The results of this review are consistent with previous findings reported by Matchaba and Moodley in a 2004 systematic review of the effect of corticosteroids in hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome (Matchaba 2004). They concluded that there was insufficient evidence to support the addition of corticosteroids to standard therapy in HELLP syndrome.

# AUTHORS' CONCLUSIONS

#### Implications for practice

There is to date insufficient evidence of benefits in terms of substantive clinical outcomes to support the use of steroids for the management of hemolysis, elevated liver enzymes and low platelets syndrome in routine clinical practice. The use of corticosteroids may be justified in clinical situations in which an increase, or increased rate of recovery, in platelet count is considered clinically worthwhile

#### Implications for research

The consistently greater improvement in platelet counts is reason for further research in this area. Future trials should be sufficiently powered to detect clinically meaningful differences in health outcomes. The very limited data reviewed here suggests that dexamethasone should be tested in preference to betamethasone in such trials.

# Acknowledgments

Translation of non-English studies was provided by volunteer translators through the Cochrane group. Alex Balistreri provided a translated summary of Kadanali 1997 and Alison Ledward provided a translated summary of Bouchnak 2005.

As part of the pre-publication editorial process, this review has been commented on by three peers (an editor and two referees who are external to the editorial team) and the Group's Statistical Adviser.

Interventions	Intervention group: dexamethasone 10 mg IV every 12 hours until delivery (no women received therapy postpartum) Comparison group: standard care (no corticosteroids). All women were continuously monitored in labor and delivery, hourly mean arterial pressure and urinary output, lab tests every 6 hours.		
Outcomes	Time to delivery. Change in MAP, urinary output, hematocrit, platelet count, LDH, AST, ALT. Neonatal death, Apgar score < 7, mean birthweight, morbidity (ARDS, intraventricular hemorrhage, retrolental fibroplasias)		
Notes	Inclusion criteria - wor	nen with class III HELLP (platelets < 150,000 cells/mm <sup>3</sup> )	
Risk of bias			
Item	Authors' judgement Description		
Adequate sequence generation?	Yes	Computer generated sequence.	
Allocation concealment?	Yes	Sealed opaque envelopes.	
Blinding? All outcomes	No	Different treatment regimens.	
Incomplete outcome data addressed? All outcomes	Unclear	Not described.	
Free of other bias?	Unclear	There was some baseline imbalance; there were more black women in the control group and the mean platelet count was higher in the control group suggesting that this group may have had less serious disease	
Overall risk of bias?	Unclear	No blinding may represent a serious source of bias.	

# Magann 1994a

Methods	Prospective RCT.		
Participants	40 women with diagnosis of HELLP in postpartum period. (HELLP defined using as presence of clinical signs and symptoms consistent with diagnosis of pre- eclampsia and lab evidence of hemolysis, hepatic dysfunction and thrombocytopenia. Mississippi triple class system: women with class 1 or 2 HELLP, i.e. platelets < 100,000 cells/mm <sup>3</sup> ) Exclusions: women with clinical evidence of chorioamnionitis at delivery		
Interventions	Intervention group: (20 women) immediately after delivery, 10 mg IV dexamethasone, then 10 mg 12 hrs later, 5 mg at 24 and 36 hrs. Total of 30 mg over 36 hrs. Control group: (20 women) routine care, no corticosteroids. Both groups were intensively monitored, MAP, urinary output every two hrs and lab tests every 6-12hrs. Both groups had magnesium sulfate IV 2 gm/hr		
Outcomes	Symptom resolution and laboratory values returning to normal (adequate urine output, change in MAP, BP < 160/100, platelet trend upwards, LDH and liver enzymes downwards) Postpartum infectious morbidity.		
Notes			
Risk of bias			
Item	Authors' judgement	Description	
Adequate sequence generation?	Yes	Computer generated card.	
Allocation concealment?	Yes "computer generated card enclosed in an opaque envelope."		
Blinding? All outcomes	Unclear 1 group received no treatment, not clear whether partial blinding was attempted		

Incomplete outcome data addressed? All outcomes	No	While there was no mention of loss to follow up there were considerable missing data for some outcomes (e.g. results for 25/40 for urinary output)
Free of other bias?	Unclear	No baseline imbalance was reported although the graphs in the results section seem to suggest a different distribution of lab values in the 2 groups. This may not be meaningful as the numbers are small and the distribution may not be normal. Results are presented in graphs that are difficult to interpret and data are not in a form that allows us to analyse using Review Manager Software (RevMan 2008).
Overall risk of bias?	Unclear	Risk of performance bias as blinding not indicated. High levels of missing data

# Mould 2006

Methods	RCT.	
Participants	37 postpartum women (outcome data available for 30). Women who had received betamethasone for fetal lung maturation (30%) waited 12 hours after delivery for entry to the study.	
Interventions	Intervention (16 women): 10 mg dexamethasone every 12 hours until platelet levels recovered (> 100,000 cells/mm <sup>3</sup> ) Comparison group (14): standard management (anti-hypertensive drugs and magnesium sulfate as indicated)	
Outcomes	Time to recovery of platelet count. Recovery of ALT, LDH, time in high care unit and complications due to steroid use	
Notes	This study was reported information on method	d in a very brief published report and there is little s or results
Risk of bias		
Item	Authors' judgement	Description
Adequate sequence generation?	Unclear	Not described.
Allocation concealment?	Yes	Described as the "sealed envelope system".
Blinding? All outcomes	Unclear	Not clear whether partial blinding was attempted. Different treatment regimens
Incomplete outcome data addressed? All outcomes	No	7/37 (19%) lost due to protocol violations or incomplete data
Free of selective reporting?	Unclear	Methods very brief so difficult to assess.
Free of other bias?	Yes	No baseline imbalance but methods reported too briefly to assess
Overall risk of bias?	Unclear	No blinding and relatively high attrition, randomization methods not clear. No placebo. This study may be at high risk of bias

## **Ozer 2009**

Methods	Prospective, randomized placebo-controlled clinical trial (non-blinded)
Participants	60 pregnant women diagnosed with HELLP syndrome class 1, 2 and 3 (platelets < 150,000 cells/mm <sup>3</sup> , AST and ALT > 40 IU/L, LDH > 600 IU/L) Exclusions: women with pyrexia, postpartum HELLP syndrome, diabetes, epilepsy, hepatic or renal disease.

Interventions	Intervention group: 12 mg betamethasone IM every 12 hours until study criteria fulfilled (symptoms and signs in remission) Control: placebo (sterile water) IM - same regimen. Women with pregnancies 26-34 weeks' gestation also had 2 doses of 12 mg betamethasone IM to encourage fetal lung maturation. All women received magnesium sulfate 4 g, then a maintenance infusion of 1-2 g/hr. Anti-hypertensives as required Monitoring of BP and urine output hourly. Lab tests 6 hourly IOL or CS if gestational age > 34 weeks or if condition worsened or there were signs of non-reassuring fetal status	
Outcomes	cardiopulmonary or hematologic hematoma, DIC, neurological or GI, infectious, metabolic compli	rventions (labor induction, vaginal delivery, CS, cal complications, need for transfusion, wound renal complications, oliguria, need for dialysis, ications, edema, ascites), length of hospitalisation. .T, AST, LDH, platelet count). MAP, systolic and weight
Notes		
Risk of bias		
Item	Authors' judgement	Description
Adequate sequence generation?	Yes	Random number table.
Allocation concealment?	Yes	Consecutively numbered sealed opaque envelopes.
Blinding? All outcomes	No	Women were told which treatment they were receiving. Blinding not attempted
Incomplete outcome data addressed? All outcomes	Yes	No loss to follow up apparent.
Free of other bias?	Yes	No baseline imbalance apparent.
Overall risk of bias?	Unclear	This study had adequate randomization but no blinding.

# Van Runnard 2006

Methods	Randomized double blind placebo controlled trial.	
Participants	32 women randomized (31 women included in analyses). Inclusion criteria: pregnant women with diagnosis of HELLP syndrome with an onset before 30 weeks' gestation in whom a prolongation of pregnancy was considered beneficial (HELLP defined as: hemolysis (LDH > 600 u/l and or haptoglobin less than or equal to 0.3 g/l), elevated liver enzymes (AST > 50 IU/L or ALT > 50 IU/L) low platelet count (< 100,000 cells/mm <sup>3</sup> )). Mean gestation at recruitment approximately 27.5 weeks. 1 twin pregnancy in each group. Exclusion criteria: women who required immediate delivery or if study medication contraindicated	
Interventions	Interventions group (15): prednisolone IV, 50 mg over 12 hours in 100 ml of sodium chloride, for 2 days after delivery or for up to 14 days in antenatal period, then tapering off (4 day oral tapering protocol of 50, 20, 10 and 5 mg of medication). If women delivered during the tapering period a stress dose was given during and after delivery every 12 hours for 48 hours) Comparison group: (16) placebo (sodium chloride IV) same regimen Prior to randomization women received 2 IM doses of betamethasone 11.4 mg 24 hrs apart for fetal lung maturation. Magnesium sulfate and anti-hypertensive drugs according to protocol. Monitoring of BP, urine output, symptoms and laboratory tests every 6-24 hrs	
Outcomes	Time to delivery, recurrent HELLP exacerbation, maternal, perinatal and neonatal infant outcomes including GA at delivery, Apgar scores, mortality, RDS grades III and IV, bronchopulmonary dysplasia, oxygen requirement at 28 days after birth, intraventricular hemorrhage, necrotizing enterocolitis, infant death in first year. Neurodevelopmental outcomes at 1 and 2 years	

#### Notes

Risk of bias		
Item	Authors' judgement	Description
Adequate sequence generation?	Yes	Computer generated in blocks of 6.
Allocation concealment?	Yes	Randomization carried out by pharmacy.
Blinding? All outcomes	Yes	"Nurses, physicians and researchers were blinded to the trial medication until the last patient was delivered and discharged."
Incomplete outcome data addressed? All outcomes	Yes	All but 1 woman accounted for in the analysis (1 woman had an emergency CS before the 1st dose of medication was administered)
Free of other bias?	Yes	No baseline imbalance apparent.
Overall risk of bias?	Unclear	Low risk of bias.

Vigil-De 1997

Methods	RCT.	
Participants	34 postpartum women affected by HELLP (diagnosed before delivery with signs and symptoms and lab evidence of hemolysis (abnormal peripheral smear, increased bilirubin > 1.2 mg/dL) decreased hemoglobin and hematocrit, elevated liver enzymes (AST > 70 IU/L, ALT > 50 IU/L, LDH > 600 IU/L) low platelets - includes HELLP categories 1, 2, 3 (platelets < 150,000 cells/mm <sup>3</sup> ) Exclusion criteria: clinical evidence of chorioamnionitis.	
Interventions	Intervention group (17) : 10 mg IV dexamethasone, repeated at 12 and 24 hrs (total 30 mg) Control group: No treatment. All women were monitored for arterial BP, urinary output and lab tests every 12 hrs for 72 hrs No magnesium sulfate was given. Anti-hypertensives to treat severe hypertension as required.	
Outcomes	Arterial BP, urinary output and laboratory tests (platelet count, LDH, AST and ALT). Postpartum infectious morbidity, metabolic disorder, wound infection, abnormal uterine bleeding or maternal death	
Notes	No details on randomization methods. Not blinded.	
Risk of bias		
Item	Authors' judgement	Description
Adequate sequence generation?	Unclear	No details of randomization methods.
Allocation concealment?	Unclear	Not described "random assignments".
Blinding? All outcomes	No	No blinding for women or clinical staff (different treatment regimens); it was not clear whether there was any attempt to blind outcome assessors
Incomplete outcome data addressed? All outcomes	Yes	No loss to follow up apparent.
Free of other bias?	No	Baseline characteristics were described as similar but platelet counts were higher at baseline in the control group

Overall risk of bias?	Unclear	No details on randomization methods. Not blinded.

## Yalcin 1998

Methods	RCT.			
Participants	30 postpartum women with a diagnosis of HELLP syndrome while pregnant from symptoms and laboratory findings. Hemolysis, elevated liver enzymes (AST > 48 IU/L, ALT > 24 IU/L) low platelets (< 100,000 cells/mm <sup>3</sup> ) All women were delivered within 72 hrs of admission (IOL initiated with CS for fetal distress). Women randomized following delivery			
Interventions	Intervention group: immediately after delivery 10 mg dexamethasone IV, then 10 mg at 12 hrs, and 5 mg at 24 and 36 hrs (total dose over 36 hrs = 30 mg) Control group: no steroids. Women in both groups had anti-convulsive therapy (IV magnesium sulfate - bolus 4 g then 1 g/hr over 48 hrs). Anti-hypertensive therapy as required (> 160/110 mmHg) Careful monitoring in both groups (arterial BP and urine output monitored 2 hrly) and lab tests 6-12 hrly All women remained in ICU until symptoms and lab tests showed signs of remission			
Outcomes	Outcomes: Mean arterial BP, urine output, laboratory findings (AST, ALT, platelet count, hematocrit). Mean length of hospital stay			
Notes				
Risk of bias				
Item	Authors' judgement	Description		
Adequate sequence generation?	Unclear	Not described.		
Allocation concealment?	Unclear	Women were "randomly assigned".		
Blinding?	Unclear	No blinding of women or clinical staf It was not clear if outcome assessors		
All outcomes		were blind		
All outcomes Incomplete outcome data addressed? All outcomes	Yes	All women seem to be accounted for the analyses. 2 women died before delivery (before randomization)		
Incomplete outcome data addressed?	Yes	All women seem to be accounted for the analyses. 2 women died before		

ALT: alanine transaminase

ARDS: acute respiratory distress syndrome

## Borekci 2008

Methods	The abstract states that participants were "evaluated prospectively" in three groups "selected randomly"
Participants	60 postpartum women with a diagnosis of HELLP.
Interventions	3 intervention groups: Group 1: dexamethasone and magnesium sulfate infusion. Group 2: betamethasone and magnesium sulfate infusion. Group 3. magnesium sulfate infusion only.
Outcomes	Platelet count, urine output and other laboratory values.
Notes	We are awaiting a translation of this paper.

#### Morrison 1992

Methods	Proposed RCT.
Participants	Women with HELLP syndrome.
Interventions	Methylprednisolone versus placebo.
Outcomes	Maternal thrombocytopenia.
Notes	We have only a very brief note of this proposed trial. It was stated that the trial was scheduled to begin in 1992. We have no evidence that this trial was completed. We have searched for any published results and have attempted to contact the author for more information, but have not yet had any response (April 2010)

HELLP: haemolysis elevated liver enzymes and low platelets

RCT: randomized controlled trial

# Characteristics of ongoing studies [ordered by study ID]

#### Fonseca 2010

Trial name or title	Dexamethasone efficacy in HELLP I syndrome, a multicentric, double-blind, placebo- controlled, randomized clinical trial
Methods	Multi-centre RCT.
Participants	Women with more than 20 weeks' gestation or during the first three days postpartum with platelet count < or = $50,000/\text{mm3}$ , AST > or = $70 \text{ U/L}$ and LDH > or = $600 \text{ U/L}$
Interventions	Experimental group: dexamethasone 10 mg. Dexamethasone sodium phosphate IV every 12 hours until delivery and 3 doses after delivery. Puerperal women three 10 mg doses after delivery Control group: placebo (sterile water); same regimen as experimental group
Outcomes	Duration of hospitalization. Recovery time of platelets to more than 100000/mm3. Recovery of AST, ALT and LDH. Transfusion of blood products
Starting date	October 2009.
Contact information	Dr Javier Fonseca, Universidad del Valle, Colombia jaenfo@gmail.com
Notes	Estimated completion date December 2011

ALT: alanine transaminase

AST: aspartate transaminase

HELLP: haemolysis elevated liver enzymes and low platelets

IV: intravenous

LDH: lactate dehydrogenase

RCT: randomized controlled trial

#### PLAIN LANGUAGE SUMMARY

#### Corticosteroids for HELLP syndrome in pregnancy

Pre-eclampsia is a serious complication of pregnancy characterized by high blood pressure with protein in the urine and sometimes progression to seizures (fits). HELLP syndrome is a more severe form of pre-eclampsia which can cause problems with liver function, blood clotting, and low platelets. HELLP may be diagnosed during pregnancy or after giving birth and is associated with ill health for the mother including liver hematoma, rupture, or failure; pulmonary edema; renal failure and death. Infant health may also be poor, primarily due to premature birth and growth restriction. This review examined the effect of treating women with HELLP syndrome using corticosteroids (which can reduce inflammation). The results of this review did not indicate that there was a clear effect on the health of pregnant women when treated with corticosteroids, or their babies. Corticosteroids did appear to improve some components of the women's blood tests, but it is not clear that this had an effect on their overall health. The review identified 11 randomized controlled trials involving 550 women that compared corticosteroid (dexamethasone, betamethasone, or prednisolone) given during pregnancy, just after delivery or in the postnatal period, or both before and after birth, with placebo or no treatment. Two further trials showed that there was no clear difference between dexamethasone and betamethasone on the substantive clinical outcomes for women or their infants. Dexamethasone did improve maternal platelet count and some biochemical measures to a greater extent than betamethasone.
