Abstract

The G protein–coupled receptor allosteric modulator SCH-202676 (N-(2,3-diphenyl-1,2,4-thiadiazol-5-(2H)-ylidene)methanamine), which affects a wide range of structurally unrelated G protein–coupled receptors, has highly divergent effects on purine receptors. SCH-202676 inhibited radioligand binding to human adenosine A₁, A_{2A}, and A₃ receptors (IC₅₀ = 0.5–0.8 μ M) and affected dissociation kinetics, but at the human P2Y₁ nucleotide receptor it had no effect. SCH-202676 (10 μ M) selectively accelerated agonist dissociation at adenosine A₃ receptors and either slowed (adenosine A₁ receptors) or accelerated (adenosine A_{2A} receptors) antagonist dissociation. Thus, SCH-202676 differentially modulated A₁, A_{2A}, and A₃ receptors as well as agonist- and antagonist-occupied receptors.

Keywords

Adenosine receptor; P2Y receptor; Allosteric modulator; 7TM receptor; SCH-202676

Introduction

Allosteric sites on cell surface receptors are emerging as important targets for drug development (Christopoulos, 2002; Christopoulos and Kenakin, 2002). Both adenosine receptors and P2Y receptors are of increasing therapeutic interest (Fredholm et al., 2001; Jacobson et al., 2002). Allosteric modulators for adenosine and P2Y receptors are of potential clinical use (Linden, 1997; Christopoulos and Kenakin, 2002).

SCH-202676 (*N*-(2,3-diphenyl-1,2,4-thiadiazol-5-(2H)-ylidene)methanamine) was recently reported to be a universal allosteric modulator of a wide variety of unrelated G protein–coupled receptors, including the human μ -, δ -, and κ -opioid, α - and β -adrenergic, muscarinic M₁ and M₂, and dopaminergic D₁ and D₂ receptors (Fawzi et al., 2001). It appeared to affect binding non-competitively, yet reversibly, to a range of structurally unrelated G protein–coupled receptors, including those coupled through Gi/Go, Gs and Gq proteins. Moreover, at 6 µM it completely blocked the ability of an agonist to activate the α_{2A} -adrenergic receptor.

However, it is not known whether SCH-202676 has any effect on G protein–coupled receptors that respond to adenosine or adenine nucleotides.

In this study we examined the ability of SCH-202676 to compete for ligand binding to human adenosine A_1 , A_{2A} , and A_3 receptors and $P2Y_1$ nucleotide receptors stably expressed in CHO, HEK-293 or 1321N1 astrocytoma cells. We also studied the effects on rates of ligand dissociation from those receptors. We found that SCH-202676 interacts with adenosine receptors but not with P2Y₁ receptors. SCH-202676 differentially modulated adenosine A_1 , A_{2A} , and A_3 receptors as well as agonist- and antagonist-occupied receptors.

Methods

Materials

CPA (N^6 -cyclopentyladenosine), NECA (5'-N-ethylcarboxamidoadenosine), Cl-IB-MECA (2-chloro-N⁶-(3-iodobenzyl)-5'-N-methylcarbamoyladenosine), and MRS2179 (N^6 -methyl-2'-deoxyadenosine-3',5'-bisphosphate) were purchased from Sigma (St. Louis, MO, USA). [¹²⁵I]I-AB-MECA (N^6 -(4-amino-3-iodobenzyl)-5'-N-methylcarboxamidoadenosine; 2000 Ci/mmol), [³H]PSB-11 (8-ethyl-4-methyl-2-phenyl-(8R)-4,5,7,8-tetrahydro-1H-imidazo[2.1-i]purin-5-one; 53 Ci/mmol), [³H]R-PIA (N^6 -(R)-phenylisopropyl]adenosine; 34 Ci/mmol), [³H]DPCPX (8-cyclopentyl-1,3-dipropylxanthine; 120 Ci/mmol), and [³H]CGS21680 (47 Ci/mmol) were from Amersham Pharmacia Biotech (Buckinghamshire, UK). [³H]ZM241385 (4-2-[7-amino-2-(2-furyl)-1,2,4-triazolo[1,5-a][1,3,5]triazin-5-ylamino] ethylphenol; 17 Ci/mmol) and SCH-202676 were from Tocris (Ballwin, MO, USA). [³H]MRS2279 (2-chloro- N^6 -methyl-(N)-methanocarba-2'-deoxyadenosine-3',5'-bisphosphate) was prepared as described (Waldo et al., 2002).

Cell culture and membrane preparation

CHO cells stably expressing recombinant human adenosine A_1 receptors and human and rat adenosine A_3 receptors, as well as HEK293 cells stably expressing human adenosine A_{2A} receptors, and human astrocytoma cells expressing human P2Y₁ receptors were cultured in Dulbecco's modified Eagle's medium (JRH Biosciences, Inc., Lenexa, KS, USA) and F12 (1:1) supplemented with 10% fetal bovine serum, 100 units penicillin/ml, 100 µg streptomycin/ml, 2 µmol glutamine/ml, and 500 µg geneticin/ml. After harvesting, the cells were homogenized and suspended and then centrifuged at 100 g for 5 min at room temperature. The pellet was resuspended in 50 mM tris(hydroxymethyl)aminomethane (Tris)·HCl buffer (pH 7.4). The suspension was homogenized with a Polytron electric homogenizer (Brinkmann, NY, USA) for 10 s and was then recentrifuged at 20,000 g for 20 min at 4 °C. The resultant pellets were resuspended in buffer in the presence of 3 units adenosine deaminase/ml, and the suspension was stored at -80 °C until the binding experiments. The protein concentration was measured with the Bradford assay (Bradford, 1976).

Radioligand binding assays

Adenosine and P2Y₁ receptor binding experiments were performed as previously described (Gao et al., 2002; Waldo et al., 2002). Briefly, the binding of $[^{3}H]R$ -PIA (2.0 nM) or

 $[^{3}H]$ DPCPX (1.0 nM) to human adenosine A₁ receptors from CHO cell membranes (40 µg protein/tube), [³H]CGS21680 (15 nM) and [³H]ZM241385 (2.0 nM) to adenosine A_{2A} receptors from HEK293 cell membranes (20 µg protein/tube) and [125I]I-AB-MECA (0.5 nM) and [³H]PSB-11 (5 nM) (Müller et al., 2002) to adenosine A₃ receptors was measured after incubation at 25 °C for 60 min in 200 µl of 50 mM TrisµHCl (pH 7.4) containing 10 mM MgCl₂. The dissociation was initiated by the addition of 1 μ M CPA, 10 μ M CGS21680, and 1 µM Cl-IB-MECA for the adenosine A1, A2A, and A3 receptors, respectively. The time course of dissociation of total binding was measured by rapid filtration at appropriate time intervals. Binding reactions were terminated by filtration through Whatman GF/B glass-fiber filters under reduced pressure with a MT-24 cell harvester (Brandel, Gaithersburg, MD, USA), and radioactivity was determined with a liquid scintillation counter (Parkard, IL, USA) or a Beckman 5500B γ-counter (Beckman, USA). For P2Y₁ receptor binding experiments, membranes (40 µg protein) from astrocytoma cells stably expressing human $P2Y_1$ receptors were incubated with [³H]MRS2279 (8 nM) for 30 min at 4 °C in a total assay volume of 100 µl. Radiolabeled ligand concentrations used in all assays approximated the $K_{\rm d}$ value of the receptor.

Binding parameters were analyzed by GraphPAD Prism software (GraphPAD, San Diego, CA, USA). Data were expressed as mean \pm standard error.

Results

It was recently shown that SCH-202676 allosterically modulated several structurally diverse G protein-coupled receptors but had no effect on G proteins (Fawzi et al., 2001). In this study, we examined the possible interaction of SCH-202676 with adenosine and P2Y₁ receptors, first by examining inhibition of agonist binding to human adenosine A_1 , A_{2A} , and A3 receptors and to the human P2Y1 receptor. As shown in Fig. 1, SCH-202676 inhibited ligand binding to adenosine A₁, A_{2A}, and A₃ receptors with similar potencies (IC₅₀ = 0.77 \pm $0.10, 0.55 \pm 0.19$, and $0.49 \pm 0.18 \mu$ M, respectively) but with slopes significantly greater than unity (Hill slopes = 1.8 ± 0.2 , 1.9 ± 0.1 , and 1.7 ± 0.2 , respectively). Unlike its effect on adenosine receptors, SCH-202676 did not inhibit the binding of the newly available $P2Y_1$ receptor antagonist [³H]MRS2279 (Waldo et al., 2002) to P2Y₁ receptors. In contrast, the selective P2Y1 receptor antagonist MRS2179 displaced the binding of [3H]MRS2279 corresponding to an IC_{50} value of 171 \pm 36 nM and a slope of 1.1 \pm 0.1. Because there is a pronounced species difference between human and rat adenosine A3 receptors, we further examined the ability of SCH-202676 to displace [125]II-AB-MECA binding to the rat adenosine A₃ receptor. The IC₅₀ and slope values were determined to be $0.82 \pm 0.11 \mu$ M and 1.7 ± 0.1 , respectively, which are similar to those of human adenosine A₃ receptors.

We next examined the effect of SCH-202676 on the dissociation of antagonists from adenosine receptors. Fig. 2 shows that 10 μ M SCH-202676 dramatically decreased the dissociation rate of [³H]DPCPX while increasing the [³H]ZM241385 dissociation rate from A₁ and A_{2A} receptors, respectively. In contrast, the dissociation rate of [³H]PSB-11 from adenosine A₃ receptors was not significantly influenced. The dissociation rate of [³H]MRS2279 from the hP2Y₁ receptor, like the dissociation rate from adenosine A₃ receptors, was not influenced by 10 μ M SCH-202676 (data not shown).

In contrast to the effects of SCH-202676 on the antagonist dissociation rates, the dissociation of agonists [³H]R-PIA from adenosine A₁ or [³H]CGS21680 from A_{2A} receptors was not significantly influenced, but the [¹²⁵I]I-AB-MECA dissociation rates from both human (Fig. 2) and rat (data not shown) adenosine A₃ receptors were significantly increased. The dissociation rates in the absence and presence of 10 μ M SCH-202676 were summarized in Table 1.

In order to explore further the effects of SCH-202676 on adenosine receptors, saturation experiments were performed on A₁ receptors in the absence and presence of a range of concentrations of SCH-202676 (Fig. 3). SCH-202676 significantly increased the K_d (5.44 \pm 0.39 nM at 3 μ M versus 2.04 \pm 0.36 nM for control) while decreasing the B_{max} values of the agonist radioligand [³H]R-PIA (p < 0.05). For binding of the antagonist radioligand [³H]DPCPX, 10 μ M SCH-202676 significantly increased the B_{max} but not the K_d value.

Discussion

The present study demonstrated that SCH-202676 is an allosteric modulator for human adenosine A_1 , A_{2A} , and A_3 receptors but not for P2Y₁ receptors, which respond to adenosine 5'-diphosphate. SCH-202676 allosterically modulated adenosine receptors in a manner that was both unique and selective. The structural basis for these differences remains to be elucidated. Fawzi et al. (2001) suggested that the allosteric effects of SCH-202676 may occur through a structural motif common to many G protein–coupled receptors or conceivably by activation or inhibition of an unidentified accessory protein that regulates the G protein–coupled receptors. We envision following these initial observations with receptor mutagenesis experiments.

Allosteric modulation of adenosine receptors has been extensively studied in adenosine A1 receptors (Bruns and Fergus, 1990; Linden, 1997; van der Klein et al., 1999; Tranberg et al., 2002) and to a lesser extent in adenosine A2A receptors (Gao and IJzerman, 2000). We recently identified and characterized several chemical classes of allosteric modulators for adenosine A₃ receptors, including the imidazoquinoline DU124183, the pyridinylisoquinoline VUF5455, and amiloride analogues (Gao et al., 2001, 2002, 2003a,b). In contrast to the effect of the classical allosteric modulator PD81723 on A1 receptors, which decreased agonist dissociation rate but did not affect antagonist dissociation (Bruns and Fergus, 1990), SCH-202676 dramatically decreased the adenosine A₁ receptor antagonist dissociation rate but did not affect adenosine A1 receptor agonist dissociation. Based on the available data, SCH-202676 appears to have a different mechanism of action compared to the prototypic adenosine receptor allosteric modulator, PD81723. SCH-202676 is different from DU124183, and VUF5455 in its effect on the A₃ receptors; it increased adenosine A3 receptor agonist dissociation without affecting A3 receptor antagonist dissociation (Gao et al., 2001, 2002). The effects of SCH-202676 are also different from those of amiloride analogues. Amiloride analogues increased antagonist dissociation rates from all three subtypes of adenosine receptors but only decreased the agonist dissociation rate from adenosine A3 receptors (Gao and IJzerman, 2000; Gao et al., 2003a,b).

SCH-202676 has potent antagonist activity for several G protein-coupled receptors (Fawzi et al., 2001), however, it is not yet known if SCH-202676 is an antagonist for adenosine receptors or not as functional assays were performed in the present study. It can be seen from Fig. 3 that SCH-202676 does not affect agonist and antagonist binding equally, which suggests that its effects on adenosine receptors and other G protein-coupled receptors are different (Fawzi et al., 2001). SCH-202676 decreased agonist binding but also increased antagonist binding at a higher concentration (10 μ M), which is similar to that of sodium ions in this respect (Gao and IJzerman, 2000). SCH-202676 apparently decreased the dissociation rate of the antagonist radioligand [³H]DPCPX, however, the binding affinity of [³H]DPCPX was not increased as demonstrated in the saturation binding, suggesting that SCH-202676 may also decrease the association rate.

In summary, SCH-202676 inhibited the binding of radiolabeled ligands to human adenosine A_1 , A_{2A} , and A_3 receptors, with IC₅₀ values in the range of 0.5–0.8 μ M, but failed to displace binding to human P2Y₁ nucleotide receptors. The rate of antagonist dissociation was dramatically slowed at the adenosine A_1 receptor, accelerated at the adenosine A_{2A} receptor, and not affected at the adenosine A_3 receptor by SCH-202676. In contrast, the dissociation rates of adenosine A_1 and A_{2A} receptor agonists were not significantly affected, and the dissociation rate of an adenosine A_3 receptor agonist increased. Thus, SCH-202676 differentially modulated adenosine A_1 , A_{2A} , and A_3 receptors as well as agonist- and antagonist-occupied receptors.

Acknowledgements

We thank Dr. Gary Stiles (Duke University, Durham, NC, USA) for gifts of CHO cells expressing human and rat adenosine A₃ receptors, Dr. Joel Linden (University of Virginia, Charlottesville, VA, USA) for the gift of HEK293 cells expressing human adenosine A_{2A} receptors, Dr. T. Kendall Harden (University of North Carolina, Durham, NC, USA) for the gift of astrocytoma cells expressing human P2Y₁ receptors, and Dr. Christa Müller (Pharmaceutical Institute, University of Bonn, Germany) for providing [³H]PSB-11.
