**Abstract:** Background: Numerous studies have evaluated the association between *NQ01* 609C>T polymorphism and gastrointestinal (GI) cancer. However, the results remain inconclusive. To obtain a more precise estimation of the relation, we conducted an analysis of all available case-control studies. Methods: Eligible studies were identified by searching the databases and finally 19 articles were included in the meta-analysis. Odds ratio (OR) with 95% confidence interval (95% CI) was applied to assess the association between *NQ01* 609C>T polymorphism and GI cancer risk. Z test was used to evaluate the significance of OR and 95% CI. Results: In the overall analysis, there existed a significant association between *NQ01* 609C>T polymorphism and GI cancer susceptibility (T vs. C: OR = 1.07, 95% CI = 1.01-1.14). The subgroup analysis based on ethnicity showed that *NQ01* 609C>T polymorphism was associated with susceptibility to GI cancer in mixed population (TT vs. CC: OR = 2.21, 95% CI = 1.44-3.40; TT vs. CT + CC: OR = 2.26, 95% CI = 1.48-3.44; Allele T vs. Allele C: OR = 1.24, 95% CI = 1.05-1.47). For the subgroup analysis according to source of control, a remark relationship of 609C>T with increased risk of GI cancer was observed in HB population (Allele T vs. Allele C: OR = 1.07, 95% CI = 1.01-1.14). Conclusion: Our results demonstrated that *NQ01* 609C>T polymorphism might be associated with susceptibility to GI cancer.

Keywords: NQ01, polymorphism, gastrointestinal cancer

#### Introduction

Gastrointestinal (GI) cancer mainly affects the digestive system that involves cancers of oesophagus, gallbladder, liver, pancreas, stomach and bowel [1-4]. It has been reported that the incidence of GI cancer is increasing, with approximately 2 million new cases worldwide per year. As we all know, GI cancer arises from stomach and small intestine [5-9], but the pathogenesis of it is still unclear. Genetic factors, including the sequence alterations and organization aberrations of the cellular genome that range from single-nucleotide substitutions to gross chromosome, could modulate important biological progresses and alter susceptibility to cancers consequently [10, 11]. Recently, many studies have investigated the role of NQ01 gene in the pathogenesis of GI cancer.

NQ01 gene is located on chromosome 16q22.1, spanning 17.2 kb and consisting of 6 exons and 5 introns [12], which encodes NAD(P)H dehydrogenase 1 [13]. The gene is a member of NAD(P)H dehydrogenase family and encodes a cytoplasmic 2-electron reductase. The studies have suggested that mutations in NQO1 are associated with increased risk of tardive dyskinesia (TD), hematotoxicity after exposure to benzene and cancers [14]. The 609C>T polymorphism, with proline-to-serine amino acid change, is implicated in pathogenesis of cancers [15]. Although the relationship of NQ01 609C>T polymorphism with GI cancer has been extensively investigated, the results were still inconclusive.

The reported genetic effects varied across the published studies, and a clear impact on can-

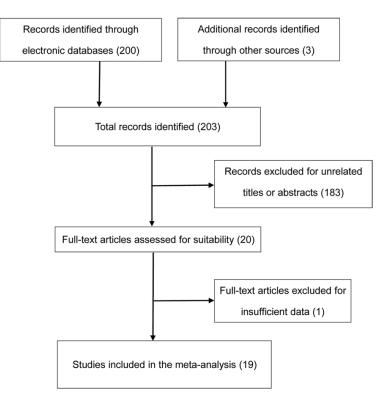

Figure 1. Flow diagram of the study selection process.

cer risk is also limited by the insufficient statistical power of these individual studies with a relatively small sample size. Therefore, we performed a meta-analysis, based on published articles, to evaluate the influence of the *NQO1* 609C>T polymorphism on the risk of Gl cancer.

# Materials and methods

# Searching strategy

Databases of PubMed, EMBASE, and other database were searched to retrieve eligible studies. Key words included "gastrointestinal", "*NQO1*", "polymorphism", "cancer", "esophageal", "stomach" and "gastric". Reference lists of related studies and reviews were manually searched for additional publications.

# Inclusion criteria

We defined inclusion criteria as follows: written in English or Chinese; case-control design; sufficient information for estimating ORs and their 95% Cls; genotype frequencies in the controls were in agreement with Hardy-Weinberg equilibrium (HWE). Meanwhile, if the studies showed overlapping data, the most recent study with larger sample size was selected.

Quality assessment

The quality of each study was assessed by the Newcastle-Ottawa quality assessment scale.

## Data extraction

Data were extracted from included studies independently by authors. For each study, the following data were collected: last name of the first author, year of publication, country, ethnicity, study design, numbers of subjects, source of controls, genotyping method, allele and genotype frequencies. In case of conflicting evaluations, disagreements were resolved through discussion by other authors.

# Statistical analysis

Hardy Weinberg Equilibrium (HWE) was tested in control group with chi-square test. The association between NQ01 609C>T polymorphism and GI cancer risk was estimated by pooled ORs with 95% CIs. Pooled ORs and 95% CI were calculated under the five genetic models of TT vs. CC, TT + CT vs. CC, TT vs. CT + CC, Allele T vs. Allele C and CT vs. CC. Z test was used to evaluate the significance of the pooled OR, and if P < 0.05, statistically significance was confirmed. Q test was used to check the statistical heterogeneity between studies. The heterogeneity was considered significant when P < 0.10. The fixed-effects model (based on Mantel-Haenszel method) or random-effects model (based on DerSimonian-Laird method) was used to calculate ORs with 95% CIs in the overall analysis. The random-effects model was employed when there was significant heterogeneity; otherwise, the fixed-effects model was applied. Sensitivity analyses were performed to identify the effect of individual study on pooled results and test the reliability of results. Potential publication bias were estimated by Begg's funnel plot and Egger's linear regression test, and P < 0.05 was considered signifi-

cant. All the analysis was conducted with STATA Version 12.0 software.

#### Results

### Study characteristics

Through literature search, a total of 203 relevant studies were identified (**Figure 1**). After careful review and selection, 19 eligible casecontrol studies were included in this meta-analysis [16-34]. The detailed characteristics of eligible studies were summarized in **Table 1**.

### Meta-analysis results

In order to explore the association between NQ01 609C>T polymorphism and the risk of GI cancer, a meta-analysis was conducted. The pooled ORs and their 95% CIs were calculated under the fixed effects model. In the overall analyses, we found that there was a significant association between NQ01 609C>T polymorphism and GI cancer susceptibility (T vs. C: OR = 1.07, 95% CI = 1.01-1.14). In addition, we conducted subgroup analysis according to ethnicity and source of control.

### Subgroup analysis for ethnicity

The meta-analysis included 10 studies in Caucasian population, 7 studies in Asian population, and 2 studies in mixed population. The

pooled ORs with their 95% CIs are shown in **Table 2**. In the analysis, a remark relationship of *NQO1* 609C>T polymorphism and risk of GI cancer was observed in mixed population (TT vs. CC: OR = 2.21, 95% CI = 1.44-3.40; TT vs. CT + CC: OR = 2.26, 95% CI = 1.48-3.44; Allele T vs. Allele C: OR = 1.24, 95% CI = 1.05-1.47).

### Subgroup analysis for source of control

The meta-analysis included 16 hospital-based (PB) studies and 3 population-based (HB) studies. The details about the ORs with 95% Cls were shown in **Table 3**. The results showed that NQO1 609C>T was associated with increased risk of Gl cancer (Allele T vs. Allele C: OR = 1.07, 95% Cl = 1.01-1.14) in HB population not in PB population.

### Sensitivity analysis

Sensitivity analysis was conducted in order to evaluate the influence of each single publication on the overall results. After excluding each study one by one at a time and comparing the results before and after, we did not find any remarkable changes, which suggested that our meta-analysis results were stable.

#### Publication bias

Begg's funnel plot and Egger's test were performed to assess the publication bias. The

	Genetic model	OR (95% CI)	P (P value of heterogeneity)
Overall			
	TT vs. CC	1.15 (0.99-1.33)	0.202
	TT + CT vs. CC	1.07 (1.00-1.14)	0.728
	TT vs. CT + CC	1.13 (0.98-1.30)	0.129
	Allele T vs. Allele C	1.07 (1.01-1.14)	0.147
	CT vs. CC	1.06 (0.99-1.44)	0.798
Ethnicity			
Caucasians	TT vs. CC	1.05 (0.81-1.37)	0.790

HB: hospital-based; PB: population-based.

shape of the funnel plot revealed no obvious asymmetry. Moreover, the Egger's test showed no obvious publication bias (P = 0.352).

#### Discussion

GI cancer is a rare, slow-growing cancer that affects certain cells in the lining of the stomach and intestines [35]. It has been demonstrated that hormones secreted by the cells could regulate the production of digestive juices and muscles that move food through the stomach and intestines. Moreover, GI cancer is associated with increased risk of other cancers of digestive system, which seriously affects population lives. To obtain more information on the pathogenesis of GI cancer, many studies have investigated the association of genes with the risk of GI cancer.

NOO1 is an important enzyme which can catalyze the two-electron reduction of quinoid compounds into hydroquinones [36]. NAD (P) H, decoded by NOO1, also plays a prominent role in maintaining cellular homeostasis [37, 38]. Additionally, NQ01 is essential for the antioxidant defense system, stabilization of tumor suppressors and activation of quinone based chemotherapeutics. Overexpression of NOO1 in solid tumors coupling with its ability to convert quinone-based chemo-therapeutics into potent cytotoxic compounds has made it a very attractive target [39, 40]. Single-nucleotide polymorphisms (SNPs) in genes coding metabolizing enzymes could modulate genetic functions and cellular toxicity in response to chemicals. NQ01 is an important detoxification enzyme involved in the catabolism of 1,4-benzoquinone (1,4-BQ), a benzene metabolite believed to be associated with bonemarrow toxicity and leukemia [41]. In recent years, the relationship of NQ01 609C>T polymorphism with GI cancer also has been reported. Since

the effects of district, country and ethnicity, no conclusive results were obtained.

In the overall analyses, we detected a significant association between *NQO1* 609C>T polymorphism and GI cancer susceptibility. Indeed, in the subgroup analysis by ethnicity, significantly relationship was also found between *NQO1* 609C>T and GI cancer in the mixed group. In the subgroup analysis by source of control, significantly increased risk of GI cancer was observed in the HB group but not in the PB group. Further investigations with large sample sizes are needed to clarify the possible effects of *NQO1* 609C>T on GI cancer.

Heterogeneity is a potential problem when interpreting the results of all meta-analyses. Throughout the overall and subgroup analyses, the heterogeneity was not detected in the meta-analyses. Moreover, the sensitivity analysis and Egger'test suggested that our results were stable and reliable. However, several limitations should be addressed. First, most of the studies were involved in Caucasians and Asians, and only two studies were mixed ethnicities. Second, only published studies were included in the meta-analysis, therefore, publication bias might have occurred, even though the statistical test showed no bias. Third, the sample sizes of included studies were relatively small and the matching criteria for the cases and controls were also not strict. In conclusion, this meta-analysis suggested that NQO1 609C>T polymorphism may be associated with increased risk of GI cancer. Future larger and well-designed studies in different ethnic populations and different sites of GI cancer are needed to validate our findings.
