Communicated by Alfred P. Wolf, June 23, 1994 (received for review March 7, 1994)

**ABSTRACT** Three distinct genes encoding members of the D<sub>1</sub> dopamine receptor family were isolated from *Xenopus laevis*. Based on the deduced amino acid sequence, two of the receptors (*Xen* D<sub>1A</sub> and *Xen* D<sub>1B</sub>) appear to be homologues of mammalian D<sub>1</sub>/D<sub>1A</sub> and D<sub>5</sub>/D<sub>1B</sub> receptors. The third receptor, termed *Xen* D<sub>1C</sub>, displays equal overall amino acid and nucleotide sequence identity (≈55%) with mammalian D<sub>1A</sub> and D<sub>1B</sub>/D<sub>5</sub> receptors. In agreement with their structural similarities, *Xen* D<sub>1A</sub> and D<sub>1B</sub> receptors, when expressed in COS-7 cells, displayed pharmacological profiles that paralleled those of their mammalian counterparts, with dopamine and 2-amino-6,7-dihydroxytetralin exhibiting 10-fold higher affinity for D<sub>1B</sub> than for D<sub>1A</sub>. The *Xen* D<sub>1C</sub> receptor displayed an overall rank order of potency and pharmacological profile clearly indicative of a D<sub>1</sub>-like receptor, with individual affinities for most agonists higher than those for either *Xen* or mammalian D<sub>1</sub>/D<sub>1A</sub> and D<sub>5</sub>/D<sub>1B</sub> receptors, whereas antagonist K<sub>i</sub> values were intermediate to those for the D<sub>1</sub>/D<sub>1A</sub> and D<sub>5</sub>/D<sub>1B</sub> receptors. All three receptors stimulated adenylate cyclase activity in response to dopamine or SKF-82526. *Xen* D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptor mRNAs were differentially distributed, with all three receptors expressed in brain and only D<sub>1B</sub> and D<sub>1C</sub> receptors expressed in kidney. The existence of a receptor which lacks appreciable overall sequence similarity to, but displays pharmacological homology with, mammalian D<sub>1</sub>-like receptors lends strong support to the contention that additional mammalian D<sub>1</sub>-like receptor gene products may exist to allow for the expression of the full spectrum of D<sub>1</sub>-like dopamine receptor-mediated events.

D<sub>1</sub> dopamine receptors have been classically defined, on the basis of pharmacological and biochemical grounds, by their ability to bind and respond to selective dopaminergic ligands, particularly to the benzazepine class, and by coupling to second-messenger systems through the stimulation of adenylate cyclase (see refs. 1–4 for reviews). Molecular biological studies have revealed that native D<sub>1</sub> receptors actually comprise two receptor subtypes, D<sub>1</sub>/D<sub>1A</sub> and D<sub>5</sub>/D<sub>1B</sub>, each of which stimulates the activity of adenylate cyclase. These receptors are, however, distinguishable on the basis of their primary structure, pharmacological profiles, mRNA distribution, and chromosomal localization (5–8).

Despite the existence of two distinct D<sub>1</sub> dopamine receptors, biochemical, pharmacological, and behavioral evidence suggests the existence of additional D<sub>1</sub>-like receptor subtypes. Thus, D<sub>1</sub> receptor stimulation in both brain and periphery has been shown to activate phospholipase C (9–12), translocate protein kinase C (13), stimulate K<sup>+</sup> efflux (14), and inhibit Na<sup>+</sup>/H<sup>+</sup> exchange, all independent of the activity of adenylate cyclase (15–17). Moreover, recent behavioral studies have differentiated agonist specific D<sub>1</sub>-like receptor-mediated behaviors from the activity of D<sub>1</sub>-stimulated adenylate cyclase (18–22). It is unclear whether all these D<sub>1</sub>-like receptor-mediated responses can be accounted

for solely by the presence of D<sub>1</sub>/D<sub>1A</sub> and D<sub>5</sub>/D<sub>1B</sub> receptors (23, 24).

We report here the existence of three distinct genes encoding functional members of the D<sub>1</sub> dopamine receptor family from *Xenopus laevis*. These include a classical D<sub>1A</sub> receptor, a D<sub>1B</sub> receptor homologue, and a distinct D<sub>1</sub> receptor variant, which we term D<sub>1C</sub>, displaying unique amino acid, pharmacological, and tissue-specific expression patterns. The cloning of a third type of vertebrate D<sub>1</sub>-like dopamine receptor suggests that additional D<sub>1</sub>-like gene products may be encoded in the mammalian genome which may account for some of the pharmacological and behavioral events following selective D<sub>1</sub>-like dopamine receptor stimulation.¶

### MATERIALS AND METHODS

**Isolation of *Xenopus* Genomic Clones.** A *X. laevis* genomic library (Stratagene) was screened first with a <sup>32</sup>P-labeled human D<sub>1</sub> dopamine receptor DNA fragment (25) corresponding to transmembrane domains 2–5. About 5 × 10<sup>5</sup> independent clones were screened under the following conditions: duplicate nylon filters (DuPont/NEN) were hybridized at 42°C in a solution (26) containing <sup>32</sup>P-labeled *Bgl* II–*Hind*III D<sub>1</sub> fragment (2 × 10<sup>6</sup> cpm/ml). Filters were washed once in 2× standard saline citrate (SSC)/1% SDS for 15 min at 60°C and then once in 1× SSC/1% SDS for 15 min at 60°C. The filters were stripped and were subsequently reprobated under identical stringency conditions with a <sup>32</sup>P-labeled D<sub>5</sub> dopamine receptor fragment (27) encoding transmembrane domains 2–5. One hybridizing clone, a 2.5-kb *Bam*HI fragment (*Xen* 1) was unique to only the D<sub>1</sub> screening, while two other clones, a 2.8-kb *Acc* I and a 3.0-kb *Pst* I fragment (*Xen* 2 and *Xen* 6, respectively), were identified by both D<sub>1</sub> and D<sub>5</sub> screenings, although *Xen* 6 hybridized poorly to the D<sub>5</sub> probe. Following subcloning into pBluescript SK(–) (Stratagene), both strands were sequenced by the Sanger dideoxy chain-termination method with 7-deaza-dGTP and Sequenase (United States Biochemical) and either specific internal primers (Biotechnology Service Centre HSC, Toronto) or T7/T3 primers.

**Cell Culture and Expression.** COS-7 monkey cells were grown on 150-mm plates in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum at 37°C, 5% CO<sub>2</sub>. The three genomic dopamine receptor clones were subcloned into the expression vector pCD-PS for transient expression (25). COS-7 cells were transfected with the CsCl gradient-purified constructs by electroporation (26).

**[<sup>3</sup>H]SCH-23390 Binding Assays.** Membranes prepared from harvested COS-7 cells grown on 150-mm plates were suspended in buffer at a protein concentration of 30–50 μg/ml

¶The sequences reported in this paper have been deposited in the GenBank data base [accession nos. U07863 (D<sub>1A</sub>), U07864 (D<sub>1B</sub>), and U07865 (D<sub>1C</sub>)].

and assayed for [<sup>3</sup>H]SCH-23390 (NEN; 85.5 Ci/mmol; 1 Ci = 37 GBq) binding activity (25). The data were analyzed by nonlinear least-squares fitting with the computer program KALEIDAGRAPH (Abelbeck Software, Reading, PA).

**cAMP Accumulation.** COS-7 cells transiently transfected with the D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> clones or untransfected cells were grown in 24-well plates. After 72 hr, the wells were washed once with prewarmed (37°C) Dulbecco's modified Eagle's medium containing 0.5 mM 3-isobutyl-1-methylxanthine and 1 μM propranolol. Cells were incubated in 0.4 ml of the aforementioned medium in the presence or absence of 1 μM SCH-23390 for 15 min at 37°C, 5% CO<sub>2</sub>. Either dopamine (10 μM) or SKF-82526 (1 μM) was added for an additional 15 min of incubation at 37°C, 5% CO<sub>2</sub>. Reactions were stopped by the addition of 500 μl of 0.2 M HCl, the cellular debris was pelleted by centrifugation at 500 × g, and supernatants (25 μl) were assayed for cAMP formation by radioimmunoassay (Amersham).

**Reverse Transcription-PCR Analysis of D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> Receptor mRNA.** Total *Xenopus* brain and kidney RNAs were isolated by using TRISOLV (Biotech Laboratories, Houston). Samples (≈1 μg) of brain and kidney total RNA were treated with DNase for 15 min at room temperature prior to first-strand cDNA synthesis with 25 pmol of oligo(dT) (Perkin-Elmer/Cetus) and 200 units of Superscript reverse transcriptase (BRL). The single-stranded cDNA was then subjected to 30 cycles of PCR amplification (94°C, 1 min; 58°C, 1.5 min; 72°C, 1.5 min) using 0.5 μg of two receptor-specific internal oligonucleotide primers encompassing the carboxyl tail regions of the three dopamine receptor clones [nucleotides: D<sub>1A</sub>, 920–943 (5'–3') and 1406–1383 (3'–5'); D<sub>1B</sub>, 988–1014 (5'–3') and 1401–1375 (3'–5'); D<sub>1C</sub>, 856–888

(5'–3') and 1464–1441 (3'–5')] and 2 units of *Taq* DNA polymerase (Perkin-Elmer/Cetus). A DNase control group in which reverse transcriptase was not added was processed in parallel. Amplified products were electrophoresed in a 1.5% agarose gel, transferred to nylon membrane for Southern blot analysis, probed with γ-<sup>32</sup>P end-labeled oligonucleotides internal to the flanking primers [D<sub>1A</sub>, 1141–1164 (5'–3'); D<sub>1B</sub>, 1306–1329 (5'–3'); D<sub>1C</sub>, 1089–1112 (5'–3')], and washed in 2× SSC/1% SDS for 15 min at room temperature and then for 15 min at 42°C.

**RESULTS AND DISCUSSION**

An approach based on homology probing and multiple subtractive screenings was used to clone three distinct members of the D<sub>1</sub> dopamine receptor family. Sequence analysis indicated that all three clones shared strong amino acid sequence homology to mammalian D<sub>1</sub>-like dopamine receptors. A putative initiation methionine codon with predicted Kozak sequence (28) was followed by long open reading frames uninterrupted by intronic sequences for all three clones. *Xen* 1, 2, and 6 contained open reading frames of 1353, 1371, and 1395 nt, encoding proteins with calculated molecular masses of 50,516, 51,622, and 52,606 Da, respectively.

The deduced amino acid sequences of the isolated clones revealed that *Xen* 1 may be an orthologue of the mammalian D<sub>1</sub>/D<sub>1A</sub> receptor and *Xen* 2, the equivalent of the D<sub>5</sub>/D<sub>1B</sub> receptor (Fig. 1). *Xen* 1 shared highest overall amino acid sequence identity (80%) with the human D<sub>1</sub> receptor and showed only 54% and 52% identity with human D<sub>5</sub> and rat D<sub>1B</sub> receptors, respectively. *Xen* 2 displayed the highest

**FIG. 1.** Alignment of the deduced amino acid sequence (single-letter symbols) of *Xenopus* D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptors with other members of the D<sub>1</sub> dopamine receptor subfamily. Boxed and shaded regions indicate amino acid residues absolutely conserved among all D<sub>1</sub>-like receptors represented. Positions of seven putative transmembrane domains are demarcated above the amino acid sequence. Putative N-linked glycosylation sites are indicated by arrows. Potential cAMP-dependent protein kinase (●) and protein kinase C (■) phosphorylation sites are indicated. Sequence sources are as follows: human D<sub>1</sub> (25, 29), rat D<sub>1A</sub> (29), goldfish D<sub>1A</sub> (30), human D<sub>5</sub> (26, 31, 32), and rat D<sub>1B</sub> rat (23).

sequence identities, 66% and 65%, with the rat D<sub>1B</sub> and human D<sub>5</sub> receptors, respectively, and only 55% identity with the human D<sub>1</sub> receptor. Although *Xen 2* displayed greater sequence divergence from mammalian D<sub>5</sub>/D<sub>1B</sub> receptors than either the rat D<sub>1B</sub> receptor from the human D<sub>5</sub> receptor ( $\approx 82\%$ ) or *Xen 1* from mammalian D<sub>1</sub>/D<sub>1A</sub> receptors ( $\approx 80\%$ ), the low overall percent homology of *Xen 2* to its mammalian counterparts is well in accord with the predicted (33) accelerated rate of evolutionary mutation exhibited by D<sub>5</sub>/D<sub>1B</sub> receptors ( $\approx 1\%$  per  $8 \times 10^6$  years) compared with D<sub>1A</sub> receptors ( $\approx 1\%$  per  $1.2 \times 10^7$  years). Consistent with the view that *Xen 2* is a D<sub>5</sub>/D<sub>1B</sub> species homologue is the fact that at the nucleotide level *Xen 2* is more homologous (66%) to the human D<sub>5</sub> receptor and its two pseudogenes (64% and 65%) than either *Xen 1* ( $\approx 53\%$ ) or *Xen 6* (59% to D<sub>5</sub>; 48% and 59% to two pseudogenes). At the amino acid level, *Xen 6* appears distinct, displaying equivalent overall sequence identities to either the rat D<sub>1B</sub> (56%) or human D<sub>1</sub> and D<sub>5</sub> receptors (54%). Within the putative transmembrane domains *Xen 1*, *2*, and *6* exhibit  $>92\%$  identity with mammalian D<sub>1</sub>-like receptors. Regions of significant sequence divergence between these receptors were particularly evident in the amino termini, third intracellular and extracellular loops, the fourth extracellular domain, and carboxyl-terminal tails. Based on the strong overall sequence homologies to either the mammalian D<sub>1</sub>/D<sub>1A</sub> or D<sub>5</sub>/D<sub>1B</sub> receptors, aligned in Fig. 1, we propose to term the proteins encoded by the *Xen 1*, *Xen 2*, and *Xen 6* clones the D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptors, respectively, in line with the nomenclature scheme originally suggested for multiple rat D<sub>1</sub> receptors (8, 23).

Consensus sequences for putative posttranslational modifications have been remarkably conserved between *Xenopus* and mammalian D<sub>1</sub>-like receptors. Two conserved N-linked glycosylation sites are found within the amino terminus and third extracellular loop for all three *Xenopus* receptors, similar to the mammalian counterparts (Fig. 1). The D<sub>1C</sub> receptor, however, contains an additional site in the amino terminus. In addition, several conserved putative protein kinase C and cAMP-dependent protein kinase phosphorylation sites are present in the third cytoplasmic loop for all three clones, at positions essentially like those in the mammalian D<sub>1</sub>-like receptors. The D<sub>1C</sub> receptor displays two additional protein kinase C consensus sites, located within the carboxyl tail (Fig. 1), whose functional significance is unknown. Notable amino acids that are conserved among the three D<sub>1</sub> clones from *Xenopus* and all other dopamine receptors include the aspartic residue in transmembrane domain 3 and two serine residues in transmembrane domain 5 that may form part of the dopamine binding pocket (34). Also conserved is a carboxyl-terminal cysteine that could serve as a site for palmitoylation (35) and two cysteine residues thought to take part in disulfide bond formation between the second and third extracellular loops (36).

To justify our proposed nomenclature scheme, we further characterized these receptors in terms of their pharmacological profiles. Following expression in COS-7 cells, all three receptors bound the D<sub>1</sub> receptor antagonist [<sup>3</sup>H]SCH-23390 in a saturable manner to a single class of binding sites with high affinity and with estimated dissociation constants ( $K_d$  values) of 250, 350, and 80 pM for the D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptors, respectively. Saturation analysis revealed receptor densities ( $B_{max}$  values) that were on average 15, 7, and 0.6 pmol/mg of protein for D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub>, respectively. [<sup>3</sup>H]SCH-23390 binding to membranes of COS-7 cells expressing D<sub>1A</sub>, D<sub>1B</sub>, or D<sub>1C</sub> receptors was inhibited by various dopaminergic agonists and antagonists, in a stereoselective, concentration-dependent, and uniphasic manner (as indexed by Hill coefficients close to unity) with a pharmacological

profile clearly indicative of a D<sub>1</sub> receptor. Estimated  $K_i$  values for these agents are listed in Table 1.

One unique distinguishing pharmacological feature between mammalian D<sub>1</sub>-like dopamine receptors is the inherent ability of the D<sub>5</sub>/D<sub>1B</sub> receptor to display higher affinity for the endogenous neurotransmitter dopamine than D<sub>1</sub>/D<sub>1A</sub> (23, 27, 31, 32). Consistent with our proposed classification of these receptors based on amino acid sequence homologies, the *Xen* D<sub>1A</sub> receptor displayed an affinity for dopamine ( $\approx 4 \mu\text{M}$ ) 10-fold less than that of the *Xen* D<sub>1B</sub> receptor ( $\approx 500 \text{ nM}$ ) (Fig. 2A), paralleling their mammalian counterparts. Moreover, like the mammalian D<sub>5</sub>/D<sub>1B</sub> receptor, 2-amino-6,7-dihydroxytetralin exhibited a 10-fold higher affinity for the *Xen* D<sub>1B</sub> receptor than for the *Xen* D<sub>1A</sub> receptor. Most antagonists, particularly butaclamol and  $\alpha$ -flupentixol, exhibited lower affinities for the D<sub>1B</sub> receptor than for the D<sub>1A</sub> receptor, similar to those seen with the rat D<sub>1B</sub> and human D<sub>5</sub> receptor. Estimated  $K_i$  values for the inhibition of [<sup>3</sup>H]SCH-23390 binding to *Xen* D<sub>1A</sub> and D<sub>1B</sub> receptors by a series of compounds were highly correlated to  $K_i$  values obtained on the human D<sub>1</sub> and D<sub>5</sub> receptors, respectively, with a virtual one-to-one correspondence in drug affinities.

The D<sub>1C</sub> receptor, however, displayed pharmacological characteristics consistent with both types of receptors, with an observed affinity for dopamine ( $K_d \approx 800 \text{ nM}$ ) somewhat intermediate to the affinities of D<sub>1</sub> and D<sub>5</sub> receptors. Similar results were obtained for 2-amino-6,7-dihydroxytetralin. All other agonists displayed somewhat higher affinity for the D<sub>1C</sub> receptor than for the D<sub>1A</sub> or D<sub>1B</sub> receptor. Most antagonists exhibited affinities at the D<sub>1C</sub> receptor intermediate to those for the D<sub>1A</sub> and D<sub>1B</sub> receptors (Table 1). Comparison of the

†Compound that distinguishes mammalian D<sub>1</sub>/D<sub>1A</sub> from D<sub>5</sub>/D<sub>1B</sub> receptors.

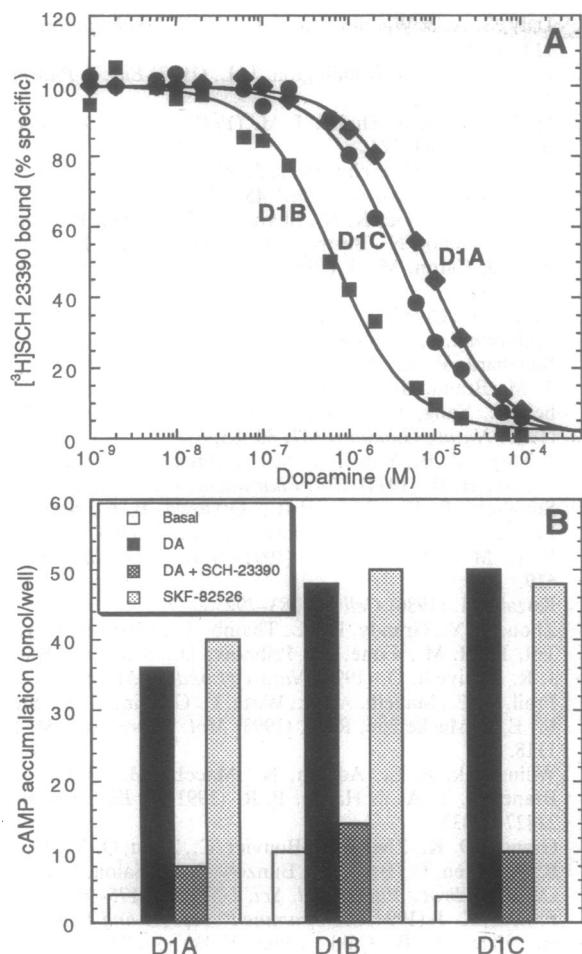

FIG. 2. Dopamine affinity and second-messenger activation of *Xenopus* D<sub>1</sub>-like receptors. (A) COS-7 cell membranes expressing either D<sub>1A</sub>, D<sub>1B</sub>, or D<sub>1C</sub> receptors were incubated with ≈300 pM [<sup>3</sup>H]SCH-23390 in the presence of the indicated concentrations of dopamine and assayed for receptor activity. Estimated  $K_i$  values for dopamine at each of these receptors are listed in Table 1. Data are representative of three independent experiments, each conducted in duplicate. (B) cAMP accumulation in COS-7 cells transiently expressing the D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptors. Approximately 2.5 × 10<sup>5</sup> cells were incubated with 10 μM dopamine (DA) or 1 μM SKF-82526 and assayed for cAMP content by radioimmunoassay. Dopamine-stimulated cAMP production was prevented by the specific D<sub>1</sub> antagonist SCH-23390 (1 μM). Basal cAMP ranged from 3 to 8 pmol per well. Stimulation of adenylate cyclase by 100 μM forskolin resulted in levels of cAMP >120 pmol per well. Data are representative of three independent experiments, each conducted in duplicate.

$K_i$  values of various agonists and antagonists revealed that the *Xen* D<sub>1C</sub> receptor displayed higher affinities for agonists and lower affinities for most nonselective D<sub>1</sub> antagonists than the human D<sub>1</sub> receptor. In contrast, comparison of the  $K_i$  values for these agents at the D<sub>1C</sub> receptor with those at the human D<sub>5</sub> receptor revealed a closer correspondence in estimated affinity values between these two receptors, albeit with some agonists, such as dopamine and apomorphine, clearly lying outside the line of equimolarity. As none of the receptors displayed guanine nucleotide-sensitive high-affinity forms (data not shown), it is possible to directly compare agonist affinities of these receptors with those of their mammalian counterparts expressed in the same cells and assayed under similar conditions.

Despite the distinct pharmacological profile of the D<sub>1C</sub> receptor, all three receptors were found to couple to the same second-messenger system when expressed in COS-7 cells.

Dopamine (10 μM) and the selective D<sub>1</sub> agonist SKF-82526 (1 μM) stimulated the production of cAMP 5- to 10-fold over basal levels, whereas pretreatment with the D<sub>1</sub> receptor antagonist SCH-23390 (1 μM) virtually abolished the stimulatory effect of dopamine (Fig. 2B). However, no consistent stimulation of phosphatidylinositol turnover was seen with dopamine or SKF-82526 up to 100 μM. It is unknown whether this lack of response in COS-7 cells is due to the inappropriate complement of subtype-specific G-protein α or βγ subunits needed for specific *Xen* D<sub>1</sub>-like receptor stimulation of phospholipase C or due to the lack of the appropriate molecular form of the enzyme. Coexpression studies with these proteins in COS-7 cells may reveal receptor-specific functional coupling to phospholipase C and phosphatidylinositol hydrolysis (37, 38).

Despite the lack of functional differentiation, D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptor mRNAs appear to be differentially distributed in central and peripheral tissues. All three receptor mRNAs were found to be expressed in brain but only the D<sub>1B</sub> and D<sub>1C</sub> receptors were present in kidney as determined by reverse transcription-PCR analysis (Fig. 3). In contrast, both the D<sub>1A</sub> and D<sub>1B</sub> receptors have been detected in opossum kidney (39), whereas the D<sub>1A</sub> receptor has been detected in the rat proximal tubule by PCR analysis (40). The selective lack of expression of D<sub>1A</sub> receptor mRNA in *Xenopus* kidney suggests that in frogs, unlike mammals, central and peripheral D<sub>1</sub>-like receptor expression is differentiated. Moreover, the expression of the D<sub>1C</sub> receptor in kidney may reflect the reported difference in pharmacological profiles between central and peripheral D<sub>1</sub>-like receptors (ref. 17 and references therein).

The D<sub>1C</sub> receptor subtype probably did not arise from a duplication event that occurred 25–30 million years ago in *Xenopus* (41), since duplicated genes in this tetraploid organism tend to be structurally more similar than predicted for these three clones. The D<sub>1A</sub> receptor shares only 59% nucleotide identity with *Xenopus* D<sub>1B</sub> and D<sub>1C</sub> receptors, while the D<sub>1B</sub> and D<sub>1C</sub> receptors are only 57% identical at the amino acid level and 61% identical at the nucleotide level. This situation is distinct from the two recently cloned dopamine D<sub>2</sub> receptors and other gene pairs from *Xenopus* such as the

FIG. 3. Tissue-specific D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptor mRNA distribution. Samples (1 μg) of *Xenopus* brain and kidney total mRNA were subjected to reverse transcription using oligo(dT) and then to PCR using two additional subtype-specific receptor oligonucleotides (Materials and Methods). Amplified cDNA products were Southern blotted and probed with receptor subtype-specific <sup>32</sup>P-labeled oligonucleotides internal to the PCR fragments. D<sub>1A</sub>, D<sub>1B</sub>, and D<sub>1C</sub> receptor transcripts of the appropriate sizes were evident in brain. Only D<sub>1B</sub> and D<sub>1C</sub> receptor mRNAs could be amplified from kidney. DNase controls with no reverse transcriptase (-) are located to the right of each hybridizing PCR product. Sizes of hybridizing bands (bp) are shown.

preproinsulins, proopiomelanocortins, and proenkephalins which share 92–95% nucleotide and amino acid identity (42–46). The low homologies displayed between the members of the *Xenopus* D<sub>1</sub> receptor family suggest that they diverged prior to the predicted duplication event, in accord with the proposed early evolutionary appearance (≈500 million years) and ancient status of the D<sub>1</sub>-like receptor subfamily (33).

The identification of the *Xen* D<sub>1C</sub> receptor, which lacks appreciable overall sequence similarity to, but displays a pharmacological profile consistent with, mammalian D<sub>1</sub>-like receptors may allow, with the use of inter- and intraspecies specific chimeras, the identification of those amino acid residues and structural motifs regulating D<sub>1</sub> ligand binding specificity, signal transduction, and receptor desensitization. Moreover, the existence of the D<sub>1C</sub> gene may aid in the isolation of mammalian homologues of this or related D<sub>1</sub> receptor variants which have so far eluded detection.
