Cell proliferation and differentiation are highly coordinated processes. These two processes are disrupted during leukemogenesis, resulting in differentiation block and uncontrolled proliferation in leukemia. To understand the mechanisms disrupting the coordination between the two processes in acute promyelocytic leukemia (APL), we investigated the regulatory mechanism of the negative cell cycle regulator *CDKN2D* by the promyelocytic leukemia/retinoic acid receptor  $\alpha$  (PML/RAR $\alpha$ ) fusion protein and the role of *CDKN2D* in cell differentiation and proliferation. We found that *CDKN2D* expression in APL cells was significantly lower than that in normal promyelocytes. By chromatin immunoprecipitation and luciferase reporter assays, we showed that PML/RAR $\alpha$  directly bound to and inhibited the transactivation of the *CDKN2D* promoter. Further evidence by the truncated and mutated *CDKN2D* promoters revealed that the everted repeat 8 (ER8) motif on the promoter was the binding site of PML/RAR $\alpha$ . Forced expression of *CDKN2D* induced G0/G1 phase arrest and partial granulocytic differentiation in APL-derived NB4 cells, suggesting the function of *CDKN2D* in regulating both cell proliferation and granulocytic differentiation. Furthermore, all-*trans* retinoic acid (ATRA) significantly induced *CDKN2D* expression in APL cells and knockdown of *CDKN2D* expression during ATRA treatment partially blocked the ATRA-induced differentiation and cell cycle arrest. Collectively, our data indicate that *CDKN2D* repression by PML/RAR $\alpha$  disrupts both cell proliferation and differentiation in the pathogenesis of APL, and induced expression of *CDKN2D* by ATRA alleviates the disruption of both processes to ensure treatment efficiency. This study provides a mechanism for coupling proliferation and differentiation in leukemic cells through the action of *CDKN2D*.

*Cell Death and Disease* (2014) 5, e1431; doi:10.1038/cddis.2014.388; published online 2 October 2014

Acute promyelocytic leukemia (APL), a distinct subtype of acute myeloid leukemia, is characterized by an oncogenic fusion protein of a translocation between chromosomes 15 and 17, promyelocytic leukemia/retinoic acid receptor  $\alpha$  (PML/RAR $\alpha$ ). PML/RAR $\alpha$  has an essential role in the leukemogenesis of APL by interfering with its target genes, eventually leading to a differentiation block at the promyelocytic stage and a hyperproliferation of blocked promyelocytes;<sup>1</sup> both are the hallmark features of APL. Pharmacological concentrations of all-*trans* retinoic acid (ATRA) can induce the degradation of PML/RAR $\alpha$  and restore the expression of those genes suppressed by PML/RAR $\alpha$ , resulting in the granulocytic differentiation and cell cycle arrest of leukemic cells.<sup>2</sup>

It has been well documented that cell proliferation and differentiation are two fundamental and distinct processes that must be coordinated during development and homeostasis.<sup>3</sup> Loss of coordination between the two processes usually leads to aberrant development and tumor formation.<sup>4</sup> A large

number of studies have shown that proliferation and differentiation in hematopoietic cells are modulated by different regulators. Cell proliferation is mainly controlled by the cell cycle machinery and apoptosis;<sup>5</sup> myeloid differentiation is generally orchestrated by tightly tuned activities of hematopoietic transcription factors.<sup>6</sup> Accordingly, during the pathogenesis of APL, abnormal differentiation block and uncontrolled cell proliferation are, respectively, attributed to disruption of differentiation- and proliferation-related regulators by PML/RAR $\alpha$ . For example, PML/RAR $\alpha$  blocks differentiation by interfering with the normal function of RAR $\alpha$  and PU.1.<sup>7,8</sup> On the other hand, PML/RAR $\alpha$  alters cell proliferation by impairing the formation of functional PML nuclear bodies, which suppresses cell growth by inducing G1-phase arrest and apoptosis.<sup>9,10</sup>

Interestingly, emerging evidence suggests that cell differentiation and proliferation can be controlled by the same regulators. Certain dual-function regulators may serve as links

for coordinating cell proliferation and differentiation. For example, HoxA10 can simultaneously affect both cell proliferation and differentiation during the development of hematopoiesis,<sup>11</sup> resulting in precise and highly coordinated developmental changes of blood cells. Dysregulation of HoxA10 participates in perturbing both cell proliferation and differentiation, resulting in the occurrence of acute myeloid leukemia.<sup>12</sup> However, the molecular mechanisms underlying the coordination of cell proliferation and differentiation are just beginning to be understood. Emerging evidence suggests that cell cycle regulators, especially CDK inhibitors (CKIs), are involved in the regulation of differentiation in addition to their well-documented function of governing the cell cycle process.<sup>3</sup> On the basis of the exploration of verified PML/RAR $\alpha$  binding sites derived from several genome-wide screening,<sup>8,13</sup> of particular interest is *CDKN2D*, one of the INK4 family CKIs encoding p19INK4D.

CDKN2D is a member of the INK4 family CKIs. The INK4 family consists of CDKN2A, CDKN2B, CDKN2C and CDKN2D, and generally regulates the G1-to-S phase transition by specifically inhibiting the activity of CDK4 and CDK6.<sup>14</sup> The genes of the INK4 family act as tumor suppressors in the pathogenesis of many malignancies, including leukemia,<sup>14</sup> and provide a direct link between tumorigenesis and the loss of negative control of cell cycle progression. However, the role of the INK4 family participating in the differentiation block of malignant cells has not been clearly explored. It has been reported that, in normal neural development, CDKN2D is capable of deciding whether differentiation starts before or after cell cycle exit,<sup>15</sup> implicating its potential role in differentiation. In myeloid differentiation, CDKN2D promotes the differentiation and maturation of megakaryocytes by arresting endomitosis,<sup>16</sup> suggesting the ability of CDKN2D to regulate differentiation. However, it is unclear whether or not CDKN2D is involved in the coordination of abnormal

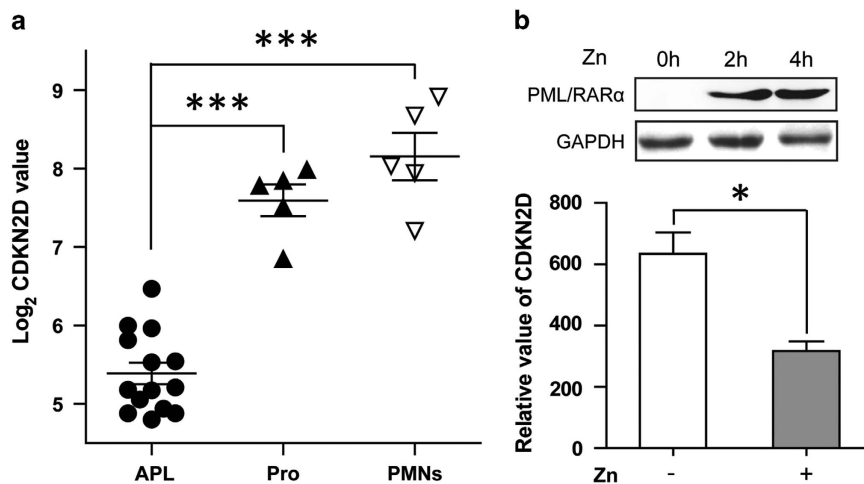

proliferation and differentiation of leukemia cells and the manner by which CDKN2D regulates these processes.

It is worth noting that CDKN2D expression is induced by 1,25-dihydroxy vitamin D3 (1,25-VD3) or retinoic acid (RA) in multiple cell lines, such as U937 myeloid leukemia cells, SCC25 head and neck squamous cell carcinoma cells and Calu-3 lung carcinoma cells,<sup>17</sup> suggesting that CDKN2D is a target of nuclear receptors and may be directly regulated by the oncogenic PML/RAR $\alpha$  fusion protein. To fully understand the leukemogenesis of APL, it is crucial to determine the role of PML/RAR $\alpha$  in the regulation of its target genes that regulate both cell proliferation and differentiation. In this study, we show that *CDKN2D* expression is directly repressed by the PML/RAR $\alpha$  fusion protein, and the decrease in *CDKN2D* expression contributes to the altered proliferation and differentiation block of APL cells. ATRA significantly induces *CDKN2D* expression, and increased expression of *CDKN2D* is linked to ATRA-induced differentiation and cell cycle arrest. Our data suggest the dual nature of CDKN2D in controlling both differentiation and proliferation.

## Results

### *CDKN2D* expression is significantly lower in APL cells than that in normal promyelocytes.

We initially compared *CDKN2D* expression in primary APL patient samples with that in normal promyelocytes. The expression profiles of samples from 14 APL patients, 5 normal promyelocytes and 5 peripheral mononuclear cells<sup>18</sup> were retrieved to perform the comparison. As shown in Figure 1a, the expression level of *CDKN2D* in APL patient samples was significantly lower than that in normal promyelocytes and peripheral mononuclear cells. To determine whether *CDKN2D* expression is inversely correlated with the PML/RAR $\alpha$  fusion protein in APL, we performed quantitative real-time RT-polymerase chain reaction (qRT-PCR) analysis to compare *CDKN2D* expression in

**Figure 1** *CDKN2D* expression is significantly lower in APL cells than that in normal promyelocytes. (a) The expression level of *CDKN2D* in APL patient samples was significantly lower than that in normal promyelocytes (Pro) and peripheral mononuclear cells (PMNs). The expression data were retrieved from microarray profiling performed by Payton JE *et al.* (GSE12662).<sup>18</sup> The expression values are absolute intensities after being log-transformed. (b) The upper panel shows the induced expression of PML/RAR $\alpha$  by ZnSO<sub>4</sub> (Zn) in PR9 cells using western blot analysis. The lower panel shows the reduced expression of *CDKN2D* after the induction of PML/RAR $\alpha$ . PR9 cells were treated with or without 100  $\mu$ M ZnSO<sub>4</sub> (Zn) for 4 h. The relative mRNA level of *CDKN2D* was normalized to GAPDH. \* indicates  $P < 0.05$ , \*\*\* indicates  $P < 0.001$

the presence or absence of PML/RAR $\alpha$  in PR9 cells, a PML/RAR $\alpha$ -inducible cell line. As shown in Figure 1b, *CDKN2D* expression was markedly decreased after the PML/RAR $\alpha$  induction. These results suggest that *CDKN2D* expression can be repressed by PML/RAR $\alpha$  in APL cells.

**PML/RAR $\alpha$  represses the transcription of *CDKN2D* through the everted repeat 8 (ER8) site on the *CDKN2D* promoter.**

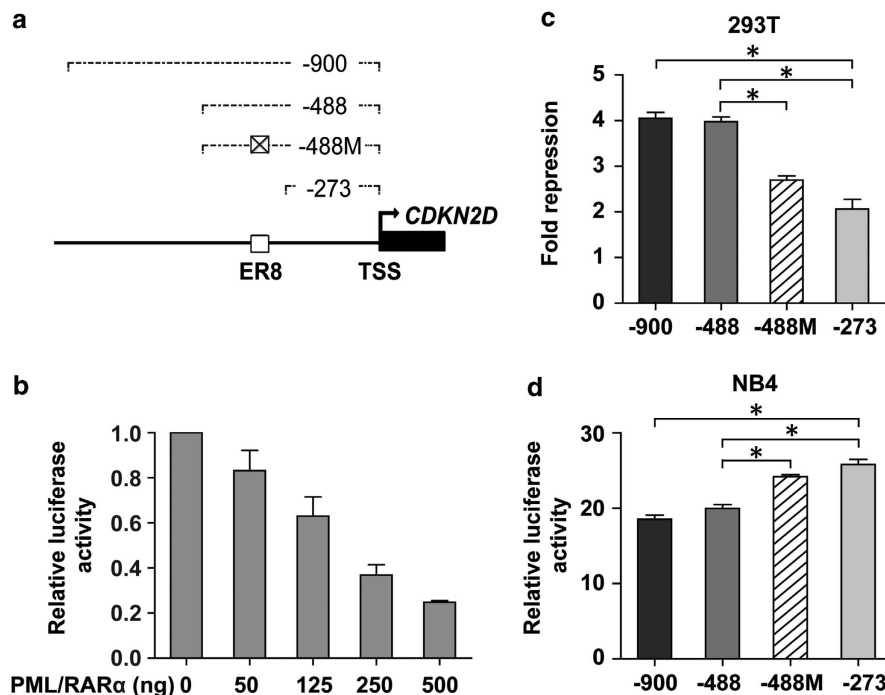

To determine whether reduced *CDKN2D* expression in APL cells is directly mediated by PML/RAR $\alpha$ , we cloned a 900-bp fragment of the *CDKN2D* promoter upstream of the transcriptional start site into a luciferase reporter plasmid to conduct promoter-reporter assays (Figure 2a). Increasing amounts of the pSG5-PML/RAR $\alpha$  expression construct were co-transfected into 293T cells along with the *CDKN2D* promoter plasmid. As shown in Figure 2b, *CDKN2D* promoter activity was repressed by PML/RAR $\alpha$  in a dose-dependent manner, indicating that *CDKN2D* expression was transcriptionally repressed by PML/RAR $\alpha$ . To locate the region within the *CDKN2D* promoter responsible for the PML/RAR $\alpha$ -mediated transcriptional repression, a series of 5' truncated luciferase constructs were co-transfected into 293T cells with the pSG5-PML/RAR $\alpha$  expression plasmid. As shown in Figure 2c, promoter activity of the -488 bp truncated form showed no significant change of the repression fold by PML/RAR $\alpha$ , as compared with the -900 bp form, indicating that the region from -900 bp to

-488 bp was less sensitive to PML/RAR $\alpha$ -mediated inhibitory effect than other regions. In contrast, truncation to -273 bp caused a significant reduction in the degree of PML/RAR $\alpha$ -mediated suppression, suggesting that the region between -488 bp and -273 bp might be essential for transcriptional repression of the *CDKN2D* promoter by PML/RAR $\alpha$ .

Analysis of the region between -488 bp and -273 bp of the *CDKN2D* promoter identified a 20 bp sequence (-368 bp to -349 bp) organized as an ER8 site, which is an everted repeat of two RA response element (RARE) half sites separated by eight nucleotides. This ER8 site has been reported to be involved in 1,25-VD<sub>3</sub>- or RA-induced *CDKN2D* expression in other cell lines,<sup>17</sup> providing the possibility that this site may be responsible for the PML/RAR $\alpha$ -mediated transrepression of *CDKN2D* in APL. To test this hypothesis, we mutated the ER8 site in the -488-bp construct and found that the repression was significantly relieved when the ER8 site was mutated (Figure 2c). The results obtained in 293T cells could also be seen in APL patient-derived NB4 cells that express the endogenous PML/RAR $\alpha$  fusion protein (Figure 2d). Collectively, the mutation analysis demonstrated that PML/RAR $\alpha$  repressed the transactivation of the *CDKN2D* promoter through the ER8 site located at -368 bp to -349 bp.

**PML/RAR $\alpha$  binds to the endogenous *CDKN2D* promoter.**

One important question that remains to be answered is

**Figure 2** PML/RAR $\alpha$  represses the promoter activity of *CDKN2D* through the ER8 site. (a) Schematic representation of the *CDKN2D* promoter region shows the different truncations/mutations used in this study. Numbering is indicated with respect to the transcriptional start site (TSS) of *CDKN2D* (bent arrow). □ represents the wild-type ER8 site and ⊠ represents the mutated ER8 site. (b) PML/RAR $\alpha$  repressed the promoter activity of *CDKN2D* in a dose-dependent manner. The *CDKN2D* promoter reporter construct (-900 bp) and increasing amounts of pSG5-PML/RAR $\alpha$  expression plasmid (PML/RAR $\alpha$ ) were cotransfected into 293T cells. Luciferase values were normalized to those of control. Values were the mean  $\pm$  S.E.M. obtained from at least three independent experiments. (c-d) The ER8 site located between -273 bp and -488 bp of the *CDKN2D* promoter is critical for PML/RAR $\alpha$ -mediated repression. The 293T cells were transfected with different truncations/mutations of the *CDKN2D* promoter reporter construct and the pSG5-PML/RAR $\alpha$  expression plasmid or the empty vector. Results in 293T cells (c) are represented as fold repression. The NB4 cells were transfected with different truncations/mutations of the *CDKN2D* promoter reporter construct. Results in NB4 cells (d) are relative to the empty vector (pGL3-basic). \* indicates  $P < 0.05$

whether PML/RAR $\alpha$  binds to the *CDKN2D* promoter *in vivo*. To address this question, we performed chromatin immunoprecipitation (ChIP)-PCR assays using anti-PML, anti-RAR $\alpha$  and a nonspecific antibody (normal IgG). Primers were designed to amplify a 207-bp amplicon covering the ER8 site (region 1) (Figure 3a). An irrelevant region (region 2), which was located far upstream of the transcriptional start site and contained no RARE sites, was selected as a negative control. As illustrated in Figure 3b (left panel), we found that the positive band was amplified in the chromatin region covering the ER8 site using the anti-RAR $\alpha$  immunoprecipitation in U937 cells, in accordance with a previous study that RAR $\alpha$  binds to the ER8 site of the *CDKN2D* promoter.<sup>17</sup> Further, we treated PR9 cells with ZnSO<sub>4</sub> to induce the expression of PML/RAR $\alpha$  and found that region 1 was highly enriched by both the anti-PML and anti-RAR $\alpha$  antibodies, but were not enriched by the nonspecific normal IgG control. In contrast, region 2 was not enriched by all of the antibodies (Figure 3b, middle panel). These results indicate that when cells express PML/RAR $\alpha$  protein, PML/RAR $\alpha$  could compete with RAR $\alpha$  to bind the ER8 site of the *CDKN2D* promoter. To further support the above finding, we performed ChIP assays in the APL-derived NB4 cells. The result was compliant with that in ZnSO<sub>4</sub>-treated PR9 cells (Figure 3b, right panel). Collectively, the results of ChIP assays show that PML/RAR $\alpha$  binds to the endogenous *CDKN2D* promoter.

#### Forced expression of CDKN2D induces cell cycle arrest and a partial granulocytic differentiation of APL cells.

The findings that *CDKN2D* was targeted and repressed by PML/RAR $\alpha$  prompted us to investigate the biological effects of *CDKN2D* restoration on APL-derived NB4 cells. We restored *CDKN2D* expression in NB4 cells with retroviral transduction (Figure 4a), and compared the differentiation potential and cell cycle status of cells before and after restoration. As shown in Figure 4b, forced expression of *CDKN2D* significantly increased the cells in the G0/G1 phase from 45.3% to 76.3% which was in accordance with the well-documented role of *CDKN2D* in cell cycle control. Forced

expression of *CDKN2D* also induced a partial granulocytic differentiation of NB4 cells, based on the observations of the elevation of the neutrophilic differentiation marker CD11b (Figure 4c) and the morphological change (Figure 4d). These data suggest that the cell cycle regulator *CDKN2D* is involved in both cell cycle regulation and granulocytic differentiation.

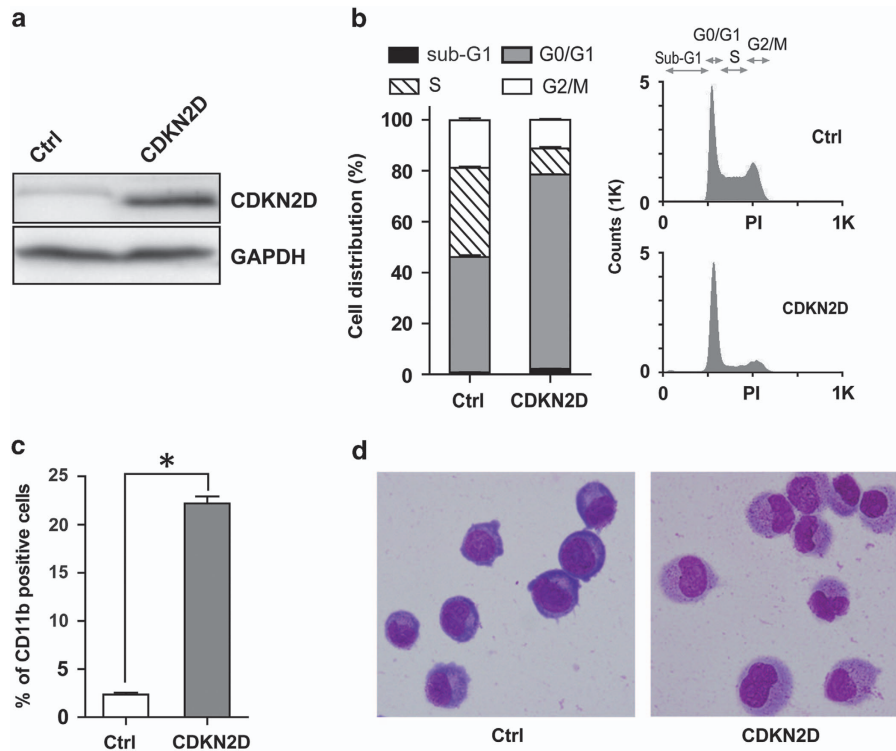

#### ATRA restores the expression of CDKN2D in APL cells.

APL is characterized by a unique clinical response to ATRA, which is able to efficiently induce differentiation of APL cells and restore the expression of genes inhibited by PML/RAR $\alpha$ .<sup>2</sup> We thus examined *CDKN2D* expression in NB4 cells treated with 1  $\mu$ M ATRA in a time course analysis by qRT-PCR. We found that ATRA treatment increased the mRNA level of *CDKN2D* in a time-dependent manner (Figure 5a). Because we found that PML/RAR $\alpha$  repressed *CDKN2D* transcription through the ER8 site, which may serve as a non-canonical site of RA signaling, we further tested whether *CDKN2D* is a direct ATRA-responsive gene independent of *de novo* protein synthesis. NB4 cells were pre-treated with or without cycloheximide, a protein synthesis inhibitor, before the addition of ATRA. The results showed that *CDKN2D* expression induced by ATRA was not perturbed by pre-treating NB4 cells with cycloheximide (Figure 5b), indicating that *CDKN2D* was a direct ATRA-responsive gene independent of *de novo* protein synthesis.

Because the endogenous VDR and RAR $\alpha$  can regulate *CDKN2D* expression at the presence of ATRA, we compared *CDKN2D* expression after ATRA treatment in cells with or without PML/RAR $\alpha$ . We treated PR9 cells before and after the addition of ZnSO<sub>4</sub> with 1  $\mu$ M ATRA and performed qRT-PCR. As expected, we found that *CDKN2D* expression was both upregulated after ATRA treatment no matter whether PR9 cells were treated with or without ZnSO<sub>4</sub>. More interestingly, ATRA treatment induced a stronger (10.5-fold) upregulation of *CDKN2D* in the presence of PML/RAR $\alpha$ , as compared with endogenous RAR $\alpha$  (2.9-fold) (Figure 5c), indicating that ATRA induced *CDKN2D* expression more efficiently in PML/RAR $\alpha$  expressing cells.

**Figure 3** PML/RAR $\alpha$  binds to the endogenous *CDKN2D* promoter. (a) Schematic representation of the *CDKN2D* promoter region. The bent arrow represents the transcriptional start site. □ represents the ER8 site. The paired arrowheads represent the primers used in the ChIP analysis. (b) The ChIP assays of PML/RAR $\alpha$  binding within the *CDKN2D* promoter were performed in U937 cells, ZnSO<sub>4</sub>-treated PR9 cells and NB4 cells. The total input and immunoprecipitated DNAs were analyzed by PCR using primers specific (region 1) or non-specific (region 2) to the ER8 site. Left: the positive band was amplified in the region 1 using the anti-RAR $\alpha$  immunoprecipitation in U937 cells. Middle: region 1 was highly enriched by both the anti-PML and anti-RAR $\alpha$  antibodies in ZnSO<sub>4</sub>-treated PR9 cells. PR9 cells were treated with 100  $\mu$ M ZnSO<sub>4</sub> for 4 h. Right: region 1 was highly enriched by both the anti-PML and anti-RAR $\alpha$  antibodies in NB4 cells. Total input and DNAs immunoprecipitated by normal IgG served as positive and negative controls, respectively

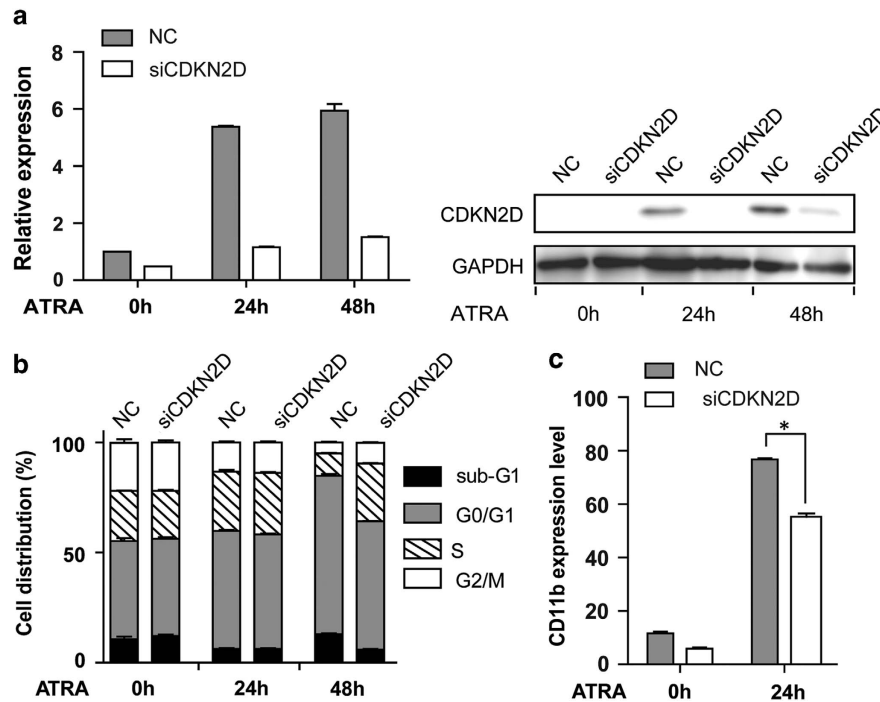

**Figure 4** Ectopic expression of CDKN2D induces cell cycle arrest and a partial granulocytic differentiation of NB4 cells. (a) Western blot analysis of CDKN2D expression in total cell lysates. NB4 cells were harvested by 72 h after MigR1 (Ctrl) or MigR1-CDKN2D (CDKN2D) infection. (b) Overexpression of CDKN2D induced G0/G1 phase arrest of NB4 cells. Cell cycle distribution was analyzed in GFP-positive cells. Values were the mean  $\pm$  S.E.M. obtained from three independent experiments. The representative DNA content histograms were shown in the right panel. (c) Overexpression of CDKN2D induced a partial granulocytic differentiation of NB4 cells. Cell surface expression of CD11b in GFP-positive cells was determined by flow cytometry. (d) Wright's staining of NB4 cells. The left panel depicted the MigR1-infected NB4 cells, and the right panel showed MigR1-CDKN2D-infected NB4 cells differentiated toward neutrophils. \* indicates  $P < 0.05$

**Figure 5** ATRA restores the expression of CDKN2D in APL cells. (a) ATRA restored the expression of CDKN2D mRNA in NB4 cells in a time-dependent manner. NB4 cells were treated with  $1 \mu\text{M}$  ATRA for the indicated times. (b) *CDKN2D* is a direct ATRA-responsive gene. NB4 cells were pretreated with or without  $10 \mu\text{g/ml}$  cycloheximide (CHX) for half an hour and then were cultured for 8 h in the presence of  $1 \mu\text{M}$  ATRA. (c) ATRA induced CDKN2D expression more efficiently in PML/RAR $\alpha$  expressing cells. PR9 cells were pretreated with or without  $100 \mu\text{M}$  ZnSO $_4$  for 4 h and then were cultured for another 12 h in the presence or absence of  $1 \mu\text{M}$  ATRA. \* indicates  $P < 0.05$

**Knockdown of CDKN2D impaired the ATRA-induced cell cycle arrest and granulocytic differentiation of APL cells.** To further elucidate the function of CDKN2D in ATRA-induced differentiation, we used a siRNA approach to knockdown CDKN2D expression in NB4 cells during ATRA treatment. The reduction of *CDKN2D* expression in cells transfected with *CDKN2D*-specific siRNA was confirmed by qRT-PCR and western blot analysis (Figure 6a). Because CDKN2D was involved in regulating both cell cycle and

granulocytic differentiation (Figures 4b and c), we next determined the interference effects of CDKN2D knockdown on cell cycle during ATRA treatment. As shown in Figure 6b, knockdown of CDKN2D expression significantly reduced the percentage of ATRA-induced G0/G1 phase cells from 72.0% to 58.2% (Figure 6b), suggesting that CDKN2D was required for ATRA-induced cell cycle arrest of APL cells. Furthermore, we detected the differentiation status of cells during ATRA treatment. As illustrated in Figure 6c, knockdown of CDKN2D

**Figure 6** Knockdown of CDKN2D impaired the ATRA-induced cell cycle arrest and granulocytic differentiation of APL cells. (a) The mRNA and protein level of CDKN2D were detected in NB4 cells transfected with siRNA specifically targeting CDKN2D (siCDKN2D) or negative control siRNA (NC). Cells were treated with 1  $\mu$ M ATRA for the indicated times. (b) Knockdown of CDKN2D decreased the G0/G1 phase cells induced by ATRA. Error bars showed the S.E.M. from three different assays. (c) Knockdown of CDKN2D impaired granulocytic differentiation of NB4 cells induced by ATRA. Cells were treated with 1  $\mu$ M ATRA for 24 h. \* indicates  $P < 0.05$

reduced the ATRA-induced differentiation (CD11b) from 76.7% to 55.2%. We also detected the effect of knockdown of CDKN2D on apoptosis following ATRA treatment and found that CDKN2D had less impact on apoptosis (data not shown). These results support the findings that CDKN2D is required for ATRA-induced cell cycle arrest and differentiation of APL cells.

## Discussion

Leukemia cells are blocked at a certain stage of hematopoietic differentiation and display a high proliferative capacity. In this study, we demonstrated that the reduced expression of *CDKN2D* by the PML/RAR $\alpha$  fusion protein contributed to both the differentiation block and altered proliferation in APL. PML/RAR $\alpha$  is the initiating factor in the pathogenesis of APL.<sup>19</sup> Genome-wide studies on the genomic landscape of PML/RAR $\alpha$  have demonstrated that PML/RAR $\alpha$  targets are involved in a variety of functional processes, including differentiation and proliferation.<sup>20</sup> However, we know relatively little about the role of PML/RAR $\alpha$  in controlling the coordination of these two processes. Our data provide a mechanism by which PML/RAR $\alpha$  disrupts the coordination between cell proliferation and differentiation by repressing CDKN2D in APL.

Although cell proliferation and differentiation are two mutually exclusive processes, a large body of evidence demonstrates that the two processes are also coordinated and can be controlled by the same regulator. Transcription factors regulating the differentiation process often directly regulate cell cycle progression. For instance, the hematopoietic specific transcription factor GATA1 controls the cell

proliferation during erythroid maturation by directly regulating the cyclin-dependent kinase inhibitor p21.<sup>21</sup> Conversely, key cell cycle regulators also participate in controlling differentiation. One of the most striking examples is cyclin-dependent kinase 6 (CDK6), that is the regulator of cell cycle progression and is capable of blocking myeloid differentiation by inhibiting Runx1 activity.<sup>22</sup> Our findings provide a new link between cell cycle regulation and granulocytic differentiation through CDKN2D. Therefore, PML/RAR $\alpha$  might disrupt both proliferation and differentiation by repressing CDKN2D expression, thus promoting the pathogenesis of APL.

In addition to the well-studied function of CDKN2D on cell cycle regulation, previous studies implicate that CDKN2D might be involved in the differentiation of hematopoietic systems. DMSO induces HL-60 cells to differentiate to granulocyte, accompanied by upregulation of CDKN2C and CDKN2D.<sup>23</sup> Increased expression of CDKN2D is also involved in the cytokine IL-6-induced growth arrest and the differentiation of M1 leukemic cells.<sup>24</sup> Overexpressed CDKN2D can induce the differentiation of immature 32Dcl3 myeloid cells to macrophage-like cells in the presence of G-CSF.<sup>25</sup> Of note, the effects of CDKN2D on differentiation seem to be dependent on the cellular contexts. CDKN2D knockdown shows no effect on differentiation of monocytic leukemia cells U937 induced by 1,25-VD3 or ATRA.<sup>26</sup> Here, we showed that the repressed expression of CDKN2D contributed to the differentiation block of APL cells, along with the abnormal proliferation. Furthermore, CDKN2D expression was increased during ATRA-induced differentiation and cell cycle arrest, and knockdown of CDKN2D expression reduced the effect of ATRA on both processes. It should be mentioned that the effect of

manipulating CDKN2D expression is relatively moderate, compared with the strong effect of ATRA. One possibility was that the transfection efficiency of siRNA did not reach 100% in all cases, which might cause an underestimation of the CDKN2D effects on cell pool assays because of the impossibility to exclude untransfected cells. Also, as CDK inhibitors usually function redundantly and cooperatively in regulating biological processes,<sup>27,28</sup> downregulation of CDKN2D may be compensated by other CDK inhibitors. In addition, this may also be partially explained by the fact that CDKN2D is one of the ATRA-responsive genes, which is required but not the only factor in ATRA-induced differentiation and cell cycle arrest. Inhibition of CDKN2D alone is unable to block the effects of other ATRA-responsive genes (data not shown), as numerous genes associated with proliferation (ID1/ID2<sup>29</sup> and UBE2D3<sup>30</sup>) and differentiation (SPI1<sup>31</sup> and CEPBE<sup>32</sup>) are induced during ATRA treatment. Collectively, our data show that CDKN2D plays a role in the cell cycle regulation and differentiation of NB4 cells, and more importantly in the coupling of these two processes.

We showed that PML/RAR $\alpha$  reduced CDKN2D expression by directly binding to its promoter and transrepressing its transcription. CDKN2D, along with CDKN2A, CDKN2B and CDKN2C, consists of the INK4 family CKIs. Inactivation of genes of the INK4 family is an important event in the pathogenesis of leukemia. For example, deletions of CDKN2A and CDKN2B frequently occur in hematopoietic malignancies.<sup>14</sup> Loss of CDKN2A increases the growth rate of myeloid colonies *in vitro* and confers hematopoietic progenitor cells an increased clonal expansion potential.<sup>33</sup> In addition to gene deletion, hypermethylation of CpG islands in the promoter regions of *CDKN2A* and *CDKN2B* has also been found to exist in a large percentage of leukemia patients, resulting in the loss of activity of the INK4 family.<sup>14</sup> However, several clinical studies have shown that gene deletion and hypermethylation are hardly observed in CDKN2D, unlike in other INK4 family CKIs.<sup>34</sup> In addition, CDKN2D has been reported to be deregulated by PLZF-RAR $\alpha$  that is generated from t(11;17) APL, and is associated with ATRA resistance.<sup>35</sup> PLZF-RAR $\alpha$  promotes leukemogenesis partially by the downregulation of CDKN2D in primary murine hematopoietic progenitors,<sup>36</sup> which supports the function of CDKN2D in the pathogenesis of APL. These findings add another layer of evidence on the inactivation of the INK4 family genes by repressing their expression directly by the oncogenic fusion protein.

PML/RAR $\alpha$  is known to act as a dominant-negative oncoprotein. As it retains the DNA-binding domain of RAR $\alpha$ , PML/RAR $\alpha$  is usually believed to compete for DNA-binding sites of RAR $\alpha$ , resulting in the dominant silencing of RAR $\alpha$  target genes.<sup>37</sup> RAR $\alpha$  forms heterodimers with RXR and RAR $\alpha$ /RXR usually binds to the canonical RAREs, which consist of direct repeats (DR) of the half consensus ([A/G]G [G/T]TCA) with spacing of 2 or 5 (DR2 or DR5).<sup>13</sup> However, emerging evidence has shown that the DNA-binding spectrum of PML/RAR $\alpha$  is more complex and versatile than that of RAR $\alpha$ . Owing to the formation of the multimers of PML/RAR $\alpha$  complexes, several studies have shown that the binding sites of PML/RAR $\alpha$  may have a variety of spatial arrangements, including other orientations of the two half sites and wide

varieties of spacing between the two half sites.<sup>38</sup> Dmitrii Kamashev *et al.*<sup>38</sup> have reported that, in addition to canonical RAREs (DR2 or DR5), PML/RAR $\alpha$  can also bind non-canonical RAREs, among which DR4 (DR of two-half sites separated by 4 nucleotides), IR0 (inverted repeat of two-half sites without spacing) and ER8 (everted repeat of two-half sites separated by 8 nucleotides) show stronger binding activity to PML/RAR $\alpha$ . These findings suggest that genes whose promoters contain non-canonical RAREs may also be targeted and inhibited by PML/RAR $\alpha$ . In accordance with these previous reports, our results demonstrated that PML/RAR $\alpha$  inhibited the promoter activity of *CDKN2D* through a non-canonical ER8 site. The feature of PML/RAR $\alpha$  with a more flexible DNA-binding specificity results in a broader spectrum of gene regulated by PML/RAR $\alpha$ , thus giving rise to a major gain of function of this fusion protein in the pathogenesis of APL. In the future, it will be very interesting to determine more PML/RAR $\alpha$  targets that participate in the cross-talk between the proliferation and differentiation programs, and finally define the network link the two programs together in APL.

#### Materials and methods

**Cell culture.** NB4, PR9 and U937 cells were cultured in RPMI 1640 medium (Gibco, Carlsbad, CA, USA) supplemented with 10% (v/v) fetal bovine serum (Gibco), and HEK 293T cells were cultured in Dulbecco's Modified Eagle's Medium (Gibco) supplemented with 10% (v/v) fetal bovine serum, in a humidified atmosphere with 5% CO<sub>2</sub> at 37 °C. ATRA and ZnSO<sub>4</sub> (Sigma, St. Louis, MO, USA) were used at final concentrations of 1  $\mu$ M and 100  $\mu$ M, respectively.

**Plasmid construction and site-directed mutagenesis.** A series of sense oligonucleotides-CAGGAGTGAGACCTGACTCA (-900), TCGTAGTAA GGGCCAATGAATG (-488), GTTGCCACTCTGACCAATC (-273) and an antisense oligonucleotide-TAACTCACCTCCCTCTCC were used to generate a series of 5' truncated DNA fragments by PCR using genomic DNA from NB4 cells. The PCR products were cloned into the pGL3 basic vector (Promega, Madison, WI, USA). Mutations of the ER8 site in the CDKN2D (-488) construct were made using the QuikChange site-directed mutagenesis kit (Stratagene, La Jolla, CA, USA) following the manufacturer's protocol. The primers were as follows: sense oligonucleotide 5'-GACCCTGCCCCAGCCTTTCTCCCTGCCTCAGTTAAACC AGCC-3', antisense oligonucleotide 5'-GGCTGGTTAACTGAGGCAGGGAGAAA GGCTGGGGCAGGGTC-3'.

**Cell transfection and luciferase reporter assays.** HEK 293T cells were seeded at a density of  $0.5 \times 10^5$  cells/well in 48-well plates for 24 h before transfection. A total of 125 ng of the tested promoter (the 900 bp full-length and the different truncations/mutations of the *CDKN2D* promoter), 2.5 ng of pRL-SV40 and pSG5-PML/RAR $\alpha$  or pSG5 empty vectors (500 ng or increasing amounts in the dose-dependent assay) were transiently transfected into 293T cells using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA). After 48 h of transfection, cells were harvested and luciferase activity was measured with a luminometer (Promega) using Dual-Luciferase Reporter Assay System reagents (Promega). The renilla luciferase plasmid pRL-SV40 was used as control for transfection efficiency.

For NB4 cells, 2  $\mu$ g promoter-luciferase reporters or pGL3 basic empty vector and 100 ng pRL-SV40 were transiently transfected into NB4 cells using the Amaxa Nucleofactor II device (Lonza, program X-001) with Nucleofactor Kit V (Lonza, Cologne, Germany). Twenty-four hours after transfection, cells were harvested. Luciferase activity was measured with a luminometer using Dual-Luciferase Reporter Assay System reagents. The renilla luciferase plasmid pRL-SV40 was used as control for transfection efficiency.

**Quantitative reverse transcription-PCR (qRT-PCR).** Total RNA was extracted from cells using Trizol Reagent (Invitrogen) according to the manufacturer's protocol. The amount of 2  $\mu$ g total RNA was reverse transcribed into cDNA using random hexamer primers and SuperScript II reverse transcriptase kit (Invitrogen) according to the manufacturer's instruction. Quantitative real-time

PCR was performed by using ABI Prism 7900HT detection system (Applied Biosystems, Foster City, CA, USA) with Power SYBR Green PCR master mix (Applied Biosystems). Relative expression was calculated as a ratio of CDKN2D to GAPDH. Primer sequences of GAPDH and CDKN2D were as follows: GAPDH (forward: 5'-GAAGGTGAAGGTCGGAGTC-3'; reverse: 5'-GAAGATGGTG ATGGGATTC-3'); CDKN2D (forward: 5'-TCACACTGCTGTGGTCAGCTTT-3'; reverse: 5'-AGGATGTCCACGAGGTCCTGA-3').

**ChIP assay.** ChIP was performed according to the Affymetrix protocol as previously described.<sup>39</sup> Briefly, PR9 cells were incubated with 100  $\mu$ M ZnSO<sub>4</sub> for 4 h; 5  $\times$  10<sup>7</sup> cells were then harvested for ChIP assays. A total of 5  $\times$  10<sup>7</sup> U937 and NB4 cells were harvested for ChIP assays. Cells were crosslinked with 1% formaldehyde and lysed. Cross-linked chromatin was sonicated to fragments with an average size of 200–1000 bp and immunoprecipitated with specific antibodies against RAR $\alpha$  (C-20x, Santa Cruz Biotechnology, Santa Cruz, CA, USA), PML (H-238x, Santa Cruz Biotechnology) and rabbit IgG (ab46540, Abcam, Cambridge, UK). The total input as well as immunoprecipitated DNA was analyzed by PCR using following primers: positive primer (region 1) (forward: 5'-TAGT GGAACCTCGGATTGGGT-3'; reverse: 5'-TGATTGGTCAGAGTGTGGCAA-3'), negative primer (region 2) (forward: 5'-TGGTCACAAGTCTCTTTTCATG-3'; reverse: 5'-CACCTACTTAGGCCTCGAGACAG-3'). Each experiment was performed in triplicate and equivalent results were obtained.

**RNA interference (siRNA) experiments.** The specific sequence used for CDKN2D silencing was selected from the WI siRNA Selection Program (<http://sirna.wi.mit.edu/>). A negative control sequence was used (AGC GUG UAG CUA GCA GAG G). A total of 2  $\times$  10<sup>6</sup> NB4 cells were suspended in 100  $\mu$ l Amaxa Nucleofector Solution V and mixed with 3  $\mu$ g siRNA. Cells were then transfected by electroporation using Amaxa Nucleofector II device and program X-001. Six hours after transfection, cells were cultured for another 48 h in the absence or presence of 1  $\mu$ M ATRA. The siRNA sequence targeting CDKN2D was as follows: forward: 5'-GUACCAGUCCAGUCCAUGAUU-3'; reverse: 5'-UCAUGGACUGGACUGGUACU-3'.

**Retroviral constructs.** The cDNA encoding full-length human CDKN2D was amplified by RT-PCR from cDNA of NB4 cells and then directionally cloned into an MSCV2.2-derived vector, MigR1, by Xho I and EcoR I sites to form plasmid MigR1-CDKN2D.

**Preparation of retroviruses and transfection.** The recombinant vectors were transfected into HEK 293T packaging cells using HilyMax (Dojindo, Gaitheburg, MD, USA). The virus-containing cell culture supernatants were collected at 48 and 72 h after transfection, centrifuged at 1500 r.p.m. for 5 min, aliquoted and stored at -80 °C. The virus was titred against 3T3-NIH cells.

NB4 cells were seeded at a density of 1  $\times$  10<sup>5</sup> per well in a six-well culture dish, and infected using viral supernatant and 8  $\mu$ g/ml Polybrene (Sigma), and centrifuged at 1500  $\times$  g for 90 min at 28 °C. The medium was changed after 6 h, and the cells were cultured normally.

**Western blot.** Total protein extracts were prepared and western blot analysis was performed as previously described.<sup>40</sup>

**Granulocytic differentiation.** Granulocytic differentiation of cells was determined by detecting the CD11b expression level. Harvested cells were incubated with anti-CD11b antibody (BD Biosciences, San Jose, CA, USA), and analyzed by a Cytomics FC-500 flow cytometer (Beckman Coulter, Miami, FL, USA). For retroviral transfected cells, GFP-positive cells were analyzed for CD11b expression level.

**Cell cycle assay.** siRNA-transfected cells were collected, washed twice with PBS and fixed in ice-cold 70% ethanol overnight at -20 °C. Then, cells were treated with 100  $\mu$ g/ml RNase A in PBS, and incubated at 37 °C for 30 min before staining with 50  $\mu$ g/ml of PI (BD Biosciences) for 30 min at room temperature. Cells were analyzed for DNA content using a Cytomics FC-500 flow cytometer (Beckman Coulter).

For retroviral transfected cells, cells were first fixed with 1% formaldehyde for 1 h at 4 °C, washed once with PBS and permeabilized with ice-cold 70% ethanol overnight at -20 °C. Then, cells were treated with 100  $\mu$ g/ml RNase A in PBS, and incubated at 37 °C for 30 min before staining with 50  $\mu$ g/ml of PI for 30 min at room temperature.

GFP-positive cells were analyzed for DNA content using a Cytomics FC-500 flow cytometer (Beckman Coulter).

**Apoptosis analysis.** Annexin V-FITC and PI (BD Biosciences) were used to detect apoptotic cells.

**Cell morphology.** Morphology was determined with Wright's stain of cells centrifuged onto slides by cytospin at 800 r.p.m. for 5 min (Shandon, Runcorn, UK).

**Statistical analysis.** Statistical significance was determined by a Student's *t* test. Values were the mean  $\pm$  S.E.M. obtained from at least three independent experiments.
