Direct Admission to Hospitals Among Children in the United States

JoAnna K. Leyenaar, MD, MPH, MSc, Meng-Shiou Shieh, PhD, Tara Lagu, MD, MPH, Penelope S. Pekow, PhD, and Peter K. Lindenauer, MD, MSc

Division of Pediatric Hospital Medicine, Department of Pediatrics, Tufts Medical Center, Boston, Massachusetts (Leyenaar); Center for Quality of Care Research, Baystate Medical Center, Springfield, Massachusetts (Shieh, Lagu, Pekow, Lindenauer); Department of Medicine, Tufts Medical Center, Boston, Massachusetts (Lagu, Lindenauer); Division of General Medicine, Baystate Medical Center, Springfield, Massachusetts (Lagu, Lindenauer); School of Public Health and Health Sciences, University of Massachusetts, Amherst (Pekow)

While a decade of research and policy interventions has begun to transform hospital discharge processes, research focused on hospital admissions is lacking. Emergency departments (EDs) are increasingly serving as portals of hospital admission, contributing to national concerns about ED volumes, wait times, and discontinuity of care.¹ Despite this, there is a paucity of research examining other options for hospital admission.

Direct admission, defined as admission to a hospital without receiving care in the hospital's ED, is 1 alternative. Although direct admission has potential benefits for patients and health care systems, little is known about its use or effectiveness. To our knowledge, only 1 study has examined outcomes associated with pediatric direct admissions and there are no national statistics about the characteristics of this admission approach.² To address this gap, we used a nationally representative data set to determine pediatric direct admission rates, characteristics, and costs relative to admission through EDs and characterize variation in direct admission rates across diagnoses and hospitals.

Methods

We analyzed the Agency for Healthcare Research and Quality's 2009 Kids' Inpatient Database, including nonneonatal, nonmaternal, and nonelective pediatric hospitalizations in

children younger than 18 years.³ Our study received institutional review board approval from the Baystate Medical Center and was deemed exempt from participation consent. Interhospital transfers, including transfers to or from a different hospital or health care facility, were excluded as a result of our inability to accurately assess total hospital costs. Reasons for hospitalization were categorized using All Patient Refined Diagnostic Related Groups.⁴ Weighted direct admission frequencies, proportions, and hospital-level variation in direct admission rates were calculated for each All Patient Refined Diagnostic Related Group. For the 10 most common All Patient Refined Diagnostic Related Groups, we assessed differences between children admitted directly and those admitted through EDs using Rao-Scott χ^2 tests for categorical variables and weighted *t* tests for continuous variables. Hierarchical generalized linear models with a random effect for hospitals were developed to assess differences in total hospital costs between children admitted directly and through EDs, using cost-to-charge ratios provided by the Kids' Inpatient Database and controlling for the characteristics shown in the Table.⁶

Results

Of 1.47 million nonelective pediatric hospitalizations, 24.6% occurred via direct admission. The 10 most common diagnoses accounted for 49.2% of these hospitalizations (Figure). Among children with these diagnoses, children admitted directly were more likely to be white, privately insured, and had lower disease severity compared with children admitted through EDs (Table). There was substantial variation in direct admission rates across conditions, ranging from 8.9% for appendectomy to 38.0% for bipolar disorder (Figure). Similarly, we observed considerable hospital-level variation, with appendectomy showing the least variation and bipolar disorder showing the greatest variation in direct admission rates. In models adjusting for patient and hospital characteristics and disease severity, direct admissions were associated with 5% to 31% lower costs than ED admissions.

Discussion

Direct admissions represent approximately 1 in 4 unscheduled pediatric hospitalizations nationally, with characteristics of children admitted directly aligning with those more likely to have a medical home, including white race/ethnicity and private health insurance coverage.⁷ The substantial variation in direct admission practices across hospitals and conditions may be influenced by disparities in access to timely outpatient acute care as well as differences in hospitals' and referring physicians' capacities to facilitate admissions without ED involvement.

While the differences in costs between direct and ED admissions were striking, we acknowledge that our findings may have been influenced by residual confounding and we were unable to draw definitive conclusions about quality, safety, and effectiveness. In addition, direct admission points of origin were not reflected in these analyses. Nevertheless, our results suggest that increasing access to direct admissions may be a means to reduce ED volumes and health care costs. To accomplish this, research is needed to better understand key stakeholders' admission preferences, the drivers of these cost differences, and conditions and procedures best suited for this admission approach.

Acknowledgments

Funding/Support: This study was supported by the Charlton Grant Research Program at Tufts University School of Medicine. Dr Lagu is supported by award K01HL114745 from the National Heart, Lung, and Blood Institute of the National Institutes of Health.

Role of the Funder/Sponsor: The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.
