# **Abstract**

2-Arylpyrrolidines occur frequently in bioactive compounds and thus methods to access them from readily available reagents are valuable. We report a copper-catalyzed intermolecular carboamination of vinylarenes with potassium N-carbamoyl-β-aminoethyltrifluoroborates. The reaction occurs with terminal, 1,2-disubstituted and 1,1-disubstituted vinylarenes bearing a number of functional groups. 1,3-Dienes are also good substrates and their reactions give 2 vinylpyrrolidines. Radical clock mechanistic experiments are consistent with the presence of carbon radical intermediates and do not support participation of carbocations.

> Functionalized pyrrolidines are important nitrogen heterocycles found in numerous bioactive compounds of both natural and synthetic origin. 2-Arylpyrrolidines in particular are ubiquitous.<sup>1-3</sup> The need to access these important moieties and related heterocycles has inspired the development of a number of methods. $4-26$  Many of these methods, however, utilize strong bases<sup>5</sup> and water sensitive organometallic reagents.<sup>7,8</sup> Additional intermolecular metal-catalyzed couplings18-20 and intramolecular metal- and Bronsted acid catalyzed cyclizations<sup>21-25</sup> have been developed, providing various routes to 2arylpyrrolidines and related products. These latter methods, however, are mainly limited to sulfonamides.

More recently, readily available vinyl arenes have been used to directly access 2-aryl pyrrolidines and related saturated heterocycles via intermolecular coupling with bifunctional heteroatom-substituted reagents that can undergo polar/radical [3+2]-type bondforming reaction sequences under mild reaction conditions.26-31 The products of these reactions, by virtue of the required substrates, often contain additional functional groups

(Schemes 1a and 1b) that may not be desired in all applications and primarily N-sulfonyl pyrrolidine synthesis has been reported.

To address existing limitations as well as to explore an orthogonal reactivity mode, we envisaged that a β-aminoethyl carbon radical could serve as a bifunctional three-atom unit to affect a net intermolecular carboamination in the presence of an oxidant (Scheme 1c). The resulting products of the coupling with vinyl arenes are simple 2-arylpyrrolidines, whose applications in medicinal chemistry endeavors can be readily envisioned. Herein is presented our development of this method and its extension to 1,3-dienes. The method is ideal for the synthesis of N-carbamoyl pyrrolidines. Carbamates are generally considered to be more attractive than sulfonamides as the latter are higher molecular weight and often require more strenuous conditions to reveal the parent amine. The utility of carbamates in medicinal chemistry has been noted.<sup>32</sup>

We recently disclosed an oxidative alkyl Heck-type reaction between alkylboron reagents and vinyl arenes.<sup>33</sup> In this transformation, alkyl radicals, generated in situ from  $\left[Cu(II)\right]$ oxidation of the alkylboron reagent, add to vinyl arenes. Oxidation of the resulting benzyl radical then provides the observed higher substituted vinyl arene products. We hypothesized that under the reaction conditions, the benzylic radical, or carbocation derived thereof, could be intercepted with an amine, resulting in 2-aryl pyrrolidine formation (Scheme 1c). The ready availability of N-carbamoyl-β-aminoethylboron reagents, due to the respective contributions of Overman and Molander,  $34,35$  presented an excellent opportunity to test this hypothesis.

Copper(II) 2-ethylhexanoate  $[Cu(eh)_2]$  is a readily available copper salt that has previously been shown to activate potassium alkyltrifluoroborates in coupling reactions with radical acceptors.33,36 However, an attempt at the copper(II) 2-ethylhexanoate-catalyzed coupling of potassium N-Cbz-β-aminoethyltrifluoroborate **1a** with 4-methoxystyrene in the presence of  $MnO<sub>2</sub>$  (2.55 equiv) as stoichiometric oxidant did not result in pyrrolidine formation (Table 1, entry 1). Upon changing the catalyst to  $[Cu(1,10{\text -}phenanthroline)](OTf)<sub>2</sub>,<sup>33</sup> oxidative$ coupling readily occurred to give 82% yield of 2-arylpyrrolidine **2a** (Table 1, entry 2). The Boc analog **1b** also provided the coupling product **2b,** but in lower yield (49%, entry 3). The boronic acid analog **1c** underwent the coupling reaction, but also less efficiently (Table 1, entry 4, 52% yield).<sup>37</sup> Lowering the copper loading from 20 mol % to 15 mol % led to a less efficient reaction with N-Cbz-β-aminoethyltrifluoroborate **1a** (Table 1, entry 5, 67% yield). Ag<sub>2</sub>CO<sub>3</sub> (2 equiv) could also serve as stoichiometric oxidant in place of MnO<sub>2</sub> (Table 1, entry 6).

A number of styrenes underwent this reaction (Chart 1). Styrenes with electron-donating substituents were most reactive. While most reactions were performed at the 0.125 mmol scale of **1a** (Chart 1), a 1.25 mmol scale for the efficient (70% yield) production of **2f** was also performed. Ethers, alkyl substitutents, sulfonamides and amides were tolerated. Halidesubstituted styrenes underwent the reaction, but longer reaction times were required. Substrates bearing two potentially reactive alkenes (terminal styrene, indole, terminal alkylsubstituted alkene) favored reaction at the terminal styrene. A styrene bearing a methyl ester also underwent the reaction but with lower efficiency. A 2-fluoropyridyl in place of a

substituted phenyl was also tolerated albeit the reaction was less efficient. 1-Phenyl-4 pentene, lacking conjugation, did not react.

Disubstituted styrenes were next evaluated (Chart 2). 1-Alkyl and 1-aryl styrenes provided 3° amines and spirocycles **3a-3e.** Coupling with indene gave cis-fused bicyclic pyrrolidine **3f.** Both trans and cis-stilbene gave the same trans-pyrrolidine adduct **3g.** 1-Phenyl-1 cyclohexene, a trisubstituted alkene, was unreactive (not shown).

Dienes and an ene-yne also underwent the coupling reaction to give the corresponding 2 vinyl and 2-propargyl pyrrolidines **4** and **5** (Scheme 2). trans-Ethyl cinnamate and an α,βunsaturated diene provided β-amino acid esters **6** and **7** with good diastereoselectivity for the 2,3-trans pyrrolidines (Scheme 2).

Bexarotene methyl ester, the methyl ester of a retinoid anticancer agent that has recently shown promise in the treatment and prevention of Alzheimer's disease,<sup>38</sup> provided pyrrolidine **8** from the coupling reaction along with two alkyl Heck-type diastereomers **9**  (Scheme 3).

These intermolecular coupling reactions appear to occur through copper-catalyzed/ $MnO<sub>2</sub>$ mediated stepwise oxidative coupling sequence (Scheme 4). Copper(II)-catalyzed oxidation of the alkylborane to its corresponding alkyl radical initiates the process.33,36,39 The alkyl radical then adds to the styrene to produce a stabilized benzylic radical intermediate. This intermediate can combine with [Cu(II)] to form an alkylcopper(III) intermediate capable of undergoing C-N bond formation via reductive elimination (path I).<sup>40</sup> Alternatively, the benzylic radical could be further oxidized by  $MnO<sub>2</sub>$  to provide a benzylic carbocation that is then trapped by the pendant amine (path II).<sup>31</sup> Oxidation of [Cu(I)] back to [Cu(II)] with  $MnO<sub>2</sub>$  then closes the catalytic cycle. At the onset of our mechanistic investigation, we could not differentiate between path I and path II because, based on oxidation potentials,  $MnO<sub>2</sub>$  is capable of oxidizing both  $\lceil Cu(I) \rceil$  and a benzylic radical, although  $\lceil Cu(I) \rceil$  is the more easily oxidized species.<sup>41</sup>

To investigate the mechanism further, a series of vinylcyclopropanes were submitted to the coupling reaction with N-Cbz-β-aminoethyltrifluoroborate **1a** (Scheme 5). Reaction with 2- (buta-1,3-dienyl)cyclopropylbenzene provided a mixture of pyrrolidine diastereomers **10,**  and no cyclopropane ring-opened products were detected. Reaction with 2- ((phenylcyclopropyl)vinyl)benzene provided both pyrrolidine diastereomers **11** and dihydronaphthalene **12.**33 The regiochemistry of **12** indicates that cyclopropane ring opening occurred at the phenyl-bearing carbon. This supports a radical cyclopropane ring-opening mechanism over a metal-mediated ring opening where the less substituted organometallic would have been preferred.<sup>42</sup> To differentiate between a carbocation and a radical cyclopropane opening, the 2-(tert-butoxy)-3-(1-phenylvinyl)cyclopropyl)benzene radical clock was applied. Newcomb has demonstrated this kind of radical clock will open at the oxygen-bearing carbon in carbocationic mechanisms, and at the phenyl-bearing carbon in radical mechanisms.43 In the event, a mixture of 4-phenylnaphthylene **13** and dihydronaphthalene **14** were obtained in this reaction. Naphthalene **13** is likely formed by elimination of  $\epsilon$ -BuOH from **14.** The regioselectivity in these reactions support involvement

of radical intermediates and do not provide evidence for carbocation intermediates. The lack of ring-opened product from reaction with the cyclopropyl diene probe could indicate that C-N bond formation is favored over ring-opening and/or radical addition to the arene when the carbon is less hindered. With increased steric hindrance at carbon, ring-opening and/or radical addition to the arene becomes competitive. While pyrrolidine formation without ringopening is feasible, it is also possible the ring could open and subsequently close prior to pyrrolidine formation.<sup>44</sup>

In summary, we have developed new conditions for the synthesis of simple 2 arylpyrrolidines from vinyl arenes and dienes. The scope of the alkene partner is broad. Radical clock experiments support a purely radical mechanism, likely involving C-N bond formation through a copper(III) intermediate. Our future efforts involve reaction refinement and scope expansion.
