#### Abstract

We report herein the use of an exonuclease III and G-quadruplex probe to construct a G-quadruplex-based luminescence detection platform for  $Hg^{2+}$ . Unlike common DNA-based  $Hg^2$ <sup>+</sup> detection methods, when using the dsDNA probe to monitor the hairpin formation, the intercalation of the dsDNA probe may be influenced by the distortion of dsDNA. This 'mix-anddetect' methodology utilized the G-quadruplex probe as the signal transducer and is simple, rapid, convenient to use and can detect down to 20 nM of  $Hg^{\tilde{2}+}$ .

Keywords: iridium(III), exonuclease III, G-quadruplex, mercury(II) ion

### 1. Introduction

Mercury ions  $(Hg^{2+})$  are a hazardous pollutant produced by refineries, factories, power station or runoff from landfills. Long-term absorption of mercury may result in kidney damage, memory impairment and other severe health problems [[1,](#page-3-0) [2](#page-3-1)]. Living organisms will absorb and then accumulate mercury in fatty tissue via eating and drinking. Therefore, exposure of the human body to mercury should be minimized due to potential metal accumulation. According to the United States Environmental Protection Agency, the maximum safe concentration of mercury in drinking water is 2 ppb, the quantitative detection of which would require a very sensitive instrument [[3](#page-3-2)–[5](#page-3-3)]. Unfortunately, existing analytical methods for the sensitive detection of  $Hg^{2+}$  are not satisfactory for in-field use due to expensive instrumentation and labor-intensive sample preparation protocols. These instrumental methods include atomic absorption spectroscopy (AAS), inductively-coupled plasma mass spectrometry (ICP-MS) [[6](#page-3-4)] and ion-selective electrodes [[7](#page-3-5), [8](#page-3-6)].

In 2004, Ono and co-workers discovered that  $Hg^{2+}$  is able to coordinate with thymine nucleobases  $[9-12]$  $[9-12]$  $[9-12]$  $[9-12]$  $[9-12]$ . This discovery has sparked a wave of novel  $Hg^{2+}$  detection methods, such as oligonucleotide-based luminescence [[13](#page-4-1)– [28](#page-4-2)], colorimetric [[29](#page-4-3)–[40](#page-4-4)], electrochemical [[41](#page-4-5), [42](#page-4-6)] and surface-enhanced Raman scattering methods [[43](#page-4-7)–[46](#page-4-8)]. Later on, they reported the crystal structure of a DNA duplex

Scheme 1. Schematic representation of the ExoIII-assisted label-free G-quadruplex-based assay for  $Hg^{2+}$ .

containing the T-Hg<sup>II</sup>-T mismatch, which showed that the T −HgII −T bond largely distorts DNA structure and also sta-bilizes B-form DNA [[12](#page-4-0)]. Moreover,  $C - Ag<sup>I</sup> - A$  [[47](#page-5-0)] and C −AgI −T mismatches have also been reported [[11](#page-4-9)].

The G-quadruplex is a DNA secondary structure which is formed from a guanine-rich DNA sequence with four or more G-tracts. It is stabilized by monovalent cations such as  $K^+$ ,  $Na<sup>+</sup>$  or  $NH<sub>4</sub><sup>+</sup>$  to form square-planar arrangements of guanine residues [[48,](#page-5-1) [49](#page-5-2)]. Because of its rich structural polymorphism, the G-quadruplex has been widely used to construct analytical detection platforms [[43](#page-4-7), [44,](#page-4-10) [50](#page-5-3)–[64](#page-5-4)] or various types of logic gates [[65](#page-5-5)–[67](#page-5-6)].

Exonuclease III (ExoIII) is a nuclease that catalyzes the stepwise removal of mononucleotides from the 3′-terminus of duplex DNA. Exo III has been used as a component of oligonucleotide-based detection platforms for different targets or as a tool for signal amplification [[68,](#page-5-7) [69](#page-5-8)]. Interestingly, ExoIII has been reported to cleave DNA duplexes containing T  $-Hg^{2+}-T$  mismatches and release  $Hg^{2+}$  into solution [[42](#page-4-6)].

In our previous study, we constructed AND, OR and INHIBIT logic gates utilizing  $Hg<sup>H</sup>$  and  $Ag<sup>I</sup>$  ions as signal inputs. The 'Klenow fragment' polymerase was utilized as one of the signal transducing elements that catalyzes the extension of designed DNA in the 5′ to 3′ direction to form a duplex product and displace the split G-quadruplex sequence in the presence of  $Ag^+$  and  $Hg^{2+}$  [[70](#page-5-9)]. Moreover, previous investigations demonstrated that the photophysical properties of iridium(III) complexes could be fine-tuned by changing the  $C^N$  or  $N^N$  donor ligand. We report herein a novel detection platform for  $Hg^{2+}$  using a novel iridium(III) complex. Unlike common detection methods using dsDNA probes to monitor the hairpin formation, which could be influenced by the distortion of dsDNA by mismatches, our approach utilized a G-quadruplex probe and is based on the newly discovered phenomenon that ExoIII cleaves DNA duplexes containing T  $-Hg^{2+}-T$  mismatches. The detection mechanism of this platform is outlined in scheme [1](#page-1-0). The DNA probe contains a G-quadruplex-forming sequence (green line), and its complementary sequence (red line), as well as 3′ and 5′ polyT (poly thymine) overhangs. The overall DNA structure assumes a hairpin formation with unhybridized 3′ and 5′ termini. Since ExoIII is unable to recognize single-stranded DNA (ssDNA) as substrate, it will not cleave the unhybridized 3′ overhang and the hairpin DNA will not be digested in the absence of  $Hg^{2+}$ . Upon exposure to  $Hg^{2+}$ however, the 3' and 5' polyT overhangs form T−Hg<sup>2+</sup>−T bridges, creating a duplex DNA structure that is vulnerable to ExoIII digestion from the 3'-terminus (red line). ExoIII cleavage releases the G-quadruplex-forming sequence. The G-quadruplex structure binds with the luminescent G-quadruplex-selective iridium(III) complex 1, with a switchon emission response. Furthermore, the  $Hg^{2+}$  may be recycled as they are re-released into solution following the ExoIII cleavage step.

#### 2. Experimental details

#### 2.1. Materials

Reagents, unless specified, were purchased from Sigma Aldrich (St. Louis, MO, USA) and used as received. Iridium chloride hydrate (IrCl<sub>3</sub>  $\cdot$  xH<sub>2</sub>O) was purchased from Precious Metals Online (Australia). All oligonucleotides were synthesized by Techdragon Inc. (Hong Kong, China).

#### 2.2. Synthesis

Complex 1 was prepared according to (modified) literature methods and was characterized by proton nuclear magnetic resonance  $(^{1}H\text{-NMR})$ ,  $^{13}C\text{-NMR}$  and high resolution mass spectrometry (HRMS). Complex 1.  ${}^{1}$ H NMR (400 MHz, acetone-d<sub>6</sub>)  $\delta$  8.80 (d, J = 8.8 Hz, 2H), 8.53 (d, J = 8.8 Hz, 2H), 8.14-8.09 (m, 4H), 7.89 (d,  $J = 8.8$  Hz, 2H), 7.83-7.81 (m, 2H), 7.67-7.63 (m, 2H), 7.42-7.38 (m, 2H), 7.31-7.27 (m, 2H), 7.21-7.17 (m, 2H), 7.15-7.06 (m, 6H), 6.58 (d,  $J = 7.6$  Hz, 2H);  $^{13}$ C NMR (100 MHz, DMSO-d6) δ 181.0, 161.3, 148.9, 148.8, 147.8, 142.1, 140.0, 132.5, 132.1, 131.7, 131.3, 129.9, 129.7, 129.6, 128.5, 127.5, 127.3, 126.9, 125.0, 123.9, 122.1, 118.1; HRMS: calculated for  $C_{44}H_{28}IrN_4S_2$  [M-PF<sub>6</sub>]<sup>+</sup> 869.1385; found 869.1332; analyzed ( $C_{44}H_{28}IrN_4S_2PF_6$ ). C, H, N: calculated 52.12, 2.78, 5.53; found 52.34, 2.77, 5.58.

# 3. Results and discussion

Complex 1 is a cyclometalated iridium(III) complex: [Ir  $(\text{pbt})_2(\text{biq})$ ]PF<sub>6</sub> (1, where  $\text{pbt} = 2$ -phenylbenzo[d]thiazole,  $biq = 2,2'$ -biquinoline, figure [1](#page-2-0)). The synthesis, characterization and photophysical properties of 1 are given in the supplementary information (table S1, figure S1). No significant change in the UV–visible absorption spectrum of 1 was observed in aqueous buffered solution over 48 h, indicating that the complex is stable in aqueous solution and may be suitable for long term use. By itself, complex 1 was weakly emissive in aqueous buffered solution (20 mM Tris, pH 7.0).

<span id="page-2-0"></span>

Figure 1. Chemical structure of cyclometalated iridium(III) complex 1.

Encouragingly, we found that a significant increase in luminescence response of 1 can be triggered by the presence of G-quadruplex DNA, as shown by emission titration experiments. We then explored the effect of the addition of various types of DNA (figure [2](#page-2-1)). ssDNA or double-stranded DNA (ds17, ds26) had only a minor effect on the luminescence of 1. However, in the presence of the Pu27 G-quadruplex, the luminescence of 1 was significantly increased (about 3-fold). We anticipate that the G-quadruplex shields the metal center of 1 from solvent quenching by non-radiative decay of the excited state, thus recovering <sup>3</sup>MLCT phosphorescence. To validate this hypothesis, the G-quadruplex fluorescent intercalator displacement (G4-FID) assay was utilized to investigate the binding affinity of 1 for G-quadruplex and dsDNA. The result showed that only 2  $\mu$ M of 1 could displace 50% of thiazole orange (TO) from G-quadruplex-TO assemble. On the other hand, only about 30% of TO could be displaced from dsDNA-TO assemble in the presence of  $5 \mu M$  of complex 1 (figure [3](#page-2-2)). It outlines the G-quadruplex selective property of complex 1.

As complex 1 displays the property of a G-quadruplexselective probe, we sought to apply it in our  $Hg^{2+}$  sensing platform. Encouragingly, we observed that the presence of  $Hg^{2+}$  enhanced the luminescence intensity of the complex 1– hairpin DNA system (figure [4](#page-2-3)). To validate that the luminescence enhancement is due to the switching of the DNA structure, we also sought to exclude the possibility of direct

<span id="page-2-2"></span>

Figure 3. Percentage of TO displaced from DNA duplex ds26 or Pu27 G-quadruplex upon addition of complex 1.

<span id="page-2-3"></span>

**Figure 4.** Emission enhancement of the system ( $[1] = 1 \mu M$ ,  $[DNA] = 1.5 \mu M$ ,  $[K^+] = 100 \text{ mM}$ ) with increasing concentration of Hg<sup>2</sup>

interaction between complex 1 and  $Hg^{2+}$  as a contributor to the response. We found that no luminescence increase was observed for the system lacking hairpin DNA (figure S2). We propose that the observed luminescence enhancement of the system is due to the formation of the T−Hg<sup>2+</sup>−T mismatched duplex in the 3' and 5' overhangs, which allows ExoIII digestion of the hairpin DNA, resulting in the release of the G-quadruplex-forming sequence and the formation of a G-quadruplex structure that is recognized by the G-quadruplex-selective complex 1 with a switch-on emission response.

The linear detection range of the system was found to be from 20 to 200 nM of  $Hg^{2+}$  (figure [4](#page-2-3)). Maximal luminescence was reached at 200 nM. The detection limit of the present assay was determined to be 20 nM of  $Hg^{2+}$  by the 3 $\sigma$  method. The selectivity of this detection platform for  $Hg^{2+}$  over other metal ions was also evaluated. The results showed that the

<span id="page-2-1"></span>

<span id="page-3-8"></span>

Figure 5. Relative luminescence intensity of the system  $([1] = 1 \mu M$ ,  $[DNA] = 2 \mu M$ ) in the presence of 10 nM Hg<sup>2+</sup> or 5-fold excess of other metal ions.

luminescence response of the system for  $Hg^{2+}$  was significantly stronger than that for 5-fold excess concentrations of the other metal ions (figure [5](#page-3-8))[.](#page-3-9)

In order to investigate the effectiveness of this  $Hg^{2+}$ assay in a practical application, we applied it to the detection of  $He^{2+}$  in spiked natural water samples. No  $He^{2+}$  was detected in the natural water samples by ICP-MS. Therefore, the natural water samples (Nam Sang Wai River in Hong Kong) were diluted 50-fold with Tris buffer and spiked with various concentrations (20, 50, 100, 200 and 500 nM) of  $Hg^{2+}$ . The samples showed a gradual increase in luminescence intensity with  $Hg^{2+}$  (figure [6](#page-3-9)). This result demonstrates that our detection platform could potentially be further developed as a sensitive probe for natural water sample analysis of  $Hg^{2+}$ .

#### 4. Conclusions

In conclusion, a novel luminescent iridium(III) complex which shows the G-quadruplex probe property, was investigated and utilized for the construction of an exonucleaseassisted, label-free G-quadruplex-based luminescence detection platform for  $Hg^{2+}$ . Compared with the modified DNA, the cost label-free approach using unmodified DNA is relatively low. Unlike common detection methods, when using the dsDNA probe to monitor the hairpin formation, the intercalation of the dsDNA probe may be influenced by the distortion of dsDNA. This 'mix-and-detect' methodology utilized the G-quadruplex probe as the signal transducer and it is simple, rapid, convenient to use and can detect down to 20 nM of  $Hg^{2+}$ , which is comparable to recently reported label-free DNA-based  $Hg^{2+}$  ion detection methods. For comparison, we have also summarized those reported methods in table S2. Furthermore, the potential application in a real water sample was also demonstrated, which shows the robustness of the system.
