Aortic stenosis is the most common valvular heart disease in the developed world. About 7% of the population over age 65 years suffers from degenerative aortic stenosis. The prognosis of patients with symptomatic severe aortic stenosis is dismal without valve replacement. Even though the American College of Cardiology recommends aortic valve replacement to treat this condition as a class I recommendation, approximately one third of these patients over the age of 75 years are not referred for surgery. Typically, this is from concern about prohibitive surgical risk associated with patient frailty, comorbidities, age, and severe left ventricular dysfunction.

The advent in France of transcatheter aortic valve replacement has raised the hope in the United States for an alternative, less invasive treatment for aortic stenosis. Two recent trials—the Placement of AoRTic TraNscathetER Valve Trial Edwards SAPIEN Transcatheter Heart Valve (PARTNER) and the CoreValve US Pivotal—have established transcatheter aortic valve replacement as the preferred approach in patients who are at high or prohibitive surgical risk. The more recently published PARTNER 2 trial has shown the feasibility of transcatheter aortic valve replacement in intermediate-surgical-risk patients as well. With a profile that promises easier use and better valve performance and delivery, newer-generation valves have shown their potential for further improvement in safety profile and overall outcomes. We review the history and status of this topic. (Tex Heart Inst J 2017;44(1):29-38)

Severe, symptomatic aortic stenosis (AS) is fatal, if left untreated: the prognosis is worse than those of most other malignancies, for the mortality rate is 50% at 2 years (Fig. 1).^{1,2} Aortic valve replacement (AVR) is the only treatment that has proved helpful in strengthening the survival prospects of these patients, and no medical therapy has shown its efficacy in improving outcomes. Despite the 2014 American College of Cardiology/American Heart Association (ACC/AHA) guidelines for AVR as a class I indication for severe symptomatic AS,³ nearly one third of patients with severe symptomatic AS are not referred for surgical AVR.² This is often because multiple comorbidities, advanced age, left ventricular (LV) dysfunction, and frailty all result in poor candidacy for surgical AVR (SAVR).^{4,5} The operative death risk for SAVR among patients with LV dysfunction is as high as 10%. A similar increase in risk is noted among SAVR patients with chronic renal disease and advanced age.^{6,7}

Aortic stenosis is an age-related degenerative process with an increase in incidence noted among advanced-age groups. Because advanced age and debility remain significant limiting factors in providing these patients access to SAVR, the emergence of transcatheter aortic valve replacement/transcatheter aortic valve implantation (TAVR/TAVI) provides a feasible and lesser-risk option for the frail and the elderly who are deemed poor candidates for surgery.

History of Transaortic Valve Replacement

The first classic description of successful surgical management of aortic insufficiency was published in 1954.⁸ The first successful replacement, however, was performed in 1960.⁹ Duran and Gunning described performing AVR in a patient in the early 1960s, using a xenograft porcine aortic valve.^{10,11} Since then, the art of open-heart valve surgery has made rapid strides.

With the evolution of minimally invasive percutaneous coronary interventions to treat complex, multivessel coronary artery disease, cardiologists aspired to treat stenotic valves percutaneously with minimal risk. This journey began with the development of balloon aortic valvuloplasty.¹² However, it failed to substantially change long-term outcomes. The experimental model of stent-mounted porcine valve implants¹³ was

Fig. 1 In a postmortem study, this was the prognosis of patients with aortic stenosis who did not undergo valve replacement or valve implantation.

From: Ross J Jr, Braunwald E. Aortic stenosis. *Circulation* 1968;38(1 Suppl):61-7.¹

followed by a successful pulmonic valve implantation in a lamb.¹⁴ In 2002, Cribier and colleagues described, in a 57-year-old man with severe calcified bicuspid AS, the first human case of TAVR.¹⁵ However, their antero-grade, transvenous approach was fraught with limitations.¹⁶ Webb and associates subsequently reported the feasibility and safety of TAVR via a transfemoral arterial approach.¹⁷ Lichtenstein and co-authors initially described the transapical approach,¹⁸ and later reported clinical and hemodynamic outcomes for patients who underwent valve-in-valve aortic valve implantation of an Edwards balloon-expandable valve through the transapical approach.¹⁹

Indications for Aortic Valve Replacement

The ACC/AHA guidelines for the indications of AVR underwent significant changes in 2014, upon the growing success of TAVR (Fig. 2).³ The ACC/AHA recommends TAVR as the choice for interventions in the following situations (Table I)³:

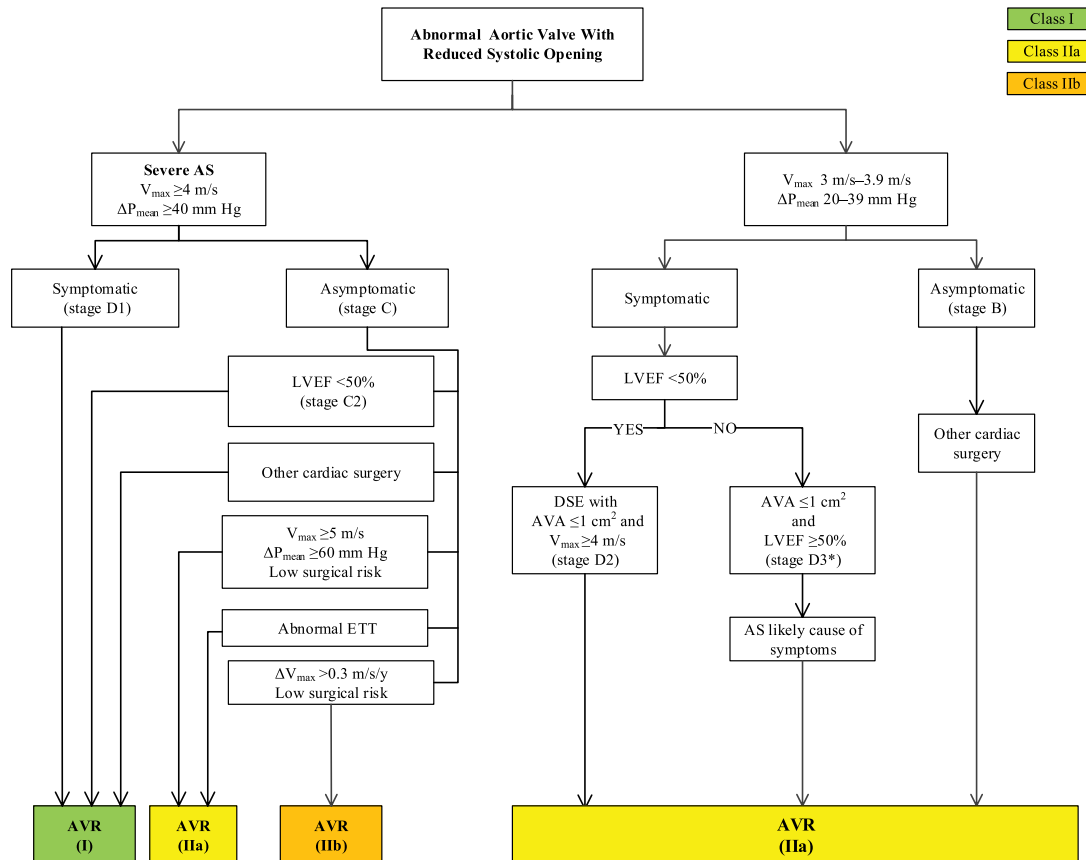

Fig. 2 Indications for aortic valve replacement in patients with aortic stenosis.

TABLE I. ACC/AHA Recommendations for Aortic Stenosis: Choice of Surgical or Transcatheter Intervention³

Recommendations	COR	LOE
Surgical AVR is recommended in patients who meet an indication for AVR with low or intermediate risk	I	A
For patients in whom TAVR or high-risk surgical AVR is being considered, members of a Heart Valve Team should collaborate to provide optimal patient care	I	C
TAVR is recommended in patients who meet an indication for AVR for AS who have prohibitive surgical risk and a predicted post-TAVR survival >12 mo	I	B
TAVR is a reasonable alternative to surgical AVR in patients who meet an indication for AVR and who have high surgical risk	IIa	B
Percutaneous aortic balloon dilation may be considered as a bridge to surgical or transcatheter AVR in severely symptomatic patients with severe AS	IIb	C
TAVR is not recommended in patients in whom existing comorbidities would preclude the expected benefit from correction of AS	III: No Benefit	B

ACC = American College of Cardiology; AHA = American Heart Association; AS = aortic stenosis; AVR = aortic valve replacement; COR = classification of recommendation; LOE = level of evidence; TAVR = transcatheter aortic valve replacement

Adaptation of Table 8 from *Circulation*: 2014;129:2440-93 for "Transcatheter Aortic Valve Replacement."

- 1) Patients considered to be at a prohibitive risk for surgery and at a predicted post-TAVR survival longer than 12 months (class I indication, level of evidence B).
- 2) As an alternative to SAVR in patients considered to be at high risk for surgery (class IIa indication, level of evidence B).

An approach by a heart valve team—consisting of experts in valvular heart disease, interventional cardiology, cardiac imaging, cardiac anesthesia, and cardiac surgery—is considered essential in patients who are being considered for TAVR or high-risk SAVR (class I indication, level of evidence C). Substantial credit for the improvement in TAVR outcomes has been attributed to the improvement in patient selection by the heart valve team.²⁰

Types of Transcatheter Valves

Two types of valves are currently approved by the U.S. Food and Drug Administration (FDA) for TAVR: the CoreValve® Revalving system (Medtronic, Inc.; Minneapolis, Minn) and the Edwards SAPIEN system (Edwards Lifesciences Corporation; Irvine, Calif). Both valves have proved their effectiveness in the recent outcomes of the CoreValve US Pivotal and PARTNER trials, respectively.

Edwards SAPIEN TAVR Valves

The Edwards SAPIEN aortic valve is a balloon-expandable, trileaflet, equine pericardial valve attached to a stainless-steel framework. The Edwards SAPIEN XT and the Edwards SAPIEN 3 valves, available in 20-mm, 23-mm, 26-mm, and 29-mm sizes, are the 2 types of Edwards SAPIEN TAVR valves available in the U.S. Either can be deployed through transfemoral, transapical, transaxillary, and transaortic approaches. The Edwards

Fig. 3 Image shows the unique features of the Edwards SAPIEN 3 Valve. (Reprinted with permission from Edwards Lifesciences Corporation.)

SAPIEN XT system has been approved by the FDA for aortic valve-in-valve procedures. The SAPIEN 3 system—with a lower device profile, improved delivery catheter, and the additional feature of a polyethylene terephthalate outer skirt—has shown reduced rates of vascular sequelae and paravalvular regurgitation (Fig. 3).

PARTNER Trial (NCT00530894)

The Placement of AoRTic TraNscathetER Valve Trial Edwards SAPIEN Transcatheter Heart Valve (PARTNER) trial was a randomized prospective trial that divided patients into 2 cohorts: PARTNER A and PARTNER B. The PARTNER A cohort compared TAVR against SAVR

in high-surgical-risk patients, defined as predicted risk of operative death $\geq 15\%$.²¹ PARTNER B included patients who were not considered suitable candidates for surgery because of combined risk of death or irreversible comorbidity of more than 50%, as agreed upon by 2 cardiac surgeons.²²

The PARTNER A trial included 351 patients undergoing SAVR and 348 undergoing TAVR. The 30-day mortality rate for TAVR was 3.4% and for SAVR was 6.5%. The 1-year mortality rate was 24.2% and 26.8% for TAVR and SAVR, respectively ($P=0.001$ for noninferiority). Reported 5-year results were comparable as well, with mortality rates reported at 67.8% in the TAVR group versus 62.4% in the SAVR group ($P=0.76$).²³

The PARTNER B trial compared TAVR versus medical therapy, with the results significantly favoring the TAVR group. The 1-year mortality rate for TAVR was 30.7%, versus 50.7% for conventional medical therapy ($P < 0.001$). The benefits of TAVR were sustained at 5 years with a significantly lower mortality rate than medical treatment (71.8% vs 93.6%; $P < 0.0001$).²⁴

CoreValve Revalving System

The CoreValve Revalving system, which has a self-expanding nitinol frame, contains a trileaflet porcine pericardial tissue prosthesis and is delivered by advancing a catheter over a guidewire in retrograde fashion from the femoral, axillary, or subclavian artery to the aortic annulus. The valve is manufactured in 4 diameters (23, 26, 29, and 31 mm) and was the first transcatheter valve approved by the FDA for valve-in-valve replacement. Evolut™ R, the latest-generation CoreValve, is configured with a low delivery profile and is the only repositionable and recapturable device available in the U.S. (Fig. 4).

CoreValve US Pivotal Trial (NCT01240902)

The CoreValve US Pivotal Trial was a multicenter noninferiority trial performed at 45 clinical sites in the U.S., which compared TAVR using a CoreValve with SAVR, in patients who had severe AS and increased

risk of death from surgery.²⁵ The inclusion criteria were New York Heart Association (NYHA) functional class II or greater, severe AS with aortic valve area ≤ 0.8 cm² or aortic valve area index ≤ 0.5 cm²/m² and a mean gradient > 40 mmHg or a peak velocity > 4 m/s whether at rest or during dobutamine echocardiography, and at increased surgical risk. The primary endpoint was all-cause death at one year, and 795 patients underwent randomization in the U.S. All-cause death at one year in the TAVR group was 14.2% versus 19.1% in the SAVR group ($P < 0.001$ for noninferiority and $P = 0.04$ for superiority). The 2-year mortality results were congruent with the 1-year results: an all-cause mortality rate at 22.2% in the TAVR group and 28.6% in the SAVR group. Hemodynamic performance was superior in the TAVR group at all times.

There have been promising results from the CoreValve Australia-New Zealand Study, the Italian CoreValve registry, and the UK TAVI registry.²⁶⁻²⁸ The results from the Italian registry showed durability with the CoreValve at the 5-year follow-up, with only 5 patients (1.4%) noted to have prosthesis failure.²⁸ The Spanish experience yielded a 30-day mortality rate of 7.4% in 108 patients who underwent TAVI.²⁹

CoreValve versus Edwards SAPIEN Valve

The Randomized Comparison of Transcatheter Heart Valves in High Risk Patients with Severe Aortic Stenosis: Medtronic CoreValve Versus Edwards SAPIEN XT (CHOICE) trial (NCT01645202) was the first head-to-head trial of a balloon-expandable TAVR valve versus a self-expandable valve.³⁰ At 30 days, device success occurred in 116 of 121 patients (95.9%) in the balloon-expandable group and 93 of 120 patients (77.5%) in the self-expandable group ($P < 0.001$). This was attributed to a significantly lower frequency of aortic regurgitation and the rare need for implanting more than one valve in the balloon-expandable group. Despite the greater device success in the balloon-expandable group, the mortality rates in these groups were comparable both at

Fig. 4 Images show the recapturability feature of the CoreValve Evolut R valve: **A**) valve too deep; **B**) recapture begins; **C**) partially recaptured; **D**) valve fully recaptured. (Reprinted with permission from Medtronic, Inc.)

the 30-day and at the 1-year follow-up. A recent meta-analysis of these 2 groups showed a similar risk of death and stroke at both stages.³¹ However, the incidence of new pacemaker implantation, aortic regurgitation, valve embolization, and the need for more than one valve was found to be higher with self-expandable valve implantation than with balloon-expandable valve implantation.

Four registries—the UK TAVI registry, the Pooled-Rotterdam-Milano-Toulouse In Collaboration (PRAGMATIC Plus Initiative), the Spanish National TAVI registry, and the Belgian TAVI Registry—reported comparable results for the Edwards SAPIEN and the CoreValve.³²⁻³⁵

Anatomic Evaluation before TAVR

Both transthoracic and transesophageal echocardiography have been found inferior to real-time 3-dimensional imaging for measuring annular size.³⁶ Multidetector computed tomography has proved to be the method of choice for pre-TAVR evaluation of the suitability of iliofemoral access and for detailed anatomic evaluation of the aortic root and valve annulus; it has also shown promise in the detection of coronary disease pre-TAVR.^{37,38} Left- and right-sided heart catheterization are used to evaluate coexisting coronary artery disease and pulmonary hypertension; pulmonary function tests are also part of the routine pre-TAVR evaluation. Although revascularization of coronary disease typically takes place before TAVR, revascularization after TAVR is feasible as well.³⁹

Procedural Success after TAVR

Although early TAVR experiences yielded a procedural success rate of 70% to 80%,⁴⁰ the Society of Thoracic Surgeons/ACC Transcatheter Valve Therapy Registry investigators have reported a 92% procedural success rate since the approval of TAVR in the U.S.⁴¹

Changes in the Heart after TAVR

Replacement of the stenotic aortic valve alleviates the increase in LV pressure load and improves LV hemodynamic performance.⁴² Transcatheter AVR has been shown to normalize ventricular-arterial coupling, decrease LV hypertrophy, and restore LV function in patients with systolic dysfunction.^{43,44} Elevated left-sided filling pressures in severe AS can lead to severe pulmonary hypertension in nearly one third of cases. Patients undergoing TAVR were noted to have a sustained reduction in pulmonary hypertension.⁴⁵ Although these results were reciprocated by balloon aortic valvuloplasty in the short term, the pulmonary pressures returned to preprocedural levels in the long term. Transthoracic echocardiograms from 95 patients evaluated before and after implantation of Edwards SAPIEN valves at selected intervals in the TRanscatheter EndoVascular Implantation of VALves (REVIVAL) trial revealed the mean valve

area (1.6 cm²) achieved after TAVR to be comparable to that achieved by SAVR, and the clinical improvements to be sustainable at 1 year.⁴⁶ Despite slight progression of the aortic regurgitation at 1 year, most patients had improvement in LV structure and function.⁴⁷

Changes in Quality of Life

Quality-of-life indices such as the Short Form 36 score, the Kansas City Cardiomyopathy Questionnaire, the Short Form 12v2 scoring system, and the Heart Failure Questionnaire have all indicated marked improvement in patients' quality of life after TAVR. The transfemoral TAVR cohort in the PARTNER A trial scored higher in the short term (via the Kansas City Cardiomyopathy Questionnaire summary score for evaluation of quality of life) than did the cohort who underwent surgery.⁴⁸

Predictors of Death after TAVR

The 2 most frequently used death-prediction models are the Logistic EuroSCORE and the Society of Thoracic Surgeons Predicted Risk of Mortality (STS-PROM) algorithms. The EuroSCORE, however, has been shown to overestimate the expected mortality rate in high-risk candidates.⁴⁹ Table II summarizes the independent predictors of death.⁵⁰ Low flow was identified as an independent predictor of death in a PARTNER trial analysis.⁵¹ The transapical approach has been associated with a higher mortality rate than has the transfemoral route.^{52,53} Sequelae of TAVR—like cerebral embolism, paravalvular regurgitation, and vascular sequelae—are well-known predictors of death. Elevation of brain-type natriuretic peptide levels at 30 days from baseline, along with moderate-to-severe aortic regurgitation, were independent predictors of death in the transfemoral cohort of the PARTNER trial.⁵⁴ Female sex, preoperative NYHA functional class IV, LV ejection fraction <0.30, preoperative intravenous inotropic agents, a higher degree of calcification, and arteriovascular disease were found to be independent predictors of severe sequelae in the German Aortic Valve Registry (GARY).⁵⁵

TABLE II. Predictors of Death after Transcatheter Aortic Valve Replacement⁴⁹

At 30 days	
Requirement for open-heart surgery	
Cardiac tamponade	
Vascular sequelae	
Poor left ventricular function (ejection fraction, <0.40)	
Prior balloon valvuloplasty	
Diabetes mellitus	
Between 30 days and 1 year	
Prior stroke	
Postprocedural paravalvular leak (≥2+)	
Prior pulmonary edema	
Chronic kidney disease	

Technical Sequelae of TAVR

The Valve Academic Research Consortium (VARC), the organization that oversees the TAVR trials, has proposed standard endpoints for the TAVR clinical trials.^{56,57} The purpose was to standardize postoperative sequelae of TAVR—such as myocardial infarction, stroke, bleeding sequelae, acute kidney injury, vascular sequelae, prosthetic valve performance, and other sequelae related to prosthetic valve placement, including death. The clinical benefit endpoints proposed by VARC are exercise performance, the judgment of NYHA functional status, and performance on various quality-of-life and frailty questionnaires. The creatine kinase-myocardial band was recommended as a periprocedural marker for myocardial infarction with a 2nd-sample requirement of a greater-than-20% increase and a 2nd-sample elevation of at least 10 times the upper limit of normal.

Cerebral Embolism. Transcatheter AVR is associated with the highest stroke rates among percutaneous cardiac interventions, ranging from 4% to 5% in the 2 large randomized clinical trials that compared TAVR and SAVR in high-risk patients.^{21,25} Although cerebral microembolism was detected via ultrasonography and magnetic resonance imaging in the earlier studies in patients undergoing TAVR,^{58,59} no deleterious effect on neurocognitive function was found at a 3-month follow-up evaluation.⁶⁰ Variation in the practices regarding antithrombotic therapy at different institutions has reverted to standard since the finding—during the Portico Re-sheathable Transcatheter Aortic Valve System U.S. Investigational Device Exemption (PORTICO IDE) trial—of reduced aortic-valve-leaflet motion on computed tomography: close scrutiny of the computed tomograms of a patient who had experienced a stroke and of an asymptomatic patient showed that leaflet motion improved upon therapeutic anticoagulation.⁶¹ Although the incidence of strokes was not statistically significant in the reduced-leaflet-motion arm (compared with the normal-leaflet-motion arm), a significant difference in the incidence of strokes or transient ischemic attacks was seen in patients with reduced leaflet motion in these pooled cohorts: Subclinical Aortic Valve Bioprosthesis Thrombosis Assessed with Four-Dimensional Computed Tomography (Savory) and Assessment of Transcatheter and Surgical Aortic Bioprosthetic Valve Thrombosis and its Treatment with Anticoagulation (Resolve).⁶¹ The FDA now requires all patients undergoing TAVR to undergo follow-up computed tomographic scanning to look for signs of leaflet immobility.

Coronary Obstruction. Transcatheter AVR is associated with low risk of coronary ostial obstruction (<1%) in patients with native-valve AS.⁶² The risk goes up 3- to 4-fold in patients who have undergone valve-in-valve TAVR.⁶² Coronary obstruction after TAVR is associated with a high mortality rate. The mechanism is

generally speculated to be direct or near-direct contact between the bioprosthetic valve and the coronary ostium.⁶³ Meticulous use of computed tomography and fluoroscopy can detect high-risk cases.^{63,64} Recognizing high-risk cases and taking measures such as the use of a retrievable prosthesis, the deliberate selection of a small-diameter prosthesis, underexpansion of the balloon-expandable valve,⁶⁵ or use of active protection (for example, placing wire and stent in the coronary vasculature before valve implantation) are options that should be considered for management of coronary obstruction.⁶³

Conduction Abnormalities and Pacemaker Necessity. The overall rates of permanent pacemaker implantation after TAVR were around 17%, versus 5% with SAVR.^{66,67} The need for a new permanent pacemaker in the PARTNER A cohort was not significantly different at 30 days (3.8% vs 3.6%), 1 year (5.7% vs 5%) and 5 years (9.7% vs 9.1%) for patients undergoing TAVR versus SAVR, respectively. Siontis and colleagues⁶⁶ suggested that male sex, baseline conduction disturbances, and intraprocedural atrioventricular block had roles as predictors of permanent pacemaker implantation after TAVR. They found the sequela to be 2.5 times more prevalent with the self-expandable valve than with the balloon-expandable valve, a finding equivalent to that of meta-analysis as well.³¹ The valve design and its potential for deeper implantation in the LV outflow tract are possible reasons for these higher rates of permanent pacemaker implantation with the self-expandable valve than with the balloon-expandable valve. However, the rates of permanent pacemaker implantation and conduction abnormalities were also found to be higher with the new Edwards SAPIEN 3 system because of prosthesis oversizing and the depth of the implantation.⁶⁷

Other Sequelae. Paravalvular leak after TAVR is a frequent occurrence that is associated with increased mortality rates.^{50,54,68} The new Edwards SAPIEN 3 valve, which features a sealing skirt at its lower position and a more accurate mechanism of valve positioning, has shown promise in decreasing the rates of paravalvular regurgitation.⁶⁹⁻⁷¹ In a recent PARTNER continued-access registry, the decreased rates of paravalvular regurgitation were attributed to improved case selection, improved procedural techniques, and increased procedural experience.⁷² Vascular sequelae are independent predictors of death, largely attributed to the wider sheaths (inner diameter, 24F–26F) required by earlier-generation devices.⁷³ As the sheath sizes decrease with the new-generation Edwards SAPIEN 3 system (inner diameter, 14F–16F) and the CoreValve Evolut R (14 F-equivalent system), the rate of vascular sequelae and the incidence of bleeding will continue to decrease.^{70,71} Acute kidney injury is frequently seen after TAVR⁷⁴; however, the rates were lower both in the PARTNER 2 trial and in a recently published meta-analysis.^{75,76} Other sequelae—

like valve embolization, mitral regurgitation, prosthetic-valve endocarditis, and ventricular septal defect—are also known.

The Future of TAVR

The results of the recently published PARTNER 2 trial, which compared TAVR outcomes (in this instance, outcomes of the SAPIEN XT valve system) with SAVR have shown similar overall outcomes with respect to primary endpoints (death and stroke) at 2 years between the 2 groups, although the results favored TAVR in patients who underwent TAVR through the transfemoral route.⁷⁶ Transcatheter AVR also resulted in fewer bleeding sequelae, lower rates of acute kidney injury and new-onset atrial fibrillation, shorter hospitalization and intensive-care stay, and larger aortic valve areas than did surgery. In comparison, TAVR had a higher rate of paravalvular regurgitation and vascular sequelae. The encouraging results of the PARTNER 2 trial come despite the drawbacks of the Edwards SAPIEN XT valve system, which has largely been replaced by the newer-generation Edwards SAPIEN 3 system.

The results of the Edwards SAPIEN 3 observational study included a reduced rate of vascular sequelae because of the smaller sheath size and a lower rate of paravalvular regurgitation because of the skirt mechanism.⁷⁰ The Surgical Replacement and Transcatheter Aortic Valve Implantation (SURTAVI) trial (NCT01586910), which is Medtronic's CoreValve version of the PARTNER 2 trial, will further extend the debate about the possibility of TAVR's use as a first-line treatment for intermediate-risk patients. In the meantime, the SAPIEN 3 prosthesis has been approved for use in intermediate-surgical-risk patients in the U.S. Moreover, the FDA has recently approved clinical trials to test the efficacy of TAVR in low-risk patients, both for the Medtronic arm using the CoreValve Evolut R System (NCT02701283) and the Edwards SAPIEN arm using the Edwards SAPIEN 3 valve system (PARTNER 3 trial, NCT02675114). The newer-generation valves have the potential to improve the success of the procedure and to reduce sequelae. The ability to reposition and recapture the Evolut R valve has given operators extra confidence during the procedure and has led to a CE mark for use in intermediate-surgical-risk patients in Europe. The Repositionable Percutaneous Replacement of Stenotic Aortic Valve Through Implantation of LOTUS Valve System Randomized Clinical Evaluation (REPRISE III) trial is currently enrolling patients to test the safety and efficacy of the LOTUS Edge™ Valve (Boston Scientific Corporation; Natick, Mass) for TAVR. Finally, the Direct Flow Medical® Transcatheter Aortic Valve System (Direct Flow Medical, Inc.; Santa Rosa, Calif), a part of the TranScatheter Aortic Valve RePlacement System US Feasibility (SALUS) trial, is designed to minimize aortic regurgitation while replacing the faulty native

aortic valve in high- and extremely high-surgical-risk patients. Rapid technological advances such as these are reinforcing the future of TAVR.
