Abstract

Multidrug-resistant Neisseria gonorrhoeae infections have been declared one of the top three urgent threats to public health. Approaches to combat resistance include targeted therapy with antibiotics previously thought to be ineffective, made possible by rapid molecular assays to predict susceptibility. Previous studies have associated the gyrase A (gyrA) gene of Neisseria gonorrhoeae with in vitro resistance to ciprofloxacin. We conducted a systematic review of studies comparing Neisseria gonorrhoeae gyrA genotype results with conventional antimicrobial susceptibility test results. We identified 31 studies meeting inclusion criteria, among which seven different loci for mutations in the gyrA gene were identified, from sixteen countries between the years of 1996 and 2016. We then performed a meta-analysis among those studies stratifying by use of real-time PCR or non-real-time PCR technique, and compared the summary receiver operating characteristic curves (sROC) between the two PCR methods. Among studies using real-time PCR the pooled estimate of sensitivity and specificity of gyrA genotype results for the prediction of Neisseria gonorrhoeae susceptibility to ciprofloxacin were 98.2% (95% CI 96.5%-99.1%) and 98.6% (95% CI 97.0%-99.3%), respectively. The sROCs for studies using real-time PCR techniques were well separated from those using non-real-time PCR techniques, with only slight overlap in the confidence intervals, suggesting that real-time PCR techniques were a more accurate approach. GyrA genotype testing is a novel approach to combating the emergence of multi drug-resistant Neisseria gonorrhoeae, and is a sensitive and specific method to predict in vitro ciprofloxacin susceptibility.

Keywords

Neisseria gonorrhoeae Resistance; Gyrase A; GyrA; Ciprofloxacin

Introduction

Multidrug-resistant *Neisseria gonorrhoeae* infections have been declared one of the top three urgent threats to public health [1]. *Neisseria gonorrhoeae* has developed resistance to all antimicrobials currently available [2, 3], and there are only a few novel antibiotics in development [4-6], therefore new approaches are urgently needed. A recently described approach calls for targeted therapy with antibiotics previously thought to be ineffective [7, 8], which has been made possible by the development of rapid molecular assays that predict *in vitro* antimicrobial susceptibility [9].

In the United States, it is estimated that approximately 80% of *Neisseria gonorrhoeae* infections are susceptible to ciprofloxacin [10]. Previous work has shown that mutation of the gyrase A (*gyrA*) gene of *Neisseria* species is associated with ciprofloxacin resistance, particularly mutation at the Ser91 codon [9] [30s]. Mutations in other loci have been shown to confer resistance to ciprofloxacin, such as parC, however prior studies have demonstrated that mutations in other locations, which confer resistance, usually occur in parallel with the *gyrA* mutation; prediction of ciprofloxacin susceptibility, therefore, may be done solely by detection of mutation in the *gyrA* gene [30s-34s]. In response, real-time polymerase chain reaction (PCR) –based molecular assays have been developed to predict gonococcal susceptibility to ciprofloxacin [33s].

Those rapid molecular genotypic assays have been studied extensively to determine how they correlate with standard agar dilution susceptibility methods [32s-43s]. Here we review the previously published reports describing the sensitivity, specificity, negative and positive predictive values of the *gyr*A genotypic assays for the prediction of *Neisseria gonorrhoeae* susceptibility to ciprofloxacin.

Methods

In September 2016, we conducted a literature search using the following text-word terms: "GYRA" OR "CIPROFLOXACIN" OR "QUINOLONE" AND "GONORRH*" with *PubMed* as a search platform. Our search resulted in over 900 studies which was further restricted to 831 in the English language. Our only inclusion criterion was the use of *gyrA* genotypic determination techniques and the comparison of genotype results with conventional methods for determining ciprofloxacin susceptibility. We excluded articles that only evaluated resistant or susceptible strains of N. gonorrhoeae because there would be no comparison of susceptibility results. Similarly, we excluded articles reporting five or fewer isolates with resistant or susceptible phenotypes. Wild-type is defined as the most prevalent sequence of the gyrase A gene, which predicts full ciprofloxacin susceptibility. One article was excluded as a cluster analysis was performed and the results provided were insufficient to distinguish which mutant or wild-type strains were associated with which susceptibility results. In total we identified 30 articles meeting inclusion criteria. We were also aware of

one article that was not available on *PubMed*, which fulfilled inclusion criteria. Here we report sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the wild-type *gyr*A gene for predicting susceptibility to ciprofloxacin from those 31 reports.

Statistical Analysis

Sensitivity, specificity and their corresponding 95% confidence intervals of individual studies were calculated and presented in forest plots (Figures 1 and 2). For studies with zero event cell count, continuity correction of 0.5 was added to each cell to enable calculations. Heterogeneities of sensitivities and specificities among included studies were assessed by Cochran Q and chi-squared test [11], respectively. Given the strong evidence of heterogeneities (p-values of Chi-squared test <0.05) and known correlation between the pair of sensitivity and specificity, we obtained the summary statistics of sensitivity and specificity by using a bivariate random effects modeling approach [12]. The summary operating characteristic curves (sROC) [13] were constructed and compared between studies using real-time PCR techniques and non-real-time PCR techniques (Figure 3). All the statistical analyses were conducted using Package MADA (Meta-Analysis of Diagnostic Accuracy) in the R statistical software environment version 3.3.1 [14].

Results

Of the 31 articles meeting inclusion criteria, seven different loci for mutations in the *gyr*A gene were identified from samples collected in sixteen countries between the years of 1996 and 2016 [30s-60s]. Eleven studies used real-time polymerase chain reaction techniques for determination of the *gyr*A genotype, while 20 were conducted using other methods such as pyrosequencingTM, probe hybridization, isothermic chimeric primer-initiated amplification, or gel electrophoresis to determine the *gyr*A genotype.

All studies compared genotype results with minimum inhibitory concentration (MIC) assay results using agar dilution techniques, except one study, which used available phenotypic susceptibility data without MIC assay results [40s]. The cutoff MIC for reduced susceptibility and resistance varied slightly among studies with cutoff values ranging from 0.06-0.125 µg/ml and 0.05-1.0 µg/ml, respectively.

Studies Using Non-Real-Time Polymerase Chain Reaction Methods for Determination of *Gyr*A Genotype

We identified twenty studies (N=2931 isolates) from seven countries using non-real-time PCR techniques for the determination of the *gyr*A genotype. The range of sensitivities and specificities of wild-type *gyr*A genotype for predicting ciprofloxacin susceptibility reported by those studies was 58.0-100% (mean of 91.2%) and 90.5-100% (mean of 99.2%), respectively (Figure 1a and 1b). Positive predictive values ranged from 76.3-100% (mean of 97.9%), while negative predictive values ranged from 72.4-100% (mean of 95.4%). The pooled estimate of sensitivity and specificity based on the bivariate mixed-effect modeling approach were 91.7% (95% CI 85.4%-95.5%) and 98.0% (95% CI 96.7%-98.8%), respectively.

Shigemura et al. used denaturing high-performance liquid chromatography and DNA sequencing in 2002 among samples collected in Japan and found 83.3% sensitivity of *gyrA* mutation for predicting reduced ciprofloxacin susceptibility, however results improved to 100% when only evaluating mutations at codon 91 of the *gyrA* gene. Similarly, Dewi et al. found 80.6% sensitivity, which improved to 93.5%; and Tanaka et al. found 75.0% sensitivity, which improved to 100% when analyzing only mutations in codon 91.

Gharizadeh et al. found 10 isolates with mutations in the *gyr*A gene (two in region Asp95 and eight in region Ser91) that showed phenotypic susceptibility to ciprofloxacin, however the median MIC was higher than for wild-type strains (0.21 µg/ml and 0.03 µg/ml, respectively). Conversely, Grad et al. report five isolates with phenotypic resistance to ciprofloxacin (MIC values > 1 µg/ml) that had no identifiable mutation in *gyr*A or *par*C.

Fourteen of the twenty studies included sequence analysis of *par*C as well as *gyr*A. Uthman et al. found slightly higher sensitivity of wild-type *par*C genotype for predicting ciprofloxacin susceptibility compared to wild-type *gyr*A genotype (100% compared to 97.8%), with similar results reported by Shigemura et al. and Grad et al. Eleven other studies, however, found wild-type *par*C was not as sensitive or specific for predicting ciprofloxacin susceptibility as wild-type *gyr*A [30s, 31s, 44s, 45s, 46s, 47s, 51s, 53s, 54s, 56s, 57s].

Studies Using Real-Time Polymerase Chain Reaction Assays to Amplify Ser91 Region of the *GyrA* Gene

In total, eleven studies (N=4777 isolates) used RT-PCR techniques to amplify the Ser91 region of the *gyr*A gene. Samples were collected from ten countries between 2007 and 2016. All studies reported high sensitivity and specificity with ranges between 93.8-100% (mean of 98.8%) and 93.2-100% (mean of 99.3%), respectively (Figures 2a and 2b). Positive and negative predictive values ranged from 94.4-100% (mean of 99.4%) and 87.5-100% (mean of 98.2%), respectively. The pooled estimate of sensitivity and specificity based on the bivariate mixed-effect modeling approach were 98.2% (95% CI 96.5%-99.1%) and 98.6% (95% CI 97.0%-99.3%), respectively.

Siedner et al.were the first to use only real-time PCR techniques for determination of the *gyr*A genotype. They reported improvement of assay sensitivity after restricting the assay to amplification of only the Ser91 codon, compared to the entire amplicon of the *gyr*A gene as was reported previously [34s]. Furthermore, four studies reported 100% specificity of mutation in the Ser91 region of the *gyr*A gene for *Neisseria gonorrhoeae* compared with other subspecies [35s-37s, 41s].

Among 252 samples from Canada, Peterson et al. compared ciprofloxacin susceptibility results with the Asp95 region of the *gyr*A gene and the Asp86 region of the *par*C gene, both previously associated with ciprofloxacin resistance. They found comparable sensitivity for Asp86 *par*C in predicting ciprofloxacin resistance. Three other studies using real-time PCR techniques, however, report that amplification of the *par*C gene was less sensitive and specific than amplification of the *gyr*A gene, though additional alteration of the *par*C gene may confer a greater degree of antimicrobial resistance [32s, 38s, 39s].

Figure 3 shows the sROC for studies using non-real-time PCR and real-time PCR techniques.

Discussion

We systematically reviewed studies that have compared *Neisseria gonorrheoae gyr*A genotype results with conventional methods of ciprofloxacin susceptibility determination. Among studies using real-time PCR techniques there appears to be strong evidence that *gyr*A genotype results are both highly sensitive and specific for the prediction of *Neisseria gonorrhoeae* susceptibility to ciprofloxacin. Furthermore, studies have shown that *gyr*A genotype determined by real-time PCR is 100% specific to *Neisseria gonorrhoeae* compared to other *Neisseria* subspecies [35s-37s, 41s].

Studies using non-real-time PCR techniques such as PyrosequencingTM and probe hybridization reported wider ranges of sensitivities. That finding is likely in part due to the incorporation of multiple different mutations in the *gyr*A gene that may not be associated with resistance; the range of sensitivities improved when only analyzing known resistance mutations. Notably, the study by Gharizadeh et al. compared *gyr*A mutation with phenotypic susceptibility results; when looking at MIC assay results it was noted that samples with mutant *gyr*A genotypes had higher median MICs than wild-type samples.

We also compared the sROC between studies using real-time PCR and non-real-time PCR techniques. The summary estimates of sensitivity and specificity were well separated, though the confidence regions overlapped slightly. Based on that, we therefore conclude that the real-time PCR technique may be a more accurate technique in gyrase A genotype testing than other techniques.

Rapid molecular assays for determination of resistance are enabling targeted antimicrobial therapy that could curb the emergence of antimicrobial resistance. The FDA-approved molecular assay for *Mycobacterium tuberculosis* uses real-time PCR for amplification and molecular probes for the detection of mutations within the rifampin-resistance determining region. That assay has an overall sensitivity of 97.6% and specificity between 98.1-99.2% [15]. Real-time PCR amplification of known resistance genes has also been shown to be clinically effective in screening for Methicillin-resistant *Staphylococcus aureus*, with low false negative and false positive rates between 0.0% to 7.3% and 0.0% to 5.4% respectively [16]. Additionally, rapid molecular assays are available for carbapenem-resistant *Enterobacteriaceae* and have been shown to detect most resistance genes without yielding false positives [17].

Therefore, given the robust performance of the real-time PCR *gyrA* assays, *Neisseria gonorrhoeae* genotyping of *gyrA* has the potential to enable reliable targeted therapy with ciprofloxacin. Targeted therapy with ciprofloxacin might reduce the ongoing selection pressure caused by the widespread empiric use of extended-spectrum cephalosporins and have implications for the enhanced control of ceftriaxone resistant *Neisseria gonorrhoeae* [8]. A recent study suggested that treatment might be a major driver of ceftriaxone resistance among *Neisseria gonorrhoeae* [18].

Allan-Blitz et al.

In November 2015, University California Los Angeles implemented routine *gyr*A testing on all *Neisseria gonorrhoeae* positive clinical specimens. Results from testing are used to promote targeted therapy with ciprofloxacin based on genotype susceptibility results [19, 20]. Further studies are underway to characterize the impact of the assay on patient clinical outcomes [21].

There were a few limitations to our study. Primarily this was an analysis of previous studies and therefore subject to the same limitations as the studies being reviewed. Additionally the prevalence of ciprofloxacin susceptible *Neisseria gonorrhoeae* differs in various regions of the world, [10, 22] and *gyr*A results may not be of substantial benefit in regions where the prevalence of ciprofloxacin resistance is very high. Furthermore, our study spanned twenty years, during which time technological advances likely impacted the sensitivity and specificity of test results. However, as most studies, including the earliest studies, report high sensitivity and specificity of *gyr*A testing for predicting ciprofloxacin susceptibility, the changes in technology likely did not impact the overall findings, but furthered the utility of *gyr*A testing, and therefore support, rather than negate our findings.

Conclusion

Gyrase A genotype testing is a novel approach to combating the emergence of multi drugresistant *Neisseria gonorrhoeae*. Among studies comparing *gyr*A genotype results with conventional methods of susceptibility testing, there appeared to be strong evidence that *gyr*A genotype results are both sensitive and specific in predicting ciprofloxacin *in vitro* susceptibility, with real-time PCR techniques being a more accurate approach compared to non-real-time PCR techniques.

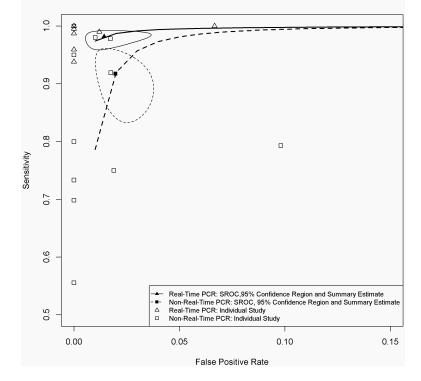

Figure 3.

Summary operating characteristic curves for sensitivity and specificity comparing studies using non-real-time PCR and real-time PCR techniques for the determination of the gyrase A genotype. Solid and dashed circled areas represent the 95% confidence regions for studies using real-time PCR and non-real-time PCR techniques, respectively.
