Objective: To explore the effect of neoadjuvant chemotherapy combined with limb salvage surgery in patients with limb osteosarcoma of Enneking stage II.

Patients and methods: Medical records of 98 patients who met the inclusion criteria were retrospectively analyzed. Of these patients, 56 cases who received neoadjuvant chemotherapy combined with limb salvage surgery were listed as group A, while another 42 patients who received limb salvage surgery combined with adjuvant chemotherapy were listed as group B. The recurrence and metastasis rate, survival rate, limb function and incidence of adverse reactions were compared between the two groups.

Results: All 98 patients completed the treatment in this study. Baseline characteristics showed no significant differences between group A and group B, including age, gender, tumor location, maximum tumor diameter and Enneking stage (all $P > 0.05$). The total metastasis and recurrence rate of group A was significantly lower than that of group B (25.0% vs 47.6%, $\chi^2 = 5.419$, $P = 0.020$). The Kaplan–Meier method showed that progression-free survival (PFS) (log-rank $\chi^2 = 4.014$, $P = 0.045$) and overall survival (OS) (log-rank $\chi^2 = 3.859$, $P = 0.049$) of group A were both significantly higher than those of group B. There was no significant difference in the incidence of grades III–IV adverse reactions between the two groups (all $P > 0.05$). The excellent and good rate of limb function in group A was significantly higher than that in group B (83.9% vs 66.7%, $\chi^2 = 3.982$, $P = 0.046$).

Conclusion: Neoadjuvant chemotherapy combined with limb salvage surgery for patients with Enneking stage IIA or IIB limb osteosarcoma patients has better efficacy and can significantly improve limb function of patients.

Keywords: limb osteosarcoma, neoadjuvant chemotherapy, limb salvage surgery, adjuvant chemotherapy

Introduction

Osteosarcoma is the most common orthopedic malignancy and often occurs in distal femur, proximal humerus, proximal tibia and metaphysis.¹ The age with peak incidence rate ranges from 14 to 26 years old.² The main clinical symptoms of osteosarcoma include progressive local pain, lumps, swelling, dysfunction and occasionally visible pathological fracture. The oncologic outcomes of osteosarcoma are poor because of its high malignancy and characteristics prone to metastasis.³ The goal of osteosarcoma treatment is to control the primary tumor and (micro-)metastatic deposits, to maintain maximal extremity function and to minimize the treatment-related adverse reactions.⁴

With the improvement of requirements to quality of life, limb salvage surgery has become the main way of treatment of limb osteosarcoma with satisfying local

control and short-term efficacy and yet limited long-term efficacy.⁵ The inclusion of aggressive polychemotherapy into an interdisciplinary treatment concept has led to dramatic prognostic improvements in young patients with seemingly localized extremity disease, with 5-year overall survival rates of ~50%–80% reported by specialized centers or multicentric groups.⁶ Neoadjuvant chemotherapy with its great advantages has been widely used in the treatment of osteosarcoma. First, neoadjuvant chemotherapy can reduce the boundaries of osteosarcoma, which contributes to the implementation of radical resection of the tumor and limb retention; second, neoadjuvant chemotherapy can eliminate the potential micrometastases and prolong relapse-free survival period.⁷ Therefore, neoadjuvant chemotherapy combined with limb salvage surgery for the treatment of non-metastatic osteosarcoma has been widely accepted by physicians and patients. Kudawara et al⁸ demonstrated the excellent outcome of neoadjuvant chemotherapy combined with limb salvage surgery for patients with limb osteosarcoma. A study by Bacci et al⁹ also indicated that neoadjuvant chemotherapy combined with limb salvage procedures did not compromise the outcome of patients with limb osteosarcoma. However, there are few studies or reports evaluating the feasibility of neoadjuvant chemotherapy combined with limb salvage surgery for Chinese patients with limb osteosarcoma. Therefore, we designed this retrospective study aiming to compare short-term efficacy, treatment-related adverse reactions and long-term survival between neoadjuvant chemotherapy combined with limb salvage surgery, and limb salvage surgery combined with adjuvant chemotherapy, for patients in Shandong province, China.

Patients and methods

Patients

This study was approved by the ethics committee of the Second Affiliated Hospital of Shandong University. When admitted, all the guardians of enrolled patients signed informed consent that the patients' medical records could be used for clinical research in the future. Inclusion criteria are as follows: 1) a histological diagnosis of limb osteosarcoma by biopsy; 2) no distant metastasis confirmed by computed tomography (CT) scan and radionuclide bone scan; 3) Enneking stage IIA or IIB; 4) the main nerve, blood vessels are not involved; 5) patients without congenital disease, cardiovascular disease and respiratory disease; and 6) patients without chemotherapy contraindications and anesthetic allergy.

From January 2010 to December 2013, a total of 98 patients met the inclusion criteria. Of these patients, 56 cases received neoadjuvant chemotherapy combined with

limb salvage surgery and were listed as group A, while another 42 patients received limb salvage surgery combined with adjuvant chemotherapy and were listed as group B.

Drugs

The chemotherapy drugs used in this study were as follows: epirubicin (EPI; Pfizer Pharmaceuticals Ltd., Jiangsu, China; H20000496); cisplatin (DDP; Biological Valley Pharmaceutical Co., Ltd., Yunnan, China; H20043888); methotrexate (MTX; Yue Kang Pharmaceutical Group Co., Ltd., Beijing, China; H20113120); ifosfamide (IFO; Pfizer Pharmaceuticals Ltd.; H10950292); calcium folinate (CF; Hengrui Medicine Co., Ltd, Jiangsu, China; H20010615) and mesna (Pfizer Pharmaceuticals Ltd.; H10950290).

Treatment

Patients in group A received neoadjuvant chemotherapy combined with limb salvage surgery. Neoadjuvant chemotherapy regimen was EPI + DDP + MTX + IFO: DDP (95 mg/m²), d1, + EPI (85 mg/m²), d1–3, + MTX (10 g/m²), d4–10, + IFO (2 g/m²), d15–19. Adequate hydration and diuretics were prescribed after injection of DDP. After the first injection of MTX, CF (15 g/m²) was administered once every 6 hours 14 times. In order to prevent cystitis, mesna (400 mg) was injected after IFO injection. The procedure was repeated every 3 weeks. Limb salvage surgery was conducted 2 weeks followed by two courses of neoadjuvant chemotherapy. The principle of osteosarcoma resection includes extensive resection of the capsule and at least 5 cm from the surgical margin to the tumor. Limb reconstruction methods included tumor inactivation and bone re-implantation, artificial knee arthroplasty, artificial prosthesis replacement and artificial hip arthroplasty. Vitro replantation was performed by ⁶⁰Co irradiation, and the bone cement or bone graft was used to repair the defect. Prosthetic replacement was performed with bone cement to fill the joint. Drugs and procedure of postoperative adjuvant chemotherapy were the same as neoadjuvant chemotherapy for four courses. Symptomatic treatment was given for adverse reactions in the process of chemotherapy.

The patients in group B were treated with limb salvage surgery and six cycles of adjuvant chemotherapy. Surgical methods and chemotherapy regimens were the same as those of group A.

Observed indicator and evaluation criterion

The local recurrence and metastasis rate of the two groups was observed and recorded. The severity of complications

was classified according to the National Cancer Institute Common Toxicity Criteria (NCI-CTC v2.0). Limb function after 6 months treatment was assessed according to the Enneking limb musculoskeletal system surgical resection postoperative functional scoring system (MSTS93), including the psychological capacity, pain, muscle strength, limb stability, joint mobility and ability to live with 5 points per item and a total of 30 points. The total score ≥ 24 is considered as excellent (E), 18–23 points is considered as good (G), 12–17 points is considered as feasible (F) and < 12 points is considered as poor (P).

Follow-up

Upon completion of treatment, patients were evaluated by chest CT scan and orthotopic and lateral X-ray of the suffering limb, every 1 or 2 months for the first and second year, every 3 months for the third year and every 6 months thereafter. Suspected cases of metastasis or recurrent disease were confirmed by CT scan and/or bone scan.

Statistical methods

SPSS v18.0 was used for all statistical analysis. Differences between the two treatment groups were assessed using a χ^2 test or Fisher's exact test for enumeration data and independent sample *t*-test for measurement data. Survival curves were obtained using the Kaplan–Meier method and were compared using nonparametric survival analysis (log-rank test). A *P*-value < 0.05 was considered statistically significant. Multivariate analysis was performed using the

Cox proportional hazard model with a stepwise method (forward selection), with *P*-values < 0.05 as inclusion criteria and *P*-values > 0.10 as exclusion criteria.

Results

Patient characteristics

All 98 patients completed the treatment in this study. Baseline characteristics showed no significant differences between group A and group B, including age, gender, tumor location, maximum tumor diameter and Enneking stage (all $P > 0.05$; Table 1). Tumor bone was inactivated by Co-ray (70 Gy) after resection and then re-implanted for 31 patients in group A, while patients in group B were not eligible for such reconstruction because they underwent surgery without neoadjuvant chemotherapy. Therefore, there was a significant difference in the type of reconstruction between the two groups ($P < 0.05$).

Recurrence and metastasis

The deadline for follow-up was December 2016. The median follow-up time was 59 months (range 36–84 months). As shown in Table 2, during the follow-up period, 14 (25.0%) patients in group A and 20 (47.6%) patients in group B experienced treatment failure. The metastatic site included lung and bone. In group A, five patients developed pulmonary metastases from 17 to 82 months (median 35 months) and one patient developed bone metastasis 28 months after the start of the first treatment, while in group B, six patients suffered pulmonary metastases from 13 to 64 months

Table 1 Comparison of general characteristics between group A and group B

Characteristics	Group A	Group B	χ^2/t	<i>P</i> -value
Total number of patients	56	42	–	–
Age, ^a years (range)	23.8 \pm 3.6 (12–46)	22.6 \pm 3.2 (13–49)	1.037*	0.381
Gender (male/female)	33/23	24/18	0.031	0.859
Tumor location			–	0.983 [#]

Table 2 Comparison of the recurrence rate and metastasis rate between group A and group B

Recurrence and metastasis	Group A (%)	Group B (%)
Local recurrence	8 (14.3)	11 (26.2)
Metastasis	6 (10.7)	8 (19.0)
Local recurrence + metastasis	0 (0.0)	1 (2.4)

Note: $\chi^2=5.419$, $P=0.020$.

(median 22 months) and two patients developed bone metastasis 19 and 26 months after the start of the first treatment. The total metastasis and recurrence rate of group A was significantly lower than that of group B (25.0% vs 47.6%, $\chi^2=5.419$, $P=0.020$).

Survival analysis

At the time of this report, 13 (23.2%) patients in group A and 18 (42.8%) patients in group B died of osteosarcoma. Mortality rates of group A were significantly lower than those of group B ($\chi^2=4.282$, $P=0.039$). Progression-free survival (PFS) and overall survival (OS) curves are shown in Figures 1 and 2, demonstrating that PFS (log-rank $\chi^2=4.014$, $P=0.045$) and OS (log-rank $\chi^2=3.859$, $P=0.049$) of group A were both significantly higher than those of group B.

Adverse reactions

There were no treatment-related deaths. Adverse reactions in both groups included hematologic toxicity, gastrointestinal

Figure 1 PFS for patients in group A and group B. Abbreviation: PFS, progression-free survival.

Figure 2 OS for patients in group A and group B. Abbreviation: OS, overall survival.

reactions and abnormal liver and kidney function, most of which were mild (grades I–II). The occurrence rate of grades III and IV adverse reaction is shown in Table 3, and there were no significant differences between group A and group B (all $P>0.05$). In addition, some patients in the two groups suffered from grades I–II peripheral neuritis, which was eased by symptomatic treatment.

Limb function

As can be seen from Table 4, the excellent and good rate of limb function in group A was significantly higher than that in group B (83.9% vs 66.7%, $\chi^2=3.982$, $P=0.046$).

Discussion

As osteosarcoma is a highly malignant systemic tumor, 80% of patients with newly diagnosed osteosarcoma have had blood micrometastases.¹⁰ Most patients died of distant metastases, mainly lung metastases after surgery. In the past,

Table 3 Comparison of the occurrence of grades III and IV adverse reactions during chemotherapy of the two groups

Adverse reactions	Group A	Group B	χ^2	P-value
Hematologic toxicities	13	9	0.044	0.834
Leukopenia	8	3		
Thrombocytopenia	5	6		
Gastrointestinal tract reaction	5	4	–	1.000 [#]
Hepatic and renal dysfunction	2	1	–	1.000 [#]

Note: [#]Fisher’s exact test.

Table 4 Comparison of the limb function between group A and group B

Limb function	Group A (%)	Group B (%)
E	27 (48.2)	15 (35.7)
G	20 (35.7)	13 (31.0)
F	7 (12.5)	7 (16.7)
P	2 (3.6)	7 (16.7)
E and G	47 (83.9)	28 (66.7)

Note: $\chi^2=3.982$, $P=0.046$.

Abbreviations: E, excellent; G, good; F, feasible; P, poor.

patients with limb osteosarcoma were mainly treated with amputation, which would lead to loss of limb function and reduced the quality of life of the patients. In the treatment of patients with limb osteosarcoma, physicians and patients not only wish to extend the survival time of patients but also aim to retain the diseased limb and save its function, and thereby improve patients' quality of life. With the advent of bone graft with blood vessels, artificial prosthesis replacement and resection and inactivation and replantation of tumor bone, amputation surgery has been gradually replaced by limb salvage surgery, which has now become the standard procedure for limb osteosarcoma.^{11,12}

Due to the combination of aggressive chemotherapy and surgery, the long-term survival for patients with osteosarcoma increased from 10%–15% to 65%–70%.¹³ In 1982, Rosen et al¹⁴ first proposed preoperative chemotherapy for the treatment of limb osteosarcoma. Neoadjuvant chemotherapy has many advantages. First of all, this method can limit or shrink the primary lesion, eliminate tumor satellite lesions and increase opportunities of limb surgery or reduce the difficulty of surgery. Neoadjuvant chemotherapy can eliminate the micrometastases in the blood and reduce tumor recurrence rate. In addition, effectiveness of chemotherapy drugs can be assessed according to tumor cell necrosis rate, and based on this, postoperative chemotherapy drugs would be prescribed.¹⁵ It is reported that neoadjuvant chemotherapy has greatly increased the 5-year survival rate of patients with osteosarcoma.^{16,17}

The EPI + DDP + MTX + IFO regimen used in this study is an internationally recognized first-line regimen for the treatment of osteosarcoma.^{18,19} EPI, DDP and IFO are all cell cycle non-specific drugs. EPI can directly embed in DNA base pairs, split DNA bonds and interfere in the synthesis of DNA and RNA; at the same time, it can damage the structure and function of cell membranes.²⁰ DDP inhibits DNA replication and cancer cell division by binding to DNA and forming a platinum compound. IFO kills tumor cells by cross-linking with DNA. EPI, DDP and IFO have synergistic effects and can significantly reduce the occurrence of drug

resistance.²¹ MTX, as a kind of cell cycle-specific drug, acts on the S phase of the cell cycle and affects the biosynthesis of the purine nucleotides and pyrimidine nucleotides in tumor tissue by inhibiting the dihydrofolate reductase, and thereby achieves the effect of inhibiting tumor cell proliferation. Kudawara et al⁸ have used this regimen for the treatment of non-metastatic osteosarcoma of the extremities and demonstrated the 5-year event-free and overall survival rates to be 83% and 98%. In this study, the tumor cell necrosis rates in group A assessed during operation were all >90%, which further illustrated that osteosarcoma cells were sensitive to these chemotherapy drugs. Therefore, the EPI + DDP + MTX + IFO regimen has continued to be used for postoperative chemotherapy.

In 2009, we introduced neoadjuvant chemotherapy combined with limb salvage surgery to treat some patients with limb osteosarcoma. This study retrospectively analyzed the patients with osteosarcoma treated in our hospital from January 2010 to December 2013. The total metastasis and recurrence rate of group A was significantly lower than that of group B, and the Kaplan–Meier method showed that PFS and OS of group A were both significantly higher than those of group B, indicating that neoadjuvant chemotherapy can give patients with osteosarcoma more survival benefit. The excellent and good rate of limb function in group A was significantly higher than that in group B, illustrating that neoadjuvant chemotherapy can reduce the tumor size, help to find the best surgical resection margin, retain limb function with the greatest degree and achieve the purpose of local radical therapy. Preventive medication or symptomatic support was given to all patients during chemotherapy, and all patients tolerated the chemotherapy well. In addition, there was no significant difference in the incidence of grades III–IV adverse reactions between the two groups.

Conclusion

This study demonstrated the excellent outcome of neoadjuvant chemotherapy combined with limb salvage surgery for the patients with limb osteosarcoma of Enneking stage II. However, this study is a retrospective study with a small sample size. In the future, a multicenter, randomized controlled trial with larger sample size will be conducted to achieve more reliable results.

Acknowledgment

We would like to express our sincere gratitude to all patients who participated in this study.
