Abstract

Motivation: Bioinformatics is a rapidly growing field that has emerged from the synergy of computer science, statistics and biology. Given the interdisciplinary nature of bioinformatics, many students from diverse fields struggle with grasping bioinformatic concepts only from classroom lectures. Interactive tools for helping students reinforce their learning would be thus desirable. Here, we present an interactive online educational tool called TeachEnG (acronym for Teaching Engine for Genomics) for reinforcing key concepts in sequence alignment and phylogenetic tree reconstruction. Our instructional games allow students to align sequences by hand, fill out the dynamic programming matrix in the Needleman–Wunsch global sequence alignment algorithm, and reconstruct phylogenetic trees via the maximum parsimony, Unweighted Pair Group Method with Arithmetic mean (UPGMA) and Neighbor-Joining algorithms. With an easily accessible interface and instant visual feedback, TeachEnG will help promote active learning in bioinformatics.

Availability and implementation: TeachEnG is freely available at <http://teacheng.illinois.edu>. The source code is available from <https://github.com/KnowEnG/TeachEnG> under the Artistic License 2.0. It is written in JavaScript and compatible with Firefox, Safari, Chrome and Microsoft Edge.

1 Introduction

Many of the tools in bioinformatics are based on algorithms developed in mathematics, statistics and computer science. For instance, sequence alignment and RNA folding prediction algorithms are based on dynamic programming (Bellman, 1952), a widely used optimization algorithm in computer science. Popular examples include the Needleman–Wunsch (NW) global sequence alignment algorithm (Needleman and Wunsch, 1970) and the Smith–Waterman local alignment algorithm. Another important concept frequently taught in bioinformatics courses is phylogenetic tree reconstruction via the maximum parsimony (Fitch, 1971), the Unweighted Pair Group Method with Arithmetic mean (UPGMA) (Sokal and Michener, 1958), and the neighbor-joining algorithms (Saitou and Nei, 1987). Given the interdisciplinary nature of bioinformatics, understanding these algorithms and mathematical concepts often pose challenges to students from diverse fields, especially those in

small colleges in the US without extensive teaching support and available resources. Hands-on training to reinforce learning would be ideal, but such opportunities are not readily available, especially in small teaching colleges. The developers of SAT (Ibarra and Melo, 2010) attempt to address this problem by providing a java package that fills out the dynamic programming matrix for sequence alignment, but the users do not have the option to manually fill out their own matrices and receive feedback.

The National Institutes of Health (NIH) has recently funded Big Data to Knowledge (BD2K) Centers and various BD2K Training projects to tackle this type of challenge and to broadly disseminate educational computational tools. As part of the KnowEnG BD2K Center, we have developed a web-based resource called TeachEnG (acronym for Teaching Engine for Genomics, and pronounced ‘teaching’) to help students reinforce their understanding of algorithms widely used in bioinformatics. Our website currently

contains four different modules that are implemented as interactive games. The ‘Sequence Alignment’ game asks the user to rearrange two sequences to get as many matches and as few mismatches and gaps as possible, and demonstrates the need for a constructive sequence alignment algorithm. In the subsequent portal ‘Sequence Alignment: Needleman–Wunsch’, the user is given two sequences and penalties for matches, mismatches, and gaps. The user then fills out the dynamic programming matrix in the NW algorithm. A natural extension to sequence alignment is to compare multiple sequences from more than two species and find evolutionary trees. Our modules ‘Maximum Parsimony’, ‘UPGMA’, and ‘Neighbor-joining’ allow the user to reconstruct phylogenetic trees from a given set of sequences and similarity measures for four species.

2 Software description

2.1 Sequence alignment

The goal of sequence alignment is to arrange two sequences in the most similar manner. Here, the similarity is measured by a weighted sum of matches, mismatches, and gaps. In the Sequence Alignment game, consisting of three levels of difficulty, the user is prompted to manually arrange two sequences to achieve the highest score. This time-consuming exercise highlights the need for a fast algorithm to complete the task, leading us to the NW algorithm.

In the NW game, the user is given two sequences v and w of lengths n and m , respectively, and a scoring matrix δ . The goal is to fill out the dynamic programming matrix S in the NW algorithm. For each entry $S_{i,j}$ in the $(n+1) \times (m+1)$ matrix, the user needs to fill in the maximum of three values: $S_{i-1,j-1} + \delta(v_i, w_j)$ (match/mismatch), $S_{i-1,j} + \delta(v_i, -)$ (gap in w), and $S_{i,j-1} + \delta(-, w_j)$ (gap in v). The program automatically checks the user input at every step and informs the user. After the matrix is completed, the program will perform backtracing and return the best alignment path. Figure 1A

shows a screenshot of the NW game in progress. In both games, the score matrix can be customized by the user.

2.2 Phylogenetic tree reconstruction

Sequence similarity explored in the previous section can be extended to comparing sequences from multiple species and reconstructing phylogenetic trees to represent evolutionary relationships. One popular method is to impose maximum parsimony, which is implemented in our third module. Given a set of four species and their corresponding short sequences, the user first guesses the correct tree by grouping similar species together; the guessed tree will be compared with the maximum parsimony tree at the final stage of the game. The user then has to select the correct informative sites to proceed to the next stage of the game and subsequently interacts with the game to evaluate the three possible tree structures. The final webpage selects the tree with the minimum score as the maximum parsimony tree and compares it to the user’s initial guess.

Another popular method, UPGMA, is based on a pre-defined distance measure between species, where short distance implies high similarity. In our second module, we implemented the UPGMA algorithm, where the user is given a distance matrix, and the goal is to iteratively select the pair with the shortest distance, merge the species, and then fill out the new distance matrix for merged nodes. When all species are grouped into one common ancestor, the program returns the completed UPGMA tree (Fig. 1B). Finally, we similarly implemented the Neighbor-Joining algorithm (Saitou and Nei, 1987) that minimizes the total branch length of a tree.

All our games have an accompanying video tutorial that demonstrates the functionality of each game and also explains the key concepts and computational procedures.

3 Conclusion

We developed an interactive tool called TeachEnG for teaching widely used algorithms in bioinformatics and computer science. The user can manually align two sequences, fill out the dynamic programming matrix, and reconstruct evolutionary trees. This interactive resource will complement lecture-based teaching methods by providing ample practice problems and instant visual feedback. TeachEnG is expandable and can easily incorporate new educational games in the future. Fisk University is an NIH-supported partner of the KnowEnG Center and is currently using TeachEnG in their bioinformatics course as homework exercises to review concepts taught in lectures. Instructors can also use our resource to visually demonstrate relevant algorithmic concepts during lecture. We envision students using our games to reinforce their understanding after initially learning about the algorithms. We hope that TeachEnG will help advance the broader bioinformatics community by educating students and researchers from diverse backgrounds.

Acknowledgement

The authors would like to thank Jiaxin Liu for helpful suggestions.

Funding

This research was supported by the NIH grants U54GM114838 and R25MD010396 and NSF Graduate Research Fellowship [DGE-1144245].

Conflict of Interest: none declared.
