Abstract

Background: Standard therapy for glioblastoma includes surgery, radiotherapy, and temozolomide. This Phase 3 trial evaluates the addition of an autologous tumor lysate-pulsed dendritic cell vaccine (DCVax[®]-L) to standard therapy for newly diagnosed glioblastoma.

Methods: After surgery and chemoradiotherapy, patients were randomized (2:1) to receive temozolomide plus DCVax-L (n = 232) or temozolomide and placebo (n = 99). Following recurrence, all patients were allowed to receive DCVax-L, without unblinding. The primary endpoint was progression free survival (PFS); the secondary endpoint was overall survival (OS).

Results: For the intent-to-treat (ITT) population (n = 331), median OS (mOS) was 23.1 months from surgery. Because of the cross-over trial design, nearly 90% of the ITT population received DCVax-L. For patients with methylated MGMT (n = 131), mOS was 34.7 months from surgery, with a 3-year survival of 46.4%. As of this analysis, 223 patients are ≥ 30 months past their surgery date; 67 of these (30.0%) have lived ≥ 30 months and have a Kaplan-Meier (KM)-derived mOS of 46.5 months. 182 patients are ≥ 36 months past surgery; 44 of these (24.2%) have lived ≥ 36 months and have a KM-derived mOS of 88.2 months. A population of extended survivors (n = 100) with mOS of 40.5 months, not explained by known prognostic factors, will be analyzed further. Only 2.1% of ITT patients (n = 7) had a grade 3

or 4 adverse event that was deemed at least possibly related to the vaccine. Overall adverse events with DCVax were comparable to standard therapy alone.

Conclusions: Addition of DCVax-L to standard therapy is feasible and safe in glioblastoma patients, and may extend survival.

Background

Glioblastoma is the most aggressive primary malignant brain tumor in adults [1]. Standard of care (SOC) consists of surgical resection followed by 6 weeks of daily radiotherapy with concurrent temozolomide, then monthly temozolomide [2]. Median overall survival (mOS) under this SOC is only 15–17 months [2, 3], and $\leq 5\%$ of patients are alive at 5 years [3]. Loco-regional therapy with alternating electric fields has recently shown an increase in median PFS (mPFS) to 6.7 months and mOS to 20.9 months from randomization, respectively [4]. However, there has been no material advance in survival with systemic therapies since the addition of temozolomide 12 years ago, despite investigations with many diverse agents [2, 5–10].

Immunotherapy is an appealing strategy because of the potential ability for immune cells to traffic to and destroy infiltrating tumor cells. Dendritic cells (DCs) are central to the immune system as key regulators of immune tolerance and immunity [11]. For more than a decade, our group and others have been testing active vaccination strategies, such as DCs pulsed with tumor lysates or synthetic peptides to induce antitumor immunity in glioblastoma patients [12, 13]. We have previously demonstrated the effectiveness of DC vaccination in pre-clinical models [14–16], and early stage clinical trials have shown substantial promise [17–19].

In this report, we describe the blinded interim data of the overall ITT patient population enrolled in a Phase 3 randomized, double-blinded, placebo-controlled clinical trial of an autologous tumor lysate-pulsed dendritic cell vaccine (DCVax[®]-L) for newly diagnosed glioblastoma. To date, we have not yet reached sufficient events (i.e., deaths) in this trial to justify unblinding. Nevertheless, since the vast majority (86.4%) of the ITT population received the experimental DC treatment at some point during the trial because of the cross-over study design, analysis of the interim data may provide early insight into the impact of DCVax-L on overall survival. A final analysis of the data obtained in this trial following unblinding will occur once sufficient events of disease progression or death have occurred

to fully elucidate patient survival data in the tail of the survival curve.

Methods

Study patients

Patients were eligible for this study if they were 18–70 years of age and had newly diagnosed glioblastoma, as determined through central pathology review. Other eligibility criteria included Karnofsky Performance Score (KPS) of ≥ 70 [20], adequate bone marrow, liver, and renal function, life expectancy of ≥ 8 weeks, no other prior malignancy within the last 5 years, no active viral infections, and sufficient resected tumor material to produce the autologous vaccine. Patients were excluded if they already had apparent early disease progression/recurrence or pseudo-progression at the baseline visit, similar to the inclusion/exclusion criteria of other recent trials in glioblastoma [4, 21].

Study design and treatments

We conducted this study at over 80 sites in 4 countries: the US, Canada, Germany, and the UK. Patient recruitment was initiated in 2007, and was paused from 2009 to 2011 for economic reasons. The midpoint of enrollment was reached in May of 2014, and the final patient was enrolled in November of 2015. The protocol was approved by the required independent ethics committees and institutional review boards. Written consent was obtained from all patients participating in the trial.

All patients underwent surgical resection and 6 weeks of chemoradiotherapy per SOC, prior to enrollment and randomization in the study.

Randomization was performed centrally and was stratified by clinical site and MGMT (O⁶-methylguanine-DNA methyltransferase) gene promoter methylation status, which was determined by a central laboratory. Patients were randomized 2:1 to SOC plus autologous DC vaccine (DCVax-L; n = 232) or SOC plus placebo (n = 99). PBMCs were used as placebo control as these cells are visually indistinguishable from DC and are considered immunologically inactive. Patients in both arms

continued to receive monthly adjuvant temozolomide (150–200 mg/m²/day × 5 days every 28 days), interspersed with the DC vaccine or placebo treatments administered on Days 0, 10 and 20, then Months 2, 4 and 8, and thereafter at 6-month intervals starting at month 12. Each DCVax-L treatment involved a dose of 2.5 million autologous tumor lysate-pulsed DCs administered intradermally in the upper arm, alternating arms between injection visits.

All patients were allowed to receive DCVax-L following tumor progression/recurrence, as well as other approved treatments per local practice. All parties (investigators, patients and sponsor) remained blinded as to which treatment each patient had received prior to crossover. All patients who chose this option were given the active treatment on a re-start schedule with immunizations at Days 0, 10 and 20, and then months 2, 4 and 8, and every 6 months thereafter beginning with month 12, with Day 0 being the day of the first vaccination post progression. To date, DCVax-L has been shipped for 286 patients (86.4%) in the trial.

Both the study treatment (DCVax-L) and placebo (PBMC) were prepared by Cognate BioServices, Inc. for all patients in the US and Canada, and by Cognate and the Fraunhofer Institute for Cell Therapy together for patients in Europe, during the chemoradiotherapy period before the baseline visit. The production of DCVax-L involved processing the resected tumor tissue into a lysate, and then collection, purification, differentiation, activation and loading of the autologous DCs. In general, approximately 2 g of tumor tissue was needed to produce the full ten doses for the 36-month treatment and follow-up schedule. The vaccine was aliquoted in individual doses and cryopreserved at < 150 °C [22]. The doses were stored centrally, and shipped individually to the clinical trial sites.

Assessments

Baseline assessments included physical examination, neurological examination, vitals, KPS, MRI of brain with and without contrast, hematology (CBC with differential, platelets), and serum chemistries (calcium, magnesium, SGOT, SGPT, alkaline phosphatase, LDH, total bilirubin, BUN, creatinine, electrolytes, glucose). Blood was collected for serum markers of autoimmune disease (anti-DNA) and immune monitoring, at the baseline visit and at treatment visits throughout the trial. MRI brain scans were performed every 2 months, per SOC, after the baseline MRI until radiological tumor progression. All MRI scans were evaluated centrally by 2 blinded independent radiologists, with adjudication by a third such radiologist if needed.

Adverse events were recorded prospectively according to the National Cancer Institute's Common Terminology

Criteria (version 3.0 NCI CTC), until 2 months after the last study treatment. Patients are followed for OS until death.

Statistical analyses

The study's primary endpoint is PFS, and the secondary endpoint is OS. PFS has not yet been evaluated for this publication and will be the subject of later analyses to allow for central, multi-factorial assessment by an expert panel, using criteria currently emerging as appropriate for immune therapy in this patient population where progression can be complex to determine and pseudo-progression is a known confounding phenomenon. Analysis of the blinded interim data on OS of the ITT population (using SAS version 9.4) was performed 34 months after the midpoint of patient enrollment, and 16 months after the last patient was enrolled and randomized.

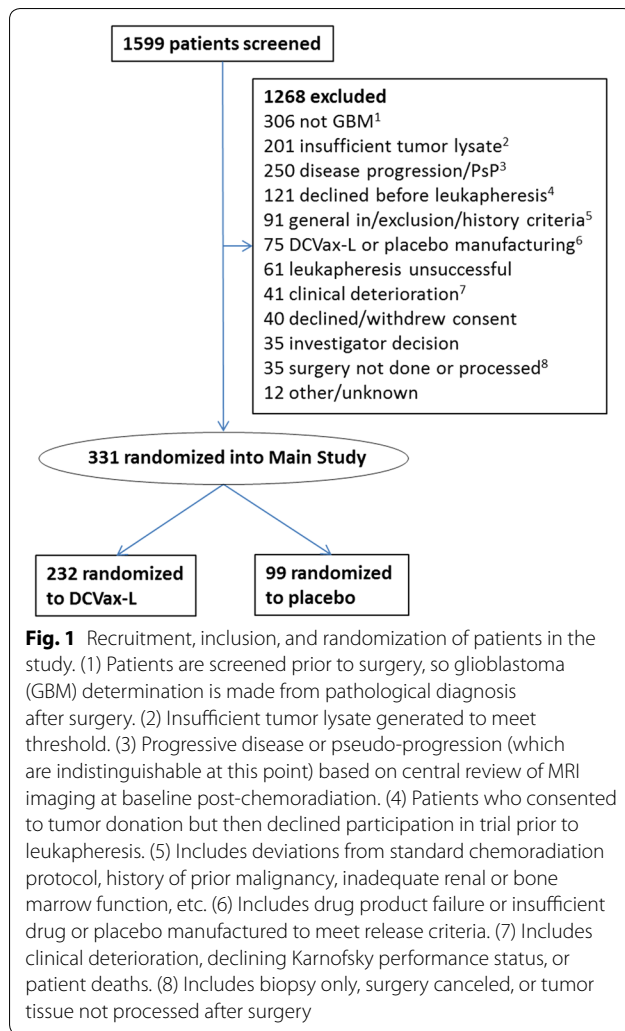

General descriptive statistics include the number of observed values, mean, standard deviation, median, and range values for continuous measures. For categorical variables, the number and percentage of subjects with a specific level of the variable are reported. For survival analyses, Kaplan–Meier (KM) curves were generated, yielding estimates of median survival times, along with the two-sided confidence intervals (95% CIs) and estimates of survival at specific time points.

Results

Study patients

From July 2007 to November 2015, 331 patients were recruited in the trial, comprising the intent-to-treat (ITT) population. A flow diagram depicting the flow of patients through the screening and enrollment process is provided in Fig. 1. The median time from surgery to randomization was 3.1 months.

The ITT population (n = 331) (Table 1) is similar to other recent glioblastoma trials [4, 21, 24], with 61% males (n = 202) and 39% females (n = 129), with 75.2% of the patients ≥ 50 years of age (range 19–73 years), and median KPS of 90. 63.1% of patients (n = 209) had gross total resection and 36.9% (n = 122) did not. The MGMT gene promoter was methylated in 39.6% of patients (n = 131) and unmethylated in 48.9% (n = 162), with information not available for 11.5% (n = 38; the missing data relates to the early patients enrolled a decade ago). Absolute lymphocyte count (ALC) was > 800 cells/mm³ in 48.6% of the patients (n = 161) and was < 800 cells/mm³ in 51.4% of patients (n = 170), a characteristic that has been associated with poor prognosis after radiation [23]. Patients with radiographic evidence of disease progression at baseline were excluded, as they have also been excluded in other recent trials for newly diagnosed glioblastoma [4, 21, 24].

Since other treatments were allowed following disease progression, we assessed their usage in this trial. While on study, three patients (1%) had another resection, 103 patients (31%) received bevacizumab, 53 patients (16%) received CCNU and 6 patients (1.8%) were treated with tumor treating fields. In multiple reported studies, neither bevacizumab nor CCNU have been shown to extend survival [9, 25].

Treatment outcomes

ITT population

At the time of this analysis, 108 the 331 patients (32.6%) were still alive. The mOS of the overall ITT population ($n = 331$) was 23.1 months from the time of surgery (95% CI 21.2–25.4), with 2 and 3-year survival rates of 46.2 and 25.4%, respectively (see Fig. 2a and Table 2). Analysis of patient survival relative to year of enrollment did not reveal a trend over time, nor meaningful differences between years.

Table 1 Baseline demographic and clinical characteristics

| Variable | n = 331 (100%) |
|----------------------------------|----------------|
| Age (year) | |
| Mean (SD) | 55.33 (10.01) |
| Median (range) | 56 (19, 73) |

Long tail among ITT population

With immune-based therapies, a key focus is on the tail of the survival curve [26]. Among the ITT patients with a surgery date ≥ 30 months prior to the data collection ($n = 223$), 30% ($n = 67$) have lived ≥ 30 months, and their KM-derived mOS estimate is 46.5 months. Among the ITT patients with a surgery date ≥ 36 months prior to the data collection ($n = 182$), 24.2% ($n = 44$) have lived ≥ 36 months and their KM-derived mOS estimate is 88.2 months.

MGMT status and extent of resection

In patients with methylated MGMT ($n = 131$), mOS was 34.7 months from surgery (95% CI 27.0–40.7), with 2 and 3-year survival rates of 66.7% and 46.4%, respectively. In patients with unmethylated MGMT ($n = 162$), mOS was 19.8 months from surgery (95% CI 17.9–21.7), with 2 and 3-year survival rates of 32.1%, and 11.0%, respectively (Fig. 2b and Table 2).

For patients with gross total surgical resection ($n = 209$), mOS was 25.4 months from surgery (95% CI

Fig. 2 Overall survival curves for patients in the intent-to-treat population. Overall survival analyses of time from date of surgery until death or last follow-up according to the Kaplan–Meier method for all patients in the intent-to-treat (ITT) population (**a**), and the ITT population stratified by MGMT gene promoter methylation status (**b**). Censored patients are annotated by a small vertical line

21.8–28.2), with 2 and 3-year survival rates of 51.2%, and 29.9%, respectively. For patients with only partial surgical resection ($n=122$), mOS from surgery was 21.1 months (95% CI 19.1–23.1), with 2 and 3-year survival rates of 37.7%, and 18.0%, respectively (Table 2).

In patients with both MGMT methylation and gross total resection ($n=83$), the mOS was 36.5 months (95% CI 31.5–46.5)—1.8 months longer than the mOS of patients with MGMT methylation and only partial resection ($n=48$). In patients with unmethylated MGMT,

Table 2 Study endpoints according to molecular genetic and clinical prognostic subgroups

| Population | n | Median OS since surgery (months) ^a | Survival at 1 year ^b | Survival at 2 years ^b | Survival at 3 years ^b |
|---------------------------|-----|---|---------------------------------|----------------------------------|----------------------------------|
| Overall | 331 | 23.1 (21.2, 25.4) | 89.3% (85.4, 92.2) | 46.2% (40.4, 51.8) | 25.4% (19.9, 31.3) |
| MGMT methylated | 131 | 34.7 (27.0, 40.7) | 94.5% (88.8, 97.3) | 66.7% (57.5, 74.4) | 46.4% (35.8, 56.3) |
| MGMT un-methylated | 162 | 19.8 (17.9, 21.7) | 86.4% (80.0, 90.8) | 32.1% (24.5, 39.9) | 11.0% (5.7, 18.2) |
| Gross total resection | 209 | 25.4 (21.8, 28.2) | 91.8% (87.1, 94.8) | 51.2% (43.9, 58.1) | 29.9% (22.6, 37.5) |
| Partial resection | 122 | 21.1 (19.1, 23.1) | 85.0% (77.2, 90.2) | 37.7% (28.6, 46.7) | 18.0% (10.5, 27.1) |
| KPS at baseline \geq 90 | 234 | 23.7 (21.8, 26.7) | 94.0% (90.0, 96.4) | 49.2% (42.3, 55.8) | 26.6% (19.9, 33.8) |
| KPS at baseline < 90 | 97 | 19.8 (16.6, 23.9) | 77.8% (68.0, 84.9) | 38.8% (28.5, 49.0) | 22.1% (13.4, 32.2) |
| ALC > 800 | 161 | 23.6 (21.7, 28.2) | 89.9% (84.0, 93.7) | 49.5% (41.1, 57.4) | 28.7% (20.6, 37.3) |
| ALC \leq 800 | 170 | 21.6 (19.9, 25.2) | 88.7% (82.8, 92.6) | 43.3% (35.4, 50.9) | 22.2% (15.0, 30.3) |
| Age < 50 years | 82 | 26.2 (21.1, 31.5) | 92.5% (84.2, 96.6) | 51.7% (39.9, 62.3) | 28.0% (16.4, 40.8) |
| Age \geq 50 years | 249 | 22.4 (20.4, 24.1) | 88.2% (83.5, 91.7) | 44.4% (37.7, 50.8) | 24.6% (18.5, 31.2) |

^a Median overall survival (OS) in months of intent-to-treat (ITT) population, followed by 95% confidence interval in parentheses

^b Annual rates of percentage surviving in ITT population, followed by 95% confidence interval in parentheses

there was no statistically significant survival advantage with gross total resection compared to only partial resection.

Unknown factors: sub-group with extended survival

Approximately 30% of the ITT population (n=100) showed particularly extended survival, with a KM derived mOS estimate of 40.5 months. This is not fully explained by known prognostic factors, as only some of these patients had positive prognostic factors: only 29% were younger than 50 years of age, 65.9% had methylated MGMT, 71% had a complete resection, and only 8% of these patients had all three positive prognostic factors. These patients will be the subject of extensive further analyses and research.

Safety and toxicity

Safety and toxicity data were assessed on a blinded basis for all 331 ITT patients. Following SOC chemoradiotherapy, and before any DCVax-L treatment, lymphopenia was the most common adverse event, occurring in approximately 170 patients (51%) [23].

The DCVax-L treatment was well tolerated, with only 7 ITT patients (2.1%) experiencing serious (NCI CTC Grades 3–4) adverse events that were deemed related

or possibly related to the DCVax-L treatment. These included cerebral edema in 3 patients (0.9%), seizures in 2 patients (0.6%), nausea in 1 patient (0.3%) and lymph gland infection in 1 patient (0.3%).

The rate of total adverse events with SOC plus DCVax-L was comparable to SOC alone (Table 3). Non-serious adverse events that were considered possibly related to the treatment included injection site reactions, fatigue, low-grade fever and night chills.

Discussion

Although enrollment was completed in 2015, this trial, including both treatments and follow-up, is still ongoing and will remain blinded until sufficient events of disease progression and/or death have occurred to more fully elucidate the tail of the survival curve. To date, due to the crossover design, nearly 90% of the ITT population received DCVax-L at some point in the trial, due to the crossover design.

DCVax-L is administered by intra-dermal injection in the arm, six times in year one and twice per year thereafter. It thereby imposes only a minimal burden on the patient.

In the overall ITT population in this trial, the mOS of 23.1 months from surgery compares favorably with the mOS of 15–17 months from surgery typically achieved

Table 3 Grades 3–4 treatment-emergent adverse events (TEAE)

| System organ class ^a | Number (%) of patients with TEAE (n = 331) |
|---|--|
| Patients reporting at least one serious TEAE (whether or not related to DC vaccine treatment) | 137 (41.1%) |
| Nervous system disorders | 93 (28.1%) |
| Infections ^b | 23 (6.9%) |
| General disorders and injection site reactions | 22 (6.6%) |
| Respiratory, thoracic and mediastinal disorders | 17 (5.1%) |
| Psychiatric disorders | 16 (4.8%) |
| Gastrointestinal disorders | 16 (4.8%) |
| Injury, poisoning, and procedural complications | 12 (3.6%) |
| Vascular disorders | 6 (1.8%) |

^b Includes surgical wound infections, meningitis, urinary tract infections, and others

^c Includes drug hypersensitivity

with SOC in past studies and clinical practice, as well as with the survival data with SOC treatment in the control arms of other trials in similar patient populations. For example, Weller et al. reported mOS of 17.4 months from randomization in the ITT population [21], and Stupp et al. reported mOS of 16.0 months from randomization in the ITT population [24].

In patients with a methylated MGMT gene promoter, the mOS of 34.7 months from surgery also compares favorably with SOC in past studies as well as with the mOS reported for the control arm SOC treatments in other recent glioblastoma trials in similar patient populations. For example, Stupp et al. reported for their control group an mOS of 21.2 months from randomization in a similar patient population [24]. The increase in survival in MGMT-methylated patients in the DCVax-L trial raises the possibility of a cooperative effect from the combination of temozolomide chemotherapy and the DCVax-L active immune therapy [17].

The mutation status of the IDH1 gene has not yet been investigated for this trial, as this factor was not included

in trial designs a decade ago when this trial began. It will be collected and analyzed later, but is unlikely to explain the overall survival results, as the mutation associated with prolonged survival occurs in less than 10% of newly diagnosed glioblastoma patients [27].

Beneficial effects of immune therapies are often observed at later time points, in the tail of the survival curve [26]. Although this Phase 3 trial requires further maturation, a picture is beginning to emerge from the blinded interim data which is consistent with an extended survival tail. For example, among the patients (n = 182) who were ≥ 36 months past their surgery date as of the date of this analysis, 24.2% (n = 44) were alive for ≥ 36 months and have a KM estimated median survival time of 88.2 months. Thus, it appears that patients who survive past certain threshold time points may continue onwards to unusually long survival times, similar to the findings in our prior Phase I/II studies of this DC-based vaccine [17–19]. Further maturation of the trial data is needed to more fully reveal the extent of the long tail of the survival curve.

DCVax-L has shown a benign safety profile in this Phase 3 study, as it has consistently done in prior early stage trials [17, 19], and in a large group of patients treated on a compassionate use basis [28]. The fact that only 7 of the 331 ITT patients (2.1%) experienced any grade 3 or 4 adverse events that were at least possibly related to the treatment makes this DC vaccine an especially well tolerated treatment.

With such a safety profile, this DC vaccine may be administered in a wide range of clinical settings, and can potentially be combined with a wide range of other treatment agents, including immune checkpoint inhibitors and targeted therapies, without resulting in undue toxicities for patients such as have been seen with some other treatment combinations [29, 30]. Further studies to explore such combinations are warranted.

Conclusions

The addition of DCVax-L autologous dendritic cell vaccine to SOC is feasible and safe. Collectively, the blinded interim survival data suggest that the patients in this Phase 3 trial are living longer than expected. These findings warrant further follow up and analyses.

Authors’ contributions

LL and MB conceived of and designed the study. LL, KA, DDT, JLC, TET, CSC, JAH, MS, ST, SDD, FMI, EJD, YAM, KAW, CPP, RA, RC, SAG, DAB, PD, JG, HE, SAT, KOL, TM, TW, SRA, AJB, SB, MGE, AK, JP, LJK, WGL, RCT, DEA, KLF, FJG, SL, JL, AES, GS, DK, H-JM, JW, RPD, CD, ABE, DM, SK, DP, MW, DSB, PZN, ML, S-AM, TJP, VT, RMG, JLV, MP, KP, MS, LPT, and PM contributed to collection of the data. EB served as the consulting statistician. All authors were involved in critical review of the data, or drafting, reviewing or revising the manuscript or approving the final version. LL enrolled the greatest number of patients in the USA and KA enrolled the greatest number of patients in the EU. All authors read and approved the final manuscript.

Acknowledgements

Supported by Northwest Biotherapeutics, Inc. and the UCLA SPORE in Brain Cancer (P50-CA211015). We thank the patients who have participated in this clinical trial and their families.

Competing interests

Dr. Bosch and Dr. Maida report being an employee of, holding stock or stock options in, and receiving reimbursement for travel expenses from Northwest Biotherapeutics, Inc.

Availability of data and materials

The datasets generated and/or analyzed during the current study are not publicly available to protect future regulatory filings but access to the data can be available through an independent statistician on a case by case basis, as necessary and under confidentiality.

Consent for publication

Not applicable.

Ethics approval and consent to participate

The study was approved by Ethics Committees/Institutional Review boards at all participating hospitals. Written consent was obtained from all patients prior to participating in the study.

Funding

Northwest Biotherapeutics, Inc. was the trial sponsor and had a role in the design and conduct of the study, along with academic advisers; collection, management, analysis, and interpretation of the data; preparation, review, and approval of the manuscript; and decision to submit the manuscript for publication. Data collected by the CRO from the investigators and their site personnel were analyzed and interpreted on a blinded basis by senior academic authors, independent statisticians, and representatives of the sponsor.

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
