The role of timely initiation of antenatal care on protective dose tetanus toxoid immunization: the case of northern Ethiopia post natal mothers

Muhabaw Shumye Mihret^{*†}, Miteku Andualem Limenih[†] and Temesgen Worku Gudayu^{*}

Abstract

Background: Globally, tetanus toxoid protective dose immunization of the mothers is one of the strategies of maternal and neonatal tetanus prevention. Ethiopia has planned the national tetanus protection at birth coverage to reach 86% by the year 2015. However, there is still low coverage with less identified associated factors. Therefore; the purpose of this study was to assess tetanus toxoid protective dose immunization at last birth and associated factors among mothers who gave birth within one year prior to the study in Debretabor town, Northwest Ethiopia, 2016.

Methods: A community based cross sectional study was conducted from May 1 to June 10 / 2016. A total of 511 mothers were included in the study. Structured questionnaire and checklists were used to collect the data. Face to face interview with cross checking documented record were employed. A systematic random sampling technique was used. The data were entered in to Epiinfo version 7.0 and then exported to SPSS version 20.0 for analysis. Both bivariate and multivariable logistic regression model were fitted and crude and Adjusted Odds ratio with 95% confidence interval were computed. Finally, statistically significant association of variables was determined based on Adjusted Odds ratio with its 95% confidence interval and p -value ≤ 0.05 .

Result: The proportion of tetanus toxoid protective dose immunization among mothers was 56.2% (95% CI: 52–60%). In the multivariable analysis; formal education (AOR = 2.09; 95%CI: 1.12, 3.90), planned last pregnancy (AOR = 6.63; 95%CI: 2.36, 18.63), four or more antenatal care visits (AOR = 5.16; 95%CI: 2.93, 11.14), timely antenatal care visit (AOR = 4.29; 95%CI: 1.94, 9.49), and perceived good quality of service (AOR = 2.20; 95% CI: 1.26, 3.84) were positively associated with tetanus toxoid protective dose immunization.

Conclusion: In this study, protective dose tetanus toxoid immunization is lower than the national target. Strengthening information education communication regarding tetanus and its prevention and encouraging timely initiation of and complete attendance of antenatal care is recommended.

Background

Protected at birth (PAB) against tetanus is the proportion of births protected from tetanus infection at birth by tetanus toxoid protective dose immunization (TTPDI) of the mothers before birth [1, 2]. World Health Organization (WHO) recommends 5 consecutive doses of tetanus toxoid (TT) vaccination for child bearing age women (CBAW) per schedule to protect the birth against tetanus [3]. Tetanus is a highly fatal, non-communicable, toxin-mediated disease caused by *Clostridium tetani* bacteria [3, 4]. Women and their newborns are at high risk of acquiring tetanus related to the birthing process [5]. Globally, tetanus toxoid (TT) immunization of the mothers is one of the preventive strategies of maternal and neonatal tetanus (MNT) at birth [5–7].

Maternal and neonatal tetanus (MNT) is a public concern mainly attributable to low maternal TT vaccination [8]. Fortunately, almost all developed countries have achieved maternal and neonatal tetanus (MNT) elimination prior to 1999 either by full coverage of TT immunization or by hygienic birth practice [9]. However, it has been a big deal in developing regions. Between 1999 and 2014, still about 33 million child bearing age women (CBAW) didn't receive two or more doses of TT vaccination [9]. Worldwide, about 36% of mothers were not immunized with TT protective dose at birth against tetanus [10]. Consequently; about 49,000 neonates and a significant numbers of mothers died of tetanus [11]. This problem is much higher in South East Asian (SEA) and Sub-Saharan African (SSA) countries where 90% of maternal and neonatal tetanus (MNT) appeared and almost all cases ended with death [11]. In Ethiopia, about 51% of pregnant women were not received valid TT vaccination [12]. The problem magnified in Amhara regional state where 56% infants were not protected at birth(PAB) against tetanus [13].

To alleviate this problem, TT vaccination of pregnant women was included in World Health Organization's (WHO) Expanded Program on Immunization (EPI) [14, 15]. World Health Organization (WHO) and its partners jointly have been working for global elimination of MNT basically through maternal TT vaccination. Accordingly, they had planned a targeted date for this goal, a reduction of neonatal tetanus incidence to below one case per 1000 live births per year in every district of the globe, to be at 1995. However, it was postponed many times due to inability to achieve the goal [14, 15]. In Ethiopia context, the Federal Ministry of Health (FMOH), in collaboration with Expanded Program of Immunization (EPI) partners, started implementing TT supplemental immunization since 1999 with the aim of MNT elimination. Moreover, the country introduced the protection at birth(PAB) method for tetanus toxoid (TT) immunization monitoring in 2009 [1]. By August

2015, 21 countries have still not reached the MNT elimination status including Somali region of Ethiopia [11].

Despite impressive efforts, coverage of PAB against tetanus is still low [9, 13–20]. Though, Ethiopia planned the national tetanus PAB coverage to reach 86% by the year 2015, it is still only 49% as of EDHS 2016 [12, 21]. Even, this magnitude is based mostly on health institutional data. Thus, this secondary data often may not depict the actual condition since the situation tends to happen in a communities with restricted access and/ or use of health facilities [22].

Therefore; with the current universal push of ending preventable deaths of newborns and children under 5 years of age, a reliable community based study on preventive strategies like TTPDI and associated factors to have representative data, is required. Having this point of view, this community based study was conducted to assess TTPDI and associated factors at last birth among mothers delivered within one year prior to the study in DebreTabor town, North West Ethiopia, 2016.

Methods

A community based cross sectional study was conducted at DebreTabor town which is the largest town in South Gondar zone Amhara regional state, Northwest Ethiopia. The town is located at 665 km from Addis Ababa (the capital city of Ethiopia) in Northwest direction.

Based on the 2007 National Census conducted by Central Statistical Agency of Ethiopia (CSAE), the projected total population in the town is about 55,596 of whom 27,644 (49.7%) are men and 27,952 (50.3%) are women. Orthodox Christians' are 96.72% of the population of the town and 2.54% are Muslims [23]. The town is divided in to four small administrative units called kebeles and has one general hospital, 3 health centers and 4 Health posts [23].

In the study area, antenatal health services are not active. In other words, if women did not attend the clinic, health providers don't go to the door to give the care. However, the health extension workers (HEWs) are responsible to go to the community home –to- home to mobilize the pregnant women, their family and the community at large so as to visit the health facilities during pregnancy for antenatal care (ANC) service. In addition, HEWs provide information for the client on the importance of antenatal care follow up by moving door to door. As far as duties for provision of ANC services concerned, midwives are primarily responsible at the health centers as well as at the hospitals. Whereas, health extension workers are responsible at health post (i.e. the smallest unit of health facility). Furthermore, there is a consultancy system between midwives and other health care professionals.

Sample size for the study was determined using an Open-Epi Version 2 software by considering the following

assumptions: ratio among married and unmarried women 1:1, OR 1.83, power 80%, CI 95% and the proportion of births PAB against tetanus among married women 77.9% [24]. So, the largest sample size for this study was 460 and by assuming 10% non response rate the final sample size turned to be 511.

All mothers in the town who gave birth within one year before the study period were included in the study. Mothers who came from other places to the town for the first time after delivery and also who resided in the town for less than six months were excluded.

First, total numbers of households (HHs), (13,837), were obtained from DebreTabor town administrative office. The sampling interval was made by dividing the total households (HHs) for total sample sizes by assuming every household (HH) had at least one eligible mother, (that is, $13,837/511 = 27$). The first HH was then selected by using lottery method among the first 1–27 HHs. And then, selection was proceeded every 27 HHs interval by employing systematic random sampling technique. Finally, a total of 511 HHs with eligible mothers were selected. In case of no eligible woman in the HH, the interviewer approached to the next closest HH. In the selected HH, adequate explanation offered; presence of eligible mother confirmed; written informed consent requested and obtained; and then the HH identification code placed at questionnaire as well as at the door. Face to face interview was then proceeded by using structured and pretested questionnaire. At times, clients have been categorized as ever or never taking TT based on their verbal history. For those mothers who admitted ever history of receiving TT dose(s), documented evidences (either TT card or EPI registration book) was reviewed. Finally, mothers categorized as whether receiving tetanus toxoid protective dose immunization or not based on the listed criteria.

Tetanus toxoid protective dose immunization (TTPDI) was defined as proportion of mothers who have been received any of the following documented TT doses:

1. Two tetanus toxoid injections during that pregnancy
2. Two or more injections, the last one within 3 years of the birth
3. Three or more injections, the last one within 5 years of the birth
4. Four or more injections, the last one within 10 years of the birth
5. Five or more injections at any time prior to the birth

Socio-demographic, obstetric and health service related variables such as maternal age, mother's educational status, husband's educational status, marital status, religion, mother's occupation, husband's occupation, family monthly income, ethnicity, owing radio /television, parity, planned

last pregnancy, having ANC visit during the recent pregnancy, number of ANC visit, time of initiating ANC visit, place of ANC visit, client perceived quality of services, time to cover the distance home to health facility, client perceived confidentiality, client trust on TT service, client perceived behavior of service provider, client perceived providers' respect of clients, purpose of taking the vaccine and reason for not taking the vaccine. In addition, checklists on regarding TT vaccination status in the recent pregnancy as well as in life like ever taking the vaccination, number of doses, timing(interval) among doses, source of information for vaccination status which categorized as history alone, card(document) alone, or both history and card. Finally, TT protective dose immunization status (yes or no) was included.

The questionnaires were first prepared in English [Additional file 1] and translated into Amharic and finally, translated back to English. Six unemployed midwifery professional graduates were recruited for data collection process. These include, four diploma midwives for data collection and two BSc midwives for supervision. A one day training was given for data collectors and supervisors. In addition, data collectors had employed the interview guide during discussion [Additional file 2]. A pretest study was done on 5% of sample size. Data were checked, coded and entered to EPI INFO version 7. Then, it was exported to SPSS version 20 for analysis. Both descriptive and analytical statistical procedures were utilized. Descriptive statistics were carried out and the results were presented using tables and texts. Binary logistic regression was used to identify factors associated with TTPDI at last birth. Then, those variables with P -value < 0.2 from Bivariate analysis, were fitted to multivariable logistic regression with Backward Stepwise Likelihood Ratio. Both COR and AOR with the corresponding 95%CI were computed to show the strength of the association. Finally, statistically significant association of variables was determined based on Adjusted Odds ratio with its 95% confidence interval and p -value ≤ 0.05 .

Result

Socio-demographic and economic characteristics

A total of 511 women were interviewed.

The median age of the participants was 27 years with (IQR =7). Majority, (83.8%), of the participants were in age group 20–34 years. More than half, (50.9%), of women were housewife by occupation and 99, (19.4%), women have never attended any formal education. Large segment, (77.5%), of respondents' family earned more than 36.00 US dollar per month [Table 1].

Obstetric and health service related factors

More than half, (52.8%), and 226, (44.2%), of the participants were primipara and grand-multipara, respectively.

Considerable, (90%), of participants' last pregnancy were planned. Substantial proportion, (95.3%), of the respondents have had ANC visit with the mean \pm SD of 2.14 ± 1.01 visits

and about 36.6% of them have had 4 or more ANC visits. More than two-third, (74.2%), of women perceived as good quality of health services and 472, (92.4%), thought as the service provider respected the women. Majority, (86.1%), women believed as there was no confidentiality problem while about 480, (93.9%), of them trusted health care providers [Table 2].

Proportion of tetanus toxoid protective dose immunization

Proportion of mothers who have been immunized with TT protective dose immunization were 56.2% (95%CI: 52–60%). Among mothers who did not take TT immunization properly; majority, (53.26%), replied that no one advised them and others reasons were not known (30.43%), no problem faced (11.96%), distance barrier (3.26%) and no service provider (1.09%).

Factors influencing tetanus toxoid protective dose immunization

Bivariate analysis

Finding from bivariate logistic regression analysis showed that mother's age, mother's educational status, marital status, ever having ANC visit, parity, perceived behavior of service providers, place of ANC visit, time of initiating ANC visit, planned last pregnancy, number of ANC visit and perceived quality of service were associated with TTPDI at last birth [Table 4]. Whereas, among socio-demographic variables, only mothers' age and educational status were statically associated with ever taking TT vaccination [Table 3].

Multivariable analysis

In the multivariable logistic regression analysis; mother's educational status, planned pregnancy, perceived quality of service, time of initiation and number of ANC visit remained statistically significantly associated with TTPDI.

Accordingly, mothers with formal education were 2.09 times more likely to have been immunized with protective doses of TT than uneducated mothers (AOR = 2.09; 95 CI: 1.12, 3.90).

Besides, the odds of having TT protective dose immunization were nearly 4 times higher among mothers who have initiated ANC visits with in first trimester compared to their counterparts (AOR = 4.29; 95%CI: 1.94,9.49). Similarly, mothers who had four or more ANC visits during the last pregnancy were 5.16 times more likely to have been immunized with TT protective dose than those who had below four ANC visit (AOR = 5.16; 95%CI: 2.93, 11.14). This study also depicted that mothers with planned last pregnancy were 6.63 times more probably to receive TT protective dose immunization than their counterpart (AOR = 6.63; 95% CI: 2.36, 18.63).

Finally, Mothers, having good perceived quality of service were 2.20 times more probably to have been immunized with protective doses of TT than their congruent (AOR = 2.20; 95% CI:1.26, 3.84) [Table 4].

Discussion

This study assessed proportion of tetanus toxoid protective dose immunization and associated factors among mothers who gave birth within one year prior to data collection period. The odds of TT protective dose immunization was higher among mothers who have attended formal education, have initiated early ANC visit, with planned last pregnancy, achieving two or more ANC visit, and with perceived good quality of service.

The study illustrated that the proportion of Tetanus toxoid protective dose immunization among mothers found to be 56.2%. The finding is in line with the Nigeria national coverage (55%) [25]. On the other hand, this magnitude is higher as compared to the study done in Lagos Nigeria (20%) [26], Umuahia Nigeria (50%) [27], Ankara Turk (27.8%) [28] and Ibadan Nigeria (38.1%) [29].

This result was also larger as compared to the Ethiopian national PAB coverage (49%) [12] and other local reports, such as Ambo town,(26.8%) [24], Afar regional (26.7%), [16] and Amhara regional PAB coverage, (43.2%), [16].

This disparity could be explained by variation in tools used to measure the outcome variable: some studies were laboratory based which measured the actual serum antibody level enough to protect against tetanus where as the current study used documented evidence to measure proportion of TT protective dose. So, the tool used in the current study might brought about higher magnitude as compared to that of the actual serum antibody measurement [29]. Besides, the discrepancy could be due to variation in the study setting; some studies have included both urban and rural residents. Studies showed that rural dwellers were less educated as compared to urban women. As the current and other studies showed, TT vaccination utilization predicted by level of mother's education (13). So, the higher magnitude of TT protective dose immunization in the current studies might be attributable to composition of the study participants that is including only urban women. In addition, as studies elucidated, lack of TT vaccination occurred in the communities with limited access to and use of healthcare services, and maternal TT vaccination was predicted by distance from the nearest immunization centre, and level of contact with health worker (35, 38, 45). Thus; those women resided in the rural and remote areas would not easily accessed to health facilities as compared to urban women although the TT service was free of charge [24]. Furthermore, the discrepancy could be variation in time of the study: some studies were done back to 5 years. But, currently trends on educational status and awareness toward the importance

of TT changed across a time. These all mentioned explanation possibly could answer why TT protective dose immunization in the current study was higher.

However, the result was considerably lower as compared to findings from national PAB coverage in Ghana (82.6%) [30] and local studies in: Pakistan in 2007-(87%)-[31], Pakistan in 2011-(90.5%)-[32], Ghana (82.6%) [30], Sudan (83%) [33] and Ethiopia (82.3%) [13]. This variation might be due to the method employed to measure the outcome variable; the current study used proofed (documented) evidence for maternal vaccination status whereas most other studies described primarily based on maternal verbal history which was prone to recalled bias and might be resulted in over estimation in the latter studies [30–33].

As this study demonstrated, the odd of TT protective dose immunization was 2.09 times among mothers with formal education than that of uneducated women. This finding is in line with the study done in different settings: in Bangladesh [34], in France [35] and in Ethiopia [24, 36]. This might be due to the fact that education increases awareness of women on the benefits of immunization, a greater decision-making power at home and perhaps escalate capacity to travel outside the home to seek health care (26).

This study also revealed that planned last pregnancy was statistically significantly associated with TT protective dose immunization; women with planned last pregnancy were more than six times more likely to have been

immunized with TT protective dose than women whose pregnancy was unplanned. This is in accordance with the study done in Bangladesh [37], Kenya [38] and Ambo town, Ethiopia [24]. This might be due to the logic those mothers with planned pregnancy possibly ready themselves to overcome physical barriers like distance, to allocate time to seek health care, to attend health related media promotion like 'the first 1000 days' and probably to search health related information either, by consulting health care providers or by reading related papers.

According to this study, TT protective dose immunization was independently predicted by frequency of ANC visit during the recent pregnancy. Hence, mothers who had four or more number of ANC visit during the last pregnancy were more than five folds more likely to have been immunized with protective dose of TT than their counter parts. This implies that attending the recommended number of ANC visit is a good opportunity for valid TT immunization utilization. This was with regard to the study done in Peshawar, Pakistan [39] and in Kenya [38]. This could be due to the reality that the higher the frequency the mother visited health facilities, the higher the mothers received appropriate health care services and correspondingly, the valid the TT doses offered. Plus to that, as the contact time with health professional increased, the mother got more health related information and this in turn might change her health seeking behavior positively.

This study also elucidated that TT protective dose immunization was influenced by time of initiating ANC visit

during the last pregnancy. Mothers with history of initiating ANC visit within the first trimester were nearly four folds more likely to have been immunized with this dose than those starting later. This suggests that if mothers started ANC visit in early gestation, they would get adequate time enough to take two or more TT vaccination based on the schedule prior to giving birth. This finding is in agreement with the study done in Lahore district, Pakistan [31].

Based on the current study, the odds of TT protective dose immunization was 2.20 times higher among mothers with perceived good quality of service than their counter parts. This suggested that no matter the real quality of service provided, simply client perception toward quality of service, matters receiving valid TT vaccination. This is consistent with the study conducted in Dormaa, Ghana [40]. This result also supported by study conducted in Hispanic and Houston, Texas [41].

Limitation of the study

The study was conducted solely in the urban area. As a result; it did not involve participants from rural areas. In addition, although using documented evidence for confirming protective dose immunization could be taken as strength, the finding of this study might be underestimated as compared to other studies which reported based on maternal verbal history alone.

Conclusion

The proportion of mothers who have been vaccinated with protective doses of TT immunization in the study area was below the national target. Formal education,

planned last pregnancy, timely ANC visit, four or more ANC visit and perceived good quality of service were factors positively associated with protective doses of TT immunization. Thus; complete ANC visit, planned pregnancy and early initiation of ANC visit should be emphasized. Similarly; female education and correcting women perception toward quality of TT service is recommended.

Acknowledgements

We would like to thank University of Gondar for ethical letter and financial support. We also like to forward our deepest and sincere appreciation to all data collectors and study participants. Our gratitude is also great to Debre Tabor town administration office for provision of support letter.

Competing interests

The authors declare that they have no competing interests.

Availability of data and materials

When ethics statement was obtained from the Woreda health office, we have agreed and signed not to publish the raw data retrieved from information of the mothers. However, the data sets collected and analyzed for the current study is available from the corresponding author and can be obtained on a reasonable request.

Authors' contributions

MSM: designed the study, performed analysis and interpretation of data and drafted and revised the manuscript. MAB: designed and approved the proposal with some revisions, participated in data analysis, and revised subsequent drafts of the paper. TWG: designed the study, approved the proposal with some revisions, participated in data analysis and revised subsequent drafts of the paper, and developed and revised the manuscript. All authors read and approved the final manuscript.

Ethics approval and consent to participate

The ethical clearance was obtained from the Institutional Review Board of University of Gondar on behalf of the Department of Midwifery, College of Medicine and Health Sciences. Ethical letter was being written to the respective officials of the study area. The administrator of Debre Tabor town

wrote the letter to each Kebele leaders. Informed written Consent of the respondents was then obtained and signed at the participant's consent sheet format [Additional file 3] after giving information and thoroughly explaining the aim of the study to each respondent. The study subjects were interviewed in their homes individually to maintain privacy.
