**Introduction:** As part of a study aimed at illuminating at least some of the complex molecular events taking place in COPD, we screened tissues by means of transcriptome analyses.

**Materials and methods:** Tissues were subjected to transcriptome analysis. Candidate genes were identified and validated by immunohistochemistry. Primary human lung cells were subjected to stimulation with cigarette smoke extract for further validation by real time PCR.

**Results:** Six candidate genes were selected for further investigations: Aquaporin 3 (*AQP3*), extracellular matrix protein 1 (*ECM1*), four and a half LIM domain 1 (*FHL1*), milk fat globule epidermal growth factor 8 (*MFGES8*, lactadherin), phosphodiesterase 4D-interacting protein (*PDE4DIP*), and creatine transporter *SLC6A8*. All six proteins were allocated to distinct cell types by immunohistochemistry. Upon stimulation with cigarette smoke extract, human type II pneumocytes showed a dose-dependent down-regulation of *MFGES8*, while *ECM1* and *FHL1* also tended to be down-regulated. Although present, none of the candidates was regulated by cigarette smoke extract in primary human macrophages.

**Discussion:** *MFGES8* turned out to be an interesting new candidate gene in COPD deserving further studies.

**Keywords:** COPD, transcriptome, MFGES8, CSE, cigarette smoke extract, ETS2

## Introduction

The complex disease mechanisms resulting in COPD are poorly understood. We investigated COPD-related changes of the gene expression in tumor-free lung tissues of COPD patients by transcriptome analysis.

## Materials and methods

### Lung tissue

Tumor-free lung tissue obtained from lobectomy or pneumectomy specimens, with a minimum distance to the tumor of 10 cm, of 19 lung cancer patients, was fixed using 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid [HEPES]-glutamic acid buffer-mediated organic solvent protection effect (HOPE) and embedded in paraffin according to DCS Innovative Diagnostik-Systeme protocol (Hamburg, Germany). Fourteen patients (mean age 66 years; 11 males; eight ex-smokers and six current smokers) had concomitant COPD; five patients served as control (mean age 69.5 years, all female and never-smokers). Detailed information is deposited at Gene Expression Omnibus (GSE106986).

This study was conducted using material from non-small-cell lung cancer resections and performed anonymously. Patient tissue was used and all experimental procedures

were performed with the permission of the local ethical committee at the University of Lübeck (AZ12-220).

## Transcriptome analysis

Microarray analysis was performed using extracted RNA of human lung tissues. RNA quality was determined with the Agilent Bioanalyzer. The Low Input Quick Amp Labeling Kit (Agilent Technologies, Santa Clara, CA, USA) was used according to the manufacturer's protocol for cDNA synthesis, amplification, and labeling with Cyanine 3-CTP (Cy3) during reverse transcription by T7 RNA polymerase. Cy3-labeled cRNA was purified using the RNeasy Mini Kit (Qiagen NV, Venlo, the Netherlands) and the specific activity was calculated using a NanoDrop 2000 spectrophotometer (Thermo Fisher Scientific, Waltham, MA, USA). Labeled cRNA was hybridized to Agilent Human Whole Genome Gene Expression 4×44 k V2 arrays and scanned with a SureScan microarray scanner (Agilent Technologies) at a resolution of 5 µm. GeneSpring software version 13 (one-color gene expression protocol) was used for quantile normalization and statistical analyses (one-way ANOVA and Benjamini–Hochberg multiple testing correction, cutoff *p*-value <0.05). The complete gene list is deposited at Gene Expression Omnibus (GSE106986).

## Histologic analyses

A tissue microarray of HOPE-fixed, paraffin-embedded tissues of 20 patients was used for analysis. The samples were dewaxed in 100% isopropanol for 10 min at 60°C. Sections were air dried, rehydrated in 70% acetone for 10 min at 4°C, and transferred into distilled water for 10 min at 4°C and 5 min at room temperature. Endogenous peroxidases were blocked by incubation in 3% H<sub>2</sub>O<sub>2</sub> for 10 min. The polymer blocking reagent (Zytomed, Bargteheide, Germany) was incubated 5 min before the first antibodies were applied. The first antibodies were used in concentrations of anti-AQP3 ab125219 5 µg/mL (Abcam, Cambridge, United Kingdom); anti-ECM1 ab3924 1 µg/mL (Abcam); anti-FHL-1 ab58067 1 µg/mL (Abcam); anti-MFGE8 MAB12684 1 µg/mL (Abnova, Heidelberg, Germany); anti-PDE4DIP ab56655 4 µg/mL (Abcam); anti-SLC6A8 ab62196 1 µg/mL (Abcam) in antibody diluent (Zytomed) for 60 min at room temperature. The CytoChem Plus HRP Polymer Kit (Zytomed) was used for detection. The tissue slides were counterstained with Mayer's hemalum solution (Merck).

## Cigarette smoke extract (CSE) stimulation of human primary alveolar pneumocytes type 2 and macrophages

Tumor-free lung tissue (around 30 g) was rinsed with phosphate-buffered saline and cut into pieces of 3 mm size.

The tissue pieces were rinsed with cell buffer (pH 6.64, 10 mM HEPES, 1.9 mM CaCl<sub>2</sub>, 1.3 mM MgSO<sub>4</sub>, 137 mM NaCl, 5.4 mM KCl, 6.2 mM glucose, 6.2 mM Na<sub>2</sub>HPO<sub>4</sub>) and incubated for 60 min at 400 rpm, at 37°C in 5% CO<sub>2</sub> in cell buffer supplemented with 200 mg Dispase II, 500 µg DNase I, and 100 µL Accutase for the enzymatic dissociation of the cells. The cells were separated by density centrifugation, resulting in single-cell suspensions of epithelial cells and immune cells. Cells were seeded on cell culture flasks to separate fast-adhering immune cells from slow-adhering epithelial cells. P2 cells were separated by negative selection of CD45. Therefore, CD45 MicroBeads (human, Miltenyi, Bergisch Gladbach, Germany) were incubated for 15 min at 4°C and the cell-bound beads were captured in an LD column (Miltenyi, Bergisch Gladbach, Germany) with the Multi-MACS magnet. The eluted CD45-negative P2 cells were seeded on 48-well plates at low density (4×10<sup>5</sup> cells/well) in RPMI (10% fetal calf serum, penicillin/streptomycin, and L-Glutamine) for 16 h.

CSE was obtained using Tobacco-Health Research cigarettes (University of Kentucky) by drawing smoke of one cigarette slowly through a water pump into a tube containing 10 mL of ddH<sub>2</sub>O (100% CSE). One percent and 5% CSE in RPMI (with penicillin/streptomycin and L-Glutamine) were used for 16 h cell stimulation. Cells were harvested and used for RNA isolation.

## Quantitative real-time polymerase chain reaction of stimulated human primary alveolar pneumocytes type 2 and macrophages

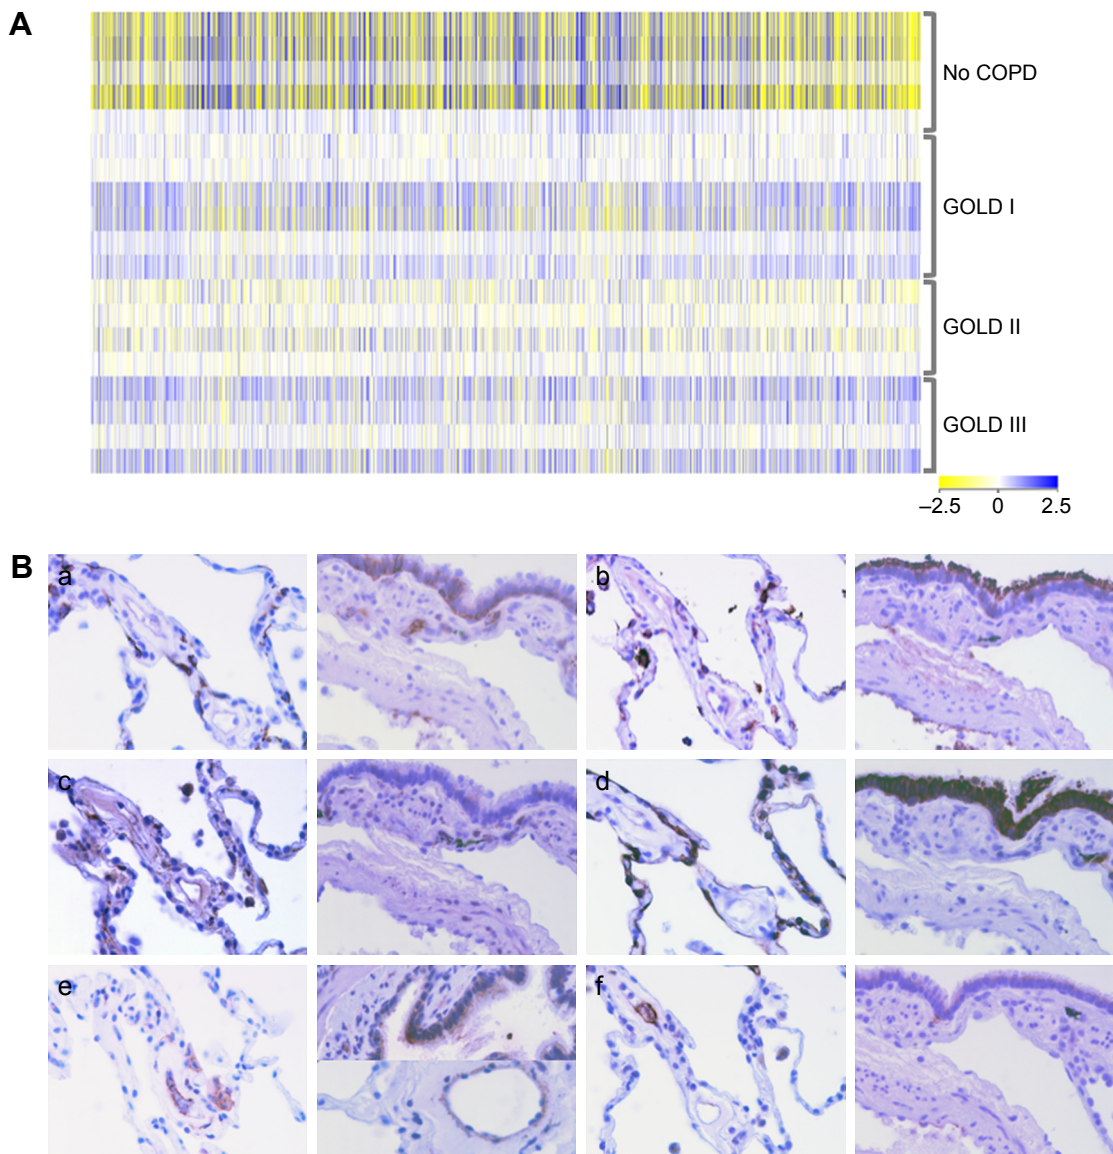

RNA was isolated using the RNeasy Plus Mini Kit (Qiagen) and quantified with the Agilent Bioanalyzer. The RevertAid First Strand cDNA Synthesis Kit (Thermo Fisher Scientific) was used for cDNA synthesis. Quantitative polymerase chain reaction was implemented with universal Probe Library equipment (Roche) and the following primers for AQP3 (for: cgccttttacagccttg/rev: caggagtgggacacgat), ECM1 (for: gctggagagggagtccaag/rev: gggtcacagtattgtcaagggtatc), FHL1 (for: gcgtggattgctacaagaact/rev: accacactggagcctttacc), IL8 (for: gagcactccataaggcacaaga/rev: atgttctctccggtggt), MFGE8 (for: ttgagctactgggctgtga/rev: ggccgtgatctgctgtgc), PDE4-DIP (for: agccactgtctttgctcagg/rev: gcttcaccaaggattcacct), SLC6A8 (for: tgggaggtgaccctttgtc/rev: cgtaggggaatgtagcagtga) in the LightCycler 480 (Roche) instrument.

## Results

After quantile normalization and ANOVA, 3,974 genes were found to be differently regulated in COPD patients

compared to non-COPD patients (Figure 1A). Six candidate genes, which have not been previously evaluated in COPD, were selected for further investigations. 1) Aquaporin 3 (AQP3), a water/glycerol channel, which is upregulated in murine asthma models and involved in the chemokine production of alveolar macrophages.<sup>1</sup> 2) Extracellular matrix protein 1 (ECM1), a secreted glycoprotein that is expected to be involved in the development of various epithelial tumors.<sup>2</sup> 3) Four and a half LIM domain 1 (FHL1), a protein that is highly expressed in muscle disorders

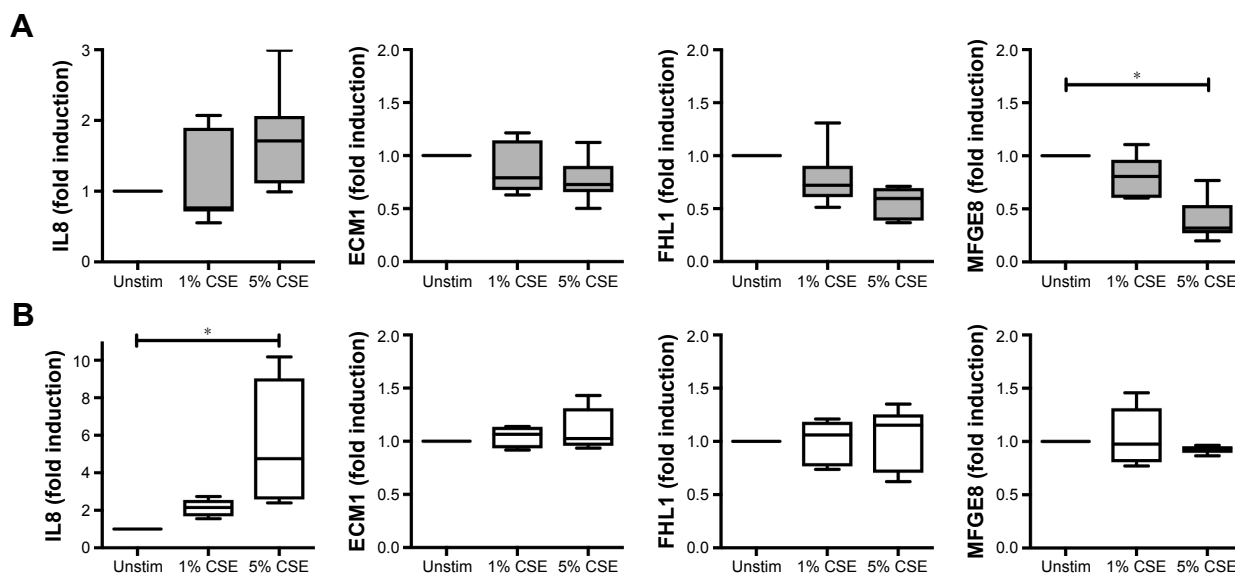

with the development of respiratory failure.<sup>3</sup> 4) Milk fat globule epidermal growth factor 8 (MFGE8, lactadherin), a secreted glycoprotein that opsonizes apoptotic cells<sup>4</sup> but also collagen for phagocytes. Furthermore, it counteracts airway smooth muscle hypercontractility through binding to integrin receptors on the muscles in an ovalbumin challenge model of asthma.<sup>5</sup> 5) Phosphodiesterase 4D-interacting protein (PDE4DIP), a protein that is a major component of skeletal muscles interacting with phosphodiesterase PDE4D. 6) Creatine transporter SLC6A8, a plasma membrane protein

**Figure 1** Transcriptome analyses and selected protein candidates in tissue microarrays.

**Notes:** (A) Heatmap of significantly regulated genes with 2.5-fold induction in individual tissue samples (one-way analysis of variance with Benjamini–Hochberg correction, cutoff  $p$ -value  $< 0.05$ ). (B) Histologic analyses of HOPE-fixed lung tissue of COPD patients. a) AQP3, b) ECM1, c) FHL1, d) MFGE8, e) PDE4DIP, and f) SLC6A8. Magnification  $\times 200$ . The presence of the respective proteins of the candidate genes in the lung tissue should validate the transcriptome results and reveal the cell types expressing the proteins.

**Abbreviations:** AQP3, aquaporin 3; ECM1, extracellular matrix protein 1; FHL1, four and a half LIM domain 1; HOPE, HEPES-glutamic acid buffer mediated organic solvent protection effect; GOLD, Global Initiative for Chronic Obstructive Lung Disease; MFGE8, milk fat globule epidermal growth factor 8; PDE4DIP, phosphodiesterase 4D-interacting protein.

**Figure 2** RNA expression levels of the candidate genes after cigarette smoke extract (CSE) stimulation.

**Notes:** (A) Isolated human primary pneumocytes type II and (B) primary alveolar macrophages were investigated for their induction of IL8, ECM1, FHL1, and MFGE8 after CSE exposure. This primary cell model exhibits the dependence of the candidate gene expression on CSE because cigarette smoke is the leading cause of COPD. Data from five independent samples of different donors were analyzed in duplicates. Statistical analysis was performed by using the repeated-measure one-way analysis of variance with a Bonferroni multiple comparison correction; \*cutoff  $p$ -value  $< 0.05$ .

**Abbreviations:** ECM1, extracellular matrix protein 1; FHL1, four and a half LIM domain 1; IL8, interleukin 8; MFGE8, milk fat globule epidermal growth factor 8; Unstim, unstimulated.

that transports creatine required for rapid ATP supply into tissues such as muscle and brain.

The corresponding proteins were assigned to distinct cell types by immunohistochemistry of tissue from COPD patients (Figure 1B). AQP3 was detected in type I pneumocytes (P1), type II pneumocytes (P2), macrophages, and bronchi; ECM1 in P2, macrophages, bronchi, and extracellular region; FHL1 in P2, macrophages, bronchi, and capillaries; MFGE8 was present in P1, P2, and bronchi; PDE4DIP in macrophages, bronchi smooth muscles, and capillaries; SLC6A8 in macrophages, bronchi, and capillaries.

In a Gene Set Enrichment Analysis (MSigDB) after Baran et al, we found a potential regulation of three of the six genes (*AQP3*, *ECM1*, and *FHL1*) by the transcription factor ETS proto-oncogene 2 (ETS2). ETS2 was described to be substantially involved in the pathogenesis of pulmonary fibrosis in its phosphorylated form,<sup>6</sup> suggesting that ETS2 might also have a role in peribronchiolar fibrosis in COPD.

We further investigated the possible regulation of the selected genes in a CSE model of primary human lung cells (Figure 2). After CSE stimulation primary human type II pneumocytes exhibited a significant, dose-dependent regulation on the RNA level for one (*MFGE8*) of the six studied candidates, while *ECM1* and *FHL1* showed a tendency to be downregulated. Despite the presence of five candidate proteins in alveolar macrophages of COPD patients

(all except *MFGE8*, Figure 1B), none of them were found to be regulated upon CSE stimulation in human primary macrophages. Thus, the protein expression of the chosen candidates in alveolar macrophages appears to be independent of CSE stimulation.

*MFGE8* is described as an inhibitor of the inflammasome-induced interleukin 1 $\beta$  (IL1 $\beta$ ) production and thus a potential candidate for reducing the inflammatory cytokines with simultaneous clearance of apoptotic cells.<sup>4</sup> Inflammatory mediators such as IL1 $\beta$ , which are increased in lungs and bronchoalveolar lavage fluids of COPD patients, might be promising targets in therapeutic studies.<sup>7</sup>

Particularly the CSE-inducible genes are valuable subjects for further investigations. In conclusion, we found an interesting protein, *MFGE8*, which is present in type II cells of human lungs and significantly downregulated after CSE stimulation, a possible contribution to the inflammatory manifestations of COPD. Thus, we will investigate in further studies *MFGE8* as a potential inhibitor for CSE-induced inflammatory effects on human lungs.

## Acknowledgments

The study was funded by the German Center for Lung Research (DZL), disease area COPD, Gen.2. Patient tissues were provided by the BioMaterialBank North, which is funded in part by the Airway Research Center North (ARCN),

a member of the German Center for Lung Research (DZL), and is a member of popgen 2.0 network (P2N), which is supported by a grant from the German Ministry for Education and Research (01EY1103). The authors thank Bettina Baron-Lühr, Patricia Prilla, Stefanie Fox, Jasmin Tiebach, Kristin Wiczkowski, and Maria Lammers for their excellent technical assistance as well as Dr Klaas F. Franzen for providing the CSE.
