METHODS. Children treated with amoxicillin-clavulanate after cardiac surgery were included in this prospective, pharmacokinetic study. Mid-dose (C_{MD}) and trough (C_{min}) plasma amoxicillin (AMO) concentrations were determined after the first dose and in assumed steady-state (after 4th dose or more) and compared to the MIC clinical breakpoint for Escherichia coli of 8 mg/L as defined by the European Committee of Antibiotic Susceptibility Testing (EUCAST).

RESULTS. 37 patients (age range: 7 days to 15 years) were included, a total of 53 mid-dose (C_{MD} AMO) samples and 97 trough (C_{min} AMO)samples were obtained. After the 1st dose, median C_{MD} AMO was 14.3 mg/L (range: 3.4-75.2 mg/L); median C_{min} AMO was 4.6 mg/L (range: 0.4-35.7 mg/L). After the 1st dose, C_{MD} AMO was below 8 mg/L in 33% and C_{min} AMO was below 8 mg/L in 64% of the samples.

In SS, median C_{MD} AMO was 19.6 mg/L (range: 4.5-132.3 mg/L); median C_{min} AMO was 6.6 mg/L (range: 0.6-75.1 mg/L). In steady-state, C_{MD} AMO was below 8 mg/L in 18% and C_{min} AMO was below 8 mg/L in 56% of the samples.

CONCLUSIONS. With standard amoxicillin-clavulanate dosing regimens, more than half of the patients did not achieve the ideal pharmacokinetic target of fT>MIC of 100%. In addition, 33% and 18% of the patients did not reach a minimum antimicrobial target of fT>MIC of 50% after the first dose or in steady-state conditions respectively. This could result in failure to treat severe postoperative infections after cardiac surgery in children, therefore evidence-based dosing regimens are needed for critically ill children.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0592

Pediatric ED focal seizures have more subtle manifestation variability then generalized seizures. For every first-line anticonvulsant minute delay (> 5 minutes), a 10% increase in decreasing anticonvulsant efficacy, increase status epilepticus (SE) incidence and duration. PED non-epileptic focal seizure, focal seizure rcSO2 readings were < 60% or >80%, with interhemispheric rcSO2 discordance >10, focal seizures correlation to abnormal focal ipsilateral rcSO2 readings and returned to pre-seizure rcSO2 readings.[1] Comparison of PED hemispheric Focal SE rcSO2 readings to seizure severity and anticonvulsant has never been investigated.

OBJECTIVES. Correlational analysis of hemispheric focal SE seizure rcSO2 readings to seizure's complexity and anticonvulsants.

METHODS. Observational study comparing focal SE rcSO2 readings to seizure complexity and anticonvulsants in PED non-traumatic, neurologically normal, first-time focal SE patients.

RESULTS. TABLE 1

Focal seizures: more seizure rcSO2 readings < 60% then >80% p< 0.001, age p=0.5/EMS duration p=0.7 not significant. Comparing seizure rcSO2 readings: rcSO2 < 60%, had longer EMS p=0.0002, PED p=0.001 seizure times, more EMS p=0.001 & PED p=0.0009 anticonvulsants then rcSO2 >80%. All focal seizures had interhemispheric discordance > 14

p< 0.0001. Overall rcSO2 < 60% had longer seizures p=0.0002 and required more anticonvulsants p=0.003. Patient's < 2 years old had more focal seizures < 60% rcSO2 readings p=0.0005 then >2 yrs who had more seizure rcSO2 readings >80% p=0.003. However, age was not associated with anticonvulsant use p=0.08 or EMS seizure duration p=0.19. Correlation of seizure rcSO2 readings < 60% to >80% during seizure´s nonresponsive anticonvulsant, both rcSO2 readings had consistent readings: delta change < 5% (p< 0.0001). Focal seizure rcSO2 readings < 60% [left 48.3% 37.8, 58.2, p=0.0007, right 42.6% 35.7, 55.3, p=0.0005, and EMS seizure duration >23 minutes p=0.005 had the greatest significance for anticonvulsants. Age p=0.17 and Focal seizure side showed no significance p=0.6. Seizure rcSO2 reading rcSO2 > 80% changed earlier than rcSO2 < 60% p=0.001 and both changed earlier than EMR seizure cessation time p=0.001.

CONCLUSION. Focal SE seizures, rcSO2 readings < 60% with EMS seizure >23 minutes correlated to greater seizure complexity by longer PED seizure duration and more anticonvulsants compared to rcSO2 >80%. During seizure´s nonresponsive anticonvulsants, both seizure rcSO2 readings < 60%, >80 had < 5% change. Both rcSO2 readings < 60%, > 80% rcSO2 readings changed significantly sooner than clinical seizure cessation with rcSO2 readings > 80% changed sooner than rcSO2 < 60%. In PED focal SE seizure, hemispheric cerebral oximetry monitoring has shown its functionality for rapid seizure cerebral physiology and anticonvulsant response assessment while initial focal seizure rcSO2 readings has potential for predicting patient´s seizure complexity and anticonvulsant needs.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0593

INTRODUCTION. Cardiac surgery-related blood transfusions remain high while the relationship with the clinical outcome is unclear.

OBJECTIVES. To compare postoperative complications after elective coronary artery bypass surgery (CABG) with the use of cardiopulmonary bypass based on transfused Red Blood Cell (RBC) units.

METHODS. Patients who underwent isolated elective CABG from June 2012 to March 2018, in G.Papanikolaou Hospital Thessaloniki Greece, were investigated. Based on number of transfused RBC we compared patients without transfusion (Group A) with those transfused with at least 1 unit (Group B). The following prospectively collected data were analyzed: Age, Euro-score II, Prolonged mechanical ventilation (>24 hours),Acute Kidney Injury-AKI (defined by RIFLE criteria), renal replacement therapy (RRT) because of AKI, use of non invasive ventilation because of postoperative respiratory dysfunction (NIV), sternal wound infections, septicemia and pneumonia. Chi square test was used for the statistical analysis. Transfusion threshold was Hb $\leq$ 8.5 g/dl. Finally, we did a second statistical analysis between group A and group B after excluding, patients who have transfused with more than 3 RBC units creating Group C.

RESULTS. From a total of 1672 elective CABG patients, 349 (20,9%) didn't receive any RBC unit. In group A, mean aged was 65.6±8.8 vs 65.1±9.5, mean Euro score II was 1.2±0.8 vs 1.6±1.4. No statistical significance was found for septicemia(p=0.15),post-op pneumonia (p=0.08) and mortality (p=0.07). Factors with statistical correlation are shown in table 1.

CONCLUSIONS. Compared with patients without any transfusions, CABG patients with at least 1 RBC unit transfusion have higher incidence of prolonged mechanical ventilation, use of NIV, AKI, AKI-RRT and sternal wound infections. Prolonged ventilation, AKI, and sternal wound infections are more often in patients with only 1- 3 RBC units compared with no transfused patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0594

INTRODUCTION. The reliability of dynamic indexes as the pulse pressure (PPV) and stroke volume (SVV) variations to predict fluid responsiveness are affected by tidal volume (Vt). To overcome this problem, functional hemodynamic tests have been proposed, which may reduce the risk of fluid overload. Among these, the end-expiratory occlusion test (EEO) was tested in 2 studies on patients having elective surgery and ventilated with a Vt higher than 6 ml/kg, showing conflicting results (1-2). The recent successful use of Vt challenge (VtC) by Myatra et al. in 20 critically ill patients stimulated the present clinical study (3).

OBJECTIVES. Primary aim: to test the VtC as a good predictor of fluid response in surgical patients ventilated with a 6 ml/kg Vt; secondary aim: to compare the reliability of VtC and EEO performed at 6 and 8 ml/kg.

METHODS. Patients having elective neurosurgery in supine position, having a continuous cardiac index (CI) monitoring by the MostCare[TM] device (Vygon Comp, Ecouen Fr). After general anesthesia and before fluid challenge (FC) decided by the attending anesthetist, the VtC was performed by increasing Vt from 6 mL/kg to 8 mL/kg of predicted body weight for one minute. The EEO was performed by interrupting the positive pressure ventilation for 30 seconds, and was repeated twice at 6 and 8 ml/kg-Vt ventilation (EEO_6 and EEO_8, respectively). The FC consisted in 250 mL saline infused over 10 minutes. Receiving operating characteristic (ROC) curve and the Area Under the Curve (AUC) were constructed comparing the variations before and after FC. The following parameters were collected: PPV and SVV for VtC and stroke volume index (SVI) and CI for EEO. To be responder to the FC, SVI had to increase $\geq$ 10%.

RESULTS. A cohort of the first 26 patients is presented. Nor PPV neither SVV at baseline could predict fluid responsiveness (AUC of 0.57 and 0.72, respectively). EEO_6 poorly predicted fluid responsiveness (AUC of CI 0.55; p = 0.66; AUC of SVI 0.52; p = 0.85). Both VtC and EEO_8 reliably predicted the responsiveness to FC (see Table 1). The AUCs of PPV and SVV after VtC application (p = 0.33) and the AUCs of SVI and CI after EEO_8 application (p = 0.42) were comparable.

CONCLUSIONS. The changes in PPV or SVV induced by VtC are more pronounced than in baseline helping to predict the FC responsiveness in anesthetized surgical patient under mechanical ventilation at 6 ml/kg. The EEO performed at 8 ml/kg and not at 6 ml/kg predicted well the fluid responsiveness. The reliability of both EEO_8 and VtC was comparable (see Table1).

INTRODUCTION. Cardiac surgery under Cardio-Pulmonary Bypass (CPB) may lead to an inflammatory response with various clinical presentations including post-cardiac surgery vasoplegia (PCSV). Preoperative copeptin level, a biomarker of vasopressin secretion, may predict PCSV (1).

OBJECTIVES. Our objective was to describe the PCSV syndrome after CPB and assess its consequences on microcirculation, organ function and outcome.

METHODS. This single-centre prospective observational study, approved by an ethics committee, included patients with written informed consent and scheduled for cardiac surgery under CPB from January to June 2017, excluding age above 80 years, chronic renal failure, sepsis and postoperative cardiogenic or haemorrhagic shock. During the first 24 hours, PCSV was defined by the need of norepinephrine infusion to maintain a mean arterial pressure above 60mmHg without low cardiac output. The primary endpoint was the duration of postoperative hospital stay, secondary endpoints were ICU admission hemodynamic and microcirculatory data, severity scores and ICU length of stay. Quantitative data were expressed as median [interquartile range], qualitative data as number of patients (%) and patients with PCSV were compared to the other patients using non-parametric or chi-square tests. A p< 0.05 was considered significant. A logistic regression was used for multivariate analysis of preoperative predictive factors (odds ratio [confidence interval 95%]).

RESULTS. Among 178 patients included (age 67yo [60-73], Euroscore 4.8% [3.2-8.2]), 81 (46%) experienced a PCSV. The hospital stay of PCSV patients was significantly longer than for controls (respectively 9 [8-12] vs 8 [7-9] days, p< 0.0001). Preoperative copeptin level higher than 14pmol/l, combined cardiac surgery, and preoperative anaemia were associated with PCSV on multivariate analysis (adjusted OR: 3.1 [1.4-6.7], 3.0 [1.5-6.1], 2.4 [1.1-5.1] respectively). Macrocirculatory parameters were comparable but oxygenation recovery slope was lower in PCSV group (3.2 [2.6-3.9] vs 3.8 [2.8-4.4] %/s, p=0.048). PCSV patients had more organ failure (SOFA score 6 [5-7] vs 3 [2-4], p< 0.0001), higher maximal lactate level (2.0 [1.6-2.9], p=0.017) within the first 24 hours and longer ICU stay (26 [22-54] vs 23 [21-25] hours, p< 0.0001).

CONCLUSIONS. Post-cardiac surgery vasoplegia is a frequent syndrome following CPB. Preoperative anaemia or high copeptin may identify patients at higher risk of vasoplegia. PCSV is a relevant complication associated with more organ dysfunction and an extended stay in ICU and in hospital. Preventive strategies and early microcirculatory optimization should be studied in high risk population for cardiac surgery.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0596

INTRODUCTION. Infection after cardiac surgery (CS) may be a very severe complication that worsens the prognosis of those patients.

OBJECTIVES. The aim of our study was to describe and evaluate infections after CS.

METHODS. Prospective, observational study at our institution from 2008 to 2012 at our institution. Baseline characteristics on admission, outcomes, infections and microbiological profile were analyzed. Statistical analysis was performed (SPSS 20.0).

RESULTS. 3031 patients were included. 63.9%(1937) were male, age was 64.7±11.6 years, APACHE II:12.5±4.9, with an infection rate of 6%(192). Pneumonia was the most frequent infection(34%) and those who suffer from mediastinitis(80%) developed bacteremia more frequently(P< 0.001). Urinay infection and catheter infection rate were 2.98 episodes/1000days of de urinary catheter and 3.35/1000days of catheter. Gram Negative Bacilli were predominant in all infections (75%). Factors associated with the development of infection after CS were longer CPB time (OR:1.004;95% IC:1.001-1.008;P=0.047), a higher drainage loss during first 12h (OR:1.002;95% IC:1.001-1.004;P< 0.001), lower levels of albumin at 24h after CS (OR:0.902;95% IC:0.860-0.946;P< 0.001) and lower PaO2/FiO2 24h after CS (OR:0.993;95% IC:0.990-0.995;P< 0.001). Patients who were infected required longer time on vasoactive drugs (OR:1.008;95% IC:1.006-1.010;P< 0.001), a longer ICU length of stay (OR:1.043;95% IC:1.021-1.065;P< 0.001) and a higher in-hospital mortality (33.3%) (OR:3.348;95% IC:1.700-6.595;P< 0.001). Those patients showed a worst long-term survival (Follow up 4.8±2.3years): 82.9%vs.52.9% (HR:3.583;95% IC:2.850-6.742;P=0.003).

CONCLUSIONS. Infections after CS are a severe complication with high impact in mortality, even in the long-term scenario. Inflammatory and nutritional factors may be associated with their occurrence. GNB and pneumonia were the most frequent isolated germ and type of infection respectively.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0597

INTRODUCTION. The presence of a preoperative malnutrition or a high nutritional risk influences outcomes after cardiac surgery (CS).

OBJECTIVES. The aim of our study was to evaluate the influence of preoperative nutritional status in patients who underwent CS.

METHODS. Prospective, observational study at our institution from 2012 to 2015 at our institution. Baseline characteristics, intraoperative variables and outcomes were analyzed. Nutritional status was evaluated by means of an screening tool for CONtrolling NUTritional status (CONUT). Statistical analysis was performed (SPSS 20.0).

RESULTS. 952 patients were included; age 65.5±10.5 years; 70.4%(670) were male; BMI:27.6±4.1Kg•m^{-2}; EuroSCORE:6.2±2.8; APACHE II:12.8±4.8; SAPS III:41.7±10.6. 42.6% were valvular and 43.7% were bypass surgeries. In-hospital mortality was 7.2%(69) and long-term mortality 21.1%(195). Based on CONUT screening, 45.9%(437) of the patients showed a preoperative normal status, whereas 43.2%(412) has low malnutrition and 10.9%(103) moderate-severe malnutrition. Univariate analysis showed more post-CS complications and mortality in those subgroups with worst nutritional status. Multivariate analysis showed higher perioperative transfusional needs (OR:1.419;95% IC:1.118-1.801;P=0.004), longer time in vasoactive drug support (OR:1.005;95% IC:1.001-1.008;P=0.011) and longer ICU length of stay (OR:1.004;95% IC:1.004-1.007;P=0.001) at the subgroup of patients with moderate-severe malnutrition compared with normal status subgroup. Long-term mortality showed a worst survival in those with worst nutritional (normal:84.8%, low:76.4%, moderate-severe:63.4%; P(LogRank)< 0.001). A higher

absolute CONUT value was associated with worst survival (HR:1.153;95% IC:1.072-1.239;P< 0.001) whereas to be included in the normal CONUT subgroup was associated with better survival (HR:0.552;95% IC:0.345-0.884;P=0.013) .

CONCLUSIONS. A worst preoperative nutritional state evaluated by means of the screening tool CONUT was associated with higher morbidities and worst long-term survival. Physicians and surgeons should be aware about nutritional status of patients in order to avoid preoperative malnutrition and plan a nutritional approach previous CS.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0598

INTRODUCTION. Cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) are treatments for peritoneal carcinomatosis in select patients with cancer (gastric, colorectal, appendiceal, ovarian cancer and primary peritoneal malignancies). This treatment is associated whit a morbidity rate around 12% to 52%, and include coagulopathy, chemotherapy induced myelosuppression and need for blood transfusion.

OBJECTIVES. To determine the hematological complications during intensive care unit (ICU) stay after CRS and HIPEC.

METHODS. Prospective observational study during 5 years. All patients admitted to ICU postoperatively after CRS and HIPEC therapy. Data recorded were age, sex, type of cancer, severity at ICU admission (APACHE II and SOFA scores), daily blood count and coagulation times, bleeding complications, ICU mortality and lenth of stay. We defined leucopenia as < 4000/μL, thrombocytopenia as < 150.000/μL, anemia as hemoglobin $\leq$ 10 gr/dL and prolongation of coagulation times as INR $\geq$1.3 and/or APTT >37seg, and hypofribrinogenemia as < 200 mgr/dl.

Qualitative variables are described as number and percentages, quantitative variables with normal distribution as mean ± S.D., quantitative variables with non-normal distribution as median (inter-quartile range).

RESULTS. We included 73 patients. 40 (55%) were males. Mean age was 60.3±9.9 years. 63 (86%) had a digestive cancer (52% colorectal, 44% gastric cancer). Mean APACHE II and SOFA scores at ICU admission were 9.6±4.2 and 2 (1-3), respectively. All patients had some type of hematological complications: 9 (12%) had leucopenia, 40 (55%) thrombocytopenia, 34 (47%) prolongation of coagulation times, 47 (64%) anemia and 10 (14%) hypofribrinogenemia. Only 11 (15%) patients had bleeding complications (45% bleeding from surgical drainages, 45% haematuria and 10% digestive hemorrhage), all were treated in a conservative manner. 14 (19%) patients needed blood transfusion and 1 (< 1%) platelet transfusion. Mean ICU stay was 5 (4-5) days. ICU mortality was 1.36%, but not related to bleeding. CONCLUSIONS: Although hematological complications in patients in early postoperative of CRS and HIPEC are frequent, the rate of severe complications is low and not related with mortality.

Correspondence: P. Polgarova
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0599

INTRODUCTION. The Intensive Care Unit (ICU) is often a disorientating and frightening environment for patients and relatives. Delirium, anxiety, depression and Post-Traumatic Stress Disorder (PTSD) (Ryu et al. 2016; Dimitry et al. 2010) often adversely affect short and long-term outcomes. The is an increasing focus on the quality of survival. The 2009 NICE guidance, 'Rehabilitation after Critical Illness (CG83)', stresses the need to address all areas of functioning: physical, psychological and cognitive in early rehabilitation (NICE 2009). We identified a significant care gap relating to psychological outcomes.

OBJECTIVES. To implement and assess a Stepped Care Psychological Well-being Model in order to improve psychological outcomes in ICU survivors and relatives while affecting culture change and improving staff resilience.

METHODS. A quality improvement initiative to integrate best psychological practice into routine multidisciplinary ICU care. New resources from February 2017 include 0.8 whole time equivalent (WTE) Senior Psychological Wellbeing Practitioner (PWP) and a 0.2 (WTE) Clinical Psychologist. Early focus was on service needs assessment, project development and validation of psychological tools while increasing targeted psychological interventions. During the first 12 months 235 patients were assessed by the PWP. 225 patients completed the Intensive care psychological assessment tool (IPAT) of which 108 (48%) scored 7 or more in keeping with psychological distress (Wade et al. 2014). 501 intervention sessions have been offered to patients and 53 to relatives as well as 32 1:1 sessions with staff members.

RESULTS.

Further subjective feedback from patient focus groups suggests that this service substantially contributes to improved psychological outcomes along the patient journey. The effect seems to be larger than actual interventions offered which suggest some background culture change in our ICU.

CONCLUSIONS. Initial results suggest that imbedding psychological services in the daily practice of our ICU MDT allows early identification and improved psychological outcomes. Within the MDT we experience integration of new knowledge and a culture of emotional resilience and well-being.

INTRODUCTION. Red blood cell (RBC) transfusion is associated with adverse outcome, in particular in the critically ill. The mechanisms are unknown, but may involve an effect on immune cells.
OBJECTIVES. To investigate the effect of RBC transfusion in recipients suffering from inflammation on priming and adhesion capacity of neutrophils.
METHODS. Healthy male volunteers were injected with Escherichia coli lipopolysaccharide(2ng/kg), and after two hours transfused with an autologous RBC unit (n=6). Blood samples were taken at baseline, 2 hours after LPS but prior to transfusion and 4 hours after transfusion. In addition, as part of an observational study on the effects of RBC transfusion, 22 critically ill patients with sepsis and 25 non-septic patients in need of 1 RBC unit were consecutively included. Blood samples were taken prior to and 24hr after transfusion, centrifuged and plasma was stored at -80˚C until further use. Healthy volunteers served as a control group. Human neutrophils were isolated from other healthy volunteers and incubated with the plasma from both study cohorts and the control group. Neutrophil priming was assessed by measuring hydrogen peroxide production (in relative fluorescence units (RFU)), after formyl-Met-Leu-Phe stimulation and by Amplex Red conversion to resorufin. Adhesion was assessed by the fluorescence of absorbent calcein-labeled neutrophils after plasma incubation. Adhesion was determined as a percentage of the total input of calcein labeled cells (100%).
RESULTS. In the endotoxemia model, LPS alone did not increase the capacity of plasma to induce ex vivo neutrophil priming or adhesion. Following RBC transfusion, ex vivo neutrophil priming increased compared to pre-transfusion levels, albeit not reaching statistical significance[580 RFU (IQR 380-1388) vs 475 RFU[IQR 287-614], p=0.053). RBC transfusion also resulted in increased capacity of plasma to induce neutrophil adhesion when compared to healthy volunteers receiving saline (13,73% [IQR 11,65-24,86] vs 9,26% [IQR 9,26-12,0] in controls, p< 0.05). In the critically ill, prior to transfusion, the capacity of plasma to induce ex vivo neutrophil priming was already increased when compared to healthy controls (616 RFU (IQR 480-894) vs 429 RFU (IQR 337-624), P< 0.05) and was not further augmented following transfusion. Neutrophil adhesion was not increased prior to transfusion when compared to plasma of healthy controls. Following transfusion, the ability of plasma to induce neutrophil adhesion versus baseline increased in the septic patients when compared to the non-septic patients (+ 3,2% (IQR 0,9- 6,3) vs 0,8% (-1,3- 3,6), p< 0.05).
CONCLUSIONS. RBC transfusion results in an increased ability to induce ex vivo neutrophil adhesion in a model of human endotoxemia as well as in a cohort of critically ill patients with sepsis. Therefore, neutrophil adhesion may be a mechanism of inducing transfusion-associated effects in individuals suffering from systemic inflammation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0601

INTRODUCTION. Platelets are involved in hemostasis and are a core component of the acute inflammatory response. Phenotypes of platelet trajectories may exist and may be associated with patient outcome.
OBJECTIVES. To identify data-driven phenotypes of long-term and short-term platelet trajectories in acutely ill patients, examine their association with clinical features and 60-day mortality, and identify predictors of phenotype membership.
METHODS. From a retrospective cohort of 164,788 ICU admissions, we focused on patients who stayed in hospital at least 7 days or at least 3 days after ICU admission. We used a two-step clustering method combining linear mixed modeling and hierarchical clustering to identify groups of trajectories. To study the association between platelet trajectory groups and 60-day mortality, logistic regression was used with age, sex, race, body-mass index, burden of chronic illness, baseline organ function, severity of disease and trauma status as additional covariates. To evaluate group membership prediction at baseline, multinomial logistic regression was used with platelet counts on days 1 and 2 of ICU admission, as well as baseline covariates. Model performance is calculated in a validation set of 33% of the study population.
RESULTS. 55,442 admissions and 108,128 admissions met 7-day and 3-day study criteria. We identified 7 groups of trajectories in the 7-day cohort and 4 groups in the 3-day cohort (Figure). Group membership was, independently associated with 60-day mortality (p< 0.001) in both cohorts. For 7-day trajectories, compared to group 1, 60-day mortality was lower in group 2 (odds ratio (OR)=0.66 95% confidence interval: (0.61-0.71)) and group 5 (OR=0.64 (0.53-0.77)), and higher in group 3 (OR=1.11 (1.03-1.21)), group 4 (OR=1.26 (1.13-1.41)) and group 7 (OR=1.68 (1.46-1.94)). AUROC was 0.74 (95% CI: 0.73, 0.75). For 3-day trajectories, compared to group 1', 60-day mortality was higher in group 3' (OR=1.08 (1.01-1.16)) and group 4' (OR=1.44 (1.35-1.54)). AUROC was 0.74 (95% CI: 0.73, 0.75). When second day platelet count was added in a model to predict group membership from baseline variables, accuracy increased from 47% to 57% for 7-day trajectories and from 68% to 79% for 3-day trajectories.
CONCLUSIONS. 7-day and 3-day platelet trajectory phenotypes were identified and were associated with 60-day mortality. First and second day platelet counts predicted trajectory phenotype with reasonable accuracy. In the 7-day cohort, a rebound shape was predictive of lower 60-day mortality. In both cohorts, consistently high platelet trajectory was predictive of higher mortality. Further analysis will focus on studying whether platelet trajectories are associated with morbidities such as late bleeding, embolism, and thrombosis.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0602

INTRODUCTION. About 30% of patients undergoing abdominal surgery for cancer still require allogeneic red blood cell transfusion (RBCT) during hospitalization, but it is still debated whether perioperative RBCT increases risk for recurrent disease after curative surgery. Cohort studies comparing patients receiving and not receiving RBCT showed a strong bias regarding most baseline, clinicopathological and surgical characteristics indicating the need to adjust for the most important confounding variables to remove their effects on outcome.
OBJECTIVES. To assess the relation of perioperative RBCT with cancer recurrence in patients undergoing abdominal surgery for cancer, considering the most important confounding variables of cancer recurrence after surgery.
METHODS. This systematic review was registered prospectively with the PROSPERO database (CRD42017052026). MEDLINE, EMBASE, and the Cochrane Library were searched systematically from January 2000 to February 2017. Eligible studies were cohort studies investigating the association of perioperative RBCT with cancer recurrence in patients undergoing abdominal surgery for cancer. The main outcome measure was disease-free survival. Summary hazard ratios (HR) and 95% confidence intervals (95% CI) were calculated with generic inverse variance method using a random effects model. Meta-regression was used to assess the impact of adjusting confounding variables on outcome.
RESULTS. A total of 25 studies were eligible for analysis. To remove the effect of confounding variables on outcome, all studies used multivariable Cox proportional hazards regression (MV-CPH), while 7 studies additionally performed propensity score methods (PSM). In PSM analyses, RBCT did not increase the risk for cancer recurrence (HR 1.06 [95% CI, 0.89-1.25], P=0.51). In contrast, in MV-CPH analyses, RBCT was related to a higher risk of cancer recurrence (HR 1.42 [95% CI, 1.27-1.58], P< 0.001). However, the number of confounding variables considered in MV-CPH analyses was lower than in PSM analyses, and meta-regression indicated that a lower degree of adjustment for confounding variables was independently related with increased HRs (Figure 1+2). Selecting MV-CPH analyses with similar high degree of adjustment for confounding variables comparable to PSM analyses revealed that RBCT was no longer related to an increased risk of cancer recurrence (HR 1.07 [95% CI, 0.90-1.27], P=0.43).
CONCLUSIONS. Many studies did not sufficiently adjust their analysis for most important confounding variables when assessing the relation of RBCT with cancer recurrence. Considering high quality studies that sufficiently adjusted their analyses, perioperative RBCT did not affect cancer recurrence after abdominal surgery for cancer. Concerns about oncological outcomes should not be an issue in the decision-making process for perioperative RBCT.

Long-term mechanical ventilation patients in intensive care units, what to do

M. Muñoz Garach, O. Moreno Romero, R. Ramierez Puerta
Hospital Universitario San Cecilio Granada, Granada, Spain
Correspondence: M. Muñoz Garach
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0603

INTRODUCTION. Patients with chronic mechanical ventilation-dependency should not stay all the time in our intensive care units. Ideally, if their personal situation allows, is to try a follow-up at home, for this it is necessary the support of a Home Mechanical Ventilation Unit where the patients can rehabilitate and adapt their family and personal needs for beeing home-ventilated.
OBJECTIVE. To describe and statistically analyse the population of a subgroup of patients with long-term mechanical ventilation in our ICU who are referred to our Home Mechanical Ventilation Unit (HMVU) and will be home-ventilated and followed up afterwards.
METHODS. Retrospectively four-year study (from 1/1/2014 to 12/31/2017) from our own data base. Variables analysed: sex, age, cause of admission to the ICU, cause of prolonged mechanical ventilation, origin hospital, dependence hours on mechanical ventilation (MV) at admission and discharge, stay days in ICU, stay in HMVU, evolution of the process and destination to discharge.
RESULTS. 12 patients, gender: men 8 (66.7%). Average age: 59.9 $\pm$7.4. Causes ICU admission: postoperative cardiac / vascular surgery / general 6 (50%) and reaguized chronic respiratory failure 6 (50%). Cause of prolonged mechanical ventilation (requires more than three tests of spontaneous breathing and / or the process lengthens during more than 7 days): 4 tetraparesis (33.3%), 5 multifactorial (weakness, COPD, obesity...) (41.7%), 2 bilateral diaphragmatic paralysis (16.7%), severe kyphoscoliosis 1 (8.4%). Origin hospital: San Cecilio 5 (41.7%), Virgen de las Nieves 6 (50%), Santa Ana-Motril 1 (8.4%). Hours dependence of MV on admission at HMVU: night-twelve hours: 5 (41.7%) and daily-twenty-four hours: 7 (58.3%). Median days stay in ICU: 93.5 (range 69-270). Median days of stay in HMVU: 176.2 (range 64-425). Evolution of the process: decanulation 6 (50%), nocturnal VM dependence 3 (50%) and daily dependence twenty-four hours 3 (25%), was impossible the weaning of VM patients with bilateral diaphragmatic paralysis and severe kyphoscoliosis. Destination at discharge: home 10 (83.3%) and exitus 2 (16.7%) due to cardiac arrest not recovered.
The beds occupancy in the ICU of the 12 patients was 1282 days, with an average stay of 106.8 $\pm$58.2 days.
CONCLUSIONS. There is a short subgroup of patients who, frequently after aggressive surgeries, remain chronically dependent on MV, resulting in prolonged ICU stay. The HMVU created in the beginning for neuromuscular patients also allows the transfer of other kind of patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0604

INTRODUCTION. Substantial variability in EOLP occurs around the world [1]. Differences in EOLP were previously reported in Europe in the Ethicus I study [2].
OBJECTIVES. Determine worldwide ICU EOLP.
METHODS. ICUs worldwide were invited to participate through their country societies. Consecutive admitted ICU patients who died or had treatments limitations during a 6 month period from 1.9.2015 to 30.9.16 were prospectively studied. Regions included North, Central and Southern Europe (NE, CE, SE), North and Latin America (NA, LA), Asia (As), Australia and New Zealand (Au) and Africa (Af). Previous EOLP definitions were used [2]. Mental competency was defined as having the capacity to make end of life decisions.
RESULTS. 199 ICUs in 36 countries participated enrolling 12,857 patients. Figure 1 shows differences in EOLP by region and Figure 2 patient competency and patient and family discussions by region.
CONCLUSIONS. Worldwide differences included more CPR in Af, LA & SE and less CPR in NE, Au & NA. There was more withdrawing (WD) in NE & Au and less WD in LA & Af. Interestingly, all regions had more withholding (WH) than WD except NE. Shortening of the dying process (SDP) was uncommon. More patients were competent in Au & NA and less were competent in Af, SE & LA. More discussions with patients occurred in NE, CE, NA & Au and more with families in NE, NA, As & Au.

Don´t write off the liver! 20 year retrospective analysis of patients with decompensated alcoholic liver disease (ALD) admitted to a single district general hospital (DGH) intensive care unit (ICU)

N. Raeside, A. Myers, T. Samuels, R. Kumar
East Surrey Hosptial, Intensive Care Unit, Redhill, United Kingdom
Correspondence: N. Raeside
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0605

INTRODUCTION. ALD is associated with high mortality and admissions to ICU for patients with decompensated ALD are increasing (1). Whilst there is some research into prognostic markers for these patients, most published studies have originated from tertiary liver referral units (2).

OBJECTIVES. To assess mortality of patients admitted to a DGH ICU with decompensated ALD and whether dysfunction of other organ systems on admission affects mortality in decompensated ALD or acute liver failure (ALF) secondary to alcohol misuse.

METHODS. Data for 120 patients with decompensated ALD or ALF secondary to alcohol misuse were collected for the period January 1998 to March 2018. Additional information included organ dysfunction on admission and/or reason for admission, such as acute renal failure (ARF), chest involvement (e.g. chest infection or pleural effusion), encephalopathy, upper gastrointestinal bleed (UGIB) and requirement for vasopressor or inotropic support. The primary outcome was hospital mortality, with secondary outcomes including ICU mortality and survival to hospital discharge.

RESULTS. Of the total (n=120), 69% were male, with a mean age of 51.2 years (SD 10.9 years). Overall ICU and hospital mortality were 51% and 69% respectively. Patients admitted with additional renal impairment had the highest ICU mortality (78%), followed by patients admitted requiring inotropes (70%) and those with chest pathology (66%). Those admitted with encephalopathy had an ICU mortality of 48%, but the lowest overall hospital mortality (66%). Patients admitted following an UGIB had the lowest ICU mortality (35%). However, these patients had the highest in-hospital mortality of out of those who survived to ICU discharge (38%).

CONCLUSIONS. Patients admitted to ICU with decompensated ALD with additional ARF have the worst outcomes. Those admitted following an UGIB have the lowest ICU mortality, but similar hospital mortality. These results are similar to a 3 year retrospective study at a tertiary liver referral ICU where patients admitted with an UGIB or encephalopathy had the lowest ICU mortality (< 50%), compared to those admitted with severe renal impairment (75%) or requiring renal replacement therapy (81%) (2).

Patients must be reviewed on a case by case basis and, while, for example, the knowledge that ARF confers an increased risk of ICU mortality in patients with decompensated ALD, this alone should not preclude admission. It does, however, assist managing the expectations of the patient, relatives and healthcare team, should the patient be admitted to ICU.

Acute-on-chronic liver failure score in acute decompensated cirrhosis: measurement and prognostic value

N. Foudhaili, S. Khadher, A. Khaled, K. Ben Ismail, M. Salem
Charles Nicolle Hospital, Digestive Intensive Care Unit, Tunis, Tunisia
Correspondence: N. Foudhaili
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0606

INTRODUCTION. Prognostic value of the North American Consortium for the Study of End-Stage Liver Disease definition of Acute-on-Chronic Liver Failure (NACSELD-ACLF score) in predicting 30-day survival was confirmed in a large recent study.

OBJECTIVES. The aim of this work was to analyze of NACSELD-ACLF score performance to predict intrahospital mortality in patients with decompensated cirrhosis.

METHODS. It was an 8-month retrospective study from March 2017 to October 2017. We enrolled patients with decompensated cirrhosis. Organ failures assessment were obtained upon admission according to NACSELD definition. Patients were analyzed in terms of prediction of 30-day using either a Chi-square test or Fisher's Exact test. Backwards elimination multi-variable logistic regression analyzing 30-day mortality was performed on all patients.

RESULTS. Fifty-seven patients were included with a sex-ratio at 0.9 and a mean age of 67±9 years (23-76). The main comorbidities were diabetes mellitus (35%) and hypertension (29%). Hepatitis C was the most common etiology of cirrhosis (44%). Child-Pugh score was mainly C (62%) and 12±2. Main MELD score was 14±8. Bacterial infection was the main cause of decompensating (52%). Patients with and without unfavorable outcome (death) had similar demographics characteristics. 30-day mortality rate was 16%. NACSELD-ACLF was ≥2 in 15% of patients. Patients who met criteria for NACSELD-ACLF had 20% 30-day survival vs 85% in patients without NACSELD-ACLF (p< 0.001) with a RR of 22 (95% IC :5.47 - 91.15).

CONCLUSIONS. NACSELD-ACLF might predict 30-day mortality in cirrhotics in decompensation with a good sensitivity and specificity. However, it concerns only 15% of patients admitted for acute decompensation of cirrhosis which makes it a very restrictive score.

0607

Prognostic value of albumin-to-bilirubin score in decompensated cirrhosis

N. Foudhaili, S. Khedher, A. Khaled, C. Abdennebi, M. Salem
Charles Nicolle Hospital, Digestive Intensive Care Unit, Tunis, Tunisia
Correspondence: N. Foudhaili
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0607

INTRODUCTION. Prognostic value of albumin-to-bilirubin (ALBI) score during liver diseases was reported in several studies.
OBJECTIVES. The aim of this work was to compare the performance of Child- Pugh score, MILD Score and ALBI score to predict intrahospital mortality in patients with decompensated cirrhosis.
METHODS. It was a 6-Month retrospective study from January 2017 to June 2017. We enrolled patients with decompensated cirrhosis. Biological markers were obtained upon admission. They were analyzed in terms of prediction of intrahospital mortality using the Receiver Operating Characteristic (ROC) curves analysis.
RESULTS. Ninety-seven patients were included with a sex-ratio at 0.95 and a mean age of 58±10 years (19-77). The main comorbidities were diabetes mellitus (42%) and hypertension (30%). Hepatitis C was the most common etiology of cirrhosis (45%). Child-Pugh score was mainly C (68%) and 10±2. Main MELD score was 13±7. Bacterial infection was the main cause of decompensating (55%). Intrahospital mortality was 13%. Demographics characteristics were similar in patients with and without unfavorable outcome (death). ALBI score was significantly higher in dead patients (-1.399±0.381 vs -0.842±0.456, p< 0.001). Comparing to Child-Pugh score and MELD score, ROC analysis of ALBI showed the highest AUC with a value of 0.810 (95% IC: 0.695-0.930, p< 0.001). The cut-off point was found to be -1.265 with a sensitivity of 85% and a specificity of 80%.
CONCLUSIONS. ALBI score might predict intra-hospital mortality in cirrhotics in decompensation with a good sensitivity and specificity.

Metabolic differences during normothermic regional preservation in donation after circulatory death type II and type III

N. Palomo-López, S. Martin-Sastre, L. Martín-Villén, Z. Ruiz de Azúa-López, S. Escalona-Rodriguez, D. Solis-Clavijo, S. Caballero-Gálvez, J.M. Carballo-Caro, J.J. Egea-Guerrero
Hospital Universitario Virgen del Rocío, Seville, Spain
Correspondence: N. Palomo-López
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0608

OBJECTIVES. To analyze metabolic differences during normothermic regional perfusion (NRP) between the dissimilar types of donation after circulatory death (DCD): type II and type III.
METHODS. Observational, prospective and cohort study. We included patients from DCD type II and type III maintained with normothermic regional perfusion (NRP) in 2017. Six consecutive blood gases were collected with determination of pH and lactic acid. Creatinine levels monitored the renal transplants at 24 hours and 3 months after transplant. Descriptive statiscal analysis was performed, presenting the qualitative variables as frequencies and percentages, and quantitative as mean (+/- SD) or median (interquartile range- ICR) depending its distribution. We use chi square for bivariate analysis of qualitative variables
RESULTS. We included 18 patients; 83,3%(15) were males ,the median age was 51 years (46-60). From the total of donors 38,9% (7) were DCD type II and 61,1 % (11) DCD type III. Of the blood gases we highlight the significant relation between the type of DCD and pH (pH 3: p=0,02, pH4 : p= 0,02 y pH 5 : p= 0,03.). There are also a significant relation with the lactic acid (Lac 1: p= 0,01, Lac 3: p=0,01, Lac 4: p= 0,016 y lac 5: 0,029). We found a significant relation

between the creatinine values 24 hours after transplantation and DCD (type II 7.04 (6.2-7, 9) vs. type III 6.2 (5.3-6.5) vs p = 0.05), and 3 months after the transplant (type II 1.9 (1.9-3.8) Vs. type III 1.1 (1-1.3) p = 0.07).
CONCLUSIONS. There are more metabolic disorders in our series in DCD type II organ donation compared with DCD type III.
The recovery of the renal function of organs from DCD type II is slower than those from type III, however; tendency is towards normality.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0609

INTRODUCTION. Considerable progress has been made in the management and prognostication of patients after successful resuscitation of a cardiac arrest. There are scarce data concerning the possibility of organ donation in patients after cardiac resuscitation. The French organ donation regulation authority (Agence de Biomédecine) reported in 2016 an increase of 2.5% of organ harvesting but also highlighted the number of unmet needs with 22.617 patients on waiting list[1]. Multimodal strategies to increase the number organ donation procedures are urgently needed.
OBJECTIVES. Describe the characteristics of patients admitted after cardiac resuscitation in the ICU of a community hospital with organ harvesting authorization over a period of 9 years.

METHODS. We performed a retrospective study from our hospital information system between January 2009 and December 2017, in a 19-bed ICU. All patients admitted after successful resuscitation of cardiac arrest were included. Patients with in-ICU cardiac arrest, admitted with the diagnosis of brain death and those transferred to a specialized center were excluded. Brain death is defined by French legislation and anoxic encephalopathy was defined as Cerebral Performance Category of (2-3-4) at ICU discharge. Data are presented as counts (%) and means (SD).

RESULTS. During the study period, 265 patients were included, of which 165 (62%) and 100 (38%) occurred after out of hospital and in-hospital cardiac arrests respectively. The mean age was 61 years (SD 16), and 159 (60%) were male. The mean SAPSII was 78 (SD 20). No flow time was less than 5 min in 136 (51%), and mean low flow was 20 min (SD 16). Thirty eight (14%) patients progressed to brain death in a mean of 3 days (SD 2). Among those patients with brain death 9 (24%) donated organ. Anoxic encephalopathy was diagnosed in 89 (34%), and among those 21 (24%) were discharged alive from the ICU. Their CPC score was of 2 in 12 (5%), 3 in 6 (2%) and 4 in 3 (1%) respectively. The other 68 (76%) patients with anoxic encephalopathy died after decision to withdrawal life support after a mean of 16 (SD 11) days post admission. Neurological prognostication could not be performed in 100 (38%) patients due to multiorgan failure.

CONCLUSIONS. After cardiac arrest, 14% of the patients sustained brain death and one fourth of those donated organs. Anoxic encephalopathy was diagnosed in 34% of the study population. Withdrawal of life support was decided in three fourth of those patients who may be eligible for a Maastricht III type organ donation procedure. This could potentially result in a significant increase in the organ harvesting activity of our center.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0610

INTRODUCTION. Donostia University Hospital is a third-level Hospital without solid organ transplantation programme, neither cardiac surgery unit nor extracorporeal membrane oxygenation (ECMO) assistance programme. Our referral transplantation center is located 100km away. These particular features are an obstacle when it comes to organ donation. In 2015, we started two programmes in donation after circulatory death (DCD): both controlled (cDCD) and uncontrolled (uDCD) donation after circulatory death. During these 3 years, we've reached an average of 88 donors pmp.

OBJECTIVES. Analysis of the characteristics of uDCD donors in a three years period.

METHODS. Prospective observational study. Center: Donostia University Hospital, reference center for a population of 700.000 inhabitants. Period of study: from March 2015 to April 2018. Sample: All patients deceased after a witnessed cardiac arrest (CA), unsuccessfully resuscitated according to advanced cardio-pulmonary resuscitation (aCPR) protocols based on international guidelines, are transferred to the Hospital for uDCD. Study variables: sex, age, cause of CA, time of CA - beginning of aCPR, time of CA - time of Intensive Care Unit (ICU) Arrival, time of CA - time of ECMO cannulation, time

of organs preservation, removed and transplanted grafts. Organ preservation technic: normothermic regional perfusion (nRP) with ECMO.

RESULTS. Total number of alerts for uDCD: 49, of which 71% were effective donors. 29% weren't effective donors due to: 8% family refusal for organ donation, 12.2% ECMO cannulation errors, 2% positive serology, 4.1% cancer and 2% increased times. CA took place during evening/night time in 73.5% of the cases, and 55% during weekends.

Thirty-six male and 13 female. Cause of CA: 42.9% STEMI, 28.6% sudden cardiac death and 28.5% other causes. Mean age: 48.5 years old [29-65]. CA - aCPR mean time: 6.8´ [0´-19´], CA - ICU mean time 61.7´[0´-123´], CA- nRP mean time 109.7´[69´-144´], nRP mean time 164.9´ [114-254´]. Total number of removed kidneys: 66. Transplanted kidneys 69.7% (46). Removed corneas 80. 26.5% donors of bone and tendons, with an average of 18 samples per donor [14-24].

CONCLUSIONS.
- Starting an uDCD program led to an increase in the number of organ donors.
- In our region, this represents up to 17.5 donors per million of population. 17.9% of the total donors.
- Our data shows that uDCD can be performed in a small city.
- If proper training is provided, all ICU staff might be able to complete the uDCD process successfully (including cannulation and ECMO).

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0611

INTRODUCTION. Brain death (BD) donors still remain the major source for organ procurement. Intensive care unit (ICU) admission conditioned to organ donation (COD) is a common practice to increase organ donation in hospitals without on site neurosurgical facilities.

OBJECTIVE. The aim of the study was to analyze patients with admission COD: time to BD, the conversion rate (CR) to effective donation (CRED) of those patients with admission COD (real CR) and the CRED of potential donors (successful CR).

METHODS. A descriptive, observational, retrospective study was undertaken from November/2013 to October/2017 in the ICU of the Guadalajara University Hospital (GUH).

We analyze patients with severe brain injury secondary to acute stroke (AS) or traumatic brain injury (TBI). All of them were refused as candidates for neurosurgical intervention, so their admission was COD.

Age, sex, diagnosis, development and time to BD, and procured organs were recorded. Qualitative variables are expressed as a percentage; quantitative variables are expressed as a median and interquartile range (IR).

RESULTS. A total of 36 patients with admission COD were included. Median age 70 years (IR, 61-80.8); 58.3% were male.

Diagnosis: AS 31 (86.1%): Ischemic 3 (8.3%) or hemorrhagic 28 (77.8%). TBI 5 (13.9%).

After ICU admission 7 patients (19.4%) were dismissed as donors; 5 rejected due to National Transplant Organization criteria (NTO) and the 2 remaining were transferred to a neurosurgery ICU after clinical reassessment.

Evolution to BD:

1) No BD: 10 patients (34.5%); 4 died in ICU after withdrawal of life support and 4 in hospital wards after ICU discharge. One patient was transferred to another center (family request) and the last one was discharged from hospital. Median ICU stay was 111.5 hours (IR, 79.9-119.7)

2) BD: 19 patients (65.5%), 15 of them (78.9%) in the first 72 hours from admission. Median time to BD was 28.7 hours (IR, 39.6-93.9).

Donation: real CR of 52.8% (19/36) and successful CR of 61.3% (19/31). Successful multi-organ procurement was achieved in 14 donors (73.68%). The most frequently procured grafts were kidney (31 grafts from 16 donors) and liver (16 donors). One double lung transplant donor and 3 heart donors.

CONCLUSIONS. In our series, 79% of patients suffered from BD in the first 72 hours. A successful CR of 61.3% is lower than published by the NTO (78%), most likely due to the characteristics of patients refused for neurosurgical intervention. Transplant coordinator 24 hours on site would help to improve real CR, decreasing economic and human costs.

Ethical evaluation before living kidney donation: a pilot study

K. Hadaya[1], M. Lamuela Naulin[2], M. Escher Imhof[3], T. Berney[4], C. Iselin[5], P.-Y. Martin[6], B. Ricou[3]

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0612

INTRODUCTION. Faced with ever-increasing demand and far exceeding supply from deceased donors, many transplantation teams have focused their programs on encouraging living kidney donation. An independent living donor advocate team to adequately inform, ensure voluntariness of the decision, and judge about the acceptability of the risk-benefit for living donors is strongly encouraged but not always possible in the organization of transplant centers. At Geneva University Hospitals, such an independent team was partially built up with a dedicated nephrologist and surgeon.

OBJECTIVES. In April 2016, Geneva University Hospitals' medical direction commissioned the Clinical Ethics Committee (CEC) to evaluate all potential living kidney donors, as was already the case for living liver donors.

METHODS. From July 2016 until February 2018, on monthly dates pre-booked for the year, 29 potential living donors (women 65%) have been evaluated by 2 members of the CEC at the end of their assessment and in the absence of medical, surgical and psychiatric contra-indications for donation. One woman could not follow this path because of organizational difficulties. Conclusions of the CEC concerning the eligibility or not of the potential living donor were sent within 24 hours to the transplant and donor's teams.

RESULTS. 27 potential living donors had been deemed eligible for donation. The 2 unfavourable opinions delivered, in connection with a lack of information on the surgical plan and regarding financial support, respectively, lead to a second evaluation between 1 and 2.5 months, that was positive this time. Following the 29 ethical evaluations, 24 renal transplantations were performed, 3 are in the process of organization and 2 were cancelled after the recipient underwent a deceased donor transplantation. No delay in the organization of transplantations was attributed to the ethical evaluation. The transplant and donor's teams were reassured in their care and were able to improve their information to potential living donors, thanks to the expertise and feedback of the CEC.

CONCLUSIONS. To best of our knowledge, we report the first systematic ethical evaluation of kidney living donors in a transplant center. As complex ethical issues relate to all kind of living donation, with kidney donors making up 95% of all worldwide, we suggest to provide each potential living donor with an independent advocacy team including an ethical evaluation.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0613

OBJECTIVES. To analyze the possibility of explantation of abdominal organs (AO), liver and kidneys, in our Unit (Medical ICU- secondary-level Hospital) in ≥ 75-year-old brain dead patients who became real donors (RD) in a 10-year-period.

METHODS. restrospective and descriptive study carried out between 2008 and 2017 of patients admitted to our ICU who were declared brain dead (BD). The following parameters were analyzed in ≥75-year-old real donors: gender, age group, causes of brain dead, medical history, use of inotropic agents needed, liver and/or kidney alterations, organ explantation (liver (Hex) and kidney (Rex)) and unexplanted organs (non viable, liver (Hne) and kidney (Rne)) and reason for this situation. Statistical analysis: quantitative variables are expressed using mean± standard deviation, and qualitative variables are expressed using %. The difference between qualitative variables are expressed using chi-square test and quantitative using an ANOVA analysis.

RESULTS. 111 patients were declared brain dead, being real donors 60 patients and 22 being ≥ 75-years-old. Gender: 11 women (11 men), age group: 14 patients (between 75-79 years old), between 80-84: 5 patients, >85 years old: 3 patients. Causes of BD: acute cerebrovascular disease (ACVD) 20 patients (hemorraghe 12, ischemic 6, subarachnoid hemorraghe 2) and anoxic encephalopathy: 2. Medical history: Hypertension:14, Diabetes: 9, alcoholism:6. Use of inotropic agents: 12. Kidney alterations: 7 and liver alterations: 4. 52 abdominal organs were explanted: 16 Hex (group 75-79 years old: 10, group 80-84 years old: 3 and >85 years old: 3), and 36 Rex (group 75-79 years old: 26, group 80-84 years old: 4, >85 years old: 4). 14 abdominal organs could not be explanted : 6 Hne (group 75-79 : 4, group 80-84: 2) and 8 Rne (group 75-79 :2 , group 80-84: 4 and group>85: 2). Reason for non explantation: Hne (fatty liver:4 and anatomical alterations: 2) and Rne (vascular abnormalities: 5 and macroscopic alterations: 3)

CONCLUSIONS. Patients in group ≥ 75 years old represent 19.8% of brain dead and 36.6% of real donors. In this group, 78.8% of the abdominal organs are viable for explantation (72.7% liver and 81.8% kidney), being dismissed for explantation 21.2% of the abdominal organs (27.3% liver and 18.2 kidneys). The most common reason for non explantation: fatty liver in Hne and vascular abnormalities in Rne.

0614

Iconographic (brain CT-scan) and clinical characteristics of patients with acute cerebrovascular disease (ACVD), hemorrhagic or ischemic, who were declared brain dead in a secondary-level university hospital in a six-year period

J.L. Martinez Melgar[1], E. Moreno Lopez[2], J.I. Cenoz Osinaga[3], J. Bravo Doviso[3], A. Ortega Montes[3], E. Sanmartin Mantiñan[3], T. Sanchez de Dios[3], A. Pais Almozara[3], P. Posada Gonzalez[3]
[1]Hosptal Montecelo, Transplant Coordination Team, Pontevedra, Spain; [2]Hospital Arquitecto Marcide, Ferrol, Spain; [3]Hospital Montecelo, Intensive Care Unit, Pontevedra, Spain
Correspondence: E. Moreno Lopez
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0614

OBJECTIVES. To analyze the iconographic (brain CT-scan (CTb)) and clinical characteristics on admission in a medical Intensive Care Unit (ICU) in a secondary-level University Hospital of patients with ACVD hemorrhagic (HIC) or ischemic (ISC) who were declared brain dead in a six-year period.

METHODS. Prospective and descriptive study , from 2012 to 2017 of patients admitted to our ICU with the diagnose of ACVD (HIC) or (ISC) who were declared brain dead (BD). Patients with traumatic brain injury (TBI), subarachnoid hemorrhage (SAH), epidural or subdural hematoma or anoxic encephalopaty were excluded. The following parameters were analyzed: age, gender, risk factors (hemorrhagic or embolic) for ACVD, characteristics of CT-scan according to the radiological report on ICU admission of patients with ACVD (location, type of herniation (h), size (>60 ml), extension of the hemorrhage into the ventricles (ev), midline shift (MLS)(< or > 1cm), as well as neurological status on admission: Glasgow Coma Scale (GCS) and pupillary condition. Statistical analysis: quantitative variables are expressed using mean± standard deviation, and qualitative variables are expressed using %. The difference between qualitative variables are expressed using chi-square test and quantitative using an ANOVA analysis.

RESULTS. 83 patients were declared BD (real donors 43, potential donors 40). 18 patients were excluded (TBI: 4, SAH:2, Epidural/subdural hematoma: 3 and anoxic encephalopaty: 9). 65 patients with ACVD were included : 51 HIC and 14 ISC. Gender: 38 male (27 female), age (66±17 years old, risk factors for hemorrhage or embolism (antiaggregants:7, oral anticoagulants:15, thrombocytopenia:3). CTb iconographic characteristics in HIC: location (cerebral hemisphere: 21, cerebellar:4, basal ganglia: 17, brain stem: 9), type of herniation (subfalcine:6, uncal:9), size(>60 ml): 22, extension into ventricles:34, MLS 35 (≤ 1 cm:15, >1 cm : 20). In patients with ischemic ACVD: location (cerebral hemisphere:9, cerebellar: 2, basal ganglia: 1 and brain stem: 2), type of herniation (subfalcine:6, uncal: 2), extension into ventricles: 3 and MLS: 11 (≤1 cm:5, >1 cm: 6). Neurological status on ICU admission: GCS score 6-8: 17 (HIC:18, ISC: 9), score 3-5: 38 (HIC:33, ISC: 5) and pupillary condition: anisocoria 39 (HIC: 30, ISC:9), mydriasis 16 (HIC:14, ISC: 2), isocoric 10 (HIC:7, ISC:3)

CONCLUSIONS. From 2012 to 2017 of 83 patients who were declared brain dead. ACVD was the reason in 78.3% (HIC: 61.5% and ISC: 16.9%). Iconographic characteristics in CT-scan of HIC: cerebral hemisphere:41%, size (>60 ml):43%, subfalcine herniation:47%, ev: 66% and MLS: 68.6%. In ISC patients: cerebral hemisphere: 64%, subfalcine herniation: 42.8% and MLS: 78.5%. GCS on admission: score 3-5 (HIC:64.7%) and 6-8 (ISC: 64.2%) and the most common pupillar condition was anisocoria (HIC: 58.8% and ISC: 64.2%).

Correspondence: B. Estébanez Montiel
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0615

INTRODUCTION. Severe brain injury, after cerebral gunshot wounds, may release large amounts of tissue factor to the circulation, may develop disseminated intravascular coagulation (DIC) and it can lead to renal dysfunction.

OBJECTIVES. Analyse the validity for transplantation of kidneys harvested from BDD following cerebral gunshot wounds and the outcome of the transplanted renal grafts.

METHODS. Retrospective descriptive study of renal allografts harvested from BDD following cerebral gunshot wounds, at a single center, between January 1, 2007 and May 31, 2017. Donors´ data (patients´ characteristics, blood tests, associated injuries) and recipients (graft survival, rejection) were collected.

RESULTS. We analysed data from six BDD following cerebral gunshot wounds (age 40.3 ± 9.6 years) without any cardiovascular risk factors, except one patient who had hypertension. All patients presented brain death in the first 24 hours of hospital admission. None of them had any associated injuries. One patient suffered a cardiopulmonary arrest (during 20 minutes) prior to ICU admission. One of the patients had elevated creatinine levels in the blood tests when he was admitted to the hospital. But, during the ICU length of stay, up to 50% of the patients presented acute renal failure. Fifty percent of the patients presented compatible or suggestive criteria for DIC. Four kidney grafts were not valid for transplantation because: acute renal failure (two kidney grafts), poor graft perfusion (one case) and complex vascular anomalies (one case). Eight kidney grafts (66.67%) were transplanted. Seven kidney grafts were transplanted in our center. One of them was explanted, in the first 24 hours after transplantation, due to cortical necrosis (pathology exam: glomerular and vascular thrombotic microangiopathy lesions). Fig 1. CT scan. The donor´s contralateral kidney was not implanted due to poor perfusion. The pathology exam of this kidney showed multiple fibrin trombi in glomerular capillaries and small-vessels (Figure 2). The remaining 6 grafts presented adequate function one year after the transplantation, except in one case which suffered underlying disease recurrence.

CONCLUSIONS. An accurate evaluation of kidney grafts from BDD following cerebral gunshot wounds is required, because they are patients at risk for DIC and acute renal failure. Pre-transplant biopsy and reduction of ischemia time may be indicated. Almost all transplanted renal allografts from BDD, following cerebral gunshot wounds, had good results in our study. Further studies with larger simple sizes are needed.

Depression and anxiety symptoms among living donor liver transplantation patients' relatives

H.K. Atalan
Acibadem Mehmet Ali Aydinlar University School of Medicine, Anesthesiiology and Reanimation, Istanbul, Turkey
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0616

INTRODUCTION. Hospitals in general, and specific wards of the hospital such as intensive care units (ICU) are the places where emotions of anxiety and/or depression can be expressed by patients' relatives (1). It's been shown that half of the patients' relatives have difficulties in understanding doctors' information about the condition of the patient (2).

OBJECTIVES. The aim of this study was to identify the symptoms of anxiety and/or depression in relatives of living donor liver transplant patients admitted in SICU and correlation of such symptoms with the relatives age, gender, degree of relationship, educational level and the patients' status.

METHODS. 147 adult relatives of 147 different patients were enrolled in this study between january 2017 and january 2018. The questionnary, including the hospital anxiety and depression scale and the demographic data of the patients' relative, was given to the patients' relatives, in early postoperative period, after visiting the patient and being informed by the doctor.

RESULTS. We observed anxiety and/or depression symptoms (ADS) in 108 of 147 patients' relatives. The anxiety symptoms were significantly higher in patients' parents and spouses than children (p=0.004). Depression symptoms were significantly higher in relatives of patients who had prior ICU stay (p< 0.001). There wasn't any significant association between ADS and relatives age, gender, educational level and the patients' medical status.

CONCLUSIONS. Relatives of LDLT patients face symptoms of anxiety and/or depression. ICU staff need to recognize these symptoms and emotional/psychological professional support must be prioritized.

Analysis of preconditioning factors influencing immediate graft function after deceased donor kidney transplantation

J.J. Kim, E.Y. Kim
Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Division of Trauma and Surgical Critical Care, Department of General Surgery, Seoul, Korea, Republic of
Correspondence: J.J. Kim
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0617

INTRODUCTION. The management of deceased donor in the intensive care unit (ICU) before organ transplantation would be important for the outcome of recipient. Herein, we analyze the preconditioning factors managed before procurement that could influence on the immediately postoperative graft function after deceased donor kidney transplantation (DDKT).

OBJECTIVES. A total of 271 DDKT which were performed at Seoul St. Mary's Hospital, Korea, from January 2009 to March 2016 was finally reviewed.

METHODS. We divided the patients into delayed graft function (DGF group) and no DGF (non-DGF group) and compared preoperative outcomes between groups. We also analyzed the predisposing factors of DGF using multivariate analysis.

RESULTS. A total of 36 cases developed DGF whereas 235 patients had no DGF and the demographic characteristics of recipients in each group had no significant difference. Regarding the preconditioning factors, the preoperative polyuria, the maximal level of serum sodium and BUN, and transfer time were significantly higher in DGF group ($p< 0.001$, respectively). In multivariable analysis, the preoperative polyuria (Odds Ratio 4.835, $p=0.036$), elevated preoperative level of sodium (Odds ratio 1.227, $p=0.001$) and the extended transfer time (Odds ratio 1.001, $p< 0.001$) were the independent risk factors of donor in preconditioning management associated with DGF.

CONCLUSIONS. The polyuria and high level of sodium before the organ procurement and the prolonged transfer time would be independent risk factors for DGF after DDKT. The active intervention and early implementation of the intensivist could be helpful to manage these factors effectively resulting in the improved graft function, ultimately.

DCD process in Italy: a growing experience

P. Fassini[1], M. Lucchelli[1], E. Borotto[1], G. Lanzillotti[1], A. Calzolari[2], D. Radrizzani[1]
[1]Ospedale di Legnano, Rianimazione, Legnano, Italy; [2]Università degli Studi di Milano, Scuola di Specializzazione Anestesia e Rianimazione, Milano, Italy

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0618

INTRODUCTION. Ethical and end of life issues still represent a main and daily challenge in ICU. Withdrawal of life sustainig therapy (WLST) deemed futile is due, this arises the chance of donation. Because of the growing gap between recipients and available organs, today the chance of donation after cardiac death (DCD) has emerged. In Italy, despite a very conservative law about determination of death (20 min for "no touch")[1], normothermic regional perfusion (NRP) allows abdominal organs donation. However thoracic organs procurement still remain a challenge.

OBJECTIVES. Due to time constriction, DCD requires a series of coordinated actions organized in a specific pathway.

METHODS.
DCD protocol consists of DCD II-III-IV. DCD II algorithm (Fig. 1-2):
DCD III: WLST is decided before any proposal of donation. After checking patient's will and eligibility WLST could start providing comfort for patient and relatives, light sedation, extubation and prevention of stridor and dispnea. After determination of death (20 min 'no touch period') we arrange femoral vessels cannulation for NRP and orotracheal intubation following 'Valenza protocol'[2].
DCD IV: after determination of death on cardiac or neurologic standard, ECLS is converted into NRP.

RESULTS. We collected 2 patients from Oct. 2016 till now, both admitted for post anoxic coma after cardiac arrest (CA). Both patients showed very poor prognostic scores that led to WLST. In the first case (53 yo male) next of kin expressed willingness to donate organs. Unfortunately technical problems impeded NRP. In the second case (63 yo male) the patient had living will to donate. Progression to CA took 21 min. After "no touch period", we started NRP and provided reintubation for lungs preservation[2]. Time to reintubation was 22 min and warm ischemia time lasted 48 min. Lungs were ready for ex vivo lung perfusion (EVLP) in 207 min. NRP proceeded for 227 min, with decrease of ALT and AST and lactate (fig. 3).
Liver was recovered in 228 min from CA. Liver and kidneys were connected to machine perfusion. All the organs were suitable for transplantation. After five months, all transplanted organs have good function.

CONCLUSIONS. DCD protocol allows solid organ donation after cardiac death, preserving the dead donor rule and the italian law. Extubation doesn't preclude lung donation. Combined lung and abdominal organs procurement is still a challenge, however thanks to team synergy we succeded in. Hospitals without ECLS program could supply lung donors through reconditioning and EVLP.

Causes of failure during the management process from identification of brain-dead potential organ donors to actual donation in Korea - 5-year data analysis (2012-2016)

J.-M. Lee[1], M.-I. Kim[2]

[1]Korea University Anam Hospital, Surgery, Seoul, Korea, Republic of;
[2]Korea University Anam Hospital, Transplantation Center, Seoul, Korea, Republic of
Correspondence: J.-M. Lee
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0619

OBJECTIVES. This is a retrospective analysis of the causes of failure in the management process from identification of brain-dead potential organ donors to actual donation, in Korea over the past 5 years.

METHOD. The data used were from 8,120 potential brain deaths reported to the Korea Organ Donation Agency, including the information received at the time of reporting, the donation suitability evaluation by the coordinator after the report, and the data obtained from interviews of hospital medical staff and the donor's family.

RESULTS. From January 2012 to December 2016, the total number of brain-dead potential organ donors in Korea was 8,120, of which 2,348 (28.9%) had undergone organ procurement surgery. The number of transplanted donors increased over time, but the ratio of transplanted donors to medically suitable brain-dead donors decreased. The most common causes of donation failure included donation refusal (27.6%), non-brain-death (15.5%), and incompatible donation (11.6%), and 104 potential donors (7.8%) were unable to donate their organs because they were not pronounced brain dead.

CONCLUSION. The organ donation success rate can be increased by analyzing the major causes of failure in the management process from identification of brain-dead potential organ donors to actual donation and through various efforts to prevent failure.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0620

INTRODUCTION. Sepsis is a state develops as a response to severe infection with high mortality rate. There is exaggerated and irregular host response in sepsis. Cytokines such as IL-1, IL-6, IL-8, TNF-α, İnterferon-γ and HMGB-1 are released as response to invading microorganisms and they play a major role in sepsis pathogenesis. Soybean proteins are used for prevention and treatment of cardiovascular diseases, osteoporosis and different cancer types. Soy isoflavons such as genistein, daidzein and glycitein are the main components for cancer prevention. Genistein is the dominant isoflavons. The main mechanism for anti-inflammatory effect of genistein is related to transcription nuclear factor Kb (NF-κB) and inhibition of chemokine-8

OBJECTIVES. To evaluate effects of genistein supplementation to oral/enteral nutrition on inflammatory cytokines in sepsis patients in the intensive care unit.

METHODS. This prospective randomized study was conducted at a Medical Intensive Care Unit of Erciyes University Hospital. The study included patients with sepsis above 18 years of age, required to stay in ICU more than 48 hours and patients receiving oral/enteral nutrition. Patients divided into two groups each containing 16 patients. Intervention group received supplemental genistein (60 mg/day)added to enteral nutrition. Control group patients received only oral/enteral nutrition. Serum IL-6, IL1- β, TNFand HMGB-1 concentrations were measured within 24 hours of sepsis diagnosis and serially at baseline, 24 hours and 72hours after entry.

RESULTS. A total of 32 subjects were included (genistein group: 16 pts, control group: 16 pts). The mean age was 56±16 years. The most commonsources of sepsis were respiratory (56%) and gastrointestinal system (19%). All patients had an Acute Physiology and Chronic Health Evaluation II score (APACHE II) of 16.4±8.7. Genistein group's APACHE II score was 17.2±9.3,and control group's APACHE II score was 15.6±8.3 (p=0.606).Genistein group had higher serum levels of IL-6 at 72 hours compared to the control group (31.6±14.9, 10.8±5.3 respectively) (p=0.000).TNF levels were lower in genistein group at 72hours compared to the control group (86.3±15.1, 104.6±23.6 respectively) (p=0.014).There were no statistically significant differences of baseline, 24 hours and 72hoursIL1-β & HMGB-1 levels between the two groups.

CONCLUSIONS. Proinflamatory cytokines IL-6 serum level was higher and TNF serum level was lower at 72hoursin patients who received Genistein supplementation. There was no difference in anti-inflammatory cytokine HMGB-1 serum levels between the two groups.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0621

INTRODUCTION. Trials of novel treatments in sepsis have failed to provide new therapies, in part, likely due to the heterogeneity of this condition. The need for a more stratified approach to trial recruitment is recognised and to achieve this goal, novel methods of patient stratification are needed.

OBJECTIVES. To apply multivariate analysis to a panel of cytokines measured in the plasma of patients with septic shock to identify subgroups that can predict outcome and could influence treatment choices.

METHODS. Nineteen cytokines were measured using LEGENDplex kits (BioLegend, UK) in the plasma of 174 patients admitted to ICU at enrolment into the VANISH clinical trial (1). Unsupervised analysis was performed with principal component analysis (PCA) and hierarchical cluster analysis to identify patient subgroups based on profiles of inflammatory mediators. Univariate statistics were applied to compare individual mediators and outcome parameters.

RESULTS. PCA identified two groups of patients: one with a hyper-inflamed phenotype (n=31) compared to the other (n=143). Several cytokines were substantially higher in the hyper-inflamed group including G-CSF (32,898pg/ml vs 349pg/ml, p< 0.001), MCP-1 (12,491pg/ml vs 1,239pg/ml, p< 0.001), IL-6 (35,000pg/ml vs 617pg/ml, p< 0.001) and IL-8 (4,210pg/ml vs 59pg/ml, p< 0.001). This group was associated with a higher mortality at 28 days (OR 3.9 (1.7-8.7), p=0.001). No interaction was seen between inflammatory group and the choice of vasopressor (noradrenaline or vasopressin) (p=0.27) or the use of hydrocortisone (p=0.50) on day 28 survival. Clinical parameters had only a moderate ability to predict cytokine grouping with APACHE II score (AUROC 0.71 (0.61-0.80), misclassification rate 26%) and lactate (AUROC 0.74 (0.64-0.83) misclassification rate 26%) performing similarly.

CONCLUSIONS. Applying unsupervised analysis to a panel of inflammatory mediators detected a subgroup categorised by higher levels of circulating cytokines and worse clinical outcome. Using such information to stratify patients into clinical trials may overcome the effects of patient heterogeneity to improve the identification of treatment responsive subgroups.

The clinical application of extracorporeal membrane oxygenation for sepsis related non pulmonary associated infection

T. Hong, H. Kim
Hallym University Sacred Heart Hospital, Surgery, Anyang-si, Korea, Republic of
Correspondence: T. Hong
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0622

INTRODUCTION. Application of Extracorporeal membrane oxygenation (ECMO) as a therapeutic option in critically ill patients is increasing. Recent studies found that using ECMO for pneumonia, asthma, trauma and burn were associated with better outcomes. However the role of ECMO as a potentially useful therapeutic option in case of sepsis or septic shock remains questionable. Besides, Role of ECMO in Sepsis induced by non-pulmonary associated infection was no clearly known, compared than pulmonary infection.

OBJECTIVES. The aim of this study is to analyze the clinical characteristics of ECMO in non-pulmonary associated infection, through the comparison of pulmonary infection group.

METHODS. The study was conducted on 32 patients who were clearly identified for infectious origin and septic shock among 154 patients who applied ECMO from a single center between January 2015 and December 2017. Medical records of these patients were reviewed. The patients divided in two groups, a pulmonary infection group and a non pulmonary associated infection group on the basis of a primary origin of infection. Patients under 18 years of age were excluded. The clinical variables related with patient were extracted and analyzed.

RESULTS. Total number of the included patients was 32. The number of pulmonary infection patients was 18 and the number of non pulmonary associated infection patients was 14. There were differences in hospital mortality, SAPS3 score, SOFA score at ECMO starting day, ICU stay, ECMO duration, time interval from ICU admission to ECMO start. The average of SAP3 score (74.5 vs 51.72) (p< 0.00) and SOFA score at ECMO starting day (14.36 vs 10.33) (p=0.001) was higher in the non pulmonary associated infection group. Also the non pulmonary associated infection group had higher mortality rate compare than the pulmonary infection group. (71.4% vs 50%) More veno-arterial ECMO applied to non pulmonary associated infection group. (78.6% vs 11.1%) The hospital stay (23.86 days vs 46.89 days) (p=0.042) and ICU stay (19.71 days vs 35.56 days) (p=0.026) of the non pulmonary associated infection group was shorter than the pulmonary infection group. Also Lactate level was higher in the non pulmonary associated infection group when ECMO was applied. (10.481 mmol/L vs 2.872 mmol/L) (p< 0.00).

CONCLUSIONS. The non pulmonary associated infection group had more severe aspect compared than the pulmonary infection group when ECMO was applied. Higher mortality of the non pulmonary associated infection group compare than that of the pulmonary infection group was cause of shorter hospital stay and ECMO duration. These results indicate that more consideration is needed when applying ECMO in non-pulmonary associated infection patient.

Effects of polymyxin B hemoperfusion on septic shock in patients after liver surgery: a pilot study

A.L. Lee[1], S.Y. Hong[2], B.W. Kim[2], H.J. Wang[2]
[1]University of Ulsan College of Medicine, Asan Medical Center, Division of Acute Care Surgery , Department of Surgery, Seoul, Korea, Republic of; [2]Ajou University School of Medicine, Department of Liver Transplantation and Hepatobiliary Surgery, Suwon, Korea, Republic of
Correspondence: A.L. Lee
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0623

INTRODUCTION. Polymyxin B direct hemoperfusion (PMX-DHP) can remove plasma endotoxins. It is considered an effective treatment for sepsis, particularly for intra-abdominal infection with gram-negative bacteria. Clinical data for the effect of PMX-DHP on septic shock in patients with liver disease are limited.

OBJECTIVES. To evaluate clinical effects of PMX-DHP treatment on septic shock in patients after hepatectomy or liver transplantation.

METHODS. From August 2016 to September 2017, 10 patients who underwent PMX-DHP treatment for septic shock after liver surgery (3 cases of hepatectomy and 7 cases of liver transplantation) in surgical intensive care unit were enrolled. PMX-DHP treatment was performed one or twice in each patient. Two patients who died within

24 hr after PMX-DHP were excluded. Changes in patient's hemodynamics and infection marker before and after PMX-DHP treatment (24hr, 48hr, 72hr, 7 day) were analyzed.

RESULTS. Most patients had Gram-negative bacteremia. Mortality in 28 days was 50%. Mean value of sequential organ failure assessment (SOFA) score and serum lactate level before PMX-DHP treatment were 17.6 (range, 13.0-22.0) and 8.3 mg/dL (range, 2.0-26.7mg/dL). After PMX-DHP treatment, serum lactate, vasoactive-inotropic scores (VIS), vasopressor dependency index (VDI), and PaO_2/FiO_2 ratio were significantly decreased (Table 1). Levels of C-reactive protein (CRP) as an infection marker were decreased after PMX-DHP treatment (Table 1).

CONCLUSIONS. Our pilot study suggests that PMX-DHP treatment can significantly improve hemodynamics in patients with septic shock after liver surgery.

Endotoxin and cytokin reduction function of the oXiris filter in a prospective double-blinded cross-over setting in patients with critical Gram- septic shock and continuous renal replacement therapy requiring acute kidney injury

M.E. Broman, M. Bodelsson
Skåne University Hospital, Lund, Perioperative and Intensive Care, Lund, Sweden
Correspondence: M.E. Broman
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0624

INTRODUCTION. In Gram-negative sepsis endotoxin (lipopolysaccharide), a component from the outer bacterial wall, is released into the circulation, causing endothelial leakage and vasodilation. The septic cascade is further escalated by triggering a host immune response mediated by cytokines. The oXiris filter for continuous renal replacement therapy (CRRT) has a 3 times thicker endotoxin-adsorbing polyethylene-imine layer than a standard ST filter.

OBJECTIVES. We wanted to investigate whether CRRT with oXiris could affect lipopolysaccharide and cytokine levels in sepsis patients with acute kidney injury (AKI).

METHODS. Sixteen patients with Gram-negative septic shock, blood endotoxin levels >0.03 EU/ml and CRRT requiring AKI were randomized in a double-blinded cross-over regime to 24 h CRRT with oXiris followed by 24 h with a standard filter (ST), or vice versa. Blood samples were drawn at 0, 1, 3, 8, 16 and 24 hours of each treatment period for measurement of endotoxin levels (turbidimetric kinetic Limulus amoebocyte lysate assay) and tumor necrosis factor (TNF)-α, interleukin (IL)-1β, -2, -4, -6, -8, -10, interferon-γ and granulocyte-macrophage colony-stimulating factor (GM-CSF, Bio-Plex multiplex immunoassay).

RESULTS. Both filters lowered the endotoxin levels over 24 h. Total endotoxin balance was negative throughout the oXiris study periods, while mean levels were positive compared to baseline during the first 8 h of the ST study periods. Levels of IL-6, -8 and TNF-α decreased significantly during use of both filters, while interferon-γ was significantly lowered only in the oXiris group. The remaining cytokines did not significantly change.

CONCLUSIONS. Both filters lower the endotoxin levels, but the oXiris filter shows an enhanced effect during the first 8 h, which could come from a more active endotoxin adsorption. The filters were equally effective in reducing cytokine levels suggesting a similar binding capacity of these mediators and/or reducing the septic inflammatory response alike.

The affecting factors for EAA (Endotoxin Activity Assay) are important in safety and efficacy of polymyxin B hemoperfusion (PMX) for septic shock (EUPHRATES) trial

M. Kang, M. Tsunoda, M. Saito, T. Oshiro, M. Takeda, A. Yaguchi
Tokyo Women's Medical University, Critical Care and Emergency Medicine, Tokyo, Japan
Correspondence: M. Kang
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0625

INTRODUCTION. Since 1994, PMX-DHP (Polymyxin B-direct hemoperfusion) (Toraymyxin®, Toray medical Co., Tokyo) has been approved as a therapy for patients with endotoxic or Gram-negative infectious severe sepsis in Japan. Recently, randomized placebo-controlled trials (such as EUPHRATES trial) shows PMX-DHP treatment improved their mortality in some population in septic shock, although did not reach statistical significance of primary endpoint.

OBJECTIVES. The purpose of the present study is to compare between EUPHRATES trial and our institution's data, and to clarify the efficacy of PMX-DHP for septic shock.

METHODS. From November 2014 to December 2017, all adult patients treated with PMX-DHP and EAA (Endotoxin Activity Assay) was measured at pre-treatment of PMX-DHP in our medico-surgical ICU of university hospital were included in this retrospective study. And of those whom, patients met both of the inclusion and exclusion criteria of EUPHRATES trial were selected and compared with EUPHRATES trial results. The criteria of Patients' data were collected from medical archives. Values were expressed as mean ± SD.

RESULTS. There were fifty two patients who were treated with PMX-DHP in all (25 men, 27 women; age [mean 63.8 ± 14.5]; 28 day mortality 30.8%). Mean SOFA score, MOD score, and EAA values at pre-treatment of PMX-DHP were 9.6 ± 4.6, 7.6 ± 3.9 and 0.58 ± 0.19, respectively. Of 52 patients, there were 7 patients with pre-treatment EAA between 0.6 and 0.9, and MODS>9. And there were only 3 patients who had 2 session treatment of PMX-DHP. Mean age, SOFA score, MOD score, EAA values at pre-treatment of PMX-DHP and 28 day mortality in those 3 patients were 64 ± 14.5, 15.3 ± 2.3, 11.7 ± 2.9, 0.73 ± 0.10 and 33.3%, respectively. Of 3 patients, one non-survivor at 28 day were giving chemotherapy for peritoneal dissemination of appendiceal cancer and showed pre-treatment WBC count was 1010/ mm^3.

CONCLUSIONS. The limitations of this study were small numbers of patients and small results were published about EUPHRATRES trial. The 28 day mortality in our patients was 33.3%, while 26.1% of EUPHRATRES trial. Non-survivor in our patients had leukocytopenia due to chemotherapy. EAA values are using for inclusion criteria of that trial and that assay is based on the reaction of neutrophils to lipopolysaccharide. Therefore, EAA value could be influenced by leukocytopenia. Such participants might be included in EUPHRATES trial. Using EAA for criteria could be difficult to show the efficacy of PMX-DHP in those patients. The analysis of subgroup in that trial should be reconsidered to regard affecting factors of EAA.

[2]Max Super Specialty Hospital, Nephrology, New Delhi, India
Correspondence: Y.P. Singh
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0626

INTRODUCTION. Sepsis results in immunologic disturbances with the release of various inflammatory mediators including cytokines[1]. Cytokines are able to damage the cells and the continuous release of inflammatory mediators leads to impaired immunity. Therefore, the reduction in cytokine levels by hemoadsorption represents a new concept for blood purification. CytoSorb® is an Extracorporeal Cytokine Adsorption Device (ECAD) which is used to reduce toxic levels of cytokines. It is designed to directly capture and reduce mid-molecular weight inflammatory mediators (~10-55 kDa) in blood including pro and anti-inflammatory cytokines, chemokines, and bacterial exotoxins[2]. The current retrospective study was carried out to understand the inflammatory status as a result of evident immuno-modulatory effect of CytoSorb® therapy.

METHODOLOGY. This retrospective study was analyzed in Max Super Specialty Hospital, Patparganj, Delhi, India for the patients who were admitted between 2015 to 2017 in compliance with current ICH-GCP and ICMR guidelines. A total of 36 patients (range [24-84 year]) were included in the analysis.

RESULTS. In the present retrospective analysis, majority of the patients were admitted in medical & surgical ICU due to infection. After CytoSorb® therapy, a significant decrease of 91% in the PCT levels within 24 hours of the therapy was observed. The post-Cytosorb, procalcitonin (PCT) level was decreased to 3.16±2.10 ng/mL from the baseline value of 36.06±33.86 ng/mL. Similarly, a 44 % decrease (i.e. from 26.4± 15.28×109/L to 16.31±6.81×109/L) in TLC levels was observed after CytoSorb® therapy. The sepsis severity scores, namely, SOFA and APACHE II, reduced to 7.8±3.67 and 11.41±3.14 from the initial value of 12.41± 4.23 and 24.4±6.01 respectively after CytoSorb® therapy. Within 24 hours after the CytoSorb® therapy, shock reversal was observed in eight (22.2%) patients. The predicted mortality for the included patients was more than 50%.

CONCLUSIONS. In the present study, most of the patients had shown significant reduction in PCT, TLC Counts & Sepsis Scores after CytoSorb® therapy. Also, the shock reversal was observed in few patients when treated with CytoSorb® therapy. This could be attributed to the known-immunomodulatory effect of CytoSorb as an adjuvant therapy. However, a larger prospective study is required to derive the above stated benefit of the ECAD therapy.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0627

INTRODUCTION. Sepsis represents a life-threatening organ dysfunction caused by a dysregulated host response to infection with massive systemic cytokine storms. Sepsis-induced acute kidney injury (S-AKI) is frequently occurring in the early course of sepsis and increases mortality significantly.[1] However, the pathophysiological pathways associated with S-AKI remain poorly understood.

High-mobility group box-1 (HMGB1) is a damage-associated molecular pattern molecule, which is thought to stimulate proinflammatory responses in tubular kidney cells and to promote acute kidney damage via Toll-like receptor 4 (TLR4).[2]

Here, we investigated the role of cytokines and DAMPS in the pathogenesis of S-AKI, and report on a randomized, controlled, open-labeled clinical trial CASAKI (NCT02588794).

OBJECTIVES. We hypothesized that treatment of patients with S-AKI with an extracorporeal cytokine and DAMP adsorber (Cytosorb) decreases IL-6 and HMGB1 levels, leading to a better clinical outcome.

METHODS. 13 patients (=control group) with S-AKI were treated in accordance to guidelines with CVVHD. Treatment group (n=12) received an additional hemoadsorption therapy by Cytosorb until serum levels of IL-6 reached < 1000 pg/ml. Serum and urine samples were taken before CRRT start and after 24h, and IL-6 and HMGB1 levels were quantified by ELISA.

RESULTS. After 24 hours a significant reduction of IL-6 serum levels was found in the treatment group (median: 22% of initial baseline levels; interquartile range 8-31%), compared to an increase of IL-6 in the control group (median: 123%; IQR 29-300%; p=0,009).

HMGB1 in urine decreased significantly in the treatment group after 24 hours (t_0: mean 46ng/ml ±22; t_{24}: mean 16ng/ml ±5; p=0,004), as well as HMGB1 in serum (t_0: mean 37ng/ml ±14; t_{24}: mean 26ng/ml ±18; p=0,043). In contrast, HMGB1 levels remained essentially unchanged in the control group.

Of note, baseline pre-therapeutic urinary HMGB1 levels correlated strongly with 28-day kidney function (spearman |r|=0,725; p=0,003).

CONCLUSIONS. Hemoadsorption therapy efficiently removed HMGB1 and IL-6 within the first 24 hours. Tendencies to increased 28-day kidney function and 90-day survival in the treatment group were observed, although not attaining significance. To confirm these effects, more patients need to be included.

Furthermore, urinary HMGB1 seems to play a major role in the pathogenesis of S-AKI, with the potential as putative biomarker in S-AKI to predict long-term renal-function.

Early therapeutic plasma exchange as rescue therapy in septic shock

K. Stahl[1], T. Idowu[1], M. Busch[1], O. Wiesner[1], T. Welte[1], M.M. Hoeper[1], J.T. Kielstein[2], S. David[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0628

INTRODUCTION. The overwhelming host response in sepsis is a key driver of morbidity and mortality. The theoretical concept of therapeutic plasma exchange (TPE) in sepsis combines two major aspects in one intervention: 1) Removal of harmful circulating molecules - as part of the injurious cytokine storm - that directly contribute to the manifestation of the disease. 2) Replacement of protective plasma proteins that compensate for the loss of factors important for coagulation, fibrinolysis and counteract inflammation and vascular leakage to ultimately restore hemostasis.

OBJECTIVES. We explored the effects of early TPE in severely ill individuals with septic shock.

METHODS. Prospective single center, open-label, non-randomized pilot study enrolling 20 patients with septic shock (**onset< 12h**) requiring high doses of norepinephrine (**NE>0.4mg/kg/min**). Clinical and biochemical data were obtained before and after TPE and plasma samples were taken for *ex vivo* stimulation of human umbilical vein endothelial cells (HUVECs) to analyze barrier function (immunocytochemistry & transendothelial electrical resistance). Cytokines were measured by cytometric bead array and enzyme linked immunosorbent assays. An immediate response was defined as >20% NE reduction from baseline to the end of TPE.

RESULTS. TPE was well tolerated without the occurrence of any adverse events and resulted in rapid reduction in NE (0.82 (0.61-1.17) vs. 0.56 (0.41-0.78) mg/kg/min, p=0.002) to maintain mean arterial pressure (MAP) above 65 mmHg. The actual overall 28-day mortality was 65%, while the expected (APACHE-II) mortality was 91.1%. Key pro-inflammatory cytokines and permeability factors (e.g. IL-6, IL-1b, Angiopoietin-2) were significantly reduced after TPE while the anti-inflammatory cytokine IL-10 was not changed. *Ex vivo* stimulation of HUVECs with plasma obtained before TPE induced substantial cellular hyper-permeability, which was completely abolished with plasma obtained after TPE.

CONCLUSIONS. In this uncontrolled pilot study, early TPE was safe and resulted in rapid hemodynamic improvement and favorable changes in the cytokine profile in patients with septic shock. It has yet to be determined whether early TPE also improves outcomes in this patient cohort. An appropriately powered multicenter RCT is desirable.

The combination of AN69ST-CRRT and PMX-DHP reduces the dosage of vasopressors needed and fluid infusion in patients with septic AKI

H. Narumiya[1], R. Iiduka[1], S. Hashimoto[2]

INTRODUCTION. Continuous blood purification for the treatment of sepsis and septic acute kidney injury (AKI) is currently widely used. After the polymethylmethacrylate (PMMA) membrane, the AN69ST membrane is the latest hemofilter for septic shock. Polymyxin B immobilized direct hemoperfusion (PMX-DHP) is one of the adjuvant

therapies for sepsis and septic shock; however, the optimal combination of blood purification and PMX-DHP remains unclear.

OBJECTIVES. This study aimed to clarify the additional effects of PMX-DHP administered alongside continuous renal replacement therapy (CRRT) for septic AKI patients.

METHODS. One-hundred-fourteen patients who received CRRT with or without PMX-DHP for septic shock during the study period were recruited. Patients were divided into the following four groups: the AN69ST-CRRT group (n=35), PMMA-CRRT group (n=29), AN69ST+PMX group (n=23), and PMMA-PMX group (n=27). The patients' baseline characteristics, including information on age, sex, APACHE II score, lactate levels, and infection details, were recorded. The primary outcome measure was 28-day all-cause mortality. Secondary outcomes included mortality after intensive care unit discharge, vasopressor dose, and total fluid dosage in 24 h.

RESULTS. While the baseline parameters were not significantly different across the groups, the lactate levels of the AN69ST+PMX group and PMMA+PMX group were significantly higher than other groups (4.0±2.4 mmol/L, 4.2±2.3 mmol/L, 5.1±2.7 mmol/L and 5.0 ±2.9mmol/L, respectively). Death occurred in in 9/35 patients in the AN69ST-CRRT group, 7/29 patients in the PMMA-CRRT group, 8/23 patients in the AN69ST+PMX group and 11/27 patients in the PMMA-PMX group. There were no significant differences in mortality between these four groups. The vasopressors significantly decreased during 24 h in the AN69ST group, with or without PMX-DHP, compared to the PMMA-CRRT group despite PMX-DHP therapy (p< 0.05). The total fluid dosage for 24 h was significantly lower in the AN69ST +PMX group (mean ± SD; 2922 ± 1499 mL). Univariate regression analysis showed that the combination of AN69ST-CRRT and PMX-DHP was independently associated with differences in fluid dosage.

CONCLUSIONS. The combination of AN69ST-CRRT and PMX-DHP reduces the dosage of vasopressors needed and fluid infusion in patients with septic AKI.

INTRODUCTION. High flow-volume intermittent hemodiafiltration (sustained high-efficiency daily diafiltration [SHEDD-fA] using a mediator-adsorbing membrane) or continuous hemofiltration (CHF) were indicated as mediator modulation therapy. We previously reported the efficacy of SHEDD-fA hemodynamics in septic patients and oxygenation in patients with acute respiratory distress syndrome [1]. Intensivists were responsible in deciding whether SHEDD-fA or CHF should be used at the initial administration in the intensive care unit (ICU) based on a daily multidisciplinary conference. However, the selection criteria in choosing between SHEDD-fA and CHF have not yet been determined.

OBJECTIVES. This preliminary case-control study aimed to retrospectively determine the selection criteria of both modalities and to associate with randomized controlled trials planned in the future.

METHODS. Patients who underwent blood purification to modulate mediators from August 2014 to December 2016 in the ICU at the Fujita Health University Hospital in Japan were selected. Parameters on infection, circulation, kidney function, respiration, coagulation, and inflammation, acute physiology and chronic health evaluation (APACHE) II score, and sequential organ failure assessment (SOFA) score during the first blood purification were evaluated. Data were presented as median and interquartile range (IQR). Chi-squared test or Mann-Whitney U-test was used for between-group comparisons. All statistical analyses were performed using EZR (Saitama, Japan), a graphical user interface for R (Vienna, Austria). This case-control study was approved by the ethics committee of the Fujita Health University School of Medicine in Japan (No. HM17-301).

RESULTS. A total of 73 patients were eligible in this retrospective study. The median (IQR) of age, APACHE II score, and SOFA score before blood purification were 68 (65-76) years, 26 (19-33), and 9.0 (6.8-10.3), respectively. About 42% (n=31) of the patients had no acute kidney injury. Among the enrolled patients, 61 underwent SHEDD-fA and 12 underwent CHF. The proportion of infectious cases was significantly higher in the SHEDD-fA group than that in the CHF group (75.4% vs. 33.3%, p=0.004). Catecholamine index (CI) tended to be higher in the SHEDD-fA group than that in the CHF group (5.0 vs. 0 μg/kg/min, p=0.11). The differences in other parameters, such as blood lactate concentration, PaO_2/F_IO_2 ratio, white blood cell count, C-reactive protein, procalcitonin, fibrin/fibrinogen degradation products, thrombin-antithrombin complex, and severity scores were statistically insignificant. SHEDD-fA was significantly selected for critically ill patients with both infections and CI 4 or others (p=0.0022).

CONCLUSIONS. We frequently selected SHEDD-fA for patients with infection and CI 4 or others at the first administration of blood purification in our ICU.

OBJECTIVE. To study the evolution of patients with gramnegative septic shock treated with B-polymyxin (B-PMX) hemoperfusion in a 16-bed ICU.

INTRODUCTION. B-polymyxin hemoperfusion is a therapy that can be used in refractory septic shock after an adequate antibiotic, hemodinamic management and focus control.

METHODS. B-PMX has an strong bactericide activity against gramnegative bacilli (GNB) and a great affinity for the endotoxin (LPS) of their wall. The cartridge with B-PMX molecules linked to polystyrene fibers can be used to neutralize LPS molecules in gramnegative sepsis through an extracorporeal therapy (hemoperfusion) with less adverse effects than administered systemically. Our study is prospective with those patients who were treated with B-PMX hemoperfusion in our unit since 2012.

RESULTS. 14 patients have been treated since then, 12 with abdominal foci (9 peritonitis, 3 biliary), t2 of unknown origin. Growing of GNB was confirmed in 8 cases (4 polymicrobial, 3 Escherischia coli, 1 Klebsiella pneumoniae), 1 Candida albicans and 5

negative cultures. All the patients were in refractory shock (noradrenalin dose required > 1 mcg/kg/min to keep MBP > 60-65 mm Hg) as well as other recommended measures according to Surviving Sepsis Campaign (SCC) guidelines, including focus drain. Eight patients were treated only with one session and other six with two. No complications due to the procedure were observed. Hospital mortality was 50%. In patients who survived a dramatical decrease 24h after B-PMX of noradrenalin requirement (1,71 ± 1,04 mcg/kg/min vs 0,46 ± 0,52 mcg/kg/min) and lactate levels (3,9 ± 1,3 mmol/L vs 2 ± 0,7 mmol/L) were observed. Patients who died received a similar noradrenalin dosage (1,44 ± 0,4 mcg/kg/min) before B-PMX compared with survivors, but had higher lactate levels (10 ± 5,2 mmol/L), the focus control was considered as suboptimal or was not done in 5 cases (71%), in front of 100% of non-indicated removal or optimal control in survivors.

CONCLUSIONS. B-PMX therapy may offer some hemodynamic improvement in patients with gramnegative septic shock, always associated with other recommended SCC measures. Patients with suboptimal focus control and higher lactate levels had a greater risk for poor response and mortality.

INTRODUCTION. The Endotoxin Activity Assay (EAA™; Spectral Diagnostics Inc., Toronto, Canada) is a rapid in vitro diagnostic test of the neutrophil's reaction to endotoxin and reflects the endotoxemia1). Recently, EAA is used to inclusion criteria for the EUPHRATES (Evaluating the Use of Polymyxin B Hemoperfusion in a Randomized controlled trial of Adults Treated for Endotoxemia and Septic shock) trial study2). And MOD score is also used as inclusion criteria in that trial.

OBJECTIVES. The purpose of the present study is to clarify which is more effective factor for 28 day mortality between EAA (Endtoxin Activity Assay) values and MOD score at pre-treatment Polymyxin B hemoperfusion (PMX-DHP).

METHODS. The present study is a single-center retrospective observational analysis. From November 2014 to December 2017, all adult patients treated with PMX-DHP in our ICU and with pre-treatment EAA between 0.6 and 0.9 were included. EAA values between immediately before and immediately after PMX-DHP therapy, and MOD score, SOFA score, mean arterial pressure (MAP)(mmHg), P/F ratio, platelet counts (x 10^4/μL), GCS and creatinine (mg/dL) immediately before PMX-DHP therapy, age and gender were compared between survivors and non-survivors at 28 day after therapy. Values are expressed as mean ± SD. Data was analysed by chi-square test and unpaired Students t-test. P values less than 0.05 were considered significant.

RESULTS. Twenty one patients (12 men and 9 women; mean age 64.2 ± 13.4 years) were studied. There were 12 survivors (6 men and 6 women) and 9 non-survivors (6 men and 3 women) at 28 day after therapy. EAA values immediately before and immediately after PMX-DHP therapy, MOD score and SOFA score, platelet counts and creatinine were statistically significant differences between survivors and non-survivors (0.68 ± 0.10 vs. 0.76 ± 0.08, p=0.03, 0.38 ± 0.10 vs. 0.71 ± 0.25, p=0.04, 6.8 ± 3.7 vs. 10.4 ± 3.8, p=0.04, 8.2 ± 4.9 vs. 13.7 ± 4.2, p=0.006, 16.6 ± 12.8 vs. 8.1 ± 5.8, p=0.03, 1.6 ± 1.1 vs. 2.8 ± 1.8, p=0.04, respectively). MAP, P/F ratio, GCS, age and gender were no significant differences between survivors and non-survivors.

CONCLUSIONS. There were significant differences in EAA values, MOD score, SOFA score, platelet counts and creatinine between survivors and non-survivors. Not only endotoxin values but also organ dysfunction such as coagulopathy and renal failure could contribute to 28 day mortality.

Initial experience of using polymyxin B hemoperfusion in abdominal septic shock: things to consider for better outcome

J.J. Kim, E.Y. Kim
Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Division of Trauma and Surgical Critical Care, Department of General Surgery, Seoul, Korea, Republic of

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0633

INTRODUCTION. Polymyxin B hemoperfusion, which treats septic shock by removing endotoxin of gram-negative bacteria (GNB), has been proposed as one of the treatment modalities for intraabdominal sepsis. However, there is a lack of studies about the factors need to be taken into consideration for a better outcome. The aim of this article is to introduce our experience of using polymyxin B hemoperfusion in abdominal septic shock and assess the factors affecting the outcome of this therapy.

OBJECTIVES AND METHODS. We performed polymyxin B hemoperfusion in 6 patients who were diagnosed with abdominal septic shock. During the treatment, the change of Sequential Organ Failure Assessment (SOFA) scores and dose of inotropic agents used were analyzed to assess the effectiveness of this therapy. Surgical outcomes and clinical courses of the patients were analyzed while reviewing the case with worse outcome to identify the negative factors affecting the outcome and the literature review was performed for the prior studies reporting polymyxin B hemoperfusion use in abdominal sepsis patients.

RESULTS. Except for one case, total SOFA score decreased steadily from the time immediately after the completion of hemoperfusion. The significant decrement of inotropic agent dosage was also observed in all of the 6 patients after hemoperfusion. There was one case of death, in which the initiation of hemoperfusion was delayed and prior source control was insufficient.

CONCLUSIONS. Authors suppose that polymyxin B hemoperfusion could be an effective therapy for treating abdominal septic shock and early use of this modality with definite initial source control might be important for the better outcome.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0634

INTRODUCTION. Fever may adversely affect outcome in critically ill patients. In patients with septic shock, fever control significantly improved 14-day mortality and reduced vasopressor use compared to baseline. However, the underlying physiological mechanisms of any potential benefit of fever control have yet to be determined.

OBJECTIVES. In this study, we aimed to investigate the effect of fever control on markers of coagulation and endothelial activation during endotoxemia in healthy volunteers.

METHODS. Healthy volunteers were injected with LPS (from *E.coli*, 2ng/kg) and randomized to either fever control to normothermia (36,0°C-38,0°C) or no fever control (n=6 per group). Fever control was achieved using an external surface cooling device (Artic Sun©), and cooled IV fluids (4°C). To control shivering, buspirone, clonidine and magnesium sulphate were given. In the control group, temperature was not managed. Both groups received an equal amount of IV fluids.

Blood samples were taken prior to LPS-infusion and 1, 3, 6, and 8 hours thereafter. Platelet levels, von Willebrand factor (vWF), conventional coagulation tests, rotational thromboelastometry (ROTEM©) analysis and calculated disseminated intravascular coagulation (DIC)-scores were used to assess the coagulation state of the volunteers. Data are presented as median (interquartile range) or mean ± standard deviation at T=3. A mixed effects model was used to asses differences between groups.

RESULTS. Mean body temperature was significantly lower in the normothermia group compared to the control group (37.2°C (36.8 - 37.7) vs 38.7°C (38.7 - 38.8), p = < 0.0001) as was SIRS-score (0 ± (0-0) vs 2 ± (1.3-2), p = 0.002). Heart rate decreased from 94 beats per minute (bpm) (84-98) to 65bpm (63-66), p = < 0.0001. Compared to the control group, the drop in platelet count was completely prevented in the normothermia group (194 x 10E9/L ± 7 vs 97 x 10E9/L ± 19, p = 0.02). Also, prolongation of PTT was prevented (23.5 sec ± (23-24) vs 20.5 sec (20-21.8), p = 0.002). D-dimer levels did not differ, but the DIC-score in the normothermia group was significantly lower compared to the control group 3 (1.5-3) vs 3.5 (3-4), p = .005). Also, there were less patients with a DIC score of >4 in the fever control group compared to control). There was no significant difference in ROTEM© results between both groups, including G values. Also, the normothermia group had significantly lower levels of vWF compared to the control group lower (208 antigen (Ag)% (164-232) vs 304 Ag% (216-359), p = 0.006.

CONCLUSIONS. Fever control prevents coagulation disturbances related to DIC in human endotoxemia. This phenomenon was associated with reduced shedding of vWF, suggesting inhibition of endothelial activation.

Circulating evil humours cause mitochondrial dysfunction in sepsis. Does size matter?

S. Pollen[1], N. Arulkumaran[1], M. Duchen[2], M. Singer[1]
[1]UCL, Bloomsbury Institute of Intensive Care Medicine, London, United Kingdom; [2]UCL, Cell and Developmental Biology, London, United Kingdom
Correspondence: S. Pollen
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0635

INTRODUCTION. We have demonstrated that exposure of naïve kidney slices to septic serum increases reactive oxygen species (ROS) generation and decreases mitochondrial membrane potential (MMP) and NADH fluorescence, and that scavenging ROS can both prevent and reverse these changes.[1] Serum contains many mediators that may induce this observed mitochondrial dysfunction. Identifying if specific components within serum are contributory would enhance understanding of the underlying pathophysiology and offer a potential therapeutic target.

OBJECTIVES. To determine whether mitochondrial dysfunction in sepsis can be attributed to humoral components in septic serum above or below 50 kDa in size.

METHODS. Serum taken from septic rats with faecal peritonitis (and sham controls) at 24 h were size fractionated at a 50kDa cut-off. Adequate separation was confirmed by measuring albumin (64 kDa). Septic concentrate was mixed with sham filtrate to create a chimeric serum, and *vice versa*, with sham concentrate and septic filtrate. Live naïve kidney slices (200 μm thick) were then exposed to either type of chimeric serum and imaged with multi-photon confocal microscopy using fluorescent dyes to detect dynamic changes in MMP (measured with tetramethylrhodamine methyl ester, TMRM), ROS (dihydroethidium, HEt) and NADH redox state (NADH autofluorescence) over 90-minutes. Experimental results were expressed as the mean (n=4, ±SD) percentage relative fluorescence intensity (RFI) at 90-minutes compared to the baseline RFI at time zero.

RESULTS. Whilst both serum chimeras induced changes consistent with those seen with whole septic serum (Fig 1), the chimera containing the concentrated septic fraction (components ≥50 kDa) induced a greater rise in reactive oxygen species generation (136% vs 116%, p=0.07) and larger falls in MMP (66% vs 86%, p< 0.05) and NADH fluorescence (85% vs 96%, p=0.09), when compared to the chimera containing the filtrated septic serum fraction (Fig 1). [Figure notation: *=p< 0.05 vs sham serum, †=p< 0.05 vs septic serum, ‡=p< 0.05 vs septic concentrate + sham filtrate].

CONCLUSIONS. This preliminary study suggests the most influential component(s) circulating in septic serum that induce tubular epithelial cell mitochondrial dysfunction are above 50 kDa in size. Whether these circulating humours are large molecules or protein-bound smaller molecules is the subject of ongoing study.

Fig 1 (abstract 0635). Relative fluorescence intensity of dyes probing mitochondrial function

proteins, and modify extracellular matrix and plasma proteins. Recently, it was hypothesized that increased dicarbonyl stress contributes to multi-organ failure in critical illness (1). In addition to hyperglycemia, hypoxia and inflammation have been shown to increase dicarbonyl stress in vitro. In vivo data are however lacking.

OBJECTIVES. To investigate the hypothesis whether hypoxia, systemic inflammation or both conditions combined induce dicarbonyl stress in humans in vivo, we infused 2.5% glucose solution as a substrate during experimental human endotoxemia.

METHODS. In 30 healthy men, mean age 21±2 years, 1,5 L 2.5% glucose solution was infused in the hour preceding administration of endotoxin (2 ng/kg lipopolysaccharide [LPS]) or saline, followed by infusion of 1.2 L 2,5% glucose during the next 8 hours. We exposed 10 men to hypoxia (arterial saturation 80-85%, using a noninvasive ventilation helmet) for 3.5 hours, starting one hour before saline administration (HYP group). We exposed 10 men to experimental endotoxemia (LPS group) and 10 men to both conditions combined, with hypoxia starting one hour before LPS administration (LPS-HYP group). We measured plasma levels of 3DG repeatedly, using ultra-performance liquid chromatography tandem mass spectrometry. Repeated data were analyzed with generalized estimating equations. We report longitudinal β(95%CI) for the HYP and LPS groups, with the LPS-HYP group as reference. The study protocol complies with the guiding principles for experimental procedures as set forth in de Declaration of Helsinki.

RESULTS. Between 0-90 minutes 3DG increased by 3806±1055 nmol/L (p< 0.001) without a statistically significant difference between experimental conditions (p-values>0.427), and this increase thus occurred before LPS or saline administration.

Throughout the whole experiment, the 3DG concentration was higher in the combined LPS-HYP group, with a lower overall concentration β(95%CI) of -181 nmol/L (-313; -48), p=0.007 for the LPS group and a lower overall concentration of -282 nmol/L (-444; -119), p=0.001 for the HYP group (Figure I).

CONCLUSIONS. Our data reveal that glucose infusion increases dicarbonyl stress. Furthermore, systemic inflammation and hypoxia combined increase dicarbonyl stress in humans. Therefore, dicarbonyl stress, as a possible multi-organ failure contributing mechanism, requires further study in critical illness as it has potential for intervention.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0637

INTRODUCTION. Hippo signaling could regulate the behavior and fate of a variety of cell types; however, its role in regulation of resistence of mesenchymal stem cells (MSCs) to oxidative stress-induced injuries remains to be clarified.

OBJECTIVES. Our aim was to determine the regulatory roles of Hippo signaling pathway in the development of resistance to oxidative stress-induced injuries in mouse bone marrow-derived mesenchymal stem cells (mMSCs).

METHODS. Primary mMSCs, isolated from C57BL/6 mice using the direct adherence method were identified by flow cytometry assay,

INTRODUCTION. Dicarbonyl stress is the accumulation of dicarbonyl metabolites, such as 3-deoxyglucosone (3DG), which damage intracellular

and osteogenic, chondrogenic, and adipogenic differentiation were induced. The primary mMSCs were differentiated into the alveolar epithelial type II (ATII) cells using different co-culturing techniques. Hippo signaling pathway was modulated using 2-deoxy-D-glucose (2-DG) and anti-Fc epsilon RI antibody (9E1), while the oxidative stress-induced injuries were induced by H_2O_2 treatment at different concentrations. The effects this treatment on the survival of mMSCs and Hippo pathway activity were assessed using the MTT and western blot assays.

RESULTS. We detected the expression of apoptosis-related proteins, Bax and Bcl-2 using immunoblotting. Hippo signaling pathway activation was induced by 2-DG in a concentration-dependent manner, which was shown to be inhibited by 9E1 treatment. H_2O_2 treatment was demonstrated to induce mMSC injuries and inhibit the activity of Hippo signaling pathway. The decrease in Bcl-2/Bax ratio may be the mechanism underlying the observed mMSC injuries. The activation of Hippo signaling pathway may induce the resistance of mMSCs to oxidative stress through the increase in the Bcl-2/Bax level ratio, whereas the inhibition of Hippo signaling pathway prevents the resistance of mMSCs to oxidative stress by decreasing this ratio.

CONCLUSIONS. In summary, Hippo signaling pathway may affect the survival of mMSCs and the resistance to oxidative stress-induced injuries by regulating the Bcl-2/Bax expression ratio.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0638

INTRODUCTION. Idiopathic pulmonary fibrosis is a prototype of chronic, progressive, and fibrotic lung disease which leads to decreased lung compliance, disrupted gas exchange, and ultimately respiatory failure[1]. Progression of lung fibrotic formation is associated with the accumulation of fibroblasts and the promotion of fibroblast to myofibroblast differentiation (FMD)[2]. TGF-β1 is one of the factors that are responsible for fibrosis as it promotes FMD and is associated with up-regulation of a-smooth muscle actin. Therefore, inhibition of FMD may represent an effective strategy for the treatment of IPF. Recently, functional circRNAs have been shown to participate in the regulatory networks governing gene expression at transcriptional and post-transcriptional level[3]. The most recent research revealed that fibroblast contains abundant circular RNA (circRNA), circHIPK3, whose role in fibroblast remains unclear. In our study, we investigated the role of circHIPK3 in TGF-β1-induced FMD.

OBJECTIVES. To elucidate whether circHIPK3 is involved in TGF-β1-induced FMD.

METHODS. Quantitative real time polymerase chain reaction, Sanger sequencing and RNA fluorescent in situ hybridization were conducted to detect the expression pattern of circHIPK3 in TGF-β1-treated lung fibroblasts and lungs from bleomycin-treated mice. Immunofluorescence, Western boltting and RNA interference were used to detect the role of circHIPK3 in TGF-β1-induced FMD in vitro.

RESULTS. In vivo study, circHIPK3 expression in pulmonary fibrosis mouse was significantly higher than control mice. In vitro FMD assay, elevated expression of circHIPK3 in TGF-β1-treated WI-38 was detected. circHIPK3 was resistant to RNase R digestion, whereas linear

HIPK3 mRNA was easily degraded. The sanger sequencing result was completely in accordance with circHIPK3 sequence as shown in circBase. circHIPK3 was mainly expressed in the cytoplasm of WI-38. We next investigated the role of circHIPK3 in WI-38. Silencing circHIPK3 significantly inhibited TGF-β1-induced expression of α-SMA and collagenI.

CONCLUSIONS. Our study highlights the involment of circHIPK3 in TGF-β1-induced FMD. Altough the precise mechanism needs further study, this study facilitates the development of circRNA-directed diagnostics and therapeutics against pulmonary fibrosis.

INTRODUCTION. Pulmonary artery (PA) dysfunction worsen outcomes in acute respiratory distress syndrome (ARDS). Magnetic resonance (MR) is a useful tool for the evaluation of complex flow patterns resulting from alterations in the vascular function which has improve the understanding and diagnosis of several cardiovascular diseases.

OBJECTIVES. To evaluate complex pulmonary flow patterns (vorticity) resulting from pulmonary vascular dysfunction caused by ARDS in a porcine model.

METHODS. 8 pigs (35.9±6.7 kg) were subjected to lung saline lavages followed by 1.5 hours of injurious mechanical ventilation to create a model of ARDS. Before and 30 minutes after injury phase contrast MR acquisition of the main PA was obtained to perform analysis of PA flow in 4 dimensions (4d, 3 spatial dimensions plus time dimension). A custom plugin for EnSight (Ansys, Canonsburg, USA) was developed to semi-automatically track PA flow and segment PA accordingly. Vortex phenomena were evaluated in a representative cardiac flow cycle (reconstruction of around 17 consecutive time frames covering the entire cardiac cycle) of each situation. Vortex was defined as the presence of helical pattern (figure 1b) in at least 2 consecutive frames. This evaluation is relevant as the presence of vortexes has been associated with an increased resistance and vascular dysfunction in several vascular diseases. From a physiological point of view, this is also important as energy could be wasted in non-forward flow streamlines (see figure 1a and 1b) Conventional pulmonary hemodynamics was also evaluated combing a PA catheter with cardiac MR cine analysis.

RESULTS. Vortexes were detected in 25% of pigs in baseline and 100% of the cases after ARDS (p=0.041). A representative image of evaluated flow patterns in baseline and after ARDS is shown in figure 1a and 1b respectively. Average duration of vortexes was 4.0±1.4 and 4.1±1.0 frames (around 24% of the entire cardiac cycle) and started at frame 4±1 and 3±1 after the maximum flow intensity frame in baseline and after ARDS, respectively. After ARDS pigs showed a higher mean PA pressure (35±6 vs 21±2 mmHg, p< 0.001) a lower compliance (2.16±0.98 vs 2.92 ±0.63 ml/mmHg, p=0.047) and a non-significant trend to higher resistance (712±379 vs 467±103 dyn.s.cm^{-5}, p=0.117) compared to baseline.

CONCLUSIONS. Vorticity was observed in 100% of cases after ARDS appearing as a complementary marker of pulmonary vascular dysfunction. Evaluation of these complex flow patterns are key to improve our understanding of the deleterious effects of ARDS on pulmonary circulation.

Fig. 1 (abstract 0639). 4d flow images before (1a) and after (1b) ARDS. A clear helical pattern (vortex) is seen after ARDS (red square). Frames in figures 1a and 1b represent a similar moment relative to the frame of maximum flow intensity.

INTRODUCTION. Recent insights have emerged regarding the impact of hypercapnia on cellular and molecular function. Hypercapnia may have potentially beneficial effects in patients with ARDS, which are independent of the benefits from ventilation with low tidal volumes[1,2]. However, other studies suggest that CO_2 can act as a signaling molecule via pH independent mechanisms resulting in deleterious effects in the lung[3].

OBJECTIVES. Determine the effects and mechanism of action of different CO_2 and pH levels in human primary alveolar type II cells (hATII).

METHODS. After signing a patient informed consent, hATII were isolated from lung biopsies of patients who underwent lobectomy, and were incubated at 37ºC with 5% CO_2 concentration (normocapnia) or 15% CO_2 concentration [pCO_2=80 mmHg]. The media in both groups was buffered with 15mM THAM to maintain pH at 7.4. Analysis of pro-inflammatory (IL6, IL1β) and anti-inflammatory markers (IL10, IL4), as well as apoptosis (caspase 3, 8 and 9) and permeability markers (CCL2) were done by qRT-PCR. Results were analyzed by one way ANOVA using the Turkey´s range test.

RESULTS. hATII at 15% CO_2 produced an increased IL6 and IL1β. IL1β peak was reversed with THAM. Hypercapnia was associated with a decrease in CCL2 levels (monocyte recruitment) and an increase in apoptosis independent of pH (caspase 3, 8 and 9). See figure 1.

CONCLUSIONS. Human alveolar cells exposed to hypercapnia produced an inflammatory response, with a decrease in monocyte recruitment and a significant increase in apoptosis, all of them independent of pH. Considering the biological effects of hypercapnia, there is a need for more evidence from well-powered RCTs in order to determine its global effects in the lung.

INTRODUCTION. The growing interest in the clinical application of human adult stem cells derived from adipose tissue (human adult adipose-derived mesenchymal stem cells, ADMSC) is based on its anti-inflammatory properties. The antioxidant effect of ADMSC has not been well documented in acute lung injury models.

OBJECTIVE. To demonstrate that ADMSCs have an antioxidative effect on lung epithelial cells subjected to cyclic stretching in vitro.

METHODS. Experimental study in the University Hospital of Getafe.Isolation of ADMSCs and human fibroblasts: Adipose tissue samples (obtained with the informed consent of patients undergoing scheduled mammary reduction surgery) will be processed to obtain, isolate and culture ADMSCs. Samples of donor dermal tissue will be obtained, with informed consent, for the isolation and culture of human dermal fibroblasts, in a standard culture condition.

Cell injury model: human Pulmonary alveolar epithelial cells (HPAEpiC) will undergo cyclic stretching, with an elongation of 15% during 24 hours (representing 50% of the total lung capacity) under standard culture conditions. The ADMSC will be added in co-culture on a 0.4 micron membrane of "transwell". The ratio will be 1: 3 (1 ADMSC / 3 HPAEpiC). As a negative control group, human fibroblasts (FBF), will be used. Six groups will be perfomed; HPAEpiC without stretching (0%); HPAEpiC alone subjected to stretching 15%; HPAEpiC without stretching (0%) with ADMSC; and HPAEpiC subjected to

stretching 15% with ADMSC, HPAEpiC without stretching (0%) with FBF; and finally HPAEpiC subjected to stretching 15% with FBF.
Measurements: At the end of the experiments, the total activity of superoxide dismutase (SOD), glutathione peroxidase (GsH) and 8-isoprostane (8-iso), catalase activity, and inducible NOS (iNOS) were measured by ELISA in the cell lysate and the supernatant, respectively. Finally, the activation of the intracellular transcription factor Nfr-2 will be measured by ELISA in the cell lysate.
Statistical analysis. The statistically significant differences will be tested by ANOVA analysis.
RESULTS. Oxidative damage was observed in HPAEpiC subjected to mechanical stretch during 24 hours and characterized by a non-significant decrease in SOD, and catalase (all p=0.234) that was not attenuated in conditions in vitro conditions of co-culture with ADMSC or FBF.
CONCLUSIONS. ADMSC showed no effect on oxidative stress when used as cell therapy in a co-culture of in vitro model of human lung alveolar cells injury induced by cyclic stretch.

INTRODUCTION. High respiratory drive associated to moderate to severe ALI in subjects on spontaneous ventilation can be deleterious due to several mechanisms, like uncontrolled transpulmonary pressures, active expiration phenomenon, and excessive regional strain and tidal recruitment in dependent lung regions.
OBJECTIVES. Our aim was to find the temporal behavior and spatial patterns of regional lung strain by 4D μ-CT and image registration techniques in extubated subjects after experimental lung injury with spontaneous ventilation.
METHODS. 12 anesthetized Sprague-Dawley 300 gr rats were randomly allocated to sham group (n = 6) or acute lung injury group (ALI group, n = 6). Lung injury was induced by surfactant depletion. The animals were placed in prone position, extubated and supported with 100% FIO$_2$. The animals remained under inhalatory anesthesia while m-CT scanning was performed at 0h and 3h of spontaneous ventilation (SkyScan 1278 in-vivo micro-CT scanner, Bruker®, Belgium). A map of regional volumetric strain was constructed from expiration to inspiration phase using a finite-element approach. Functional residual capacity (FRC), VT and global strain were determined from lung segmentation volumes by comparing the end-expiration and end-inspiration volumes in each case.
RESULTS. Animals in ALI group were more hypoxemic and tachypneic at 0 and 3h respect to sham group. Lung CT at 0 and 3h showed more collapsed lung in ALI group compared to Sham (Figure 1). A higher regional strain was observed in injured animals (ALI group) compared to sham at 0h. After 3h of spontaneous breathing regional strain augmented in ALI group and decreased in sham group, increasing the difference between groups (Figure 2 and 3).

CONCLUSIONS. Temporal evolution of global and regional strain in extubated subjects with spontaneous ventilation shows a sustained intensification. Opposite effect was observed in sham group, decreasing measured strain after intervention. Future studies should clarify the role of regional deformation as a mechanism producing pathological mechanotransduction and inflammation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0643

INTRODUCTION. Hyperoxia can cause injury to normal lung tissue. However, patients with acute respiratory distress syndrome frequently be exposed to very high FiO_2 ($FiO_2 \geq 0.9$).

OBJECTIVES. The purpose of this study is to evaluate the effect of hyperoxia exposure in acute lung injury state.

METHODS. Lipopolysaccharide (LPS, 055:B5, 2 mg/kg) or PBS was administered intratracheally in male C57BL/6J mice (7-8 weeks old). After 2h, mice were divided into two groups, and then exposed to normoxia or hyperoxia condition for 48h. Hyperoxia groups were placed within their cages in a Plexiglass chamber, in which an atmosphere of 95% O_2 was constantly monitored using an oxygen analyzer.

RESULTS. From BAL fluid, numbers of total cells and neutrophils significantly increased in LPS + normoxia and LPS + hyperoxia group compared with the control normoxia group ([**]$p < 0.01$). Lung wet/dry ratio was also significantly increased in LPS + normoxia and LPS + hyperoxia group compared with the control normoxia group ([**]$p < 0.01$). However, there were no significant differences in numbers of total cells, neutrophils and lung wet/dry ratio between LPS + normoxia and LPS + hyperoxia group. By histological evaluation of H&E stained lung

tissue sections, edema, interstitial thickening, and inflammatory cell influx showed no significant difference between LPS + normoxia and LPS + hyperoxia group.

CONCLUSION. In LPS induced acute lung injury mouse model, no significant differences were seen in lung inflammation and lung injury between LPS + normoxia and LPS + hyperoxia group. From our results, hyperoxia did not augment LPS-induced lung injury in mice.

INTRODUCTION. Hypoventilation, increased dead space ventilation and venous admixture are important reasons for hypoxemia in critically ill patients leading to mismatch of the ventilation (V) and perfusion (Q) ratio (V/Q). The multiple inert gas elimination technique (MIGET) is the current gold standard for measuring V/Q[1]. Due to high technical and personnel efforts, MIGET cannot be routinely employed in clinical practice. Changes in ventilation and perfusion modulate heat transfer in the lung[2,3,4]. Therefore, measuring respiratory enthalpy (RE) may be an alternative technique to investigate V/Q. RE can be measured using the novel VQm[TM] monitor (Rostrum Medical Innovations, Vancouver, CA), which is connected to the breathing circuit. This bedside monitoring of V/Q may allow evaluation of the effect associated with specific therapy and support personalized ventilator care.

OBJECTIVES. We tested whether shifts of V/Q can be monitored by measuring RE using the VQm[TM] monitor in a porcine model.

METHODS. We designed four pathophysiologic interventions (I) to manipulate V/Q in 11 anesthetized pigs (51-83kg): IA: shunt, achieved by single-lung-ventilation due to blocking of the left lung (low V/Q); IB: high cardiac output, achieved by infusion of dobutamine (low V/Q); IC: dead space, achieved by wedging of the left or right pulmonary artery using an inflatable intravascular balloon (high V/Q) and ID: ARDS simulation, achieved by repetitive lung-lavage until PaO2 < 80mmHg at FiO2 1.0 (low V/Q). Effects on V/Q were validated by micropore membrane inlet mass spectrometry MIGET.

RESULTS. Baseline RE was very variable among different animals (114 ± 63 Joules/min, mean ± SD). Therefore, RE results were normalized to the individual baseline measurement. MIGET data, conventional calculations of dead space and shunt, and the PaO2/FiO2-ratio demonstrated that our interventions lead to the expected manipulation of V/Q (*Fig. 1* and *Fig. 2*). In contrast, RE measured by the VQm™ monitor did not change significantly. Results are summarized in *Table 1*.

CONCLUSIONS. In the present experimental model, we did not find significant changes in RE measured by the VQm™ monitor.

INTRODUCTION. Acute respiratory distress syndrome (ARDS) is characterized by decreased lung compliance, but with normal resistance. However, respiratory system resistance is mainly determined by the large airways and there is scarce information regarding the resistance or reactivity of the small airways.
OBJECTIVES. To evaluate ex vivo the reactivity of the small airways, by means of a precision-cut lung slices (PCLS) technique, in lungs obtained from rats previously subjected to a model of acute lung injury (ALI) secondary to hydrochloric acid (HCl) instillation.

METHODS. Under deep anesthesia, 12 male sprague dawley rats (300-350 grams) were tracheostomized and then instilled intratracheally with HCl (2 ml/Kg, 0,1 N and pH 1.5) (ALI group), or NaCl 0.9% (2 ml/kg) (control group); (n= 6 each). Thereafter, rats were connected to mechanical ventilation (vt=7 ml/kg, respiratory rate 95 bpm, I:E of 1:2, y FiO_2 1.0) and maintained with deep anesthesia, neuromuscular blockade and invasive blood pressure monitoring. After 4 hours rats were euthanized and the lungs extracted by thoracotomy. The left lung was insufflated with 2% agarose and 150 μm thick lung slices were cut and cultured (37℃ y CO_2 5%) for 12 hours. Then, by means of phase contrast video microscopy, the bronchoconstrictor response to carbachol (CCh) (0.001 to 100 μM) and histamine (0.001 to 100 μM) was assessed in bronchioles of 100 to 200μm diameter.

RESULTS. Rats from the ALI group exhibited hypoxemia until the end of the experimental period (PaO_2/FiO_2 118 vs 306 of the control group) (p=0.004) and lung edema (wet/dry weight ratio 7.15 vs 5.84 of the control group) (p= 0.002). The bronchoconstrictor response was significantly higher in the ALI group, both for carbachol and histamine (Figures 1-3). Differences with the control group were evident at high concentrations.

CONCLUSIONS. In an ALI model secondary to HCL instillation we observed small airway hyperresponsiveness. This is the first description of small airway reactivity in ALI. This finding may have implications for ALI pathophysiology, but more studies are required in different experimental models of ALI, and in ARDS patients, to determine its clinical relevance.

The washout of CO_2 from anatomical dead space is the same with Hi-VNI and Optiflow

Y. Onodera[1], N. Nakamura[1], R. Akimoto[1], H. Suzuki[1], M. Nakane[2], K. Kawamae[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0646

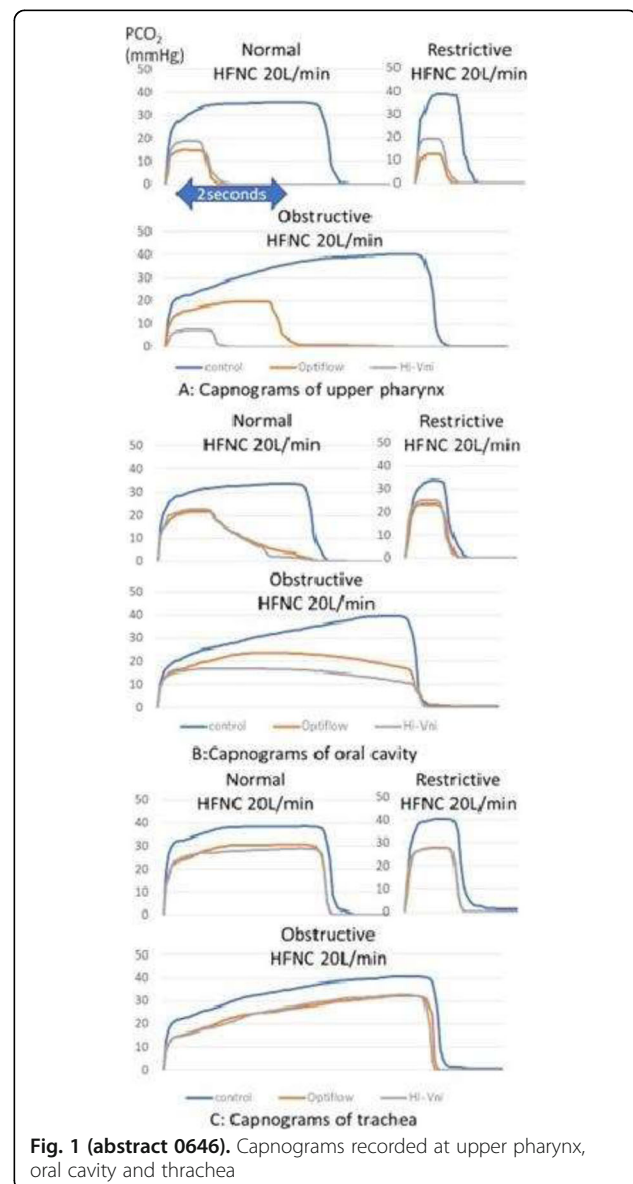
INTRODUCTION. Several high-flow nasal cannula (HFNC) interfaces are now commercially available. The Hi-VNI® (Vapotherm, New Hampshire, USA) is a new interface that delivers higher gas flow velocity than other interfaces due to a narrower tip outlet. This difference in flow velocity between interfaces might influence CO_2 washout, but this has only been evaluated in a computational model that did not simulate breathing. Therefore, we compared Hi-VNI and Optiflow™ (Fisher and Paykel Healthcare, Auckland, NZ) using a sophisticated respiratory model to determine if interface affects CO_2 washout form anatomical dead space.

OBJECTIVE. To compare CO_2 washout form anatomical dead space of two different HFNC interfaces.

METHODS. An airway model was created by a 3D printer using craniocervical 3D-CT data from a healthy, 32-year-old male with a height of 170 cm and ideal body weight of 65 kg. Sampling ports were placed to measure capnograms of the upper pharynx, oral cavity, and trachea. Anatomical dead space was adjusted to 3 ml/kg, and CO_2 was infused into the model (LUNGOO: Air Water Safety Service Inc., Kobe, Japan). The model parameters were adjusted to simulate normal respiration (compliance [C], 50 ml/cmH$_2$O; resistance [R], 5 cmH$_2$O/L/s; VT, 520 ml (8 ml/kg); Ti, 1.0 sec; RR, 15/min), and restrictive (C, 30 ml/cmH$_2$O; R, 5 cmH$_2$O/L/s; VT, 320 ml (5 ml/kg); Ti, 1.0 sec; RR, 30/min) or obstructive (C, 80 ml/cmH$_2$O; R, 15 cmH$_2$O/L/s; VT, 700 ml (11 ml/kg); Ti,1.0 sec; RR, 10/min) respiration with a $P_{ET}CO_2$ of 40 mmHg in the trachea. Either the Optiflow or Hi-VNI was attached to the airway model for 3 minutes, and flow was increased in steps of 10 L/min from 10 to 50 L/min. Capnograms were recorded from breaths after each phase.

RESULTS. Capnograms of the upper pharynx showed that CO_2 was fully washed out by both interfaces before the start of the next inspiration, with HFNC flow of 20 L/min in all three respiratory states (Figure A). Capnograms of the oral cavity showed that CO_2 was washed out by both interfaces, but PCO$_2$

before the start of the next inspiration was slightly lower with Hi-VNI than Optiflow in obstructive respiration (Figure B). Tracheal capnograms showed the same waveform with both interfaces in each respiratory state; thus, neither interface washed CO_2 out of the trachea (Figure C). To compare the efficiency of CO_2 washout between interfaces, $P_{ET}CO_2$ was recorded in the trachea (Figure D). Both Hi-VNI and Optiflow showed the same trends in each respiratory state; thus, both interfaces washed out about the same amount of CO_2 from the anatomical dead space.

The slight difference in capnograms recorded at the oral cavity with obstructive respiration may have been caused by a higher flow velocity generated by Hi-VNI, but the difference was not sufficient to improve CO_2 washout form anatomical dead space.


**CONCLUSIONS.** The CO_2 washout was the same with Hi-VNI and Optiflow.

RESULTS. LPS plus injurious ventilation resulted in pulmonary inflammation and coagulopathy.

RecAP did not affect pulmonary inflammation or coagulation. (Figure 1)

CONCLUSIONS. RecAP does not affect pulmonary inflammation or coagulation in the acute phase of this established two-hit lung injury model in rats. Further investigations are needed to expand on the knowledge about the effects of alkaline phosphatase within the pulmonary compartment.

INTRODUCTION. Sepsis-induced acute respiratory distress syndrome (ARDS) shares common pathophysiological features with sepsis-induced acute kidney injury (AKI), such as an uncontrolled inflammatory response and coagulopathy. Alkaline phosphatase (recAP) improved renal function in sepsis patients with AKI (1), decreased inflammatory markers and improved outcome in preclinical studies (2-4).

OBJECTIVES. To assess potential beneficial effects of recAP on inflammation and coagulation in the acute phase of lung injury.

METHODS. Lung injury was induced in male Wistar rats by intravenous administration of LPS (10 mg/kg) and subsequent injurious ventilation with high tidal volumes (12-15 ml/kg) for 4 hours. At start of ventilation animals received recAP (1500 IU/kg) or saline (N = 8 animals per group); control animals received neither LPS, nor ventilation or treatment (N = 4). Endpoints were markers of inflammation (e.g. CINC-3: Cytokine-Induced Neutrophil Chemoattractant-3) and coagulation

Transpulmonary thermodilution during ECMO: detection of a potential loss of indicator by a second, extra-corporeal thermodilution catheter within the ECMO-circuit: the HEUREKA-IV animal study

W. Huber, M. Konrad, S. Kammerzell, R. Schmid, A. Herner
Klinikum rechts der Isar; Technical University of Munich, Medizinische Klinik und Poliklinik II, Munich, Germany
Correspondence: W. Huber
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0648

INTRODUCTION. Feasibility of pulmonary arterial (PAC) and transpulmonary thermodilution (TPTD) during ECMO is questionned due to a potential direct loss of indicator (DLOI) into the extracorporeal circuit.

OBJECTIVES. To detect DLOI with a second thermodilution catheter introduced into the ECMO circuit at the connection of drainage cannula and ECMO circuit.

METHODS. 8 pigs (49.4±4.2kg) with a PAC and a CVC (both via jugular vein) and two PiCCO catheters (Pulsion, Germany) introduced into the femoral artery and into the ECMO-circuit. Veno-venous ECMO (CARDIOHELP; Maquet/Getinge; Rastatt, Germany) via a femoral drainage and a jugular return cannula.

Indicator injection into the jugular CVC and into femoral catheters during different (0-3.5L/min) ECMO-flows.

Due to the explorative type of analysis in a limited number of animals and in part different experimental settings, each of the authors independently performed a response to a structured protocol regarding the main endpoints (see results 1-8). The statements were only included in the results section in case of complete (4/4) agreement of the four investigators WH, MK, SK and AH.

RESULTS. All four investigators (4/4) agreed on the following findings:

1.) Irrespective of indicator injection there were minor periodic variations of the temperature curve (PVTC) detected by the thermistor in the extracorporeal circuit.

2.) The frequency of PVTC agreed with the ventilator respiratory rate.

3.) PVTC could be abolished by inspiratory or expiratory ventilator hold.

4.) Indicator injection resulted in an extra-corporeally detectable signal in the 2nd PiCCO in a substantial number of measurements.

5.) This "indicator induced extracorporeal signal" (IIES) resulted in different types of processing of the signal:

a.) An early peak of change in temperature was strongly associated with indicator injection close to the drainage cannula and/or high ECMO flow. This peak reflects DLOI and occurs within 10s after injection.

b.) A second, markedly later peak occurred after the peak of the femoral arterial TPTD-curve. This is in line with recirculation of the signal into the ECMO not associated with DLOI.

6.) Both signals were in part sufficient to initiate the processing of the dilution curve by the 2nd PiCCO.

7.) The early signal induced by DLOI in part resulted in flow values ("CI"_ECMO) within the range of the simultaneous CI derived from the TPTD-curve in the femoral artery. In these cases similar amounts of indicator might have been withdrawn into ECMO and stayed within systemic circulation.

8.) DLOI could be detected with maximum sensitivity (1ml of injectate), if the indicator was injected close to the drainage canula.

CONCLUSIONS.

1.) The loss of indicator into the ECMO-circuit can be detected with high sensitivity by a 2nd TPTD-catheter in the ECMO-circuit.

2.) Detection of DLOI could be used as a "red flag" for the use of thermodilution techniques with indicator injection into the right atrium (PAC, TPTD).

Modulation of Hippo signaling promotes mesenchymal stem cells to optimize lung injury repair in murine lipopolysaccharide induced ARDS

L. Dong, L. Li
Wuxi People's Hospital affiliated to Nanjing Medical University, Intensive Care Unit, Wuxi, China
Correspondence: L. Dong
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0649

INTRODUCTION. Mesenchymal stem cells (MSCs)-mediated repair of injured alveolar epithelial cells hold promise of cure for acute respiratory distress syndrome (ARDS), however, their repairing effect is limited by poor homing and differentiation.

OBJECTIVES. To determine the effects of modulation of Hippo signaling on lung repair of marrow mesenchymal stem cells (mMSCs) in murine lipopolysaccharide (LPS) induced ARDS.

METHODS. Mouse MSCs transfected with LATS1 shRNA or green fluorescent protein control were transplanted intratracheally into the ARDS mice induced by LPS. Lung tissue injury and repair assessment were examined using haematoxylin and eosin staining, lung injury scoring, Masson's trichrome staining and fibrosis scoring. Homing and differentiation of mouse MSCs were assayed by labelling and tracing MSCs using NIR815 dye, immunofluorescent staining, and Western immunoblot analysis. The inflammation and permeability were evaluated by detecting the cytokine and protein measurements in bronchoalveolar lavage fluid using enzyme-linked immunosorbent assay.

RESULTS. LATS1-underexpressing MSC engraftment led to more significant effects than the GFP controls, including the retention of the MSCs in the lung, differentiation into type II alveolar epithelial cells, improvement in pulmonary inflammation and alveolar epithelial permeability, and the pathologic impairment of the lung tissue.

CONCLUSIONS. Inhibition of Hippo signaling pathway through underexpression of LATS1 could improve the therapeutic effects of mMSCs in murine LPS induced ARDS.

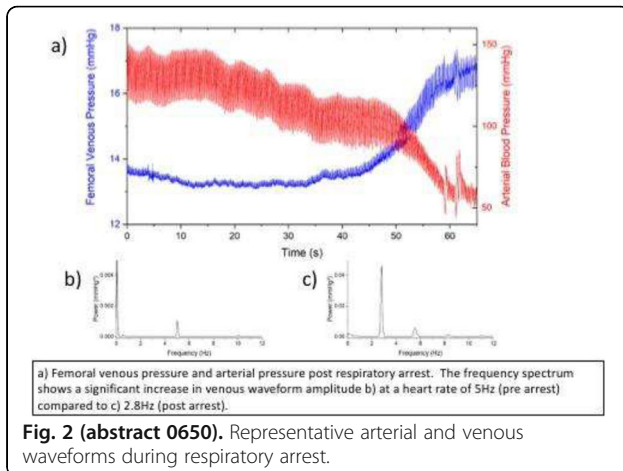
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0650

INTRODUCTION. Continuous measurement of right ventricular (RV) function in the setting of pulmonary disease is challenging in hospitalized patients. Central venous pressure (CVP) continues to be used to assess RV function despite pitfalls of static measurement. Intravenous analysis (IVA) has been shown to be more sensitive than CVP in human and porcine models for detecting hemorrhage and volume overload (1,2). We hypothesize that IVA will be more sensitive than CVP for detecting RV failure during respiratory arrest in a rat model.

OBJECTIVES.

1. Determine the utility of IVA to detect RV failure;

2. Compare the change in IVA to CVP during respiratory arrest


METHODS. Four Wistar rats were studied under an Institutional Animal Care and Use Committee approved protocol at Vanderbilt University. Rats were intubated with a 14g angiocatheter and mechanically ventilated. IV Pentobarbital was used for maintenance of anesthesia. Venous access was established via surgical cut-down using a 22g 1" angiocatheter (Smiths Medical, OH, USA) in the following locations: right internal jugular vein, femoral vein, and femoral artery. A TruWave pressure transducer (Edwards Lifesciences, CA, USA) was connected directly each catheter. CVP, mean arterial pressure (MAP), and femoral venous waveforms were recorded using LabChart (AD Instruments, Australia). Respiratory arrest was achieved with IV Rocuronium discontinuation of ventilation. Femoral venous waveform was analyzed using fast Fourier transformation (FFT). Right ventricular diameter was calculated from an apical 4-chamber view on transthoracic echocardiography. All measurements were obtained within the first 4 minutes of arrest. A T-test was performed to test for significant changes for IVA, CVP, RV diameter, and MAP.

RESULTS. Four Wistar rats were successfully cannulated and underwent respiratory arrest for 4 minutes. All rats had acute RV dilation and failure and developed severe tricuspid regurgitation (Figure 1). There was significant (P< 0.05) increase in IVA 42±21 mmHg^2 and RV diameter of 63%±17%, and a significant decrease in MAP 72±21 mmHg. There was no significant change in CVP. Representative data for IVA and MAP are shown in Figure 2.

CONCLUSIONS. IVA is more sensitive than CVP for detecting acute RV failure during respiratory arrest. Further studies are warranted to determine sensitivity of IVA in other settings of acute RV failure, such as sepsis.

INTRODUCTION. Sleep disruptions frequently occur in hospitalized patients in particular critically ill, mechanically ventilated patients. Severely altered sleep architectures result in unclassifiable sleep stage according to the conventional Rechtschaffen and Kales criteria. A new classification for sleep scoring including atypical sleep (AS) and pathological wakefulness (PW) has been proposed. This study aims to assess the prevalence of AS and PW in patients with acute respiratory failure and whether there is relationship with clinical outcomes.

OBJECTIVES.

- To determine the prevalence of AS and PW in mechanically ventilated patients with acute respiratory failure.
- To identify clinical factors affecting poor sleep quality, AS and PW.
- To assess the relationship between AS and PW and clinical outcomes.

METHODS. In this prospective cohort study, polysomnography was performed in 38 patients receiving mechanical ventilation due to acute respiratory failure at Respiratory Care Unit (RCU) of Siriraj Hospital from February to December 2017. Sleep stage was analyzed by conventional rules and new classification for AS and PW. The association between presence of AS or PW and patient characteristics was analyzed. Correlations between delirium and weaning outcome with AS or PW were also determined.

RESULTS. According to new classification, 14 out of 38 (prevalence of 36.8%) mechanically ventilated patients had AS. The prevalence of PW was 36.8% and either AS or PW was 52.6%. Most of patients had poor sleep quality with median sleep efficiency [IQR] of 35.9% [18.5, 62.3]) and significantly decreased slow wave sleep (median [IQR] 0.4% [0.00, 5.70]) and REM (median [IQR] 1.3% [0.00, 6.43]). In multivariate analysis, higher respiratory rate was significantly associated with AS (odds ratio [OR] 1.24, 95% confidence interval [CI] 1.04 to 1.47, p = 0.014), while longer duration of mechanical ventilation and higher sleep efficiency were associated with the presence of PW (OR 1.36, 95%CI 1.03 to 1.81, p = 0.032 and OR 1.09, 95%CI 1.03 to 1.15, p = 0.004 respectively for sleep efficiency). Subsequent delirium occurred in 2 out of 37 (5.4%) patients and relationship with AS or PW was not established. Only PW was correlated with longer ventilator days after sleep study (p = 0.003).

CONCLUSIONS.
Other than reduced sleep quality, atypical sleep and pathological wakefulness were frequently found among critically ill, mechanically ventilated patients with acute respiratory failure and may be associated with longer duration of mechanical ventilation.

Customized spontaneous breathing trials determined by electrical impedance tomography improved successful weaning rate in prolong mechanical ventilated patients

Y.-L. Hsu[1], M.-Y. Chang[2], Z. Zhao[3]
[1]Far Eastern Memorial Hospital, Respiratory Care Center, Pulmonary Division, Internal Medicine, New Taipei City, Taiwan, Province of China; [2]Far Eastern Memorial Hospital, Devision of pulmonary medicine, Respiratory Therapy, New Taipei city, Taiwan, Province of China; [3]Institute of Technical Medicine, Furtwangen University, Jakob-Kienzle-Straße 17, D-78054, Villingen-Schwenningen, Germany
Correspondence: Y.-L. Hsu
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0652

INTRODUCTION.
Different spontaneous breathing trials (SBT) are used on prolonged mechanical ventilated patients to liberate them from ventilators. However, up to 40% of the patients who pass SBT may still fail to wean from mechanical ventilation.
OBJECTIVES.
EIT is able to monitor SBT during the weaning process. The results revealed that ventilation was redistributed towards dorsal regions during lower support levels.[1] Furthermore, regional ventilation distribution patterns and trends during inspiration were associated with weaning outcomes.[2] In the present study, we try to customize the SBT protocols determined by the EIT results. The outcomes including successful weaning rates and the total ventilation days were analyzed.
METHODS.
There were four patterns of ventilation distribution in the course of tidal inflation during ACMV and SBT with automatic tube compensation (ATC) 100 and 70 % found in previous study .[2] In this study, we enrolled 80 patients (each pattern 20 pts) during the pre-SBT stage. Patient characteristics, EIT-derived parameter values (center of ventilation (CoV), ratio of tidal ventilation (RTV), end-expiratory lung impedence (EELI)) for patients with different inspiratory ventilation distribution patterns, patient weaning parameters after the first SBT day with different inspiratory ventilation distribution patterns were recorded. SBT weaning protocols with ATC 100% (10 pts) and customized weaning protocol (CWP) according to EIT results (10 pts) were applied to each pattern patients. The outcomes of these patients including successful weaning rate, total mechanical ventilation days were analyzed.
RESULTS.
In pattern 1 patients, 100% of both groups were successful weaned. In pattern 2 patients, the successful weaning rate was 60% among ATC 100% group and 80% among CWP group and the total ventilation days was 1.5 days shorter among CWP group. In pattern 3 patients, none was successful weaned among ATC 100% group and only 30% was successful weaned among CWP group, the total ventilation days of successful weaned patients was much longer then the pattern 1 and 2 groups. In patterns 4 patients, the successful weaning rate was 60% and 70% among ATC 100% and CWP groups separately.
CONCLUSIONS.
The preliminary results show that customized SBT determined by EIT improved successful weaning rate in prolong mechanical ventilated patients with poor respiratory muscle strength and endurance.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0653

INTRODUCTION. Ventilator-associated pneumonia (VAP) is a common and severe ICU complication. Maintaining an endotracheal tube cuff pressure (P_{cuff}) > 20cmH$_2$O may prevent microaspiration of subglottic secretions, which is one of the main mechanisms accounting for VAP [1]. Mechanical and electronic devices have been developed to automatically control P_{cuff} during invasive mechanical ventilation.
OBJECTIVES. To compare the efficiency of an electronic device (Tracoe®) and a mechanical device (Nosten®) to prevent P_{cuff} underinflation in mechanically ventilated patients.
METHODS. We conducted a cross-over observational study in a 26-bed ICU. All patients intubated and ventilated more than 12 hours were eligible. Three periods of 2 hours were studied in a random order: 1) P_{cuff} controlled with Tracoe® (TRA); 2) P_{cuff} controlled with Nosten®(NOS); 3) without P_{cuff} control (CTR). P_{cuff} was continuously recorded using Physiotrace software[2]. P_{cuff} underinflation was defined as a P_{cuff} < 20 CmH$_2$O for more than five seconds during each period. The primary endpoint was the number of patients in whom P_{cuff} underinflation was detected. The secondary endpoints were the efficiency of each device to maintain P_{cuff} within the normal range, defined as a P_{cuff} between 20 cmH$_2$O and 30 cmH$_2$O; and the number of patients with P_{cuff} underinflation when ventilated with volume-controlled (VCV) or pressure support modes (PSV) for each device. Sample size was calculated to show a 30% of difference in P_{cuff} underinflation between the 2 devices with a power of 90% and a alpha risk of 5%.
RESULTS. Thirty-six patients were included, 21 ventilated with VCV and 15 with PSV. None of the patients showed P_{cuff} underinflation using NOS whereas respectively 17 patients (47%) and 23 patients (64%) had P_{cuff} underinflation using TRA and during CTR. The percentage of the time spent on P_{cuff} normal range was significantly longer with NOS than with TRA and CTR (table). For each device, the proportion of the patients with P_{cuff} underinflation was not different between the 2 ventilation modes.
CONCLUSIONS. Nosten is more efficient than Tracoe to prevent tube cuff pressure underinflation and maintain cuff pressure within the normal range.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0654

INTRODUCTION. Duration of invasive mechanical ventilation is a very important role in the postoperative of cardiac surgery, the ventilation time is associated with an increase in mortality, prolonged stay, and complications.Ventilator-free hours (VFHs) is a concept adapted from ventilator-free days (VFDs) used a measure of outcome in acute respiratory distress syndrome (ARDS).VFHs has defined arbitrarily as the number of hours from successful extubation of invasive mechanical ventilation and the patient remains alive at 60 hours after arriving at the intensive care unit (ICU).

OBJECTIVES. Compare the prognostic value for adverse outcomes of VFHs versus mechanical ventilation time after cardiac surgery.

METHODS. We conducted a retrospective observational study in patients admitted to our institution at Mexico City. Patients older than 18 years underwent cardiac surgery between January 1 and December 2017 were included. Patients were excluded from cardiac surgery of congenital and non-cardiac surgery.The median hours of ventilation in the ICU of our institution is 24 hours; the diagnostic capacity of ventilation time versus VFHs was analyzed using the ROC analysis, we obtained the largest area under the curve in VFHs taking 36 hours as the cut-off point (figure 1). Based on this, the population was divided into two groups: Group 1 (equal or less than 36 VFHs) and Group 2 (more than 36 VFHs).Continuous variables were expressed in median and interquartile ranges and categories variables as number and percentages. Continuous variables were analyzed using the Mann-Whitney U test and categories variables were evaluated using the Fisher exact test. We applied multivariate logistic regression analysis to evaluate variables that had statistical significance.

RESULTS. Of the 564 patients operated in 2017, 301 in group 1 and 263 in group 2 in the demographic variables we didn´t find significant differences.For EuroScore II and extracorporeal circulation time (CEC), we found significant differences with a higher percentage in group 1. In outcomes, we observed: higher in-hospital mortality, mortality in the ICU, cerebrovascular disease (CVD), delirium, acute renal injury and nosocomial pneumonia in group 1. For logistic regression analysis, we included those that showed the greatest association: in-hospital mortality with an OR of 9.9 (95% CI, 4.2-23.7) $p < 0.0005$, mortality in the ICU an OR of 11.9 (95% CI, 4.2-34) $p < 0.0005$, EVC OR 4.7 (95% CI, 1.1-7.4) $p = 0.05$, nosocomial pneumonia OR 2.8 (95% CI, 1.1-7.4) $p = 0.03$, and delirium OR 7.3 (95% CI, 1.6-32.8) $p = 0.009$.

CONCLUSIONS. By comparing the ventilation time versus VFHs, we show VFHs as a better predictor. Less free hours of mechanical ventilation is associated with worse results after cardiac surgery in adults

Accuracy of the functional residual capacity (FRC) of a lung simulator (TestChest®) using a modified nitrogen washout/washin technique by using an agreement analysis with an ICU ventilator

J. Berger-Estilita[1], M. Hänggi[2], D. Berger[2]

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0655

INTRODUCTION. Training on ventilation modes with simulation is crucial for patient safety in the ICU[1]. The TestChest® is a high fidelity lung simulator, capable of replicating pulmonary mechanics, lung volumes, gas exchange and hemodynamic responses of the healthy and pathological adult. Its manufacturer claims that the large volume of the apparatus ensures a realistic replication of vital capacity and FRC of a critically ill adult patient. There are so far no reference measurements available.

OBJECTIVES. The aim of this study is to validate the settings of the TestChest® Simulator and determine its accuracy.

METHODS. We used our TestChest® Simulator (ORGANIS GmbH, Switzerland), after proper calibration, with a Carescape R860 ICU Respirator (General Electrics®, Baden, Switzerland). Three functional residual capacities (1500 mL, 2000 mL, 2500 mL) were set on the TestChest® and measured with the Carescape Respirator by the N_2washin/washout open circuit method[2]. Measurements were taken at PEEP of 5, 8, 12 and 15 cmH_2O in order to create changes in FRC and at three different FiO_2(40%, 50%, 60%). Agreement between methods and trends were assessed with Bland Altman and four quadrant plots. Repeatability of methods was assessed with Cronbachs α.

RESULTS. We performed 135 measurements. The overall correlation (r^2=0,909) between FRC measured with nitrogen washin-washoutand and the FRC set in the TestChest® was excellent (Graph 1). The bias was -602 mL (red line) with upper and lower limits of agreement of -252 and -953 mL, respectively (green lines) (Graph 2), with random variability of measurements[HM1]. Repeatability was excellent (Cronbach's α0.99). Changes in FiO_2did not affect accuracy (Cronbach's α0.984). Changes in FRC by PEEP were accurately reflected by the TestChest.

CONCLUSION. The TestChest allows accurate settings of FRC with a constant, clinically relevant bias over wide ranges of end expiratory lung volumes. Changes of end expiratory volume by increasing PEEP levels were adequately simulated, when compared to a nitrogen washin-washout method.

INTRODUCTION. While mechanical ventilation has been shown to have detrimental effects on the diaphragm, a recent systematic review concluded that inspiratory muscle training (IMT) can improve patient outcome in selected intensive care patients. Diaphragm ultrasound could identify diaphragm dysfunction in real-time, thereby facilitating the identification of patients most likely to benefit from IMT.

OBJECTIVES. The aim of this study was to describe the change in the contractile activity of the diaphragm during the course of mechanical ventilation, until successful extubation.

METHODS. Prospective observational cohort study. Sonographic measurements of the diaphragm were taken daily until 24 hours after extubation. Diaphragm thickness was measured in the zone of apposition using a 5-12 MHz ultrasound transducer. Diaphragm thickness (Tdi), diaphragm thickening fraction (DTF) and daily rate of change in both Tdi and DTF related to the previous day were calculated.

RESULTS. 45 participants (27, 60% male) with a mean (SD) age of 45 (17) years were recruited. The mean (SD) APACHE score was 17.08 (9.57) and participants were ventilated for mean (SD) 105.65 (77.84) hours. The median (IQR) baseline Tdi was 1.47mm (1.17-1.86). The mean (SD) rate of change in Tdi related to the previous day was 3.92% (18.38). Three groups of participants emerged (n,%):

1) In (9, 20%) of participants there was a mean decrease of more than 10% in daily Tdi :

2) In (14, 31.1%) the mean Tdi increased by more than 10%, and

3) In (22, 48.9%) the change was negligible.

Participants in the decreased Tdi group presented with significantly (p< 0.01) higher baseline Tdi compared to the no change and increased Tdi groups. The median (IQR) DTF at baseline was 24.64% (17.95-33.58), the median (IQR) for the daily rate of change in DTF was 6.67% (-7.10- 22.26). Again, three groups of participants (n,%) emerged 1) In (10, 22.2%) the mean DTF decreased by more than 10%; 2) In (17, 37.8%) participants there was no change; and 3) In (18, 40%) there was an increase of more than 10% in DTF. The decreased DTF group showed a significant decrease in Tdi between the first and second day of mechanical ventilation (p< 0.01).

Participants in the decrease DTF group showed a significant decrease in Tdi between baseline and last measurement (p< 0.01); and significantly lower Tdi post-extubation as compared to their baseline Tdi (p=0.03). There were no significant between group differences for the first, last and post-extubation Tdi measurements (p>0.05). Participants in the six groups were similar with regard to age, gender, presence of comorbidities, smoking, sedation, ventilation modes or alcohol use (p>0.05).

CONCLUSIONS. While the contractile activity and the structure of the diaphragm changes during the course of mechanical ventilation, the pattern and rate of change is not the same in all participants. Work is now needed to understand the clinical relevance of the findings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0657

INTRODUCTION. Lung recruitability varies extremely in patients with acute respiratory distress syndrome (ARDS) and is strongly correlated with the response to positive end expiratory pressure (PEEP) [1]. Although traditional pressure-volume curve was considered as a rather standard method to assess the lung recruitment volume, mapping pressure-volume (P-V) curve still need disconnecting of patient from the ventilator to obtain PEEP induced volume change [2]. The electrical impedance tomography (EIT) could monitor change of lung volume at the bedside without disturbing the ventilation [3].

OBJECTIVES. We aimed to compare the lung recruitment volume measurement by the EIT with the traditional P-V curve method.

METHODS. Six anesthetized and ventilated pigs with normal lung and acute injured-lung (induced by hydrochloric acid) received decremental PEEP of 15, 10 5, and 0 cmH_2O. During each level of PEEP, multiply P-V curves were plotted using standard low-flow technique [3]. The lung recruitment between two adjacent levels of PEEP was measured at the fixed pressure of 20 cmH_2O (Fig.1). Pressure-impedance (P-I) curves derived from EIT were also plotted, and the difference of impedance was obtained between different PEEP levels at the same pressure of 20 cmH_2O. The recruitment volume was estimated as the difference of impedance multiplied by the ratio of tidal volume and corresponding tidal impedance change. The agreement of estimated (by EIT P-I curve) and measured (by traditional P-V curve method) global recruitment volume were analyzed. Regional P-I curves obtained by EIT were further used to estimate the regional lung recruitment [4].

RESULTS. The global lung recruitment volume assessed by EIT and traditional P-V curves showed close correlation ($R^2 = 0.68$, $p < 0.001$) and a mean bias of 5 ml with limits of agreement of −125 to 137 ml (Fig.2). In the normal lungs, no significant difference was found between the dependent and the nondependent lung recruitment (107 ± 37 vs 113±44 ml, $p = 0.069$). But for the injured-lung, the dependent lung recruitment volume was significantly lower than that in the nondependent region (70±31 vs 95±53 ml, $p < 0.001$), especially in low level of PEEP.

CONCLUSIONS. The P-I curves derived from the EIT could assess lung recruitment volume accurately and provide an opportunity to estimate the regional lung recruitment at the bedside.

INTRODUCTION. Patients with acute exacerbation of chronic obstructive pulmonary disease (COPD) (AECOPD) and severe asthma attack (SAA) frequently require invasive mechanical ventilator (IMV) support; however, the mortality rate still very high with a range from 11-52%. Two ICS/LABA MDIs -Foster® (beclomethasone dipropionate and formoterol fumarate) and Seretide® evohaler (fluticasone and salmeterol) are treatment of choice for ventilated AECOPD/SAA patients in the MICU.
OBJECTIVES. In this project, we intend to use a non-invasive electrical impedance tomography (EIT) to promptly monitor the clinical treatment efficacy of MDIs in these patients.
METHODS. In this project, patients would be randomize assigned to two groups either receiving Foster® or Seretide® evohaler MDIs. A non-invasive study would be applied within three days of admission and be evaluated the ICS/LABA effect on ventilation function by using the EIT equipment for three consecutive days. The values of dynamic airway resistance, dynamic compliance, tidal volume, inspiration pressure, PEEP applied, and flow-volume curve images (scooping loop 2-3 figures) were record
RESULTS. We compared the pre- and post-bronchodilator resistance changes in the Seretide group. We observed that compared to baseline (30 min pre MDI), the resistance showed minimal immediate response after 30 min post Seretide MDI (-0.84 + 1.23 cmH20/L•S-1,

p=0.018), after 60 min post Foster MDI (-0.66 + 1.54 cmH20/L•S-1, p=0.108), and after 120 min post Foster MDI (-0.40 + 1.94 cmH20/L•S-1, p=0.426). the compliance showed slightly increase, but huge variation, after 30 min post Foster MDI (0.88 + 5.82 L/cmH2O, p=0.124), after 60 min post Foster MDI (3.6 + 7.7 L/cmH2O, p=0.062), and after 120 min post Foster MDI (3.87 + 7.59 L/cmH2O, p=0.028). Therefore, there was better lung compliance after Seretide MDI treatment in such patients .
CONCLUSIONS. In this study, we observed the immediate effect of two ICS/LABA MDIs inhalation in severe asthma or COPD AE under mechanical ventilator support and ICU admission. Foster® MDI contains extrafine particles that reaching both large and small airways, provides better disease control.

The measurement of the hysteresis in a pressure-volume curve, with a post tracheal tube pressure sensor, during a PEEP trial could allow to evaluating the variation of the recruited pulmonary volume by the tidal volume at each level of PEEP

INTRODUCTION. The static pressure volume curve (PV curve) is the reference technique to evaluate the lung mechanical. This technique is not easy to perform at the bedside. With a pressure sensor placed at the end of the tracheal tube, we can perform a PV curve without the pressure induced by the tracheal tube resistance so approaching a static PV curve. The volume of hysteresis obtained with this PV curve is the volume of lung recruited at each inspiratory by the tidal volume so we can approach it at each level of PEEP.
OBJECTIVES. The aim of this study is to determine the value of this hysteresis in ARDS patient, and if we have, during a digressive PEEP trial, a modification of this hysteresis.
METHODS. It is a single center study, in an intensive care unit. We included patients with moderated or severe ARDS. The patients are sedated and curarized in volume control mode with a Carescape R860 ventilator (General Electrique). We placed a pressure captor after the end of the tracheal tube, at the bottom of the trachea, to do the measurement of the PV curve. Before inclusion, we did a recruitment manoeuver (PEEP=25cm H2O during 40 seconds) and after we did a digressive PEEP trial (15, 12, 10, 8 and 5 cmH2O). We decreased the PEEP every 15 minutes. For each level of PEEP, we did a PV curve and we measured the maximum hysteresis (mHyst) obtained. We also measured blood gas, the plateau pressure, the total peep and the driving pressure. We calculated the ratio between hysteresis and tidal volume (mHyst/Vt) and the variation of this ratio between PEEP 15 and 5 cmH2O. We analysed the variation of the parameters using a ANOVA test for repeated measures with medcalc.
RESULTS. We included 17 patients, the mean age was 67.1 (47 to 85) years old, 9 men and 8 women. The cause of the ards was 13

pneumonia, 1 endocarditis, 1 peritonitis and 1 post cardiac arrest patient. The mortality was 47%. In the table one we present the variation of the parameters. The mean variation of the mHyst/Vt between 15 and 5 cmH2O was 15% (27 to 4), 4 patients had a variation lower than 10% and 4 patients more than 20% of the Vt.

CONCLUSIONS. The measurement of the Hyst using a tracheal pressure sensor during a digressive PEEP trial could allow evaluating the variation of the volume recruited during the respiratory circle. We have an increased of this volume when we decrease the PEEP. We could evaluate a population of patient with a few variation of this recruited volume and a population with a big variation with the PEEP trial. So we apprehend if we improve the ventilator induced lung injury induces by the pulmonary volume collapse and open by the respiratory circle when we change the PEEP. More studies are necessary to apprehend if this measurement is useful to adapt the strategy of ventilation.

INTRODUCTION. Diaphragmatic Ultrasound (DU) is an useful tool in monitoring patients (pts) during invasive and non invasive ventilation (NIV) [1, 2]. However DU could play a role in the early phase of NIV application in the early phases of Hypoxic-Hypercapnic Acute Respiratory Failure (HHARF) in order to identify pts at risk of NIV failure.

OBJECTIVES. The first aim was to evaluate diaphragm ultrasound (DU) feasibility in HHARF requiring NIV over two 2 hours period from admission. The secondary aim was any relationship between diaphragmatic function expressed in terms of diaphragmatic excursion (DE), thickness and thickening, arterial blood gases (ABGs) and NIV duration (Nd).

METHODS. Forty-three consecutive HHARF pts requiring NIV were screened in the Emergency Department (ED). Twenty pts were enrolled. DU and ABGs were performed on admission before starting NIV (T0), after one (T1) and two hours (T2) of NIV. Pts were divided in two groups: a) NIV responders (NIVr) with normal pH values and b) NIV non-responders (NIVnr) with persistent respiratory acidosis.

RESULTS. In 1 of the patient, the study was interrupted because of a poor DU window. Figure 1 depicts DE over first two hours of patients admission. DE was significantly reduced at T1 in NIVnr group with respect to NIVr (p < 0,001). DE at T1 with cut-off of 1,650 cm had a sensitivity of 100% and specificity of 91,67% in predicting NIV failure at two hours (figure 2). Finally, as depicted in figure 3, NIVr group underwent to Nd minor than NIVnr (p = 0,0284).

CONCLUSIONS. In our experience, DU was a feasible tool in HHARF pts requiring NIV in the ED. In particular DE, seems to play a leading role in monitoring our pts population over the first two hours from emergency department admission.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0661

INTRODUCTION. Regional lung strain has been correlated with regional inflammation, supporting that strain might be a determinant of ventilator-induced lung injury. Therefore, information on regional strain distribution in mechanically ventilated patients with acute respiratory distress syndrome (ARDS) may be important to develop lung protective ventilation strategies. Electrical impedance tomography (EIT) is capable of monitoring imbalances in regional lung ventilation and it could provide a surrogate of the strain estimated by CT at bedside.

OBJECTIVES. To compare regional strain estimated by CT and EIT monitoring, in patients who presented moderate-severe ARDS.

METHODS. Four patients underwent whole-lung CT during breath-holding sessions at end expiration and end inspiration (with PEEP 5 and best PEEP according EIT, applied in random order). A recruitment maneuver was performed before each PEEP change. Low radiation CT protocol was applied. ADMIRE reconstruction algorithm and iterative reconstruction with IRIS-Software (Kernel: I40 filter) were applied. Using Nifty-Reg package (1), a transformation mapping was generated between a fixed image (end inspiration) and a target image (end expiration), which calculates displacement of every point inside the lung from inspiration to expiration. Following, a biomechanical analysis method was used (2) to construct 3D maps of the volumetric strain distribution for each patient´s lungs (See figure 1). Electric impedance tomography (EIT, Enlight®: Timpel, Brazil) was used to visualize the regional distribution of inflation (3). Strain maps were divided into 4 regions of interest (Upper and Lower, Right and Left), coinciding spatially with the regions upon which inflation was calculated for EIT method. CT and EIT examinations were performed simultaneously. The correlation between CT and EIT variables was addressed by multiple lineal regressions.

RESULTS. Significant correlations were found between CT and EIT for global and regional strain, on PEEP 5 and best PEEP according to EIT (Table 1).

CONCLUSIONS. Global and regional lung strain, estimated by CT, were accurately correlated with EIT in patients who presented moderate-severe ARDS in spite CT-based strain method was related to the whole lung

INTRODUCTION. Measurement of pulse-oximetric oxygen saturation (SpO$_2$) is widely used to monitor oxygenation status in critically ill patients. Recently, to avoid unnecessary hyperoxemic state, it is recommended to keep SpO$_2$ in a certain range in mechanical ventilated patients. In this regard, INTELLiVENT-ASV®, with the function of automatic F$_I$O$_2$ control by monitoring SpO$_2$ attached with the ventilator,

might have potential benefit. However, it is unclear how accurate the measured SpO_2 by the system of INTELLiVENT-ASV® compared with the actual SaO_2.

OBJECTIVES. To evaluate the accuracy of SpO_2 (Nihon Kohden) attached with INTELLiVENT-ASV® and another type of SpO_2 (Masimo) compared with the actual SaO_2.

METHODS. This is a single center, prospective observational study (UMIN000027671). Consecutive adult patients who were admitted to a general-ICU and mechanically ventilated with G5 ventilator (Hamilton Medical, Rhäzüns, Switzerland) between June 2017 and March 2018 were included. SpO_2 were measured by TL-271T3 (Nihon Kohden, Tokyo, Japan) attached with G5 ventilator and simultaneously by RD SET^{TM}NEO (Masimo, Irvine, CA, USA). Seal type of sensor probes were used and attached on the same side of patient's hand. Patients who presented quality index of SpO_2 (Nihon Kohden) < 50%, unstable value of SpO_2 due to change F_IO_2 just before blood drawing and with smoke inhalation were excluded. Time of blood drawings or analyzing blood gases were recorded and compared with SaO_2 and SpO_2. The timing of blood gas analyses were depending on physician's decision. Blood samples were immediately transferred and measured by RAPIDLAB1265 (Siemens Healthcare Diagnostics Inc., Tarrytown, NY, USA). The relationship between measured SaO_2 and SpO_2 were evaluated by simple linear regression analysis and Bland Altman plot.

RESULTS. Forty-nine mechanically ventilated patients and 701 points of arterial blood gas analysis were analyzed. Mean value of SaO_2, SpO_2 (Nihon Kohden) and SpO_2 (Masimo) were 95.8%, 96.3% and 97.1%, respectively. Comparing with each SpO_2 and SaO_2 by Bland Altman plot, bias was significantly smaller in SpO_2 (Nihon Kohden) than SpO_2 (Masimo), although precision was not significantly different (Mean ± SD,0.49±1.78% vs. 1.27±1.76%, $P< 0.0001$). The correlation coefficient was 0.889 in SpO_2 (Nihon Kohden) and 0.891 in SpO_2 (Masimo). The thresholds of SpO_2 with no patients with $SaO_2<$ 90% were 94% in SpO_2 (Nihon Kohden) and 97% in SpO_2 (Masimo).

CONCLUSIONS.

We found that SpO_2 (Nihon Kohden) presented lower bias than SpO_2 (Masimo) compared with actual SaO_2. On the other hand, precision of SpO_2 and correlation coefficient were relatively the same with both devices. This study suggests that when using INTELLiVENT-ASV® and selecting automatic control of oxygenation in mechanically ventilated patients, adequate SpO_2 sensors should be used to avoid unexpected hypoxemia and hyperoxemia.

INTRODUCTION. Adaptive support ventilation (ASV) is a novel electronic ventilator protocol that incorporates the recent and sophisticated measurement tools and algorithms.

The target tidal volume and respiratory rate are continually adapted to patient's respiratory physics and varying medical conditions. In injured lung, the ASV should actively adjust ventilatory parameters achieving minimal work of breathing to meet the lung protective strategies. But there were little literatures describing its efficacy when applied to Korean population.

OBJECTIVES. We monitored the efficacy of ASV in Korean patients with acute lung injury

METHODS. We observed initial mechanical ventilation parameters in 114 patients receiving ASV due to various causes (48 lung injuries including 27 community acquired pneumonia, 9 hospital acquired pneumonia, 5 interstitial lung diseases, 4 pulmonary tuberculosis and 3 idiopathic cases; 66 without lung injury which comprise 33 trauma cases, 18 strokes, 9 suicidal attempts and 6 other cases). The mean age of studied population was 57.5 years (male: female=42:15). The data were collected within the first 12 hours of mechanical ventilation.

RESULTS. Mean age of lung injury group was 63 years (53.3 for normal lung group; $p < 0.05$), PaO_2 per inspired fraction of O_2 (PF ratio) was 207.7 ± 61.2 (388 ± 103 for normal lung group, p < 0.05), minute volume was 7.6 ±2.21 l (7.1 ± 1.83 l for normal lung group, $p > 0.05$), inspiratory flow was 43.0 ±8.2 l/min (39.2 ± 10.3 l/min for normal lung group, $p > 0.05$), expiratory flow was 41.8 ± 11.4 L/min (39.2 ± 12.2 l/min for normal lung group, $p > 0.05$), peak pressure and plateau pressure were 26.8 ± 10.2 cmH_2O and 23.8 ± 6.0 cmH_2O (20.3 ± 4.8 cmH_2O, 16.2 ± 3.9 cmH_2O for normal lung group, $p > 0.05$), inspiratory resistance was 13.5 ± 5.6 $cmH_2O/s/l$ (12.4 ± 5.3 $cmH_2O/s/l$ for normal lung group, $p > 0.05$). Static compliance was measured at 26.7 ± 7.9 ml/cmH_2O in lung injury group (60.7 ± 12.2 ml/cmH_2O in normal lungs; $p < 0.05$), and inspiratory to expiratory time ratio in lung injuries was 0.5 (0.55 in normal lungs, $p > 0.05$). Expiratory time constant (RCexp) in lung injuries was 0.54 ± 1.7 s (0.79 ± 2.2 s in normal lungs). In lung injury patients, the tidal volume was smaller (8.35 ± 2.38 ml/Kg vs 6.20 ± 1.89 ml/Kg in normal lung group, $p < 0.05$) and respiratory rate was higher (19.8 breaths/min vs 15.2 breaths/min for normal lung group, $p < 0.05$).

CONCLUSIONS. As expected, adaptive support ventilation delivered smaller tidal volume and higher respiratory rates for injured lungs.

ASV efficiently operated in Korean ALI patients without any serious drawbacks and favorably adjusted the tidal volume and respiratory rates combination in relation with RCexp to meet lung protective strategies.

Tuning the ventilator using diaphragmatic ultrasonography

M. Vasileiou, E. Soilemezi, C. Spyridonidou, P. Sotiriou, M. Tsagourias, D. Matamis
Papageorgiou General Hospital, ICU, Thessaloniki, Greece
Correspondence: E. Soilemezi

INTRODUCTION. Patient-ventilator asynchrony is well known to adversely affect outcome in ICU patients. Recordings of esophageal pressure are traditionally used in the assessment of patient-ventilator interactions; however, esophageal pressure monitoring is an invasive and cumbersome method to be applied in everyday practice. On the other hand, an increasing number of ICU physicians are using diaphragmatic ultrasonography in their clinical work.

OBJECTIVE. This study investigates whether ultrasound can replace the information given by esophageal pressure monitoring to effectively recognize the presence of patient-ventilator asynchrony and, therefore, to appropriately set the ventilator according to the patients' inspiratory effort.

METHODS. All ICU patients breathing in assisted modes of ventilation, in which airway pressure, volume and flow waveforms displayed on the ventilator screen indicated patient-ventilator asynchrony, were assessed. In all patients, the ultrasonographically measured diaphragmatic excursion and the esophageal pressure were simultaneously recorded and compared for detection and documentation of patient-ventilator asynchrony.

RESULTS. Diaphragmatic ultrasound was equally efficient with esophageal pressure monitoring to identify all forms of patient-ventilator asynchrony, associated both with low respiratory drive and excessive ventilator assistance, namely ineffective efforts (fig.1), auto-triggering and reverse triggering, and also patient ventilator interactions associated with increased respiratory drive and/or insufficient ventilator assistance, namely double triggering or breath stacking (fig.2).

CONCLUSIONS. Diaphragmatic ultrasonography is a non invasive and less cumbersome method compared to esophageal pressure recording to successfully identify incidents of patient-ventilator asynchrony, allowing appropriate adjustment of the ventilator settings to match each patient's unique needs.

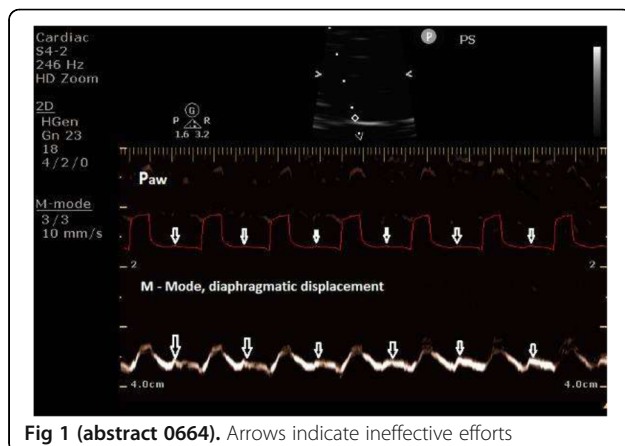

**Fig 1 (abstract 0664).** Arrows indicate ineffective efforts

MOTIVE: MOnitoring TIdal VolumEs. A feasibility trial measuring the tidal volume of every breath during invasive ventilation

M.J. Leong[1,2], T.M. De Vries[2], P. Shanmugasundaram[2]

INTRODUCTION. Invasive ventilation in critical care requires careful monitoring of numerous values including the delivered tidal volumes (Vt). However, many randomised control trials comparing ventilation strategies only record Vt on a daily basis (1, 2). Published audits of lung protective ventilation have compared the delivered Vt to the expected standard on an hourly basis (3). The effect of failing to record the Vt of all the breaths delivered is not known.

OBJECTIVES. The objectives of this study were to:
- Examine the feasibility of recording the Vt of every breath delivered by a ventilator to a patient on an Intensive Care Unit (ICU).
- Identify any discrepancy between the charted Vt values in the hourly bedside record and the actual delivered Vt.

METHODS. The EView (GE Healthcare, Milwaukee, WI, USA) is a data logging device which allows downloading of ventilatory data. It was installed to an Engström Carestation ventilator (GE Healthcare) and Vt data was collected during pressure control/support ventilation of patients. The charted Vt values on the bedside record were then compared to the ventilator recorded values during the period 30 minutes before and after.

RESULTS. A total of 373 hours of data, representing nearly 400,000 ventilator breaths, was analysed across four different patients. The median difference between the charted Vt and median recorded Vt in that hour was 5% (IQR=2%-12%). The charted Vt was outside the 5th or 95th percentile of the breaths delivered in the associated hour 14.5% of the time. There was a statistically significant difference in the proportion of charted Vt values that were within the ICU's target lung protection range (6-8ml/kg) compared to the recorded breaths (47.7% vs 28.8%, p< 0.01).

CONCLUSIONS. It is feasible to record the Vt of every single breath delivered during invasive ventilation. There is a discrepancy between the charted bedside Vt and the actual Vt delivered by the ventilator. This discrepancy may be sufficient to affect the results of randomised control trials and audits. Further work should look at the feasibility of large-scale data collection, recording other ventilation parameters and their role within research trials, audits and daily clinical care.

INTRODUCTION. Non-invasive mechanical ventilation (NIV) is a standard respiratory support technique used in the intensive care unit (ICU). A tendency to use non-invasive forms is growing, and the use of High-Flow Nasal Cannula (HFNC) devices have come into widespread use in ICU. NIV and HFNC can create positive oropharyngeal airway pressure, but it is unclear how their use affects lung volume.

OBJECTIVES. To compare the differences generated by two respiratory support devices, NIV and HFNC, regarding pulmonary aeration and respiratory measures using Electrical Impedance tomography (EIT) measurements in healthy subjects.

METHODS. This is a unicentric prospective interventionist cohort study, conducted at the Critical Care Department of the Hospital del Mar in Barcelona and its research group (Critical Illness Research Group, GREPAC) at the Hospital del Mar's Institute of Medical Investigations (IMIM), (IRB: 2015/6444/I).

Subjects were recruited and consecutively included in the study to receive NIV or HFNC, parameters of respiratory support were predetermined. Clinical data was registered and lung impedance measurements were done before and after 30 minutes of respiratory support. The data was expressed as mean (standard deviation) or as median (interquartile range). Significance was set to $p < 0.05$.

RESULTS. A total of 20 healthy subjects were included, 10 of them were ventilated with NIV and 10 of them with HFNC. There were no differences in demographic data. After 30 minutes of respiratory support, subjects in both groups showed a significant reduction in respiratory rate, more pronounced in the HFNC group (NIV:14.4 (4.1) vs 10.4 (1.6), p=0.009; HFNC:13.6 (4.3) vs 7.9 (1.5)bpm, p=0.002), and a significant increase in the end-expiratory lung impedance (EELI) (NIV:66,348(10,761) vs 73,697 (6,858), p=0.005; HFNC:66,252 (9,793)vs69,869 (9,135), p=0.012). NIV subjects also showed a significant increase of non-dependent silent spaces (4.13(2.25) vs 5.81 (1.49), p=0.037), while this changes were more homogeneous in HFNC. Both technics showed a variation of EELI (ΔEELI), that trended to be higher in NIV than in HFNC (8,137.08 (6,152.04) vs 3,616.94 (3,623.03), p=0.077).

CONCLUSIONS. NIV and HFNC increased EELI in healthy subjects, suggesting an increase in the functional residual capacity in both modalities. Despite EELI increment was higher with NIV, HFNC produced more homogeneous changes in lung ventilation distribution which could mean overdistention with NIV.

Omecamtiv mecarbil treatment improves post-resuscitation cardiac output and neurological outcome in an animal model

C.-H. Huang[1], M.-S. Tsai[2], W.-J. Chen[2]
[1]National Taiwan University Hospital, Department of Emergency Medicine, Taipei, Taiwan, Province of China; [2]National Taiwan University Hospital, Taipei, Taiwan, Province of China
Correspondence: C.-H. Huang

INTRODUCTION. Myocardial dysfunction is one of the major causes leading to poor outcomes in the post-cardiac arrest period. Omecamtiv mecarbil (OM) is a selective small molecule activator of cardiac myosin that prolongs myocardial systole and increases stroke volume without apparent effects on myocardial oxygen demand (1). OM administration is safe and improves the cardiac function for acute heart failure patients. Whether the OM improves post-resuscitation myocardial dysfunction remains unclear.

OBJECTIVES. To investigate the effect of OM treatment on post-resuscitation myocardial dysfunction and outcomes.

METHODS. Adult male rats were resuscitated after 9.5 mins asphyxia-induced cardiac arrest. OM was continuously intravenously infused after ROSC with 0.25 mg/kg/hr for 4 hours in the experiment group and normal saline was given at the same volume per hour in the control group (n=20 in each group). Body temperature was kept on 36.5°C during treatment. Hemodynamic parameters were measured every hour and monitored for four hours after cardiac arrest. Recovery of neurological function was evaluated by neurological functioning scores (0-12) for rats at 72 h after cardiac arrest (2). The neurological score reaching up to 11 or 12 was defined as favorable neurological outcome.

RESULTS. OM treatment prolonged the left ventricular ejection time and improved the post-resuscitation cardiac output (figure 1). Heart rate, left ventricular systolic (dP/dt$_{40}$) and diastolic function (maximal negative dP/dt) were not different between two groups in the post-resuscitation period (figure 2). Kaplan-Meier analysis showed higher, but not statistically different 72-hour survival in OM group (72.2% (13/18) vs. 58.8% (10/17), p=0.386 by log-rank test). OM group had higher chance of having favorable neurological outcome for the survived at 72 hours after cardiac arrest (84.6% (11/13) vs. 40% (4/10), p=0.026). The percentage of damaged neuron was less in the OM group in histology study at 72 hours after cardiac arrest (55.5±2.3 vs. 76.2±10.2 %, p=0.004).

CONCLUSIONS. OM treatment can improve post-resuscitation myocardial dysfunction and neurological outcome in an animal model. These findings could be the basis for further pre-clinical studies for improving the outcome in post-cardiac arrest care.

INTRODUCTION. Although current guidelines for resuscitation recommend maintaining temperature between 32-36⁰C and Mean Arterial Pressure (MAP) 60-90 mmHg, there is very limited science to guide the balancing act between the brain's need for perfusion and the heart's need for restitution. There are also important gaps in knowledge of how cerebral perfusion needs vary with various temperatures.
OBJECTIVES. To determine whether maintaining a MAP of 90 mmHg would yield improved cerebral blood flow and less ischemia compared to 60 mmHg in a porcine model of cardiac arrest, and to assess whether Targeted Temperature management at 33⁰C (TTM) might attenuate some of the resulting ischemia.
METHODS. Forty-one 35 kg swine were anesthetized and instrumented prior to electrical induction of ventricular fibrillation. After 10 minutes of cardiac arrest, animals were resuscitated using a heart-lung machine at 100 ml/kg/min for 2 minutes before defibrillation. After ROSC, animals were randomized to TTM or no TTM, and MAP 60 or MAP 90; yielding four groups. TTM was managed by intravasal cooling, and blood pressure targets were managed with vasopressin, norepinephrine and nitroprusside. After a 30 minute stabilization period, animals were observed for an additional 2 hours. Cerebral perfusion pressure (CPP), flow (CF), pressure reactivity index (PRx), tissue pCO_2 and microdialysis were measured continuously, analyzed for 15 minute epochs, and compared using mixed models.
RESULTS. MAP 90 animals had significantly higher CPP (p< 0.001 for both no-TTM and TTM groups) and CF (p< 0.001 for both no-TTM and TTM groups) compared to MAP 60 animals. MAP 90 animals also showed less signs of ischemic insult with lower PRx values (indicating improved autoregulation), (p=0.04 for no TTM and p=0.001 for TTM group), lower brain tissue pCO_2 (p=0.017 for no TTM and p< 0.001 for TTM group) compared to MAP 60 animals. Preliminary results from microdialysis show increased lactate/pyruvate ratios among normothermic MAP 60 animals compared to MAP 90 animals (0.017). Samples from TTM treated animals are being analyzed.
CONCLUSION. Preliminary results suggest targeting mean arterial pressure to 90 mmHg after cardiac attest might provide better cerebral perfusion and less ischemic insult at both normothermia and hypothermia (33⁰C) compared to 60 mmHg in a porcine model.

Commencing one-handed chest compressions while activating emergency medical system by handheld mobile device in lone rescuer basic life support: a randomised crossover simulation study

D. Lee[1], S.M. Park[2]
[1]Seoul National University Bundang Hospital, Emergency Department, Anyang si, Korea, Republic of; [2]Seoul National University Bundang Hospital, Emergency Department, Seongnam, Korea, Republic of

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0669

OBJECTIVES. In current basic life support (c-BLS), lone rescuer is recommended to start chest compressions (CC) after activating the emergency medical system. To realize earlier CC in lone-rescuer BLS, we designed a modified BLS (m-BLS) sequence in which lone rescuer commences one-handed CC while calling for help using a handheld cellular telephone with the other free hand. The aim of this study is to compare the quality of BLS between the c-BLS and the m-BLS.
METHODS. This is a simulation study performed by a randomized cross-over controlled trial design. One-hundred eight university students were finally enrolled. After training for both c-BLS and m-BLS, participants performed 3 minutes of c-BLS and m-BLS on a manikin with a Skill-Reporter™ at random cross-over order. The quality of BLS was compared between the c-BLS and m-BLS.
RESULTS. Comparing with the c-BLS, m-BLS could reduce the mean lag time before initiation of CCs (18.4 vs. 51.5sec, respectively; p < 0.001), could deliver higher number of CCs (217.9 vs. 162.9, respectively; p < 0.001), and increased the mean fraction of CC (63.6 vs. 48.0 %, respectively; p < 0.001), significantly during the first 3 minutes of BLS. Also, higher numbers of CC with correct depth (defined by 5-6 cm) were delivered in the m-BLS than in the c-BLS (185.8 vs. 158.1 in c-BLS; p < 0.001). There were no differences in the correct hand positions, compression rate and interruption time for ventilation between the two groups.
CONCLUSIONS. In simulated lone rescuer BLS, the m-BLS sequence could deliver significantly earlier CC than the c-BLS while maintaining high-quality cardiopulmonary resuscitation.

INTRODUCTION. Glucose is the main energetic substrate for the brain and myocardium during severe ischemia. Nevertheless, a very little is known about the metabolism of glucose and insulin during cardiac arrest.[1]

OBJECTIVES. We decided to describe glucose and insulin plasmatic levels during induced experimental cardiac arrest, to assess the impact of adrenaline administration on them and to evaluate the impact of glucose load immediately after induction of cardiac arrest on their metabolism.

METHODS. We induced ventricular fibrillation for 15 minutes (2 minutes of unresuscitated cardiac arrest, 3 minutes of continuous cardiac compressions only and 10 minutes of cardiac compressions and mechanical ventilation) in 21 anesthetized domestic pigs. Before that, blood samples were taken to determine baseline plasmatic levels of glucose, insulin, cortisol and adrenaline and the experimental animals were randomized to undergo induced cardiac arrest as described above (Group A, n=7); or to undergo group A protocol supplemented by administration of 15 μg/kg of adrenaline in the 5th and 10th minute of cardiac arrest (Group B, n=7); or to undergo group A protocol enriched by rapid i.v. administration of 16 g of glucose as soon as possible after cardiac arrest induction (Group C, n=7). After 15 minutes of cardiac arrest the animals were defibrillated and observed for 20 minutes. Blood samples to evaluate glucose, insulin, cortisol and adrenaline plasmatic levels were taken in regular intervals throughout the protocol.

RESULTS. All animals in the group B reached return of spontaneous circulation, while only 5 in the group A and 3 in the group C. A gradual increase of glycaemia during induced cardiac arrest was observed in all groups from the baseline to the 15th minute of induced cardiac arrest (Group A: from 5.4±2.0 to 7.8±2.1 mmol/l, p=0.049; group B: from 5.6 ±2.0 to 9.3±1.8 mmol/l, p=0.003; group C: from 4.8±0.8 to 21.3 mmol/l, p< 0.001). Insulin levels did not change significantly in the group A (from 2.8±2.1 to 2.0±0.4 pmol/l, p=0.342) and the group C (from 3.2±2.1 to 2.8±1.9 pmol/l, p=0.715), while significant decrease of insulin levels was observed in the group B (from 6.3±4.0 to 2.3±1.1 pmol/l, p=0.025). Adrenaline administration did not affect glucose levels significantly in the group B in comparison with the group A. Initial glucose load in the group C had no impact on the further insulin release.

CONCLUSIONS. We observed a gradual increase of plasmatic glucose levels without any change of insulin levels in our porcine model of cardiac arrest. Adrenaline administration led to decrease of insulin levels. Load of glucose administered as soon as possible after cardiac arrest induction did not induced additional insulin release.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0671

INTRODUCTION/ OBJECTIVES. Adherence to CPR treatment algorithms is often not ideal. Alternative algorithms and modifications of the official CPR guidelines are in use. The aim of the present study was to compare three CPR algorithms with regard to adherence and measures relevant for patients' outcomes (i.e. hands on-time).

METHODS. 287 teams, consisting of three to five physicians each, were randomized to perform CPR in a simulated unwitnessed cardiac arrest according to the current guidelines ("2min"), the cardiocerebral resuscitation ("CCR") protocol (200 chest compressions with no ventilation), or a local modification of the current guidelines (200 chest compressions with ventilation via a rapidly inserted laryngeal tube, the "Arnsberg" algorithm). Data analysis was performed using video-recordings obtained during simulations. The primary endpoint was hands-on time and secondary endpoints were adherence to allocated algorithm.

RESULTS. Hands-on time was 85 ± 7% in the "2min" teams, 86 ± 4% in the "Arnsberg" teams (P = 0.025 vs "2min"), and 87 ± 5% in "CCR" teams (P = 0.005 vs "2 min"; P = 0.33 vs "Arnsberg"). "2min" teams deviated significantly more (P < 0.001) from target (range of ± 20 % of a time interval of 2min or 200 chest compressions respectively between subsequent defibrillations) than "CCR" and "Arnsberg" teams. "CCR" teams demonstrated the closest adherence to target and the least within-team and between-team variance with regard to cycle length (P = 0.03) and delivered chest compressions (P = 0.001) in subsequent cycles.

CONCLUSIONS. Different CPR algorithm may substantially vary in adherence. Reducing the complexity of CPR algorithms can result in better adherence, less variance and better hand-on times.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0672

INTRODUCTION. International guidelines recommend adrenaline during resuscitation despite lack of evidence on survival benefits. There is some evidence that the beta-adrenergic effects of adrenaline are harmful due to increased myocardial oxygen consumption, post-defibrillation ventricular arrhythmias and increased severity of post-arrest myocardial dysfunction. Esmolol may counteract the unfavorable effects of adrenaline and thus preserve post-arrest myocardial function.
OBJECTIVES. To test whether esmolol administered prior to adrenaline preserves post-arrest myocardial function in an ischemic cardiac-arrest pig model with low-flow (2.5L/min) VA-ECMO resuscitation.
METHODS. Twenty anesthetized pigs had a myocardial infarction induced by an inflated PCI-balloon in the circumflex artery, and ventricular-fibrillation (VF) was induced electrically 15 min later. After 10 min of untreated VF, resuscitation by VA-ECMO was initiated and the animals were randomized to receive an injection of either 1mg/kg esmolol or placebo, prior to adrenaline 1mg/dose. Subsequent successful defibrillation was followed by a one-hour high-flow VA-ECMO support before ECMO weaning and an additional one-hour stabilization period. The PCI-balloon was deflated 40 min after inflation. Cardiac function post-arrest was assessed by MRI and invasive pressure measurements. Myocardial injury was estimated by serum concentrations of cardiac troponinT.
RESULTS. Seven esmolol-treated and five placebo pigs survived until post-arrest measurements with substantial myocardial injury. MRI revealed a severe reduction of myocardial function without significant differences between the two treatment groups (Table1). Invasive pressures and ventricular pressure-derivates did not significantly change. The 60% reductions of stroke-volumes were partly compensated for by increases in heart-rate.
CONCLUSIONS. Beta$_1$-blockade prior to adrenaline during low-flow VA-ECMO resuscitation did not preserve post-arrest cardiac function nor decrease the magnitude of myocardial injury in pigs, compared to placebo.

Table 1 (abstract 0672). See text for description.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0673

INTRODUCTION. Sudden out-of-hospital cardiac arrest is a frequent cause of death that requires immediate bystander cardiopulmonary resuscitation (CPR). Repeated training helps retain knowledge and skills in CPR.
OBJECTIVES. The aim of this study was to evaluate impact of basic life support (BLS) training on practical skills and knowledge of BLS including the use of an automated external defibrillator (AED).
METHODS. A prospective study of 90 students (43.3% males, median age 18 [IQR, 16-19] years) was conducted. Participants were divided into three groups: students who had not previously received any BLS training (group 1, n=30), students who only had attended a non-practical BLS course (group 2, n=30), and students who had just attended a BLS-AED course (group 3, n=30). Each participant completed CPR on a manikin which tracks chest compressions, lung ventilation and compression time in percentage. Total CPR result was calculated based on these measures. Both resuscitation knowledge (questionnaire) and practical skills (compression (%), ventilation (%), total CPR score (%), mistakes, use of AED) were analyzed. Set resuscitation time was 2 minutes. Data analysis performed with SPSS 24.0 program.
RESULTS. Mean total CPR score: 28.0 (SD 13.1) % in group 1, 40.8 (SD 18.2) % group 2 and 50.7 (SD 19.4) % group 3; (p< 0.001). Median chest compression results: 1% [IQR, 0-10] in group 1, 9% [IQR, 0-47] group 2, 51% [IQR, 21-79] group 3; (p< 0.001). Nineteen (21.1%) people did not compress: 33.3% in group 1, 10% in group 2 and 20% in group 3. Median ammount of practical mistakes according to groups (12 criteria): 9 in group 1 [IQR, 7.8-10], 5 in group 2 [IQR, 2-7] and 3 in group 3 [IQR, 2-6.3]; (p< 0.001). Mean use of AED score in groups (of total 4 points): 1 group 2.8 (SD 0.9), 2 group 3.3 (SD 0.8), 3 group 3.8 (SD 0.41). Mean score for test (total 10 points) was: 1 group 4.8 pts (SD 1.5), 2 group 5.7 pts (SD 1.3), 3 group 8.9 pts (SD 0.9); (p< 0.001).
CONCLUSIONS. The results of this study showed that better resuscitation results are achieved with prior both hands-on and theoretical courses. BLS-AED training should be a standard part of school education.

INTRODUCTION. Basic life support for cardiac arrest associates cardiopulmonary resuscitation and defibrillation. Among the numerous marketed models of automated external defibrillators (AED), some provide real-time feedback about the quality of the chest compressions, some are able to perform rhythm analysis during chest compressions but none offers these two functions.
OBJECTIVES. The aim of the present study is to compare the quality of chest compression during cardiopulmonary resuscitation with two models of AED, one analyzing cardiac rhythm during chest compressions (AED#1, model Lifepak CR2, manufactured by Physio-Control, USA) and the other one providing real-time feedback about the quality of the chest compressions (AED #2, model AED3 manufactured by Zoll Medical, USA).

METHODS. 39 teams of firemen performed cardiopulmonary resuscitation on a manikin following the same scenario. CC were continuous as ventilation was performed by continuous insufflation of oxygen. Each team of firemen was randomized to use either AED#1 or AED#2. Data on the quality of the cardiopulmonary resuscitation were obtained from the manikin's sensors and were analyzed according to the current guidelines. The CPR fraction (ratio of the duration of the chest compressions on the duration of the cardiopulmonary resuscitation) was measured.

RESULTS. 19 teams were randomized to the AED#1 and 20 to the AED#2. 91% of the chest compressions respected the recommended rate in the AED#1group and 92% in the AED#2 group (p 0.8). Only 28% of the chest compressions were in the targeted depth in the AED#1 group versus 69% for the AED#2 group (p < 0.001). The CPR fraction was higher in the AED#1 group (96% versus 93%, p < 0.01).

CONCLUSIONS. The model of AED used modifies cardiopulmonary resuscitation quality. Rhythm analysis during chest compressions by the AED increased slightly CPR fraction. Real-time feedback on cardiopulmonary resuscitation by the AED dramatically increased quality of chest compressions.

Evaluation of the quality of cardiopulmonary resuscitation according to vehicle driving pattern, using a virtual reality ambulance driving system: a prospective, crossover, randomised study

Y.S. Park
Yonsei University College of Medicine, Seoul, Korea, Republic of
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0675

BACKGROUND. We aimed to analyse changes in the quality of cardiopulmonary resuscitation (CPR) according to driving patterns encountered during ambulance transport, using a virtual reality ambulance simulator.

METHODS. A total of 48 participants were paired; the pairs performed chest compression for 8 minutes each in a stationary and driving (virtual reality ambulance simulating 10 driving patterns) state. Several CPR quality parameters such as chest compression depth and its variability were collected.

RESULTS. The mean chest compression depths were 54.8 mm and 55.3 mm during the stationary and driving states, respectively (p = 0.41). The standard deviation of the chest compression depth was significantly higher while in the driving (7.6 mm) than while in the stationary state (6.5 mm; p = 0.04). The comparison of CPR quality parameters according to driving patterns showed that the compression depths in the speed bump and sudden stop sections were 51.5 mm and 50.6 mm, respectively, which is shallower than those in all other sections (p < 0.001). The correct hand position rate was low in the speed bump, sudden stop, and right-hand cornering sections (65.4%, 71.5%, and 72.5%, respectively; p = 0.001)

CONCLUSIONS. Although we found no differences in chest compression quality parameters between the stationary and driving states, the variability in the chest compression depth increased in the driving state. In the speed bump and sudden stop sections, we noted a shallower compression depth, increased variability, and decreased correct hand position rate. In the right-hand cornering section, we observed a decreased correct hand position rate.

INTRODUCTION. Mild therapeutic hypothermia (TH) has been integrated into management strategies for improving the neurological outcome of post cardiac arrest syndrome (PCAS) for out of hospital cardiac arrest. Some devices are produced to achieve hypothermia with surface or core-cooling. The extracorporeal membrane oxygenation (ECMO) works for the management of refractory cardiac arrest not only to establish extracorporeal cardiopulmonary resuscitation (E-CPR), but also to induct TH as a core-cooling device. We report our preliminary experiences in establishing a therapeutic hypothermia for PCAS with ECMO. This study is a single center, retrospective, observational study.

METHODS. The PCAS cases of out-of-hospital cardiac arrest were induced TH with ECMO. The TH was indicated for unconscious cardiogenic ROSC patients under 75 years of age, and excluded existing brain hemorrhage, traumatic or respiratory cardiac arrest, and any risk of bleeding. Target temperature was set at 34℃ for 24 to 48 hours. ECMO for TH were quickly induced hypothermia on low-perfusion flow (1 l/min) with minimal anticoagulation. Intra-aortic balloon pumping was only used to achieve an improvement coronary artery flow or LV unload. Initial E-CPR was excepted in this study. Any complications, temperature stability, shivering and neurological outcomes were compared. A favorable neurological outcome was defined as a Cerebral Performance Category (CPC)1 after 90 days of cardiac arrest.

RESULTS. From January 2007 to December 2015, 41 patients were induced TH with ECMO. 31 favorable outcome cases (76%) were seen. All cases could reach to target temperature within 15 min. Shivering was seen 11 cases (27%), ventilator associated pneumonia was the leading complication for 9 cases (22%). bleeding from cannulation site was 8 cases (20%), and temperature over-cooling and instability was 2 cases (5%) each. ECLS for unstable circulation was performed 5 cases (12%). No fatal complications were seen except intra cranial hemorrhage was 2 cases (5%). There were no significant characteristic differences between group CPC1 vs CPC2-5.

CONCLUSIONS. We suggest not only ECMO works immediate TH initiation and stable circulation support for PCAS satisfactory, but ECMO is feasible and associated with a relatively high favorable neurological survival rate.

INTRODUCTION. Basic Life Support (BLS) technical skills are vital to achieve successful cardiopulmonary resuscitation (CPR) and general ward healthcare providers play a vital role as first responders, even

when Advance Life Support (ALS) team is available (1). Successful outcomes are affected by a plethora of non-technical aspects raising concern about how human factors affect technical skills and CPR outcomes (2). Guidelines support non-technical skills (NTS) inclusion in ALS training (3), but the impact of it´s inclusion during BLS training is not clear.

OBJECTIVE. To explore the impact of intra-hospital contextualization and NTS education during BLS training in CPR performance.

METHODS. Prospective quasi-experimental study. General ward healthcare providers (nurses and healthcare assistants) from two different medical wards of a University Hospital were assigned to receive either standard BLS training (StdBLS) or standard BLS training plus intra-hospital contextualization features and NTS principles (IHBLS). After training and during a regular shift they were confronted with a ward unexpected CPR simulation. They were asked to intervene in teams of 3 elements. Footage video was collected and a BLS simulator manikin with remote digital access was used to extract performance data. NTS were evaluated according with the Team Emergency Assessment Measure (TEAM) scale, measuring leadership, team work and task management. Informed consent was collected from all participant and the study was authorized by the local ethics committee.

RESULTS. Preliminary data were obtained. Thirty individuals were enrolled in the training sessions. Seven (23%) did not have any previous BLS training. Three teams of each group were submitted to a CPR simulation. When analyzing outcomes concerning TEAM scale dimensions, IHBLS group showed higher scores in teamwork, overall NTS performance and TEAM total score. Both groups had comparable scores in leadership and task management and achieved similar CPR performance.

CONCLUSIONS. Considering our preliminary data, the inclusion of hospital contextualization and NTS education during BLS training of healthcare providers did not demonstrate an impact in BLS resuscitation performance when compared with standard BLS training. However, it was noted a slight tendency of increase in NTS global performance by IHBLS teams. The wider sample obtained in demographics data brings out a worrisome training gap in BLS skills. It raises concern about hospital educational strategy in critical care. Facing the institutional commitment with the present project, we intent to proceed with the data collection.collection.

INTRODUCTION. In hemorrhaging trauma patients, the endothelium is activated, resulting in excessive endothelial synthesis of von Willebrand Factor (vWF)(1), which may enhance micro-thrombi formation, with obstruction of the microcirculation and endothelial injury, aggravating bleeding as well as contributing to organ failure. Under normal conditions, vWF is cleaved by the metalloprotease ADAMTS-13. After trauma, ADAMTS-13 levels are typically low(2).

OBJECTIVES. We aimed to assess the use of recombinant human (rh) ADAMTS-13 to inhibit endothelial injury and improve coagulation in our rat trauma-transfusion model.

METHODS. Blood products were prepared from syngeneic rat blood according to blood bank standards. Polytrauma was induced in Sprague Dawley rats by crush injury to the intestines and liver and by fracture of the femur. The rats were hemorrhaged by phlebotomy until a mean arterial pressure (MAP) of 40mmHg was reached. Rats were randomized (n=8 per group) to receive transfusion of RBCs, FFPs and platelets in a 1:1:1 ratio to achieve a MAP of 60 mmHg, with or without the addition of rhADAMTS-13 (50µg/kg). Blood samples were taken up to 6h after trauma to assess biochemistry and coagulation status by rotational thromboelastometry (ROTEM). Organ damage was assessed by histopathology. Animals were continuously monitored with an arterial and urinary catheter.

RESULTS. Following resuscitation, rats receiving rhADAMTS-13 had a higher MAP compared to controls (80 (64-83) vs 66 (37-75) mmHg, p=0.03). Also, it took controls longer to reach a MAP over 60 mmHg (30.0±23.6 vs 17.5±11.9 minutes), although not statistically significant (p=0.10). The coagulation status of rats receiving rhADAMTS-13 improved, as reflected by a higher maximum clot formation ability (EXTEM MCF 67.0±2.9 vs 61.2±4.9 mm, p=0.02) directly after transfusion. This seemed to be mainly platelet-dependent, since EXTEM CA5 minus FIBTEM CA5 was 45.0±2.8 mm in the rhADAMTS-13 group compared to 38.7±3.7 mm in controls (p< 0.01). However, no significant differences between groups was found in organ injury, as assessed by histopathologic examination and levels of creatinine, ASAT and ALAT.

CONCLUSIONS. The use of rhADAMTS-13 in a rat trauma-transfusion model improves coagulation, without abrogating the amount of organ injury. These results suggest that the use of rhADAMTS-13 affects platelet-based coagulation and might be a feasible therapeutic application to treat coagulopathy.

INTRODUCTION. Haemorrhagic shock (HS) can cause early death after injury or alternatively lead to inflammatory cascades and organ failure in resuscitated survivors. The ability for clinicians to mitigate ischemia-reperfusion secondary damages remains insufficient. The impact of xanthine oxidase (XO)-derived reactive oxygen species has been identified as one of the sources of oxidative stress leading to organ and endothelial damage. Recently, renewed interest in the pharmacological potential of XO inhibitors has emerged [1]; no systematic analysis of existing animal data, regarding harms or benefits after HS has been carried out.

OBJECTIVES. The objective was to systematically review the literature, in order to identify and evaluate the effects of XO inhibitors on mortality and organ failure, in animal models of HS.

METHODS. Studies including controlled interventions comparing pharmacological agents to a placebo of preclinical hemorrhage model were considered. Research using MeSH terms and text words related to haemorrhage, ischemia repercussion, organ failure and xanthine oxidase were carried out in PubMed/Ovid MEDLINE and EMBASE. Data were extracted independently and in duplicate.

RESULTS. The search process produced 3069 abstracts and 83 publications were considered relevant following exclusions and inclusions criteria. A total of 32 articles, all published between 1969 and 2000, were included for review after full text assessment for eligibility. Seven different animal species experimental models stood out in the included studies, with rats and dogs predominating. In most of the studies, HS resulted from blood withdrawal (75%) and resuscitation was done with reinfusion of shed blood (84%). The main pharmacological intervention to inhibit XO was allopurinol in > 90 %, followed by tungsten sodium administration. Allopurinol given before HS was associated with a reduction in animal mortality (40 to 60% on average); administration during resuscitation had anecdotic effects. XO inhibition also prevented the deterioration in myocardial function and overall haemodynamics, but inconsistently between studies. Various metabolic, enzymatic and functional (endothelium) benefits were reported. Intestinal injuries and bacterial translocation were also decreased by XO inhibition. Finally, certain inflammatory reactions (cytokine or neutrophil infiltration) were blunted by XO inhibitor administration.

CONCLUSIONS. Intervention before HS with XO inhibitor leads to measurable benefits in animal models, particularly mortality. However, the ability to intervene on the metabolic culprit responsible for the effect, during resuscitation, needs to be further investigated in preclinical setting before the transposition of such an intervention to humans.

INTRODUCTION. Hemorrhagic shock (HS) leads to hypoxia-induced systemic inflammation[1], which can cause acute lung injury (ALI)[2]. ALI, a frequent complication of trauma, is aggravated by lung co-morbidities like chronic obstructive pulmonary disease (COPD)[3]. COPD is characterized by both pulmonary and systemic inflammation, and the most common cause for COPD is cigarette smoke (CS) exposure. The glucocorticoid receptor (GR) mediates its effects via two different mechanisms, as a GR monomer or GR dimer. We previously observed that mice lacking the GR dimer (GR^{dim}) had a higher mortality in lipopolysaccharide- and cecal ligation and puncture-induced inflammation and are refractory to exogenous GCs to ameliorate inflammation in a murine model of ALI[4,5]. This demonstrates that the GR dimer is of importance for the repression of inflammation.

OBJECTIVES. We hypothesized that impaired GR dimerization in mice (GR^{dim}) would further impair organ function after HS with pre-existing CS-induced COPD.

METHODS. After 3 weeks of CS-exposure, anesthetized and mechanically ventilated GR^{dim} and GR$^{+/+}$ mice (n=7-9) underwent pressure-controlled HS (mean arterial pressure [MAP]=35mmHg) for 1h via blood withdrawal followed by 4h of resuscitation with re-transfusion of shed blood, colloid fluid infusion and continuous i.v. norepinephrine (NA) to maintain MAP>55mmHg. Lung function was determined via measurements of lung compliance and gas exchange together with systemic hemodynamics, metabolism, and acid-base status. Data is presented as median and interquartile range.

RESULTS. After CS exposure, GR^{dim} mice needed similar doses of NA to keep target hemodynamics as GR$^{+/+}$ mice (0.42 [0.24;0.60] vs. 0.07 [0;0.42] $\mu g \cdot kg^{-1} \cdot minute^{-1}$, p=0.05), had similar lactate levels (1.2 [1.1;1.7] vs. 1.3 (1.1;1.6) $mmol \cdot L^{-1}$, p>0.99), but presented with a decreased lung compliance (99 [91;108] vs. 136 [127;139] $\mu l \cdot cmH_2O^{-1}$, p< 0.01) at the end of experiment. When animals were not exposed to CS, GR^{dim} mice had higher NA requirements to keep target hemodynamics as GR$^{+/+}$ mice (0.20 [0.11;0.34] vs. 0.00 [0.00;0.00] $\mu g \cdot kg^{-1} \cdot minute^{-1}$, p=0.04), higher lactate levels (2.3 [1.4; 4.6] vs. 1.2 [0.8;1.5] $mmol \cdot L^{-1}$, p< 0.01), and decreased lung compliance (87 [82;100] vs. 128 [108;134] $\mu l \cdot cmH_2O^{-1}$, p< 0.01) at the end of the experiment.

CONCLUSION. We demonstrate that the GR dimer is an important mediator of hemodynamic stability and lung function during resuscitation from HS and its selective activation might be a promising clinical tool to improve outcome in patients after HS.

INTRODUCTION. Recent evocative data suggest that the expansion of myeloid-derived suppressor cells (MDSCs) in acute inflammatory processes play a beneficial role by increasing immune surveillance and innate immune responses. However, because of the brain's unique immune system, the role of MDSCs across the blood-brain barrier is far from understood.

OBJECTIVES. In this study, we explored the suppressive role of MDSCs in cerebral inflammatory reactions after traumatic brain injury (TBI) using *in vivo* imaging.

METHODS. In a controlled cortical impact (CCI) model, flow cytometry, immunohistochemistry including Giemsa counterstaining, and T-cell proliferation tests were performed to define the cells infiltrating the injured brain as MDSCs. After CCI mice received Gr-1 antibody or isotype control antibody treatment in order to deplete MDSCs, positron emission tomography (PET) imaging of Translocator

protein (TSPO) uptake for quantitative analysis of neuroinflammation was performed at 7 days post injury.

RESULTS. Cells co-expressing Gr-1 and CD11b accumulated in the injured brain, increasing by 1 day post injury, then decreasing progressively until 7 days post injury. Clearly, these populations are heterogeneous and include both immature and mature myeloid populations, containing monocytic and polymorphonuclear subpopulations. CD4[+] T-cell proliferation was significantly suppressed when sorted Gr-1[+] cells from the injured brain were co-cultured at a ratio of 1:1 and 1:2 with CD4[+] T cells. At 1 week post-CCI, in mice treated with Gr-1 antibody TSPO uptake was observed over broader volume including the ipsilateral thalamus and cortex compared with controls (control vs Gr-1 antibody: 0.033 ± 0.0064 vs. 0.078 ± 0.0121 ccm, p = 0.03).

CONCLUSIONS. We determined CD11b[+]Gr-1[+] cells infiltrating the contusion area as MDSCs using morphological and functional analysis along with phenotypic markers. Our results also suggest that infiltrating MDSCs suppress the neuronal inflammation following focal TBI.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0682

INTRODUCTION. In traumatic bleeding, a high platelet (PLT) to red blood cell (RBC) ratio of 1:1 seems more effective in achieving hemostasis than a 1:2 ratio or lower suggesting correction of trauma-induced coagulopathy (TIC)[1]. This underlines the finding that platelet functioning is severely disturbed in trauma[2]. It is unknown whether higher doses of platelets confer more benefit in correcting TIC, while avoiding (micro)thrombi formation and subsequently organ failure.

OBJECTIVES. To examine the effect of high (PLT:FFP:RBC in a ratio of 2:1:1) versus standard (PLT:FFP:RBC in a ratio of 1:1:1) PLT transfusion ratio on product use, correction of TIC and organ damage in a rat trauma and hemorrhagic shock model.

METHODS. Blood products were made using syngeneic donor rats according to national blood bank standards. Sprague Dawley rats were mechanically ventilated and traumatized by crush injury to both intestines and liver and by a femur fracture, followed by exsanguination until a MAP of 40 mmHg (~30% of circulating volume). Then, rats were randomized to receive resuscitation with high or standard PLT dose until a MAP of 60 mmHg was reached. Monitoring was done with a cannula in the carotid artery. Blood samples were taken for biochemical assessment and coagulation

assays by ROTEM. Organs were harvested for histopathological analysis. Data are median (IQR).

RESULTS. Mortality rate was 19%, yielding n=5 in the standard and n=8 in the high PLT dose group. All rats were shocked with a base excess of -6,4 (-18,2 - -4,3) in standard vs -5,1 (-9,5 - -3,6) in high PLT group (p=0,6). The volume of transfusion needed to reach the pretargetted MAP was lower in the group receiving high PLT dose compared to the standard, albeit not statistically significant (2,5 (0,9 - 4,3) vs 7,2 (2,4 - 10,0) ml, p=0,054). Transfusion with a high PLT dose resulted in higher EXTEM CA5 compared to the standard after 120 min (55,5 (52,2 - 58,8) vs 47,0 (43,0 - 49,0) mm, p< 0,001), while FIBTEM CA5 did not differ between groups, indicating improved functional platelet activity. Transaminases and creatinine levels were similar between groups. Also, histopathology did not show any differences.

CONCLUSIONS. In this model, a high PLT dose was more effective in treating TIC, with a trend towards reduced transfusion volumes. Also, transfusion of a high PLT dose did not aggravate organ damage. These results indicate that a higher PLT dose might be a feasible treatment option in hemorrhaging trauma patients for the correction of coagulopathy.

Perioperative risk factors of deteriorating lung oxygenation after cardiac surgery

H. Taenaka, A. Uchiyama, Y. Fujino
Osaka University Graduate School of Medicine, Department of Anesthesiology and Intensive Care Medicine, Suita-shi, Japan
Correspondence: H. Taenaka
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0683

INTRODUCTION. Deteriorating lung oxygenation is one of popular causes of prolonged mechanical ventilation after cardiac surgery. Recognizing risk factors of deteriorated lung oxygenation allow us to improve postoperative respiratory management and reduce postoperative complications.

OBJECTIVES. The aim of this study is to clarify risk factors of deteriorating lung oxygenation after cardiac surgery.

METHODS. After institutional review board approval, we retrospectively reviewed patients' records of all adult patients who admitted to our ICU and received planned extubation after cardiac

surgery between December 2016 and November 2017. We divided the patients into two groups according to ratio of an arterial partial pressure of oxygen by fraction of inspired oxygen (PF) at the admission to ICU. The threshold of deteriorated lung oxygenation was defined as 250 mmHg of PF. We compared perioperative data between the two groups. A multivariate logistic analysis was performed to identify independent risk factors for deteriorating lung oxygenation.

RESULTS. In enrolled 226 patients, 36 patients (15.9%) were classified into group with deteriorated lung oxygenation (Group L). The other patients were classified into Group N. In Group L, body mass index (BMI) was higher, operation time was longer, and mean pulmonary arterial pressure (mPAP) and central venous pressure at the admission were higher than those in Group N (25.1±4.4 vs 22.5±3.2 kg/m^2; p< 0.01, 332±99 vs 297±95 min; p=0.04, 23.1±5.3 vs 20.4±4.6 mmHg; p< 0.01, and 10.4±3.1 vs 8.8±2.6 mmHg; p< 0.01). However, mPAP just before the extubation were not different between two groups (19.6 ±2.9 vs 19.4±4 mmHg; p=0.78). Duration of mechanical ventilation and ICU stay of Group L were longer than those of Group N (37.8±43.8 vs 14.3±16.8 h; p< 0.01, and 5.5±4.4 vs 3.8±3.2 days; p=0.01). Multivariate logistic analysis showed that larger BMI (odds ratio [OR] per kg/m^2 1.21; 95% confidence interval [CI] 1.08-1.35, p< 0.01) and higher mPAP at the admission (OR per mmHg 1.14, 95%CI 1.05-1.24, p< 0.01) were risk factors for deteriorating lung oxygenation.

CONCLUSIONS. Larger BMI and higher mPAP at the admission of ICU were risk factors for deteriorating lung oxygenation after cardiac surgery.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0684

OBJECTIVES. To know the characteristics, surgical indication, mortality rate and re-entry of the patients surgically treated in our Adult Congenital Heart Disease Unit. Know factors associated with death and hospital readmission in these patients.

MATERIAL AND METHODS. Retrospective cohort study, which included all adult patients (over 16 years of age) undergoing surgery for congenital heart disease in our unit from January 2012 to December 2017. Re-entry was defined as non-elective hospitalization after the discharge from cardiac surgery and patients with loss of follow-up were discarded.

RESULTS. A total of 91 patients were intervened, mean age 37.2 ± 17.2 years, being 43.7% women. The mean time of extracorporeal circulation was 118.8 ± 67 minutes and clamping 71.3 ± 45.4 minutes. The mortality rate was 8.5% and the readmission rate was 15.5%, with an average time from discharge of 9.5 ± 9.5 months, the most common causes being cardiac (atrial fibrillation, heart failure and valvular leaks) and infectious. Regarding the surgical indications, 20% corresponded to aortic pathology, 23% to interatrial communication (of any type), 20% to pathology of the outflow tract of the right ventricle, and 37% classified as other congenital heart diseases. According to bivariate analysis, patients with severe pulmonary hypertension (p < 0.001, Chi2 13.05), those with more than 2 previous cardiovascular surgery interventions (p = 0.023, Chi2 5.202) and RACHS-1 scale of 4 (p = 0.022 Ji 5,245). On the other hand, patients with a history of atrial fibrillation were associated with a higher probability of admission (p = 0.008, Chi2 6.98).

CONCLUSIONS. The most frequent causes of re-entry in patients undergoing cardiac surgery in adults with congenital heart disease are AF, heart failure and valvular leaks. The presence of severe pulmonary hypertension, RACHS-1 of 4 or patients with more than 2 cardiac surgeries could be predictors of mortality. Despite long CPB times due to technical complexity, the mortality rate is similar to that of non-congenital cardiac surgery.

Statins prevent bleeding in patients undergoing myocardial revascularization surgery

M.D. Fernández Zamora[1], M.J. Chaparro[1], V. Olea[1], L. Olivencia[2], A. Gordillo-Brenes[3], R. Hinojosa Pérez[4], E. Curiel-Balsera[1], ARIAM ANDALUCIA

Correspondence: M.D. Fernández Zamora
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0685

OBJECTIVES. To analyze whether patients treated with statins before undergoing coronary artery bypass surgery present a lower bleeding rate, reoperation for bleeding and transfusion of blood products than patients who have not been previously treated with statins.

METHODS. Observational, prospective and multicenter study of patients in the ARIAM Andalusia registry of cardiac surgery who underwent CABG between 2010 and 2017. Clinical epidemiological variables of the patients have been analyzed, as well as the complications derived from the bleeding occurred during the immediate postoperative period. Likewise, the transfusions received in the ICU have been analyzed. The variables are presented as mean and standard deviation or absolute number and percentage. Chi-square and t-student tests were used according to need. For the multivariate analysis, binary logistic regression has been used. Max alpha error of 5% has been used.

RESULTS. 3218 patients were analyzed, 82.7% men. The average age was 63 ± 35.8 years. Dyslipidemia (66.9%) and diabetes (51%) were the most frequent antecedents. A total of 2,552 patients were being treated with statins prior to surgery (79.3%). Up to 929 patients (28.9%) did not require any transfusion, red blood cells in 26.5%, platelets in 15.6% and plasma in 4.8%. The reoperation rate due to bleeding was 2.8% (89 patients). In patients treated with statins it was 2.4% and in the others it was 4.1% (p = 0.023). Regarding the transfusion of blood products, we did not find differences in the red blood cells (27.7% in patients with statins versus 25.6%) but we did so in platelet transfusion (6.1 versus 8.6%) p = 0.042 and plasma (7.8% vs 11.4%) p = 0.009. The multivariate analysis maintained the protective effect of statins in terms of reintervention due to bleeding after adjusting for EuroScore, extracorporeal circulation time and taking antiplatelet drugs or anticoagulants in the 24 hours prior to surgery OR 0.554 IC 95% (0.361-0.976).

CONCLUSIONS. Patients undergoing treatment with statins prior to myocardial revascularization surgery have a lower rate of reoperation due to bleeding and less need for transfusion of plasma and platelets.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0686

OBJECTIVES. To describe and compare mortality and prognostic scores in patients with infective endocarditis (IE) depending the valve affected: native vs. prosthetic.

METHODS. Observational, prospective and cohort study. We included patients with IE from January 2008 to December 2017 who needed surgery and were admitted to the ICU of a third level hospital. We collected demographic variables, type of valvular surgery (emergency or elective), doses of amines at admission (classified into two groups: low doses < 0.3 mcg/ kg/ hr and moderate doses > 0.3 mcg/ kg/ hr) and microbiological results. We collected also analytical data at admission (PCR and leukocytes) and we calculated prognostic scores at admission (SOFA and APACHE II). Descriptive statiscal analysis was performed, presenting the qualitative variables as frequencies and percentages, and quantitative as mean (+/- SD) or median (interquartile range ICR) depending its distribution. We use chi square for bivariate analysis of qualitative variables.

RESULTS. We included 107 patients with EI, 88 (82,1 %)were native valve (NV) and 19 (17,8 %) prosthetic valve (PV). Median age in NV was 59 years (51- 60) and 67 (48-69) in PV. A total of 69 patients (78,4%) were males in native group and 13 (68,4%) in prosthetic. Emergency surgery occurs in 37 cases (42,5%) among NV and in 14 (73,7%) in PV with a significant relation(p= 0.021).

S. Epidermidis was the most common infecting microorganisms, in both NV and PV (14,8% and 42,1% respectively) followed by methicillin-sensitive Staphylococci (11,4% vs. and 15,8%). 42.5% of native and 47.5% of prosthetics needed low doses of amines at admission, while 4.6% of NV and 15.8% of PV needed moderate doses with any statistical difference (p = 0.146). There was no statistical difference about SOFA and PCR between both groups (p = 0.556 and p = 0.104 respectively). There was a significant relation between leukocytes and APACHE II according the type of valve operated: leukocytes in NV were 10000mm3 / dl (7000-15000) vs. 17000mm3 / dl (13400-20000) in PV with p = 0.03. APACHE II were 8 (5-13) in NV vs. 9 (6 - 18.5) in PV with p = 0.024. Mortality rate was higher in prosthetics (11.1% NV vs. 35.3% PV) with p = 0.022.

CONCLUSIONS. Emergency surgery on prosthetic valve endocarditis is more frequent than those that occur on native valves.

Prosthetic valve endocarditis has a higher mortality rate in our series comparing with native valve endocarditis. We find a significant relation in APACHE II and leukocytes at admission between those both groups

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0687

INTRODUCTION. The effect of early surgical intervention on mortality in patients with infective endocarditis (IE) remains controversial and, in developing countries, the feasibility of early surgical access remains challenging. In addition, data on early versus late surgical intervention in intensive care setting remain sparse.

OBJECTIVES. This study investigates the complications and mortality in patients with complicated IE admitted to ICU who underwent surgical intervention

METHODS. We retrospectively evaluated case notes, echocardiographic and surgical data for all patients fulfilled definite diagnosis of IE requiring admission to ICU from 1998 to 2017. All patients undergo both transthoracic echocardiography (TTE) and transesophageal echocardiography (TOE) within 3 days on presentation. Patients were stratified according to timing of surgery - early (≤4 weeks from diagnosis) or conventional (after 4-6 weeks of antibiotic therapy). Outcome measures were length of stay and in-hospital and 30-day mortality.

RESULTS. 110 patients, with a mean age of 59.7 ± 4.1 years, were diagnosed with complicated IE, in which, 76 (69%) of them were male. A total of 51 survivors from total patients of 110 were identified. 104 patients required inotropic support and 94 patients developed multi-organ failure. 42% of the patients developed mobitz type II heart block or complete heart block. Of the 110 patients, 60 patients (mean age 60.5±2.2) underwent surgery. The most commonly affected valves were mitral (n= 38 63%) and aortic (n=22 37%). In the early surgery group (n=23), indication for intervention was uncontrollable sepsis (n=8), embolic phenomena (n=4), heart failure (n=6) and cavity seen on echocardiogram indicating abscess formation (n=5). Using multivariate analysis, patients who developed acute kidney injury prior transfer to ICU (OR 9 95% CI 1.18-23.00, P = 0.03) or echocardiographic evidence of vegetation size > 15mm (OR 7 95% CI 1.09-17.77 P = 0.03) were identified as predictors for in-patient death. Patients with early surgery had significantly shorter hospital stay (30±3 vs 46±3 days, P< 0.05). In-hospital mortality was substantially lower in the early surgery cohort (11.6% vs 16.0% P< 0.05)

CONCLUSIONS. Our study concludes that markers for severity of illness (scores and organ failure) and echocardiographic findings of vegetations size >15 mm are independent risk factors for poor prognosis and mortality. In this cohort, early surgical intervention for complicated IE appears to be associated with similar outcome to uncomplicated IE treated by conventional means. This data may challenge the misconception that early surgery should be avoided.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0688

INTRODUCTION. Treatment strategy for the management of Infective Endocarditis (IE) continues to be a debate. Although medical treatment reduced the cases of death, the mortality of IE patients is still high. Because of the limitation in medical treatment, surgical therapy has been used for the treatment in some patients with IE

OBJECTIVES. This study investigates the complications and mortality in patients with complicated IE admitted to ICU who medically treated versus surgical intervention

METHODS. We retrospectively evaluated case notes, echocardiographic and microbiological data for all patients fulfilled the modified Duke Criteria for definite diagnosis of IE requiring admission to ICU from 1998 through 2017. Patients were stratified according to patients who medically treated versus patients who underwent surgical intervention. Outcome measures were length of stay and in-hospital and 30-day mortality.

RESULTS. 110 patients, with a mean age of 59.7 ± 4.1 years, were diagnosed with complicated IE, in which, 76 (69%) of them were male. IE survivors were defined as patients who survived after being discharged from ICU and at 6 months follow up with a documented diagnosis of IE. A total of 51 survivors form total patients of 110 were identified. 104 patients required inotropic support and 94 patients developed multi-organ failure. Of the 110 patients, 60 patients (mean age 60.5±2.2) underwent surgery and the remaining were medically treated. Commonly affected valves were mitral (n= 38 63%) and aortic (n=22 37%). Biomarkers of acute infection, APACHE II as well as echocardiographic findings were analyzed. Total mortality for patients who were treated medically and those underwent surgical intervention were n=29 and n =30 respectively. Using multivariate analysis, patients who developed acute kidney injury prior transfer to ICU (OR 9 95% CI 1.18-23.00, P = 0.03) or echocardiographic evidence of vegetation size > 15mm (OR 7 95% CI 1.09-17.77 P = 0.03) were identified as predictors for in-patient death. Patients underwent surgery had comparatively shorter hospital stay (40±1, P< 0.05) compared to those treated medically (44±1 p< 0.05).

CONCLUSIONS. Our study concludes that markers for severity of illness (scores and organ failure) as well as echocardiographic findings of vegetations size >15 mm are independent risk factors for poor prognosis and mortality. In this cohort, early surgical intervention for complicated IE appears to be associated with similar outcome to uncomplicated IE treated by conventional means. This data may challenge the misconception that early surgery should be avoided.

Bleeding and need of polytransfusion in obese population who has undergone heart surgery

E. Trujillo García, J. Muñoz Bono, E. Curiel Balsera, M.D. Fernández Zamora, M. Álvarez Bueno

H. R. U de Málaga, Intensive Care, Málaga, Spain

Correspondence: E. Trujillo García

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0689

OBJECTIVE. Analysing the demographic features and the need of polytransfusion after bleeding, as well as the need of reoperation in obese population who has undergone heart surgery.

MATERIAL AND METHODS. Observational, prospective and multicentre study of all patients who have undergone heart surgery in Andalusian hospitals taking part in the ARIAM Project.

The ARIAM Heart Surgery Register defines polytransfusion as the transfusion of three packs of red blood cells. Reoperation criteria due to rebleeding in the ARIAM Register are clinical —according to drainage debit, as well as to the existence of signs of cardiac tamponade.

RESULTS. A total number of 7276 patients who had undergone heart surgery from March 2008 to July 2012 were analysed. 61.1% of the operated patients were males, their average age being 63.9±12.4 years, while 34.9% had a BMI over 30Kg/m^2 and therefore considered obese. Over 30% of the patients were smokers and over 50% showed some cardiovascular risk factor, the most frequent vascular risk factor being arterial hypertension.

According to WHO criteria, 34.9% (no=2361) of the patients were considered obese (BMI>30 Kg/m^2). Average age of the obese population was 65±11 years, 58% of them being males. The most frequent cardiovascular risk was arterial hypertension (73.6%). The

average EuroScore of this population whose BMI was over 30 kg/m^2 was 5.68+2.9, while average SAPs 3 score was 40.6±10.2.

Additionally, 68.5% of the obese patients had undergone heart valve replacement surgery, 23.5% had undergone coronary revascularization surgery, and 4.1% had undergone ascending aortic surgery. 88.7% of these surgery procedures were elective, 8.3% were acute, and 3% were emergencies.

Average time of extracorporeal surgery was 109±49 minutes, and 5.8% of the patients had previously undergone heart surgery. 13.1% of the patients showed a massive bleeding episode (defined as bleeding over 1L in the first 6 hours upon hospital admission), and 3% were reoperated within immediate post-operation time (first 24 hours after ICU admission). Some hemoderivative was transfused to 17.7% of obese patients, while 5.5% needed polytransfusion.

Regarding complications, 23.5% of the bleeding patients developed postoperative acute kidney injury. 5.6% (no=133) showed hemothorax, and 13.3% (no=314) needed mechanical ventilation (MV) for over 24 hours. Average ICU stay was 5±11 days, and hospital stay was 21±21 days. ICU death rate was 9.5% (no=205) for this population.

CONCLUSIONS. The profile of the obese patient who undergoes heart surgery is a male —65 years old, with high blood pressure, dyslipidemia, and high EuroScore and SAPs 3 scores— who undergoes operation electively for heart valve replacement with long extracorporeal time and low incidence of bleeding, polytransfusion and bleeding-related reoperation. The most frequent postoperative complication in bleeding obese patients was kidney failure.

R. U de Málaga, Málaga, Spain

Correspondence: M.D. Fernández Zamora

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0690

OBJECTIVES. To know the risk factors, the demographic characteristics, the complications and the mortality of the patients older than 70 years surgically revascularized with respect to those under 70

MATERIAL AND METHODS. Prospective observational study, from January 2010 to December 2017, of the patients collected in the ARIAM database of public hospitals in Andalusia. The group of patients < 70 years of age was compared with the group of older age. Quantitative variables are expressed as mean and SD or median and interquartile range for asymmetric variables. The qualitative variables as absolute number and percentage. Chi-square and student t-tests were used, as needed, with an alpha error < 5%. A multivariate analysis with binary logistic regression was carried out.

RESULTS. 3218 patients were collected, 82.7% were male. The mean age was 63.7 ± 9.4 years; The Euroescore was 3.56 ± 2.62. We found significant differences in ICU and hospital mortality in the group of older patients compared to the younger age group (OR 2.1 CI 95% (1.4-31) for ICU and OR mortality 2.4 IC95 % (1.7-3.3) for overall hospital mortality).

When adjusting hospital mortality by risk measured with EuroSCORE, we did not find differences between both age groups (OR 1.32

IC95% (0.92-1.91)). However, when recoding EurosCORE, subtracting the points derived from age, to avoid collinearity, the in- hospital mortality of the group of patients> 70 years, was significantly higher than that of the group of younger age OR 2.32 IC95% (1.67 -3.23).

CONCLUSIONS. Patients> 70 years of age undergoing revascularization surgery presented more complications and higher mortality than the group of younger patients in our series.

0691

Post-operative follow-up of patients who underwent surgery for congenital cardiopathies of adults in the ICU

M.D. Fernández Zamora[1], I. Navarrete-Espinosa[2], E. Curiel-Balsera[1], J. Muñoz-Bono[1], J. Cano-Nieto[2]
[1]H. R. U de Málaga, Medicina Intensiva, Málaga, Spain; [2]H. R. U de Málaga, Cardiología, Málaga, Spain
Correspondence: M.D. Fernández Zamora
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0691

OBJECTIVES. To know the risk factors, the demographic characteristics, the type of surgery, the complications and the mortality of the patients intervened of congenital cardiopathy of the adult admitted in our unit.

MATERIAL AND METHODS. Prospective observational study of patients registered in the ARIAM database from January 2012 to December 2017 in our unit. Quantitative variables are presented as mean ± standard deviation and qualitative variables as absolute numbers and percentages.

RESULTS. A total of 53 patients were collected, of which 56.6% were men, 43.3% were women. The average age is 40.2 ± 17.6. The Euroescore was 4.6 ± 2.3. 37.7% of the patients had undergone some cardiac surgery previously.

43.4% did not present cardiovascular risk factors. 57% were in functional grade I of NYHA, 34.7% in II, 6.1% in III and 2% in IV. They presented moderate-severe PHT after 13.2%. The preoperative diagnosis was CIA 35.8%, CIV 11.3%, Fallot 9.4%, Pulmonary stenosis 5.7%, Transposition of large vessels 3.8%, other 6%.

The CEC time was 121.8 ± 63.9 and the clamping time was 80.8 ± 48.15. 35.8% required vasoactive support and 34% transfusion of blood products.

47.2% did not present postoperative complications, 15% presented bleeding> 1l and 3 patients (5.7%) were reoperated.

The mortality rate was 7.54%, one patient died in the operating room and 3 in the ICU..

CONCLUSIONS. Patients undergoing Cogenital Heart Disease in adulthood present few associated comorbidities, mostly intervening in a good functional degree. They require long extracorporeal surgery times due to their greater complexity. They present few complications and mortality is lower than that recorded in global cardiac surgery in our unit.

Analysis of the impact of early surgery on in-hospital mortality in patients with infective endocarditis

S. Escalona Rodriguez[1], N. Palomo López[1], G. Rivera Rubiales[2], Y. Corcia Palomo[1], L. Martin-Villen[1]
[1]Hospital Universitario Virgen del Rocío, Critical Care, Seville, Spain; [2]Hospital Quirón Sagrado Corazón, Seville, Spain
Correspondence: S. Escalona Rodriguez
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0692

INTRODUCTION. Despite medical and surgical advances in the last decades, infective endocarditis (IE) is a pathology with high mortality, which often requires admission to the Intensive Care Unit (ICU). Currently, surgery is the treatment of choice in more than 50% of patients.

OBJECTIVES. Description and analysis of the impact of early surgery on in-hospital mortality of infective endocarditis admitted to the ICU of a tertiary care hospital.

METHODS. A prospective observational study of IE patients admitted to the ICU who required early valve surgery, during the 2008-2017 period in a third-level hospital. Demographic data, valve disease, the clinical (renal failure, the need of renal replacement therapy (RRT), the dose of amines) and laboratory parameters (leukocytes, C-reactive protein (CRP)), SOFA and APACHE II scores and mortality on ICU and in-hospital were collected. Doses of noradrenaline greater or equal than 0.3 mcg/kg/min were considered high and less than 0.3 mcg/kg/min were considered low. Qualitative variables were described by absolute number and frequency and quantitative variables by median and interquartile range. For the analysis of the data, Chi-square statistical test was used for qualitative variables and U Mann Whitney was used for the quantitative ones.

RESULTS. Fifty patients were included, with a median age of 65 years (52-73), of whom 39 were males (78%). The most affected valve was the aortic valve constituting 56% of the cases. APACHE II on admission was 10 (7-15) and SOFA score was 4 (2-7). On admission, 7 patients (14%) had high doses of noradrenaline. Acute renal damage developed in 31 cases (63.3%), of which 8 (16.3%) required RRT. The PCR was 72 mg/l (18-141) and leukocytes 13.000 /mm^3 (8.150-18.050) on admission. In-hospital mortality was 34%.

No statistically significant association was observed between leukocyte levels (p = 0.208), CRP (p = 0.303), high amines dose (p = 0.086) and prognostic scores (p = 0.143 p = 0.177 for SOFA and APACHE II, respectively) with mortality. However, a significant association was found between the acute renal damage that required RRT with global mortality (p = 0.047).

CONCLUSIONS. Acute renal damage was the most frequent complication in patients admitted to the ICU. Moreover, the renal failure that required RRT was significantly associated with higher in-hospital mortality.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0693

INTRODUCTION. Delirium is a frequent and serious adverse event after cardiac surgery. It results from the interplay of a wide range of precipitating noxious events, predisposing preoperative and perioperative risk factors that affect cardiac surgery patients, especially the vulnerable old ones. Treatment of delirium is difficult., so prevention is critical. It is of great importance to identify patients at risk for developing delirium, in order to focus on preventive strategies.

OBJECTIVES. To determine the incidence of delirium, its association with dexmedetomidine and specific preoperative risk factors in cardiac surgery patients.

METHODS. This prospective cohort interventional study enrolled patients between 1/2015-12/2016 at the Heart Centre of a Tertiary Care University Hospital. 164 patients, undergoing elective and urgent cardiac surgery with cardiopulmonary bypass, were evaluated. Specific data on patients were collected preoperatively and perioperatively. Cognitive function and impairment, cerebrovascular and neurological pathology, psychiatric and depression disease information were collected at baseline from medical history, interview and the Montreal Assessment test (1). Dexmedetomidine, a highly selective a2-adrenoceptor agonist, was administered in high risk patients during the early postoperative period. High risk were characterized patients of age 65 years, with smoking and alcohol abuse habits, urgent surgery, cognitive impairment, psychiatric illness, history of stroke, cerebrovascular and neurological disease and chronic obstructive pulmonary patients (n=75). Postoperative delirium was assessed using the Confusion

Assessment Method for Intensive Care Unit or conventional Confusion Assessment Method after discharge from ICU, starting on 1st post-surgery day at 12-h intervals.

RESULTS. Prevalence of postoperative delirium in total sample (n=164) was 17 patients (10.4%). In dexmedetomidine group (n=75) was 12 (16%), and non-dexmedetomidine group (n=89) 5 patients (5.6%). Age [OR 1.08; 95%CI (1.02-1.15); p 0.008], preoperative cognitive impairment [OR 5.05; 95% CI (1.76-14.50); p 0.001] and dexmedetomidine [OR 3.20; 95%CI (1.07-9.55); p 0.30] were associated with an increased risk for delirium. Dexmedetomidine increased delirium 3.20 times. Further analysis of five risk factors within groups revealed no difference.

CONCLUSIONS. Delirium is a common complication after cardiac surgery. Dexmedetomidine didn't decrease postoperative delirium. However, preoperative assessment may identify high risk patients who would benefit from delirium prevention strategies, because of increased baseline risk for delirium.

Dialysis-dependent chronic renal failure is a risk factor for post-cardiac surgery vasoplegic syndrome

S. Masafumi, T. Shimozono, D. Kawakami, J. Ito, Y. Asaka, H. Ueta, H. Mima, R. Seo, T. Koyama
Kobe City Medical Center General Hospital, Kobe, Japan
Correspondence: S. Masafumi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0694

INTRODUCTION. Vasoplegic syndrome (VS) frequently occurs in the early postoperative period in patients who have undergone cardiac surgery. VS is characterized by severe hypotension, with decreased systemic vascular resistance, and increased requirements for vasopressive agents despite adequate cardiac output. Suggested risk factors include preoperative use of angiotensin-converting enzyme (ACE) inhibitors and beta blockers, low left ventricular ejection fraction (LVEF), and use ofcardiopulmonary bypass (CPB), as well as other factors with a discordant correlation. Chronic hemodialysishas not been identified as a VS risk factor, but we would expect a higher incidence of VS in chronic hemodialysis patients undergoing cardiac surgery.

OBJECTIVES. Our goal was to determine whether chronic hemodialysisis a risk factor for VS after cardiac surgery.

METHODS. This retrospective, single-center study included 563 patients who had undergonecardiac surgery in a tertiary hospital between 2015 and 2016. The patients were divided into 2 groups according to whether they were chronic hemodialysis-dependent. We assessed the incidence of postoperative VS in the 2 groups.

RESULTS. Preoperative patient characteristics were not significantly different between the 2 groups. The chronic hemodialysis group included 41 patients (7.3%) and the control group included 521 patients (92.7%). The median age was 73 years ([IQR] 65-78 years). The study included all coronary artery bypass graft procedures (on-pump N = 101 and off-pump N = 37), all valvular procedures (N = 259), and large vascular surgery with use of CPB (N = 149). A total of 66 patients (10%) developed VS. The incidence of VS was higher (P < 0.0001) in the chronic hemodialysis group (39.0%) than in the control group (9.6%). Age and known risk factors for VS (preoperative use of ACE inhibitors and beta blockers, low LVEF, and CPB time >180 minutes) were entered into multivariate regression analysis, and chronic hemodialysis was found to be an independent predictor of post-cardiac surgery VS (OR:6.33, 95%CI, 3.08-12.79).

CONCLUSIONS. Chronic hemodialysis-dependent renal failure was an independent risk factor for post-cardiac surgery VS.

Evolution of ruptured abdominal aortic aneurysm treatment: a ten-year overview in ICU

O. Moreno Romero, A. Carranza Pinel, M. Muñoz Garach
Hospital Universitario San Cecilio, Granada, Spain
Correspondence: O. Moreno Romero
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0695

INTRODUCTION. In the treatment of the Acute Aortic Syndromes the endovascular approach has become an alternative over open surgery, specially in the ruptured Abdominal Aortic Aneurysm (rAAA), with the publication of the results of three clinical trials (AJAX, ECAR and IMPROVE), though with conflicting data.

OBJECTIVES. First, to describe the characteristics of patients with rAAA, surgical procedure used, anesthetic technic and their complications in ICU in a ten-year period (2007-2017). Second, to analyse the risk factor related to mortality.

METHODS. Retrospective observational study of patients admitted in our ICU (18 beds) with rAAA from 2007 to 2017. Variables registered: age, sex, Apache II, hemodynamic instability prior to surgery (No vasopressors, norepinefrine< 0.5 mcg/kg/h or >0.5 mcg/kg/h), lactate level (normal or >3 mg/dl), need for transfusion, need for sedation and orotracheal intubation, surgical procedure (open, endovascular), anesthesia (general or local), complications after surgery (renal replacement therapy, abdominal compartment syndrome and reintervention) and ICU mortality. Describe the risk factors mortality-related.

RESULTS. 29 patients. Mean age 76±9.5. 73% male. Mean Apache II 21% (RIQ: 17-26). Instability prior to surgery: 12 (41.5%) with no vasopressors, 10 (34.5%) with norepinefrine (< 0.5 mcg/kg/h) and 7 (24%) with high norepinefrine. Lactate leves >3mg/dl in 25% (86%). In 4 patients (12.3%) blood transfusion was needed before surgery, in 27 (93%) was administered during or after surgery. In 3 patients (10.3%) no transfusion was needed at all. 7 patients (24%) needed early prior sedation and intubation due to instability. Technics: 5 (17.25%) open surgery directly (all in the first 5 years) and 24 (82.75%) endovascular, from these, 7 (29%) were converted to open surgery at the same time (mostly due to abdominal bleeding and high abdominal pressure). General anesthesia in 18 (62%) patients (including the 7 converted to open surgery) and local in 11 (38%). Complications after surgery: 10 (34.5%) needed renal replacement therapy, 8 (27.58%) developed abdominal compartment syndrome and 4 of them (50%) had decompressive surgery. ICU mortality: 19 (65.5%) patients. From these, 15 (78.9%) had general anesthesia: 5 open surgery, 4 endovascular reconverted and 6 totally endovascular. 4 (21%) patients with local anesthesia. Mortality-related risk factos: general anesthesia OR 2.45 (CI95:1.37-2.89 and p 0.035), open surgery OR 3.5 (CI95: 2.25-5.2 and p 0.018) and hemodynamic instability OR 2.27 (CI95: 1.18-2.65 and p 0.04).

CONCLUSIONS. In the last years, even before the publication of the relevant clinical trials (AJAX, ECAR and IMPROVE) the tendance has been to perform endovascular treatment, if possible, derived from higher positive outcomes. In our study, although it's a small sample, the mortality-related risks were general anesthesia, open surgery and hemodynamic instability.

Analysis of effective responders by inhaled nitric oxide in adult cardiovascular surgery with pulmonary hypertension

H. Kamohara, K. Sagishima, N. Narimatsu, T. Kikuchi, M. Ejima, K. Tokunaga, H. Tanigawa, T. Yamamoto
Kumamoto University Hospital, Devision of Critical Care Medicine, Kumamoto, Japan
Correspondence: H. Kamohara
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0696

INTRODUCTION. Inhaled nitric oxide (iNO) was authorized in the hypoxic respiratory failure in pulmonary hypertension in the newborn ten years ago in Japan. iNO was clinically applied for pulmonary hypertension in the perioperative period of adult cardiac surgery three years ago. It remains lots of unclear points on the evaluation of responder for iNO in adult cardiac surgery(#1).

OBJECTIVES. The purpose of this study was to analyze the effective factors in the indicators of respiration and circulation by iNO, and to reveal any groups of effective patients.

METHODS. In Kumamoto university hospital for the past three years (2015.4-2018.3), it was 648 cases that entered the ICU after cardiac surgery. Twelve cases received iNO therapy in the perioperative period for pulmonary hypertension. Two cases were excluded in non-pulmonary artery catheters for this study. Mean PAP (mPAP), PVRI, mPAP/mBP, CI, Svo2, SVRI, Cathecholamin Index (CAI), PF ratio, and PEEP were used as indicators of respiration and circulation. Data were collected and analyzed for 6 hours after iNO therapy, affecting the host response in the short time. In the next, to identify iNO responded factors, we evaluated various condition of patients who had disease background and device support, such as dialysis, ventilator, and IABP. Data were analyzed using JMP statistical software.

RESULTS. The age average of is 74.7 ± 12.0 years in 10 patients who consist of 6 men and 4 female. Operation was underwent for valve replacement surgery in all cases, coronary artery graft bypass in 4 cases, and major vascular graft replacement in 1 case. The average operative time was 360 ± 160 minutes, and cardiopulmonary support was 151 ± 40 minutes. All cases was analyzed by using Wilcoxon analysis of the pared transition before and after iNO therapy. mPAP (p = 0.026), PVRI (p = 0.024), mPAP/mBP (p = 0.023.) were significantly improved after iNO therapy. Furthermore, to identify the good responders of mPAP, PVRI and mPAP/mBP by iNO therapy, we examined patients related various factors. These demonstrated that mPAP (p = 0.039) and mPAP./mBP (p = 0.031) were improved by iNO therapy in the lower PEEP Group (PEEP< 10 cmH$_2$O). Other factors (dialysis, left cardiac function, or diabetes mellitus etc.) were not observed significantly.

CONCLUSIONS. Inhald NO improved pulmonary artey pressure and vascular resistance in the perioperative of adult cardiovascular surgery. Respiratory management in the lower PEEP could demonstrate good responder of iNO therapy, but offsetting in the higher group.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0697

INTRODUCTION. Pulmonary hypertension (PH) and heart disease are leading causes of morbidity and mortality after pneumonectomy [1,2]. The pathophysiology is still poorly understood. Overflow in pulmonary arteries is suspected to play a key role.

OBJECTIVES. To investigate *in vivo* cardiopulmonary consequences of pneumonectomy in rats, and *in vitro* in a model of human stretched cells reproducing overflow.

METHODS. Sixty *Sprague-Dawley* male rats randomly underwent either a right pneumonectomy (PN group) or sham surgery (sham group). Ten rats/group were respectively sacrificed on postoperative days 3, 7, 28 (D3, D7, D28). Cardiopulmonary alterations were investigated by echocardiographic, hemodynamic, gravimetric and histological analyses. *In vitro*, the shear stress of overflow was reproduced using a *FlexCell Tension System™* cyclic strain on cultured human pulmonary endothelial cells (P-ECs) to investigate the impact on pulmonary artery smooth muscle cell (PA-SMC) growth. Data were expressed as mean ±SEM. Two-way ANOVAs were performed. P-values < 0.05 were considered significant.

RESULTS. Mean pulmonary arterial pressure gradually increased in the PN group to reach 35±3 mmHg on D28, *vs.* 18±2 in sham (p< 0.01), likewise the proportion of muscularized distal pulmonary arteries, 83 ±1% *vs.* 5±1% respectively (p< 0.001), related to an *in situ* PA-SMC proliferation (*Fig1*). In accordance with PH, the right ventricle (RV) area and RV lateral wall thickness doubled in the PN group on D28 (1.2±0.1 *vs.* 0.5±0.1 in sham, p< 0.001). The left ventricle ejection fraction decreased in the PN group on D7 and D28, respectively 66±3% *vs.* 74±2% (p< 0.05) and 65±2% *vs.* 78±2% in sham (p< 0.01), while RV function was maintained over time (*Fig2*). RV hypertrophy was confirmed by the Fulton index (RV/[LV+ septum] weight) increased on D3, D7 and D28 in PN groups, respectively 39±1%, 43±2% and 55±3% (p< 0.05 *vs.* sham). An early and transient pulmonary œdema was found on D3, as the wet/dry ratio increased to 5.5±0.1 *vs.* 4.9±0.1 in sham (p< 0.001). *In vitro*, the human PA-SMC proliferation was larger when stimulated with stretched P-EC media *vs.* non-stretched P-EC media (p< 0.05) highlighting the deregulation of the P-EC paracrine function (*Fig3*).

CONCLUSIONS. Pneumonectomy in rats induced moderate PH with a proportional right heart remodelling. The overflow appears to play a key role by altering the crosstalk between P-ECs and PA- SMCs leading to pulmonary vascular remodelling. Once the growth factors are identified, our model will be instrumental for future studies of targeted therapies to prevent the post-pneumonectomy syndrome or other high-blood-flow-related PH syndromes.

Interaction of ventricular arterial coupling in postoperative aortic valve replacement

I. Lima Lucero, J. Garduño Lopez, E. Bucio Reta, F. Baranda Tovar, R. Barajas Campos, M. Hernández Márquez, G. Mendoza Copa
Mexican Cardiology National Institute 'Ignacio Chávez', Surgical Intensive Care Unit, Mexico City, Mexico
Correspondence: I. Lima Lucero
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0698

INTRODUCTION. The interaction between the left ventricle and arterial system, termed usually ventricular - arterial coupling is recognized nowadays as a key determinant of global cardiovascular performance. The cardiovascular system is structured to provide adequate pressure and flow to the tissues all time. The analysis of this interaction requires left ventricle and arterial system to be described in similar mathematical terms. The ventricular- arterial coupling is commonly calculated by the ratio of effective arterial elastance (EA), as measure of afterload, to left ventricle end systolic elastance (EES), a relatively load independent measure of left ventricle chamber performance. Ventricular arterial coupling is approximately equal to 1.0, that means left ventricle and arterial system are optimally coupled to produce stroke work. When this ratio is < 1.0, the stroke work remains close to optimal values, but when the ratio is > 1.0 the stroke work significantly falls and the left ventricle becomes less efficient.

In cardiac surgery ventricular - arterial coupling has being studied in patient with aortic stenosis where the ratio was increased in patients with symptoms or heart failure due to increased EA and reduces EES. In the postoperative of aortic valve replacement the ventricular arterial coupling wasn´t be studied.

OBJECTIVES.
1. Evaluate the ventricular - arterial coupling using EA/EES ratio in patients with aortic valve replacement.
2. Determine if the ventricular arterial coupling is related with the length of stay in the ICU and state at ICU discharge.

METHODS. The cohort consisted in 56 patients older than 18 years; post operate of aortic valve replacement from the surgical ICU of the Mexican Cardiology Institute "Ignacio Chávez". EA and EES were estimated noninvasively. Patients were divided in those with ratio < 0.6, ratio between 0.7 to 1.4, and ratio > 1.4.

RESULTS. EA was increased in those patients whom had longer ICU stay (OR 1.3, IC 95% 1.1 - 1.5 p< 0.05) but mortality at discharge was not different (0.98 IC 95% 0.76 - 1.45 p= 0.24). Most of patients had EES alteration less than 0.7 (68%).

CONCLUSIONS. Ventricular arterial coupling is a good reference of interaction between the left ventricle and the arterial system. In aortic valve surgery this ratio is related with length of ICU stay. The most common alteration was decreased EES maybe by extra circulatory bypass.

Correspondence: T. Maes
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0699

INTRODUCTION. Patients undergoing coronary artery bypass graft (CABG) surgery receive plentiful intravenous (IV) fluid therapy in the immediate postoperative phase [1]. Standardized protocols are

generally provided for maintenance and replacement fluids. However, non-intended fluid sources (analgesics, sedative drugs, antibiotics and oral solutions) are not always considered within the IV fluid planning. The impact of such additional fluid load on total fluid intake is poorly documented.

OBJECTIVES. We examined the ratios between maintenance (M) fluids, resuscitation (R) fluids and unintended (U) fluids in elective CABG patients during their first and second postoperative day in ICU.

METHODS. Data on IV and oral fluid administration and fluid output were retrospectively collected from the electronic medical file of consecutive CABG patients. Fluid prescriptions included routine fluid administration, any additional fluid, and blood products. The ratios of M, R, and U fluids to total fluid intake were calculated for the first and second day in ICU. The composition of M, R and U fluids was documented. Values are given as means ± standard deviation.

RESULTS. Sixty patients (46 male, 14 female; age 67 ± 11 years; body weight 81 ± 17kg) were included. Mean overall (IV + oral) fluid administration was 2922 ± 831 ml on day 1 and 3128 ± 695 ml on day 2. M fluids represented 1177 ± 310 ml (40%) and 1197 ± 394ml (38%), R fluids 847 ± 542 ml (29%) and 338 ± 559 ml (11%), U fluids 898 ± 469 ml (31%) and 1593 ± 643ml (51%) respectively on day 1 and day 2. Fifty-four percent of the R fluids consisted of additionally prescribed fluid, 33% being synthetic colloids and 13% transfusions. U fluids consisted of oral intake (51%), paracetamol (22%), other medication (22%), and antibiotics (5%). Mean oral intake increased almost four-fold on the second day, while fluids used for analgesia remained stable with a mean of 247 ± 93 ml on day 1 and 302 ± 119 ml on day 2.

CONCLUSION. Postoperative prescription of M fluids in combination with R fluids is responsible for most of the observed total effective fluid load during the first two days of ICU stay after elective CABG surgery. U fluid load is high and primarily determined by administration of medication on the first day and oral intake on the second day. Our study suggests further research on the impact of lowering M fluid load and/or withholding unnecessary U fluids on patient outcome [2].

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0700

INTRODUCTION. We previously reported high prevalence of alcohol misuse in critically ill patients admitted to the intensive care unit (ICU). However, a higher rate of low-risk admission diagnoses was reported in patients with alcohol misuse resulting in a better 1-year survival. (1). Some studies suggest alcoholic patients having higher long-term mortality after ICU admission but only a few recent studies focus on the associations between the alcohol misuse and the causes of death (2-3).

OBJECTIVES. The aim was to compare the long-term mortality and the causes of death in patients with or without alcohol misuse admitted to ICU.

METHODS. This retrospective study included all non-trauma admissions to ICU in Oulu University Hospital, Finland between January 1, 2014 and December 31, 2014. The electronic medical records and the ICU patient data management system were used to obtain data of the history of alcohol misuse, alcohol-related health problems, and

ICU treatment profile. The patients were followed until the end of the year 2017 and the Statistics Finland provided the causes of death of non-survivors.

RESULTS. From a total of 847 patients 329 (38.8%) died during the 3-year follow-up. In the alcohol misuse group 90 patients (33.6%) died compared with the 239 patients (41.3%) in the non-alcohol group (*p*=0.033). The non-survivors in the alcohol misuse group were younger and more often men (Table 1). In the alcohol misuse group, the location of death was more often home than institution, and the post mortem examination was performed more frequently. The most common cause of death in total was cardiovascular causes (Table 2). The patients in the alcohol misuse group died more often due to traumas or alcohol-related causes compared with the non-alcohol group. Cardiovascular causes and malignancies were more common causes of death in the non-alcohol group.

CONCLUSIONS According to our data, the patients with alcohol-related health problems have better 3-year survival after ICU admission compared with the non-alcoholic patients. The patients with alcohol misuse die younger and more often due to traumas or alcohol-related causes.

Length of stay in the intensive care unit (ICU) and associated critical care outcomes: aretrospective review of 12,975 patients

S. Weetman, A. Myers, T. Samuels
Surrey and Sussex Healthcare NHS Trust, Critical Care Medicine, Redhill, United Kingdom
Correspondence: S. Weetman
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0701

INTRODUCTION. Previous work has suggested that length of stay (LOS) in critical care is not an independent risk factor for in-hospital mortality (1). Understanding the relationship between LOS and ICU mortality facilitates improved communication with patients, relatives and other healthcare professionals in terms of managing expectations.

OBJECTIVES.

1. To examine the relationship between increasing length of stay and mortality rate.

2. To investigate how the length of stay in days is related to timing of death in ICU.

METHODS. Records were reviewed for all patients admitted to a busy mixed medical and surgical UK district general hospital critical care unit with 16 level two and three beds during a 25 year period. Length of stay in ICU, day of death in ICU and all cause in-hospital mortality data was collected for 12975 patients.

RESULTS. The overall ICU mortality for patients was 18.8%. Figure 1 shows ICU mortality against length of stay. Excluding those admitted for less than 24 hours or more than three weeks, there is a weak positive correlation between ICU mortality prevalence and length of stay with an R^2 of 0.4887. Figure 2 shows total number of deaths on ICU against length of stay. There is a strong negative exponential relationship between number of deaths on ICU and length of stay, with most deaths occurring within the first 2 days.

CONCLUSIONS. Increasing length of stay on ICU is weakly associated with a higher mortality rate. This is in keeping with previous studies (2) and may represent the physiological burden of prolonged ICU stays and the associated morbidity. The majority of ICU deaths happen in the first 2 days of admission, but the mortality prevalence at this time is only 16.7%. Patients admitted for less than 48hrs tend to either recover quickly from their acute illness and are subsequently discharged or die. Only a minority go on to have a prolonged ICU length of stay and these have an associated higher mortality. The data helps us to understand the likely outcomes for patients admitted to ICU for prolonged periods, but ultimately, individual patients need to be managed on a case-by-case basis.

One-year follow up of high-risk patients admitted in ICU after elective surgery from 2011 to 2016

G. Nattino[1], A. Forastieri Molinari[1], G. Macchi[2], M. Ticozzi[2], E.R. Vascotto[1]

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0702

INTRODUCTION. In literature, there is growing interest in assessing the usefulness of post-operative monitoring in intensive care unit

(ICU) after elective surgery and in evaluating patient long-term outcomes following ICU admission.

OBJECTIVES. The objective of this study was to analyse data and follow-up at one year after discharge in high-risk patients admitted in ICU for observation after uncomplicated elective surgery.

METHODS. In this study, we analysed five years data, from 2011 to 2016, about patients admitted in our general secondary ICU for postoperative monitoring after elective surgery, cardio and neuro surgery excluded, in our tertiary major acute hospital. Of all patients admitted we distinguished two groups considering recovery in ICU less or greater than 48 hours, then we compared the characteristics of the two groups (type of surgery, organ dysfunction, SOFA, SAPS II) in order to assess whether some could be predictive of prolonged stay. Finally, we analysed, the long-term outcome in group with complicated post-operative course. Information were abstracted from our electronic medical record and from registry of follow up service, active from 2011, for clinical and psychological evaluations one year after discharge from ICU. Data were analysed using univariate analysis, a p value < 0.01 was considered significant.

RESULTS. From 2011 to 2016, 614 patients were admitted in ICU for post-operative monitoring after elective surgery. 49 patients (8%) stayed more than 48 hours in ICU. Characteristics of the groups are summaries in table 1. We identified patients that had a greater statistically significant risk of stay more than 48 hours in ICU: patients presenting 2 organ dysfunctions (odds ratio 5.2) and patients presenting an infection at ICU admission (odds ratio 4.2). No correlation was found regarding the type of surgery. Patients with ICU stay longer than 72 hours had a greater incidence of complications occurred (p < 0.01). Despite all, the two groups had no differences in ICU and in hospital mortality. Figure 1 shows the Extended Glasgow Outcome Scale (GOSE) at one-year follow-up for the "complicated" group, only 10 patients (20%) had a good recovery (GOSE > 7).

CONCLUSIONS. Our analysis reveals that high-risk patients after elective surgery with 2 organ dysfunctions or presenting an infection appear to be at a greater risk for postoperative complications. Postoperative monitoring in ICU seems to be useful and effective in treating early postoperative complications (not different mortality in two groups). At 1-year follow-up disability analysis, only 10 (20%) of the complicated group patients had a Good Recovery (GOSE >7), this will need some considerations on the role of surgery. Further studies and analyses are needed.

ICU follow-up clinic: which patients benefit the most?

A.R. Costa, I. Furtado, M. Capuepue, W. Mphandi, M.J. Malheiro, S. Pinto, J. Ribeiro, A.F. Cardoso, F. Seabra-Pereira, T. Cardoso
Centro Hospitalar do Porto, Unidade de Cuidados Intensivos Polivalente, Porto, Portugal

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0704

INTRODUCTION. The Intensive Care Unit (ICU) follow-up clinic has been increasingly recognized as a quality indicator. Previous published works have selected patients for follow-up based on the intensity of organ support (as more than 48h of invasive mechanical ventilation or duration of sedation). However, until now, no clear criteria have been defined regarding which patients should be observed at the ICU follow-up clinic.

OBJECTIVE. To identify which patients benefit from an ICU follow-up appointment based on their clinical characteristics and/or level of ICU support.

METHODS. Prospective cohort study of all patients discharged from mixed a ICU at a tertiary care hospital between 1st January of 2015 and 31st December 2016, who attended the ICU follow-up clinic. The need of further referral after observation was defined as the dependent variable.

RESULTS. During the study period, 280 patients were observed at the follow-up clinic, 70 (25%) needed further referral, namely to: 29 (41%) to psychology/psychiatry, 27 (39%) to surgical specialties, 17
(24%) to medical specialties, 6 (9%) to rehabilitation therapy and 3 (4%) to the chronic pain clinic. There was no significant association of further referral at the outpatient clinic with gender, age, Charlson comorbidity score index, previous comorbidities (neurologic or psychiatric), type of admission (medical or surgical), reason for ICU admission like post-cardio-pulmonary arrest, head injury, acute neurologic condition, acute psychiatric disease; level of intensive care (sedation, paralysis, invasive mechanical ventilation, vasopressor, inotropic or renal replacement therapy), the occurrence of agitation or delirium or ICU length of stay. Only time until observation in the follow-up clinic revealed to be significantly associated with the need for further referral (OR - 0.828, per increase month) (table 1).

CONCLUSION. A significant proportion of patients benefit from attending the out-patient clinic. There wasn't a significant association with patients' comorbidities, personal history or level of ICU treatment but patients evaluated earlier seem to benefit most. Therefore, we suggest observing all patients discharged from the at the follow-up clinic.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0705

INTRODUCTION. Intensive care units (ICU) have become places where high scientific and technical quality medical care is provided. However, such care must also be accompanied by special attention and treatment of patients and their families.

OBJECTIVES. To determine the level of satisfaction among both the relatives of surviving patients and the relatives of patients that died and to measure the level of satisfaction among the ICU discharged patients themselves.

METHODS.

Design: multicenter prospective, descriptive observational study carried out during 3-month period in 2017 involving ICUs in different hospitals in Spain.

Population of the study:
1) competent patients discharged from ICU after a stay of over 24 hours,
2) their relatives, and
3) Families of patients who died in ICU after, at least, 24 hours of admission.

Measurement Instrument: Family satisfaction in the Intensive Care Unit (FS -ICU 24) in its Spanish language version for relatives, and an adaptation of it for patients.

Statistical analysis: means, standard deviations, frequency tables, rates and proportions to describe patients, respondents and their answers. Conversion of the answers from a likert scale to a numerical one was necessary to apply the required statistical calculations.

RESULTS. 52 ICUs participated in the study, belonging to 40 hospitals in 23 Spanish provinces (figure 1). A total of 4914 surveys (2430 questionnaires of relatives of surviving patients, 2342 surveys of patients and 142 questionnaires of family members of non-surviving patients (Figure 2).

Patient characteristics: 2858 patients. Mean age 62,22±15,40 years. 1822 men. Mean APACHE II score 15,16±7,81 (n=2431) SOFA score 4,24±3,46 (n=2228).

38,80% needed mechanical ventilation. Mean length of ICU stay 6,65 ±10,30 days.

Most of patients were admitted to ICU with a medical diagnosis (coronary syndrome, sepsis, trauma and pneumonia).

Family characteristics: 2430 families were asked. Mean age 50,76 ±13,91 years. Mostly were women. The most frequent kinship: wives (27,3%) followed by daughters (24,1%).

Satisfaction: The majority of respondents were satisfied with overall care and with decision making process (89,13±10,15 and 80,43±13,34 for family of surviving patients, 91,02±10,12 and 83,25±13,88 for patients, and 86,09±13,84 and 77,67±14,97 for relatives of non-surviving patients).

When examining individual item scores, satisfaction with the waiting room atmosphere and communication items scored lowest. For patients, items that measured ICU environment were scored lowest.

Families of survivors were more satisfied with their ICU experience than the families of non-survivors.

CONCLUSIONS. Overall, most families were satisfied with care provided to them and their critically ill relative. Patients satisfaction was high too. However, opportunities for improvement exist.

Be interested in knowing the opinions of the patient and his family will allow us to provide a better care and a quality medicine adapted to their specific needs.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0706

INTRODUCTION. Status epilepticus (SE) is a common neurological emergency associated with a high morbidity and mortality. Predicting the prognosis in critically ill patients with SE through the use of appropriate scoring systems could be useful.

OBJECTIVES. The purpose of this study was to assess the predictive prognostic value of different severity scoring systems used in critically ill patients and those more specific for SE.

METHODS. Study of a cohort of patients admitted to ICU with a diagnosis of SE between the years 2015-2016. Analysis of the standard scoring systems used in ICU (APACHE II, SOFA) and severity scores specifically designed for status epilepticus: STESS (Status Epilepticus Severity Score) and EMSE (Epidemiology-based Mortality score in Status Epilepticus).

Descriptive analysis was expressed as mean (SD) or median (IQR) for continuous variables and percentages for categorical data. An unfavourable prognosis was considered as a score $\geq$ 4 points on the Rankin scale (severe disability or death). Through a simple logistic regression analysis each score was associated to the prognosis and the effect was estimated by its corresponding Odds Ratio (OR).

The ability of the scoring systems to discriminate prognosis was assessed using the area under the receiver operating characteristic curve (AUROC). Estimation of their calibration was established through the Hosmer-Lemeshow goodness of fit test.

RESULTS. Fifty-eight patients, age 55±18 years, 53% male and 34% high comorbidity (Charlson Comorbidity Index $\geq$ 3 points). The epileptic seizures occurred out-of-hospital in 57% of patients, 83% were generalized tonic-clonic and 35% presented a structural lesion in computed tomography imaging. Benzodiazepines (78%) and Levetiracetam (36%) were the antiepileptic drugs most commonly used. The level of consciousness on initial evaluation was GCS of 6±3 points and 76% of patients required endotracheal intubation and mechanical ventilation (2 days, 1-9). Severity scores: APACHE II 17 ±10 points, SOFA 5±3 points, STESS 3±1 points and EMSE 61±33 points. The ICU stay was 3 days (2-7) and hospital stay was 11 days (6-18). The prognosis was unfavourable in 29% of patients, with a 14% of mortality.

All severity scores analysed, except the STESS score, were good predictors of unfavourable prognosis: **APACHE II** (OR 1.13; 95% CI 1.02-1.25), **SOFA** (OR 1.38; 95% CI 1.09-1.75), **STESS** (OR 1.73; 95% CI 0.98-3.04) and **EMSE** (OR 1.03; 95% CI 1.01-1.06).

Using the AUROC curves, the **APACHE II score** was found to be the most reliable scoring system to discriminate unfavourable prognosis (AUROC 0.81, 95% CI 0.65-0.95), with a good calibration ability (Chi-squared 4.09, p=0.84) (Table 1).

CONCLUSIONS. Our data show that the prognostic scoring systems specifically designed for status epilepticus were not superior to the

INTRODUCTION. Frailty is associated with worse hospital outcomes but in critically ill patients is not well known yet.

OBJECTIVE. To estimate the prevalence of frailty in patients > 65 years of age admitted to the intensive care unit (ICU) and its impact on mortality and long-term functional outcomes.

MATERIAL AND METHODS. Multicentric prospective observational study in patients> 65 years admitted to the ICU, between June 2016 and October 2017. Frailty was measured according to FRAIL scale (based on the Frailty Phenotype). Demographic variables, disability and cognitive function (Barthel index [BI], Lawton index [LI]) were registered upon admission, and at 1 and 6 months after discharge from the ICU. Data are presented as proportions and means and standard deviation. They are compared using the Chi-square test for categorical variables and by parametric (Student's t test). A p value < 0.05 was considered statistically significant. The approval of the corresponding Ethical Committees and the informed consent of the participating subjects were obtained.

RESULTS. 132 patients, 86 (65.2%) non frail and 46 frail (34.9%). Frail patients, compared with nonfrail patients: age 78.8 ± 7.2 versus 78.6 ± 6.4 years (p = 0.43), males 43.8% versus 56.3% (p = 0.10),, SOFA 4.7 ± 2.9 versus 4.6 ± 2.9 (p = 0.75), APACHE II 17.8 ± 7 versus 16.1 ± 6.6 (p = 0.13), need for mechanical ventilation (VM) 33.3% versus 66.7% (p = 0.75), days of VM 5.6 ± 15 versus 4.3 ± 8.1 (p = 0.57), ICU length of stay 11.2 ± 16 versus 11.3 ± 16.3 (p = 0.38), ICU mortality 54.5% versus 45.5% (p = 0.15), mortality 1 month 62.5% versus 37.5% (p = 0.04), mortality 6 months 55.6% versus 44.4% (p = 0.03), BI admission 74.1 ± 27.3 versus 96.8 ± 7.5 (p = 0.001), BI 1 month 50.7 ± 38.7 versus 72.6 ± 35.7 (p = 0.001), BI 6 months 46 ± 43.4 versus 68.5 ± 40.9 (p = 0.003), LI admission 4.4 ± 2.7 versus 5.9 ± 2 (p = 0.001), LI 1 month 2.6 ± 2.7 versus 4.1 ± 2.9 (p = 0.02), LI 6 months 2.7 ± 3.1 versus 4.2 ± 3.1 (p = 0.03).

CONCLUSIONS. Critically ill frail patients have worse functional situation upon ICU admission, similar ICU outcomes and mortality, and higher mortality after ICU discharge.

INTRODUCTION. Stress-strain relationship of the lung parenchymal tissue depends on the elastic property of the alveolar walls, the surface tension characteristics and the alveolar geometry. This nonlinear relationship is described in Newtonian equation of motion. Low tidal volume is the only ventilation strategy that has been shown to improve mortality but there is still a huge gap to its application.

OBJECTIVES. To assess the airway pressures' discriminative properties in the prediction of mortality in non-COPD medical ICU mechanically ventilated (MV) patients.

METHODS. A retrospective charts' review of MV patients admitted to a medical ICU of Farhat Hached hospital from November 2015 to February 2018. Were collected patients' characteristics at admission and respective airway pressures (Peak, plateau, driving and intrinsic PEEP) at admission and at day 4. High pressure ratio (HPR) is defined as the number of days spent with high pressures : Peak ≥40 and/or plateau ≥30; and/or driving pressure ≥15 and/or; intrinsic PEEP ≥6; divided by length of stay) and outcomes were recorded. Univariate and multivariate regression analyses were performed to identify factors independently associated with mortality. ROC curves were used to check for the discriminative properties of the significant factors.

RESULTS. 304 mechanically ventilated patients were collected within the study period. 199(65%) were non-COPD patients. They were 50±18years aged ; ARDS, 25(12.6%) ; pneumonia, 14(7%) Pulmonary edema, 11(5.52%) ; SAPS II, 35.1±15.7 ; pH, 7.31±0.14 ; PCO2, 42.4±19.9 ; PaO2/FiO2, 210.6±109.2mmHg ; MV duration, 8.9±9.4days ; tracheostomy, 18(9%) ; length of stay, 10±10days. Mortality, 114(57%).

Mean airway pressures were respectively at admission : Peak, plateau, driving, intrinsic PEEP; 30.2±8.9, 20.2±6.2, 13.4±4.8, 2.7±4.2cmH2O and at day 4: 30.9±8.9, 20.8±6.9, 13.7±5.7, 2.4±3.8 cmH2O. HPR, 0.25±0.35.

Univariate analysis showed an association between the following factors and ICU mortality: At admission, plateau (21.3±5.9 vs 18.1±6.2cmH2O, p=0.005), driving (13.9±5.2 vs 12.7±4.02cmH2O, p=0.003). At day 4, Peak (34.2±8.8 vs 26.2±6.7cmH2O, p≤10^{-3}), plateau (23.3±7.1 vs 17.1±4.8cmH2O, p≤10^{-3}), driving (14.8±6.5 vs 12.1±3.9cmH2O, p=0.003). HPR (0.4±0.4 vs 0.1±0.2, p≤10^{-3}). Multivariate logistic regression analysis identified Peak at day 4 (OR, 1.12 ; 95%CI, [1.03-1.22] ; p=0.006), plateau at day 4 (OR, 1.12 ; 95%CI, [1.01-1.25] ; p=0.04) and HPR (OR, 6.92 ; 95%CI, [1.1-43.6] ; p=0.04), as factors independently associated with mortality.

Respective ROC AUC for Peak, plateau and HPR confirmed interesting discriminative properties 0.81, 0.78, 0.72 to predict mortality.

CONCLUSIONS. The present study reflecting the daily practice in the management of MV non-COPD patients demonstrated that high airway pressures and/or persistent elevated airway pressures account at least in part in mortality.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0709

INTRODUCTION. Acute respiratory failure (ARF) is the most common cause that critically ill patients require intensive care unit (ICU) admission. Although some patients have favorable outcomes and early ICU discharges, others require a prolonged ICU stay. However, some complications such as muscle weakness, pressure ulcers, device-associated infections, pulmonary embolism, and delirium can develop during a prolonged ICU stay. Moreover, a prolonged ICU stay can be associated with increased hospital mortality, increased morbidity and hospital stay and poor long-term prognosis. In addition, critically ill patients with a prolonged ICU stay will require a greater than average medical resources.

OBJECTIVES. We aimed to investigate outcomes and identify risk factors of patients with ARF who required a prolonged ICU stay over 21 days

METHODS. In this retrospective study, all patients with ARF who required a prolonged ICU stay (≥ 21 days) in Chi Mei medical center between January 2000 and December 2017 were identified. The primary outcome was in-hospital mortality.

RESULTS. Totally 1371 patients were collected. Lung infection (n = 494, 36.0%) was the most common cause of prolonged ICU stays, followed by decompensated heart disease (n = 143, 10.4%), neuromuscular disease (n = 204, 14.9%), infection other than pneumonia (n = 279, 20.4%) , decompensated gastrointestinal disease (n = 179,13.1%), post operation (n = 35, 2.6%) and others (n = 37, 2.6%). The in-hospital mortality rate was 54.4% (n = 746). After using multivariable logistic regression, we identified five risk factors of death: age > 75 years (adjusted odds ratio (AOR), 1.36, 95% confidence interval (CI), 1.06-1.76, p = 0.017), ICU stay for more than 28 days (AOR, 1.48, 95% CI, 1.17-1.86, p = 0.001), APACHE II score ≥ 25 (AOR, 1.47, 95% CI, 1.15-1.87, p = 0.02), decompensated gastrointestinal disease (AOR, 2.95, 95% CI, 2.01-4.32, p = 0.002), and hemodialysis (AOR, 3.14, 95% CI, 2.44-4.05, p < 0.001). The mortality rate was up to 85.7% for patients with five risk factors.

CONCLUSIONS. The prognosis of patients with ARF who required a prolonged ICU stay were poor. Age > 75 years, an ICU stay > 28 days, an APACHE II score ≥ 25, decompensated gastrointestinal disease, and hemodialysis were associated with a high risk of in-hospital mortality. It should help us better predict outcomes for such patients.

OBJECTIVES. To observe the incidence and mortality of MOF in septic patients in Catalonia.

MATERIALS AND METHODS. Data was collected from the CatSalut morbidity database (hospitals, primary care, emergency room..) between the years 2005 to 2016.
To identify sepsis cases, the methodology described by Angus, consisitng on cross referencing the diagnosis of acute infection with multiple organ failure, was implemented (Crit Care Med 2001;29:1303-101).

RESULTS. During the analysis period, 224.396 cases were detected. The annual incidence rate of sepsis in Catalonia has increased from 1.6 (2005) to 3.9 (2016) cases per 1000 inhabitants per year. There are differences in the incidence rates adjusted by age, sex, morbidity and income level. The most frequent source of infection was the genitourinary tract (37.4%), respiratory (32.7%) and digestive (11.5%). The mean stay decreased from 19.2 to 13.4 days (p < 0.0001), the need for organ support techniques from 33.1% to 19.4% (p < 0.0001) and in-hospital mortality from 25.7% to 16.8% (p < 0.0001). 79.3% presented failure of a single organ, 15.6% of two organs and 5.1% of three or more, with a mortality of 15.7, 32.9 and 53.3% respectively. The most frequent organ failure is renal (54.6%), followed by cardiovascular (24%), altered mental status (18.7%), respiratory failure (16.5%), hematologic (10%) and liver failure (1%). The organ failure associated with a higher mortality was liver failure (55.3%) followed by cardiovascular (37.4%), respiratory (35.9%) and renal failure (20.6%). There was a statistically significant reduction in the mortality of septic patients with cardiovascular failure (46% to 29%, p < 0.0001), respiratory failure (40% to 25%, p < 0.0001) and renal failure (25% to 18%, p < 0.0001).

CONCLUSIONS. The incidence of sepsis in Catalonia has increased from 1.6 to 3.9 cases per 1000 inhabitants per year. The percentage of patients with MOF has remained stable, around 21.7%. The need for organ support techniques has been reduced by 37.5%, as well as the hospital stay by 46% and the associated mortality by 34.6%. A statistically significant reduction in the mortality of septic patients is observed in patients with cardiovascular (46% to 29%, p < 0.0001), respiratory (40% to 25%, p < 0.0001) and renal failure (25% to 18%, p < 0.0001).

INTRODUCTION. Patients (pts) with malignancies comprise about 15% of the total Intensive Care Unit (ICU) population in Europe and their outcome is comparable to this of the rest ICU population.

OBJECTIVES. To compare the outcomes of oncology vs non-oncology ICU pts.

METHODS. All 267 oncology pts admitted to the ICU of the General and Oncology Hospital "Agioi Anargiroi" between January 2013 and October 2017 were retrospectively assessed in terms of ICU mortality and compared to the rest of ICU population (575pts). Categorical

variables are presented as N(%) and continuous variables as mean ± SD or median (IR). Comparisons between groups were assessed by the chi square (x2) test, student´s t test or the Mann Whitney U test. The risk of death was estimated by the Kaplan-Meier (log rank) test and the Cox's regression method. Statistical analysis was performed using SPSS version 21.0 (SPSS, Inc., Chicago, Illinois).

RESULTS. All except two oncology pts had solid tumors, 67 (26%) had a medical reason of admission (respiratory failure 19, septic shock 16, pulmonary edema 7, ARDS 5) and from the 200 pts admitted after a sursical procedure, 22 (11%) underwent emergency surgery. The mortality of the oncology pts was lower than the non oncology pts (18% vs 31%, p< 0.001), nevertheless the difference was reversed when pts were categorised according the type of admission (medical and surgical). The clinical characteristics of the pts are shown in table.
The higher risk of dying was noted in medical-oncology pts, followed by medical, surgical and surgical-oncology pt (picture).
Cox proportional hazards regression analysis showed that medical oncology pts had a dying hazard ratio >2 times bigger than medical pts (Exp(B) 2.218, 95%CI 1,266-3,886, P = 0.005).

CONCLUSIONS. Oncology pts represented almost 32% of ICU population and comprised of heterogeneous populations with different outcomes. The mortality of cancer pts with a medical reason for admission was significantly higher compared to the rest medical pts, even though the severity of illness according the APACHE and SOFA scores was similar between the two groups.

OBJECTIVE. Getting to know the survival rate and the functional state of patients diagnosed with sepsis after 18 months in patients who had sepsis during the years 2015 and 2016 in Catalonia.

MATERIALS AND METHODS. Data was extracted from the CatSalut database, a base that integrates exhaustive information of the resident population in Catalonia. Between the years 2015 and 2016, all cases of sepsis in Catalonia (54.671) were identified through the methodology described by Angus [Crit Care Med 2011; 29: 1303-101] and tracking was performed up to 18 months from diagnosis.

RESULTS. 15 days after the sepsis diagnose, the overall mortality is 14.6%. 29.7% of the patients are still hospitalized and 13.4% are institutionalized in a social health center or a nursing home. 42.3% have been discharged home.

By the third month of sepsis diagnose, the overall mortality is 30.1%. 3.3% are still hospitalized and 12.8% are admitted to a healthcare center. 53.8% are home.

18 months from diagnose the overall mortality is 48.6%. A remaining 0.7% are still hospitalized and 6.9% are institutionalized in a social health center or a residence. 43.8% are at home.

CONCLUSIONS. Although the mortality of sepsis has decreased in recent years, it continues to be a serious health problem in our society. Almost half of the patients who suffered from sepsis between the years 2015 and 2016 died during the course of the 18 months following diagnosis.

Of the patients who survived, 15% were still not functionally independent and needed health resources at 18 months of diagnosis.

Any intervention to improve detection, diagnosis or treatment could directly influence the morbidity and mortality of these patients in the long term.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0713

INTRODUCTION. After being discharged from an intensive care unit (ICU), patients face different challenges and difficulties. Some develop cognitive, psychiatric and /or physical disability after treatment in ICU, which is now recognized as post intensive care syndrome (PICS). The ICU follow-up clinic is crucial for the global assessment of these patients' population and to prompt the orientation of specific and/or new problems.

OBJECTIVE. To evaluate the post intensive care syndrome (PICS) in a mixed ICU population.

METHODS. Prospective cohort study of all patients discharged from a mixed ICU between 1st January of 2015 and 31st December 2016, observed at the follow-up clinic. PICS is defined as new or worsening impairment in physical (ICU-acquired neuromuscular weakness), cognitive (thinking and judgment), and mental health status after critical illness and persisting beyond discharge from the acute care setting.

RESULTS. Of the 793 patients discharged from the ICU: 351 died before follow-up and 442 were invited to the clinic, of these, 280 (63%) attended (figure 1). Patients seen at the clinic had a mean age of 58±16 years old and 62% were male. Charlson co-morbidity index was 3 (1-5). A medical condition motivated ICU admission in 188 patients (67%) *vs.* 92 (33%) surgical patients. Regarding organ support: 209 (75%) patients were mechanically ventilated, 201 (72%) sedated, 134 (48%) needed vasopressors, 11 (4%) neuromuscular blockage and 7 (2.5%) required dialysis. Agitation and delirium were present in 22 (8%) and 31 (11%) patients, respectively. Median ICU length of stay was 5 (2-9) days. Patients were evaluated at the follow-up clinic 3 (2-5) months after ICU discharge: 116 were professionally active before ICU admission, of these 80 (69%) hadn't yet returned to usual professional activity at follow-up. At follow-up 83 patients (34%) presented with new complaints and 65 (23%) needed further specific referral. Regarding performance status, most patients were independent previous to ICU admission with a Karnofsky performance scale of 100 (90-100). At follow-up, the Karnofsky scale decreased in 159 (57%) patients, to a median of 80 (70-90). Furthermore, 24 (9%) patients presented moderate to severe depression (Beck Depression Inventory) and 22 (8%) risk for post-traumatic stress disorder (PTSD - 14). Regarding the five domains of quality of life (EQ-5D), 128 patients (55%) had mobility difficulties, 76 (33%) had problems with self-care, 147 (63%) with usual activities, 118 (51%) referred pain and 108 (47%) anxiety/depression.

CONCLUSIONS. PICS has a high prevalence among ICU survivors. Prevention during ICU stay is crucial and prompt recognition at the follow-up clinic is essential to provide multidisciplinary support to the patients and family.

Incidence and risk factors associated with ocular surface disorders in ventilated ICU patients and impact of protocolised eye care

V. Bhagat, M.S. Khan, N.R. Prabu, A.P. Kulkarni, J.V. Divatia, S.N. Myatra
Tata Memorial Hospital, Mumbai, India
Correspondence: V. Bhagat
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0714

INTRODUCTION. Critically ill patients frequently have poor eyelid closure, reduced tear production and a reduced protective blink reflex due to sedation during mechanical ventilation. ICU patients are more susceptible to infections and decreased venous return may lead to conjunctival chemosis. These factors increase the risk of ocular surface disorders (OSDs) which may lead to adverse long-term outcome such as leucoma, astigmatism and decreased vision, if untreated.

OBJECTIVES.
Primary objective: To identify the incidence of OSDs in sedated, ventilated patients in our ICU with the current eye care practices and the impact of a protocolised eye care on the incidence and outcome
Secondary objective: To determine the correlation of ICU-acquired risk factors with the incidence of OSDs in ventilated patients

METHODS. This study was done in our mixed medical surgical ICU. It had a prospective cohort design and was done as before and after study in two phases (Phase I and Phase II). In phase I existing eye care practices were continued and incidence of OSDs was noted. In phase II protocolised eye care was implemented (Included routine eye care plus nurses education, identification of eye warning sign, special ointment plus eye shield in lagophthalmos and precautions during suction). All patients who were mechanically ventilated for > 24 hours were included in the study. Patients with pre-existing OSDs were excluded. Study completion criteria was development of OSD, discharge from ICU or death. In both phases an Ophthalmologist (study investigator) examined the eyes at baseline and every 72 hours using a hand-held slit-lamp. Patients diagnosed with OSD were referred to another ophthalmologist for management. An independent ophthalmologist re-assessed the eye findings by the study investigator on the same day to check for bias. At the end of study interobserver agreement was calculated

RESULTS. Total number of patients included was 125 (phase I: 62 and phase II: 63). There was no difference in demographic variables in both the groups at baseline. Incidence of OSD was higher in phase I with 64.5% of patients (40/62) developing OSD while in phase II it was 34.9%(22/63). This difference in incidence was significant (p=0.001). Interobserver agreement among the study investigator and the independent ophthalmologist was very good in both the phases (Kappa index in phase I 0.927, in phase II 0.908) On univariate and multivariate analysis, increased depth of sedation (p = 0.0001) and absence of protocolised eye care (p=0.001) were associated with higher incidence of OSDs.

CONCLUSIONS. Incidence of Ocular surface disorders (OSDs) is high in sedated ventilated patients in ICU. Protocolised eye care helps in decreasing the incidence of OSDs. Increased depth of sedation and absence of protocolised eye care are independent risk factors associated with OSDs in ICU.

Multicenter binational investigation of necrotizing soft tissue infections from diagnosis and to six months: patient and family perspective. A presentation of three sub-studies

I. Egerod[1], A.E. Andersson[2], A.-M. Fagerdahl[3], V.E. Knudsen[1]
[1]Copenhagen University Hospital Rigshospitalet, Intensive Care Unit, Copenhagen O, Denmark; [2]Sahlgrenska Academy, Institute of Health Care Sciences, Gothenburg, Sweden; [3]Karolinska Institute, Department of Clinical Science and Education, Stockholm, Sweden
Correspondence: I. Egerod
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0715

INTRODUCTION. Necrotizing soft tissue infection (NSTI) is a serious and potentially life-threatening condition requiring immediate diagnosis and treatment. The prevalence is about 1-2 in 100.000. The disease progresses rapidly, but little is known of the human cost for patient and family.

OBJECTIVES. The objective was through a series of studies to explore the experience of patient and family during the acute stage of NSTI and up to six months.

METHODS. The overall design was qualitative using different sources and methods. The presented sub-studies are based on six-month interviews with patients (n=27) and family (n=23) from university hospitals in Denmark and Sweden. The study was embedded in the EU funded study INFECT with the goal of advancing understanding of pathophysiological mechanisms, prognosis and diagnosis of NSTI. The present study P-INFECT reflects the patient and family perspective. Patient and public involvement was applied in constructing the study.

RESULTS. We present the results from sub-studies 2-4 based on 50 interviews with patients infected at the extremities, groin/genitals and lower abdomen, face and throat, and back, and family.
Study 2: Focus on patient and family during the acute stage. We identified three main themes: Duration of disease onset, Stages of symptom severity, and Types of treatment and delay. Although most studies describe NSTI as a rapidly progressive disease, our data suggest a slow, moderate or rapid disease onset. We identified three stages of disease severity: lingering, progressive and unbearable symptoms. Immediate attention was required when symptoms became unbearable. Types of treatment delay were: patient-related, primary care related and hospital related, suggesting modifiable factors.
Study 3: Focus on family caregiver the first 6 months. Three chronological themes emerged: In ICU: coping with illness and intensive care, At the ward: coping with injury and post-intensive care, and At home: coping with recovery and new home life. We concluded that challenges facing family caregivers are still under-recognized. Families and stakeholders need access to information and planned care to bridge knowledge gap across care environments.
Study 4: Focus on the patient the first 6 months. The main themes described transitions: From Fear to Gratitude, From First Class to Economy, and From Relief to Challenge. Fear of infections and disfigurement were particular to NSTI.

CONCLUSIONS. The most surprising and novel finding was the description of varying onset of disease and symptom progression that might facilitate diagnosis, particularly unbearable pain that must not be overlooked. Many responses to NSTI were generic to ICU, but some issues were particular to NSTI. We recommend the provision of more information on what to expect with NSTI and improved transitional care between ICU and the ward to alleviate feelings of abandonment and uncertainty.

Nurse perception of support for young children during their visit of an adult beloved one in the ICU

E.M. van Hooff, L.F. Roggeveen, H.J.S. de Grooth, A. van Galen, A.R.J. Girbes
VU University Medical Center, Amsterdam, Netherlands
Correspondence: E.M. van Hooff
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0716

INTRODUCTION. Several authors have described the experiences of children visiting the adult ICU and most studies report it positive, provided they are well prepared and guided[1]. Kean showed that often restrictions are imposed to children to visit a patient in the adult ICU[2]. Little is known about the opinion of nurses on this topic.
OBJECTIVES. The main objective of this study is to describe practices of children visiting in the adult ICU in the Netherlands from a nurse perspective.
METHODS. We performed a multicenter survey among ICU nurses in the Netherlands with questions focused on quality and quantity of visits of young children, aged 4-12 years. For content validity, the questions focused on quality were first processed by an open peer review. Each answer was divided into distinct categories. Data were described using descriptive statistics.
RESULTS. Fifty-two centers were included in this study and 3629 nurses were invited to participate in the study and 13,650 answers were reviewed by 5 investigators. The overall survey response rate was 30%. All ICU's allow in general children to visit patients in the ICU. Determining factors to refuse children to visit their adult beloved ones are a combination of medical reasons such as an infection risk to the patient or child, as well as psychological reasons. Nurses aged between 25 to 36 years, believe that it is very important to allow children to visit a beloved one in the ICU. However, with increasing age, nurses deemed this as less important (P=< 0.01). The majority of the nurses prepare a child for a visit. When a child is prepared for a visit, 38% use education material, 42% provide explanations about the setting. Seventy-eight percent of all nurses believe that the responsibility to prepare a child for an adult ICU visit lies within the nursing staff, while a high percentage of them (46%) emphasizes the joint responsibility of nurses, doctors and the parents. Less than 1% of the nurses consider this the sole responsibility of the doctor. The survey showed that the guidance of children was mainly based on intuition and practical experiences.
CONCLUSIONS. There is a general acceptance of the right of young children to visit their beloved one in the ICU. Most nurses consider it the responsibility of the nurse to prepare this visit. There appears to be no standard rules and guidelines for preparing young children to visit the ICU. Further research is needed to develop appropriate support interventions both for the children and for the nursing staff.

Nursing model of end of life care: from curative interventions to palliative measures

J.M. Latour[1], R. Endacott[1,2], J. Benbenishty[3]
[1]University of Plymouth, School of Nursing and Midwifery, Faculty of Health and Human Sciences, Plymouth, United Kingdom; [2]Monash University, Melbourne, Australia; [3]Hadassah Hebrew University Medical Center, Jerusalem, Israel
Correspondence: J. Benbenishty
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0717

INTRODUCTION. The care transition from curative interventions to palliative care is complex processes in treating intensive care patients. Identifying critical junctures of patients in transition from active to palliative care are challenges for healthcare staff and families. Decision making within this transition has three stages: diagnosis of dying; managing end of life (EOL) consensus; and pushing the door open to facilitate family grieving.

OBJECTIVES. To examine EOL situations in intensive care and demonstrate the integral work of nurses in calming, organizing and making sense of ICU life and death conditions by providing and adhering to an EOL care bundle.
METHODS. In order to encapsulate the range of evidence, a scoping review method was chosen. PubMed, Embase, CINAHL, and PsycINFO were used. Studies were included if they were conducted in Europe, all languages were considered. Thematic analysis was used identifying major themes to classify and understand transition to EOL care practices in Europe.
RESULTS. The identified and developed model demonstrates incorporation of critical junctures in the transition from curative interventions to palliative measures into EOL intensive care bundle. The theoretical framework structure combines complex steps needed for this transition in ICU end of life setting.The EOL ICU bundle, identified and developed by the current evidence, includes seven critical junctures (CJ):
CJ 1: Time Out - Redefine goals from ICU treatment to comfort care.
CJ 2: Shared Decisions - Communication with team, patient and family- investment in gaining family, team and if possible patient involvement in decision making on transition of goals of care.
CJ 3: Consensus - nurse mediation between families is usually successful in resolving conflicts until resolution has occurred.
CJ 4: Comfort Care - focusing on providing symptom management and comfort care.
CJ 5: Family Care- Directing practice towards the family is imperative for the impending death to be perceived as a quality experience.
CJ 6: Deceased Care- A good death means to promote interventions ensuring the right to physical integrity, preserving the good body image and ensuring dignity.
CJ 7: Follow-Up- After the death of a loved one, bereaved family members may still face questions or issues and may leave the ICU unsatisfied or confused.
CONCLUSIONS. This EOL care bundle provides synthesis of evidence for interventions during transition from curative treatment and care to EOL care. It provides a scientific practical tool for ICU clinicians. The evidence is presented for each juncture and the end of life trajectory as an intervention bundle.

Embedding clinical research into the culture of clinical practice within the critical care environment

S. Bean, K. Burt, J. Paddle
Royal Cornwall Hospital Trust, Critical Care Unit, Truro Cornwall, United Kingdom
Correspondence: S. Bean
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0718

INTRODUCTION. Conducting clinical research in the acute Critical Care area can be challenging. Patients often lack autonomous decision making capacity, there is high morbidity and mortality, along with short time frames to recruit and initiate interventions. Critical Care is a fast-paced, acute care environment where the unpredictable nature of the patients' condition potentially results with a sudden deterioration in illness (1).
OBJECTIVES. Using a multicentre randomised controlled trial conducted in 24 acute NHS hospitals throughout the UK (2) as an example we aim to highlight some methods used to embed research into our clinical practice demonstrating the importance of a positive research culture in the clinical setting.
METHODS. We looked to develop a multi-faceted approach to promoting Critical Care research in the ICU (3). All staff undertook a short e-learning course designed by the trial team. Three nurses undertook further training which concentrated on the values and aspects of the trial. This focused on the psychological effects of critical illness and how to recognise psychological stress and ways to create a less stressful environment. We produced regular newsletters and notice board displays with each month being used to highlight a different aspect of psychological wellbeing. We developed a toolbox

talk to ensure that all staff were confident in using the CAM ICU tool. Regular discussions and updates of the trial were presented at monthly clinical governance meetings and anonymized patient experiences were used to reflect on the trial's relevance to our patient group.

RESULTS. The benefits of collaborative working on Critical Care trials can be advantageous for the clinical team, research teams and more importantly the patient. As a result of collaborative working we recruited to target and also recruited the 1st and 1000th patient to the trial. Our uptake to the online training was above 95%. We noticed an improved compliance with CAM ICU scoring and also received positive feedback from the clinical team.

CONCLUSIONS. Critical Care is a complex field of medicine with clinical research in the Critical Care unit being challenging. Clinical research therefore should not be seen as a stand-alone activity. Embedding research into the culture of clinical practice, along with a collaborative working environment, can enrich patient outcomes ultimately providing new medical knowledge, therapies and technologies to optimise patient care.

Patients' experience regarding night time and sleep deprivation in ICU: results from a metasynthesis

M. Danielis, E. Mattiussi, M. Vidoni, L. Venuti, A. Palese
Faculty of Nursing, Udine, Italy
Correspondence: M. Danielis
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0719

INTRODUCTION. In Intensive Care Unit (ICU) patients are frequently subjected to sleep deprivation or to poor quality of sleep. Despite its relevant for short and late term outcomes, to our best knowledge no systematic review with regard patient experience on sleep in ICU have been published. Understanding their experience may help in developing interventions aimed at increasing both the quality and the quantity of sleep in ICU patients.

OBJECTIVES. The general intent of this study was to advance the knowledge available by exploring the patients' perspective of night time and sleep deprivation in ICU.

METHODS. A meta-synthesis was performed. Three phases were followed: (1) conceiving the synthesis, searching and retrieving literature, (2) appraising and classifying findings, and (3) synthesizing findings into a meta-summary and a meta-synthesis. CINHAL, MEDLINE (PubMed) and Scopus were consulted. The database research yielded 1,006 initial citations. Of those, 683 were for first excluded; 18 studies were duplicates. On the remaining 305 studies, only eight studies were selected on the basis of the title and the abstract. At the end, only seven studies met the inclusion criteria.

RESULTS. A total of 109 patients reporting their own experience. Data were collected by using interviews conducted in different times: in one study patients were interviewed in the ICU when possible, but generally all patients were interviewed after ICU discharge or immediately after hospital discharge in their homes within a variable. Three studies used a phenomenology approach, one a narrative approach, two hermeneutic approach and one a qualitative approach with semi-structured interviews. An abstraction process aiming at generating a conceptual diagram was performed. A total of 13 categories emerged categorized in five main themes: (1) *Environment* (nursing activities, acceptable sounds, frightful or disturbing sounds), (2) *Emotions and feelings* (fear/concerns, state of abandon, inexplicable insomnia), (3) *Perception of safety* (feeling to be safe/unsafe), (4) *Consequences of disease/ICU* (physical pain, time/space disorientation) and (5) *Patients' abilities* (inability to move, inability to talk). Finally, a meta-summary to calculate manifest frequency and intensity effect sizes was achieved.

CONCLUSIONS. Future qualitative research should focus on the experiences of ICUs' patients of night time and sleep deprivation for better representing this scenario. However, this metasynthesis can represent good suggestions for clinical practice because it is born from the original patients' perspectives in different cultural contexts.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0720

INTRODUCTION. Temperature management is an essential tool in critical care patients. The determination of the right temperature can provide the clinical team information to screen patients for infections or to identify and treat undesirable states of hiper or hypothermia. When available, invasive thermometers, such as pulmonary artery (PA) and vesical temperature, are reliable and can be use to monitor patients temperatures. However, many times invasive thermometers aren't being used and the medical and nurse staff must rely in non-invasive thermometers. In currently literature there isn't a consensus about accuracy and precision of methods such oral, axillary, tympanic membrane (TM), temporal artery (TA) and new methods like the Zero Heat Flux (ZHF) temperature.

OBJECTIVE. Therefore, this meta-analysis was conduct to identify the accuracy and precision of non-invasive thermometers in comparison to PA temperature.

METHODS. The review project was registered on PROSPERO (CRD42018089447). Studies were identified through a systematic search using PubMed, BVS/BIREME, EMBASE; CINAHL and WOS. Studies that compare any of the 5 non-invasive temperatures methods studied (oral, axillary, tympanic membrane, temporal artery temperature and Zero Heat Flux) with the pulmonary artery

temperature were included in this review. Election was performed by three independent researchers and included the following criteria: trials and observational studies; studies that compare PA temperature with non-invasive temperatures (oral, axillary, tympanic membrane, temporal artery and zero heat flux); studies that report the mean difference of the PA measurements and the non-invasive temperature measurements, and their standard deviation. The data were analyzed in Meta Essentials workbook. Fixed or random effects models effect model was used to derive the meta-analytic estimates. The effect measure was calculated by the standardized mean difference, all with a 95% confidence interval (CI). The heterogeneity was evaluated by the chi-square test and the I2 statistic. To explore the heterogeneity and potential factors that could modify the measure of effect, subgroup analyzes were performed for hyperthermia and hypothermia, when available data.

RESULTS. We selected 57 studies in 41 publications. The studies involved a total of 2806 and 48048 temperatures measurement (789 - oral; 4189 - axillary; 6013 - TM; 874 - TA; and 36183 - ZHF). The effect size (ES) and standard error (SE) of non-invasive methods compared with PA were: oral ES: 0.21, SE: 0.08 (CI95% 0.02 - 0.41); axillary ES: 0.35, SE: 0.06 (CI95% 0.22 - 0.47); Tympanic Membrane ES: 0.05, SE: 0.05 (CI95% -0.07 - 0.16); Temporal Artery ES: 0.22, SE: 0.26 (CI95% -0.49 - 0.93); Zero Heat Flux ES: 0.04, SE: 0.03 (CI95% -0.11 - 0.19).

CONCLUSION. The non-invasive methods showed a good clinical agreement from the PA temperature. Oral and TM were the most accurate methods and temporal artery was the least accurate one.

The impact of follow-up visits and diaries on patient outcome after ICU discharge: a descriptive and explorative study

E. Åkerman[1,2], A. Langius-Eklöf[2]
[1]Karolinska University Hospital, Perioperative Medicin and Intensive Care PMI, Stockholm, Sweden; [2]Karolinska Institute, Division of Nursing, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden
Correspondence: E. Åkerman
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0721

INTRODUCTION. Interventions such as follow-up clinics and diaries have been developed to support the patients during their recovery after ICU stay, but the evidence about impact of patients' outcome is sparse

OBJECTIVES. To explore the possible effects of ICU follow up visits and the keeping of diaries and patients´ experiences of follow-up visits and diaries after discharge from the ICU.

METHOD. Adult patients with a length of ICU stay for 24 hours or more, responded to the questionnaire 3-set 4P. The questionnaire was sent out at 2,6 and 12 months post ICU discharge. The patients outcome scores were analysed in groups depending on weather they have had /not had follow-up visits or diaries.

RESULTS. A majority of the patients experienced the follow-up-visit and the diary valuable and helpful during their recovery even if no strong effects of the follow up on physical or psychosocial problems were detected. The outcome of the survey did not show uniform results and thus, the follow-up group reported more problems in the domains Mood and Memory at 12 months. The diary group reported more problems in the domains, Change in appearance, Mood, Memory and less problems in Social life. Longer LOS was found a predictor for unfavourable scoring in the domains Change in appearance, and Memory but showed a favourable scoring in the domain Social life.

CONCLUSION. A strong overall effect of follow-up or diary on patients' outcomes were not found. However, the patients experienced that the interventions was helpful during their recovery and the results also to showed beneficial indications in social function. Thus, further exploration of ICU follow up procedures are needed in the on going process to enhance and coach the recovery of former ICU patients.

Nurse leaded intravenous (IV) team in a post surgical critical care unit: evaluation of the insertion technique of peripherally inserted central catheters (PICC)

N. Cortes Rey, S. Vecino Vazquez, M. Porteiro Sanchez
Hospital Universitario de A Coruña, Reanimation- Post Surgical Critical Care Unit, A Coruña, Spain
Correspondence: N. Cortes Rey
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0722

INTRODUCTION. Before implementing a new evidence-based (EB) protocol of selection and management of vascular access devices[1], peripheral venous capital of middle/long stay patients at the post-surgical critical care unit of University Hospital of A Coruña was frequently exhausted. Sometimes central accesses were damaged as well. In September 2015 it was created an IV Team initially constituted by 5 nurses. Progressively the team expanded to 10 nurses. All of them received training in choice and management of vascular accesses. The training for PICC insertion was performed according to WoCoVA recommendations [2](study of theory, practice in phantoms, supervised practice in real patients, insertions without tutor and finally, audit of technique). They also learnt to use a cost / effective catheter tip location system (Sherlock 3 CG©) based on study of intracavitary electrocardiography (EKG).

OBJECTIVES. To evaluate the quality of the implementation of the PICC insertion technique by the IV Team after two years of work.

METHODS. Analysis of PICC insertion data from September 2015 to 2017. Quality indicators: nº of PICC inserted with US guided punction, nº of exit site in Dawson's red zone[3], nº of catheter /vein ratio < 45%, nº of shots needed, accuracy of EKG detection system.

RESULTS. 311 PICC were successfully inserted to post-surgical critical patients. (94.22% of the total attempts). All of them were inserted with US- guided technique. 36 were inserted without tip location system (were checked by X- ray). Sherlock 3 CG system was accurate in >95% of patients without P-wave pathology. 100% of PICC had a catheter/vein ratio < 45%. Zero PICC had the exit site in Dawson's red zone. 66.7% were inserted in one shot, 23.5% in 2-3 shots and 9.8% needed more than 3 shots.

CONCLUSIONS. The IV Team has a high level of efficiency during PICC insertion. WoCoVA criteria for training is highly recommended in order to perform a safe technique. Working with an EB-protocol helps to offer high quality care. Education and practice are essential for nurses in charge of inserting and caring vascular accesses. The use of an EKG tip location system like Sherlock 3CG allows the immediate utilization of the PICC and reduces possible costs and risks of re-location in patients without P-wave pathology.

Sustainability in critical care practice

H. Baid
University of Brighton, School of Health Sciences, Brighton, United Kingdom
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0723

INTRODUCTION. The ability to maintain the resources needed to sustain high-quality, critical care practice is challenging. There are strategic plans in place for the National Health Service in England to become more sustainable [1]. However, there is minimal research into what the concept of sustainability means to practitioners working in critical care and a theoretical framework to explain processes related to sustainability and critical care is lacking.

OBJECTIVES. This research study aimed to develop a theory of sustainability in critical care practice to address the following two questions:

- How is sustainability constructed by practitioners working in critical care?
- What are the social processes involved in making sustainability a component of critical care practice?

METHODS. The qualitative research design followed Charmaz´s [2] constructivist grounded theory approach. Data were collected from in-depth, semi-structured interviews (n=11) and the participants were nurses, physiotherapists and a technician working in critical care units in the South of England.

RESULTS. The research participants viewed sustainability as maintaining necessary financial, environmental and social resources across the micro, meso and macro systems of critical care practice. Decision-making related to *satisficing* [3] was identified as the most pertinent process enabling the sustainability of critical care practice. *Satisficing* was when a decision-maker reached a satisfaction goal that quality care was given, but still sufficed within the limits of available financial, environmental and social resources. Emerging from the data was a continuum where increased *satisficing* facilitated critical care practice to fulfil normative, responsible, sustainable and flourishing stages [4]. *Bounded rationality* was another significant concept which explained the cognitive and environmental factors influencing 'how' *satisficing* occurred [3]. Finally, *stewarding* was 'why' practitioners satisficed as an ethical drive to use resources responsibly.

CONCLUSIONS. The grounded theory generated from this research defined sustainability from the perspective of people working in critical care practice and presented a theoretical framework to explain the social processes involved with embedding sustainability into critical care practice.

A concept analysis of discomfort: differentiating pain and discomfort

S. Ashkenazy[1], F. Dekeyser Ganz[2]
[1]Henrietta Szold School of Nursing, Hebrew University, General Intensive Care Unit, Jerusalem, Israel; [2]Henrietta Szold School of Nursing, Hebrew University, Faculty of Medicine, Jerusalem, Israel
Correspondence: S. Ashkenazy
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0724

INTRODUCTION. Comfort and discomfort can be recognized within the nursing clinical context. Discomfort is a concept found in the literature, usually related to pain. While some sources do not distinguish between pain and discomfort, others refer to different sources of discomfort. Therefore there is a lack of conceptual clarity. Concept analysis is a strategy that lets us explore the attributes or characteristics of a concept and allows us to decide which phenomena are good examples of the concept and which are not. This type of analysis can promote communication among colleagues, theory development and research. Concept analysis also is effective for tool development (Walker & Avant, 1983) and allows for proper patient assessment, diagnosis and treatment.

OBJECTIVES. The objective of this work is to present a concept analysis of discomfort

METHODS. We used full text articles published between 1970- 2016 in English to characterize "discomfort". Articles were taken from CINAHL, Medline and PsycNet databases.A total of 7,406 articles and 120 abstracts were identified for evaluation. After initial review, 42 articles were further analyzed. Two reviewers independently evaluated the selected publications.

RESULTS. Discomfort can be divided into two main domains, physical discomfort and psychological and is characterized by an unpleasant feeling resulting in a natural response of avoidance or reduction of the source of the discomfort. Pain is one of the main causes for discomfort found in the literature but not every discomfort can be attributed to pain. It is identified by self-report or observation. Discomfort in non-communicative patients is assessed and measured by behavioral expression, which can misinterpreted as pain and agitation in some conditions. In a non-communicative patient, like critically ill patient on mechanical ventilation sometimes, we can assume pain as the reason for patient behavior while other reasons for discomfort are exist.

CONCLUSIONS. In order to provide optimal quality of nursing care, a clarification of the concept discomfort will leads to a more accurate theoretical and operational definition and can help nurses to make more accurate nursing diagnoses. Misinterpretation of patient behavior might lead to inappropriate treatment of other symptoms, like pain, such as administering an analgesic when the patient is uncomfortable but not in pain.

The challenge in decreasing central line associated bloodstream infections (CLABSI)

T. Sonin Yehuda, T. Yaav, V. Nudelman, N. Shimoni, N. Pines- Zada, I. Tal, G. Rahav, G. Regev- Yochay, Y. Haviv
Sheba Tel HaShomer, Ramat Gan, Israel
Correspondence: T. Sonin Yehuda
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0725

INTRODUCTION. The respiratory intensive care unit at the Sheba Medical Center at Tel Hashomer treats a wide range of complex patients who require a multi-disciplinary staff during their hospitalization.

Patients are monitored with many central line catheters, which are a source of entry and growth for external pollutants, in addition to low risk factors and immune status, which are unable to cope with further infection, resulting in increased morbidity and mortality of patients.

The data from the hospital´s Infection prevention unit were shown to be alarming in CLABSI cases. Therefore, an intervention program for CLABSI prevention was presented in cooperation with the intensive care unit and the infection prevention unit in Tel Hashomer.

The purpose of the intervention program was to implement wise and continuous use of a central line catheter to reduce the CLABSI rate below 4 cases per 1000 catheter days.

OBJECTIVES. Reducing central line associated bloodstream infections (CLABSI) rate to zero.

METHODS. A management meeting was set up between the ICU head nurse, the infection prevention manager and the Infection

Prevention unit team. To plan a nursing intervention program included simulation, individual training, implementation of CLABSI bundle.

A preliminary study with 3M Company which provided to the unit 3M™ Curos™ disinfecting caps for needless connectors.

RESULTS. The CLABSI rate for 1000 catheter days in 2015 was 3.9, whereas the CLABSI rate for 2016 was 2.58 cases per 1,000 catheter days and in 2017 was 1.7 per 1000 catheter days. The teams use Alcohol caps with compliance rate over 85% since the beginning of the implementation.

CONCLUSIONS. In the general intensive care unit at Sheba, where the use of a central line catheter is high, CLABSI prevention is challenging due to an intensive work environment and extensive use of the catheter, and therefore it can be concluded that the intervention of the caregiver in the reduction of CLABSI cases was proven by an increase in the efficiency of the nursing work methods such as the introduction of alcohol caps for needleless connectors, training days and deceptive methods of practice using simulations.

A comparison of international ICU nurse involvement in EOL decisions: 2002 versus 2017

J. Benbenishty[1], F. Dekeyser-Ganz[1], A. Robertsen[2], J. Ulrich[3], ETHICUS II
[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Oslo University Hospital, Oslo, Norway; [3]Kommunalunternehmen Klinikum Augsburg, Munchen, Germany
Correspondence: J. Benbenishty
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0726

INTRODUCTION. Reports in the literature show a change in end-of-life care practices in recent years. Nurses are important in ICU teams, but there are variations around the world in their role. If nurses were included and to what degree they participate in the different steps of end-of life processes were some of the questions raised in the ETHICUS study (study of end-of life practices). In 2001, Ethicus I studied 31,417 patients admitted to 37 adult ICUs in 17 countries. Ethicus II (2017) provides new information concerning worldwide trends in end-of-life decision making processes.

OBJECTIVES. To compare results about nurse involvement in end of life decision making processes in ICUs worldwide (ETHICUS I compared with EHICUS II)

METHODS. The same methodology was used in ETHICUS I and ETHICUS II: All consecutive adult patients admitted to ICU over a six month period who died or had life-saving therapy limitations were prospectively studied. Patients were followed until discharge from ICU, death or 2 months from the decision to limit therapy. Data were collected through an internet questionnaire. Ethicus II included 22 of the original sites. Four study questions related to nurse involvement in the decision-making process were analyzed. These questions were: Were nurses involved in *the discussion* about whether to withhold, withdraw or shortening the dying process? Were nurses involved in *making the decisions*? Did a nurse initiate the EOL question? Did MDs

and nurses agree about EOL decisions? In addition we looked at the question: Did nurses participate in data-collection?

RESULTS. In Ethicus I, 0% nurses contributed data as opposed to 859 nurses (6.7%) in Ethicus II. In the majority of cases, there was agreement between the physicians and nurses about the decision Ethicus I: 63% in southern European countries to 98% in northern European countries; Ethicus II: average 67.9%. However there up to 36% cases where the answer selected was nurse involvement was "not applicable" in Ethicus I and 12.9% in Ethicus II.

CONCLUSIONS. In this preliminary data analysis a difference in EOL decision making process, nurse involvement and nurses contributing to data collection was found. During the past decades an increased awareness and an escalation of nurse participation in EOL involvement.

Organised nurse teaching program by senior ICU nurses improves nurse led cardiac output monitor guided management of severe septic shock

M. Di Pierro, H. Donald, R. Mahroof
Addenbrooke's Cambridge University Hospitals NHS Trust, John Farman ICU, Cambridge, United Kingdom
Correspondence: M. Di Pierro
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0727

INTRODUCTION. Patients(pts) with complex acute problems & chronic co-morbidities get admitted to ICUs. Effective & successful delivery of care in this challenging group of pts needs a multi-disciplinary approach, from medical & nursing teams.

GPICS require 1:1 nurse ratio for Level 3 ICU pts. Doctors provide management (mx) plans, but bedside event-by-event mx of multiple organ support is done by a nurse assigned to that pt. Understanding & managing various forms of isolated/combined forms of shock can be daunting. Cardiac output monitor (COM) guided mx may be beneficial, if treating clinicians are competent to make appropriate responses to the derived data. Teaching, training & maintaining COM skills amongst nurses can be an arduous task; given that COMs are used in a small subset.

We report a narrative description of how a structured CPD program devised & run by senior ICU nursing staff for ICU nurses has developed a culture of supportive learning,teamwork & confidence in managing complex pts in a busy tertiary academic ICU. An example of COMs in severe septic shock has provided encouraging results.

OBJECTIVES. To review the structural organisation of nursing team in a tertiary ICU focusing on the role played by the practice development team (PDT) in maintaining a good level of practice in the use of minimally invasive COMs (LiDCO/PiCCO).

METHODS. Clinical & biochemical data for 75 pts with severe septic shock on >0.1 mcg/kg/min of norepinephrine (NE) were analysed. Pts with COM guided mx were compared to who didnt. Improvement in biochemistry used as surrogates for improving shock. PDT senior staff were interviewed to ascertain organisation & delivery of teaching & support for COM guided shock mx.

RESULTS. 34/75(45%) had a COM. COM vs non-COM, median NE start dose 0.17vs0.14 mcg/kg/min,p=0.0042, multiple vasopressor 38vs5%,p=0.0003 & inotropes 35vs2%,p=0.0002. Median time to resolution by survival analysis for metabolic acidosis (MA), lactataemia (L)(< 2) & NE (< 0.05 mcg/kg/min) in COM vs non-COM: MA 48vs24hrs (HR & 95% CI)(HR 0.87(0.4-1.6),p=0.56), L 32vs16hrs (HR 0.85(0.45-1.59),p=0.62), NE 54vs30hrs (HR 0.36(0.21-0.62),p=0.0002). P values log-rank test.

130 ICU nurses led by 4 senior PDT nurses with a series of compulsory (funded) lectures/practical demos/regular study days. Combination of theory & practical bedside teaching is used to embed & develop confidence in using shock/COM data, & good fluid & ino-pressor mx. Starters have 6 wk bedside induction pre-clinical

work - update core-skills on a regular basis & advance to completing a university-based ICU course +/- higher degree.

CONCLUSIONS. COM pts had more pressor/inotropes, but they resolve their acidosis & lactataemia within a time-frame which is not significantly different to non-COM pts. Nurse led analysis & mx of COM guided shock appears appropriate. Structured & well supported CPD for nurses has beneficial impacts in managing complex adjuncts & monitoring aids in multiple organ failure.

An investigation of the cultural perspectives of a group of patients and relatives on blood donation and blood transfusion in Turkey

A. Koyuncu[1], A. Yava[1], F. Eti Aslan[2], D. Çınar[3], N. Olgun[1]
[1]Hasan Kalyoncu University, Faculty of Health Sciences, Nursing Department, Gaziantep, Turkey; [2]Bahcesehir University, Faculty of Health Sciences, Nursing Department, Istanbul, Turkey; [3]Balikesir military hospital, Balıkesir, Turkey
Correspondence: A. Koyuncu
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0728

OBJECTIVE. It is aimed to examine the religious and cultural perspectives of patients and their relatives on blood donation and blood transfusion in an outpatient clinic area of an education and research hospital.

MATERIALS AND METHODS. The study was a descriptive study with 320 volunteers and relatives conducted between 3 March and 10 April 2015. The research data were collected through a data collection form questioning the introductory features, religious and cultural perspective on blood donation and blood transfusion. p < 0.05 was accepted as a statistical significance level.

FINDINGS. The average age of the participants was 39.71 ± 14.17 years, 59.1% of them were male, 35.3% of them had graduated from higher education, 68.1% of the participants´ residence and the birthplace of 51.3% were the Central Anatolia region. 56.9% of the participants actively work, 54.4% are married and 80.9% have health insurance. 60.3% of participants were Muslim. 18.1% did not want to explain their religious belief. 55.9% of the participants had never donated blood before. When inquired about the significance of blood donation in their beliefs ; 80.9% stated that it is advisable according to their religion and 15.9% said that they had no knowledge. When asked about the cases in which blood transfusions are required for relatives, 73.8% of the participants stated that they would "approve immediately" while 24.4% would "only approve in an emergency". 92.5% of the participants stated that being informed on blood transfusion has effect on their giving permission. It was found that participants would like the recipient to be informed before the transfer about whether the precautions were taken for diseases such as AIDS and hepatitis (97,5%) risks posed by blood transfusion (89,9%), alternative treatments (74%), and whether the blood transfusion will alter the genetic properties of the recipient (64,4%). When blood transfusion was required for the patient or his / her relatives, differences on the approval or disapproval of the procedure rate according to sex, region of residence, marital status, the difference were not statistically significant (p> 0.05). According to education status, the rate of approval for blood transfusion was higher in those with upper secondary education (Chi-square = 17.044, p = 0.002).

RESULT. It was concluded that the religious and cultural perspectives of the participants affected the thoughts and attitudes towards blood donation and blood transfusion and that there was a correlation between education level and likeliness of approval for blood transfusion, in that those with higher education were more reluctant in approving blood donation. It has been assessed that information tailored to the needs and cultural and religious perspectives of people may be influential on attitudes towards blood donation and blood transfusion and that it may increase the approval rate for blood transfusion when necessary.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0729

INTRODUCTION. Endotracheal tube cuff pressure needs to be kept within the best range to maintain ventilation and prevent aspiration while functioning to assist in perfusing the lungs [1]. The endotracheal tube cuff pressure must be maintained in a certain range to reduce the risk of aspirations of secretions, which may cause VAP. According to Sole, Su, et al. [1], a minimum pressure of 20 cmH2O is suggested for the prevention of VAP.

OBJECTIVES. A aim of the study is to compare infrequent endotracheal tube cuff pressure monitoring (once a day) with frequent endotracheal tube cuff pressure monitoring (three times per day).

METHODS. The study was to consist of two groups of patients treated in the Intensive Care Unit, mechanically ventilated. The first group (Group 1) were to be whom the pressure in the balloon is measured once a day by nurses. Additional measurement performed by authors and its value was recorded. In one patient the interval between measurements was at least 2 days. Then, a questionnaire and training on the correct balloon pressure was conducted among doctors and nurses. The procedure of the balloon pressure rate was changed. In patients, the nurses evaluated three times a day at 6, 14 and 22 (Group 2). Additional measurement performed by authors and its value was recorded. In one patient the interval between measurements was at least 2 days. At each measurement, if there was such a need, the pressure was corrected to the correct value (20-30 cmH2O).

RESULTS. There were 188 patients aged 18-89 qualified for the study. In group I, 45 patients had 141 measurements, and in group 2 in 73 patients 506 measurements were made.
The mean balloon pressure in Group 1 was 27 ± 20 cmH2O. Only 28 (20%) measurements showed correct pressure value. In 73 (52%) measurements, the pressure was below the accepted standard, and in 40 (28%) cases above norm. In Group 2, the average pressure was 25 ± 11 cm H2O (p< 0,001). The correct balloon pressure was obtained in 376 (74%) measurements. The cuff pressure was too low in 77 (15%) cases, and too high in 53 measurements (11%).

CONCLUSIONS. More frequent cuff pressure monitoring was associated with better control of cuff pressure.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0730

INTRODUCTION. The mortality rate for patients discharged from ICUs in the UK is higher than other hospitalised groups considered to be at high risk, and is more than five times the annual number of UK road traffic accident deaths[1]. The Recovery Following Intensive Care Treatment (REFLECT) study is a UK based multicentre mixed methods exploratory study examining ward care delivery to patients discharged from intensive care. One of the methods used to evaluate ward care delivery was a Retrospective Case Record Review (RCRR). This approach has been used extensively in other patient groups, but not previously in this population.

OBJECTIVES. To develop a multidisciplinary approach to evaluating care following ICU discharge using a Retrospective Case Record Review technique as part of the REFLECT study.

METHODS. Medical notes of patients transferred to wards from ICU and subsequently died were examined using an RCRR technique. This method is currently being adopted by the Department of Health (DoH) as a clinical governance tool within trusts as the National Mortality Care Record Review Programme. This study used an adaptation of the validated tool used by the DoH for making safety and quality judgements about care delivery. Structured judgement statements were explicit, value-based comments on care delivery. The output is a relatively short but rich account of care delivery, identifying both good and poor care, with all records allocated an 'avoidability of death score'. Cases where differences in care delivery could improve outcomes were further analysed using the 'change analysis' method. The analysis allowed identification of areas where novel care processes could change patient outcomes.

RESULTS. 300 medical records from 3 separate UK NHS sites were reviewed by a multidisciplinary team consisting of an ICU consultant, nurse, follow-up practitioner and physiotherapist. All staff attended the NHS Structured Mortality Review Training prior to undertaking RCRR. 30 medical records scored sufficiently to undergo an in-depth qualitative analysis.

CONCLUSIONS. A multidisciplinary case records review of patients discharged from ICU was a successful approach in identifying areas of care where changes could alter patient outcome. The multidisciplinary approach enabled identification of a diverse range of care aspects for further exploration.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0731

INTRODUCTION. The effect of nutrition support therapy on long-term prognosis, such as readmission, among acute heart failure patients in an intensive care unit (ICU) setting remains unclear due to lack of evidence.

OBJECTIVES. We hypothesized that nutrition support therapy in the acute phase might affect readmission rate among acute heart failure patients admitted to the ICU. Thus, we conducted a single-center prospective observational study to verify this hypothesis.

METHODS. Consecutive patients diagnosed with acute heart failure and admitted to the ICU between April 2016 and March 2017 were enrolled in this study. Of these, patients admitted for more than 14 days were included in the analysis. The primary outcome was the relationship between nutritional intake and hospital readmission at 180 days after discharge. We divided the participants into 2 groups: patients who were not readmitted to hospital within 180 days after discharge (non-readmission group) and patients who were readmitted within this timeframe (readmission group). Data were expressed as median (interquartile range). A p value < 0.05 was considered statistically significant. Per the study protocol, variables with p values of < 0.05 in the univariate analysis were included in the multivariate analysis.

RESULTS. A total of 230 patients remained in the hospital for ≥ 14 days and 103 patients (44.8%) required readmission within 180 days after hospital discharge. The median age and body mass index were similar in both the readmission and non-readmission groups [84 (75, 88) vs 84 (77, 90) years; 22.6 (20.2, 24.8) vs 22.0 (19.1, 24.4) kg/m^2, respectively]. The median BNP values were also similar [732 (465, 1197) vs. 844 (420, 1316) pg/mL]. The median duration of ICU were not significantly different [7 (4, 10) vs. 6 (4, 8) days]. Serum creatinine levels were significantly higher in the readmission group than in the non-readmission group [1.0 (0.7, 1.3) vs. 1.3 (0.9, 1.8) mg/dL, p = 0.003]. The calorie and protein intake on day 3 after ICU admission in the readmission group was significantly higher than that in the non-readmission group [25.8 (20.0, 30.2) vs. 20.5 (14.2, 27.8) kcal/kg/day, p=0.002: 0.9 (0.6, 1.1) vs. 0.7 (0.5, 0.9) g/kg/day, p=0.002, respectively]. Similarly, the protein intake values on day 7 was also significantly higher in the readmission group [0.9 (0.7, 1.2) vs. 0.8 (0.6, 1.0), p=0.04, respectively]. Multivariate analysis indicated that total caloric intake on day 3 was an independent factor affecting readmission (odds ratio=1.03, 95% confidence interval=1.00-1.06, p=0.04).

CONCLUSIONS. Our data showed that nutrition support therapy in the acute phase might affect readmission among acute heart failure patients. Furthermore, total caloric intake on day 3 was an independent factor that affected readmission. Further studies should be conducted to refute or confirm our findings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0732

INTRODUCTION. The critically ill "state" has several characteristics that promote malnutrition, mainly hypercatabolism. Without an adequate nutritional support, there is an energy deficit that sustains the development of lean mass consumption, and therefore the aggravation of this situation. It is believed that the severity of the disease makes energy intake difficult and the deficit degree in the intensive care stay increases the risk of complications and mortality.

OBJECTIVES. To evaluate the impact of energy deficit in the first week of hospitalisation and the severity measured by admission SOFA in 60-day mortality in critically ill patients.

METHODS. This is a prospective study, in which patient data were collected from electronic health records and followed by trained dietitians until discharge. Inclusion criteria were individuals older than 18 years old, who stayed more than 48h in the ICU. Determination of the caloric intake was estimated through the amount of time in which the patient stayed in *nil per os* (NPO) during the first week of ICU admission. Hence, ingestion in the first week was classified into five energetic quintiles, with a variation of 25% each.

RESULTS. From the 300 patients included in the study, 64% were male. The main medical diagnoses found were trauma (31%) and neurological (33.7%). 163 (54.3%) patients received $\geq 75\%$ of the planned calories for

the first week, of whom 36.4% did not survive. Among those who remained on NPO (1.3%), none survived. Mean SOFA for non-survivors was 9.55 points (95% CI 8,66 - 7,58; p = 0.0001), whereas non-survivors had 7,01 points (95% CI 6,44 - 7,58; p = 0.0001). Non-survivors stayed on NPO for 1,57 days on average (± 1,83 [interquartile range = 3]), whilst survivors had a mean of 0,92 days of fasting (± 1,52 [interquartile range = 1]; p = 0,016). We also observed that patients who had an intake ≥75% than the planned for the first week (mean survival of 144 days [95% CI 33.3 - 254]; p = 0.0001) had lower mortality in 60 days compared with those with intake < 75% (mean survival of 72 days [95% CI 51.9 - 92]; p = 0.0001). A logistic regression showed that for each SOFA unit increment, there was a 16% increase in mortality risk (OR 1.16 [95% CI 1.08 - 1.24], p = 0.0001) and for each point of decrease in energy quintile in the first week, there was a 71% increase in mortality risk (OR 1.71 [1.33 - 2.21], p = 0.0001).

CONCLUSIONS. Energy deficit in the first week has deleterious effects on 60-day mortality. Survival is greater in patients receiving ≥75% of the energy planned. In addition, the admission SOFA score has a good predictive potential to mortality risk.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0733

INTRODUCTION. It is known that more than 40% of pregnant women have a deficiency of vitamin D. In addition to the classic symptoms of preeclampsia, more than a quarter of century, many foreign clinicians as preeclampsia indicator used by the hyperuricemia.

OBJECTIVES. We study the relationship of pain in childbirth, characteristics of epidural analgesia in patients with preeclampsia and the level of vitamin D, the concentration of uric acid in the blood serum.

METHODS. The study group included patients with severe and moderate preeclampsia, alone have given birth vaginally with epidural analgesia. The control group included patients with physiological pregnancy, independently gave birth vaginally with epidural analgesia. The material of the study was to peripheral blood of pregnant women taken at admission to the hospital for delivery. Vitamin D level was performed by enzyme immunoassay kits. The concentration of uric acid was determined spectrophotometrically. Primary study end points defining a base for the conclusions were as follows: the level of vitamin D in ng / ml, the concentration of uric acid in the blood mcmol/l, the average period for delivery systolic and diastolic blood pressure in mmHg, the dose of local anesthetic in mg.

RESULTS. In patients with severe preeclampsia revealed: a pronounced deficiency of vitamin D, a tough hyperuricemia, had higher numbers mean arterial pressure during labor epidural analgesia in the background: on average during all periods of childbirth 140/90150/100 mm Hg. In patients with moderate preeclampsia was diagnosed moderate vitamin D deficiency, mild hyperuricemia, blood pressure during childbirth averaged 130/90125/85 mm Hg. In the control group the level of vitamin D and the concentration of uric acid were in the normal range, blood pressure during labor averaged 105/60 120/70 mm Hg. The results

also gave evidence to suggest that patients with preeclampsia who have previously been registered low levels of vitamin D and an increased concentration of uric acid in the birth have a greater need for a local anesthetic to reduce pain and stabilize blood pressure than patients with higher levels of vitamin D and smaller uric acid.

CONCLUSIONS. In women with preeclampsia during childbirth epidural analgesia, low levels of vitamin D and hyperuricemia are associated a higher demand for local anesthetics.

0734

Vitamin d levels of patients in intensive care unit and its association with nutritional risk screening 2002 score

A. Zerman[1], S. Keskek[2]
[1]Adana Sehir Training and Research Hospital, Intensive Care, Adana, Turkey; [2]Numune Training and Research Hospital, Adana, Turkey
Correspondence: A. Zerman
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0734

INTRODUCTION. Vitamin d is an immune modulator hormone which has major effects on nearly all cells of the immune system. The deficiency of vitamin d has been found to be associated with many diseases. Malnutrition is a broad term which has been used to describe any imbalance in nutrition. It is commonly encountered in critically ill patients. Early identification of malnutrition among hospitalised patients is essential to institute appropriate patient-specific nutritional strategies.

OBJECTIVE. The aim of this study was to investigate the level of vitamin d and its association with NRS (nutritional risk screening) 2002.

METHODS. A total of 140 patients from internal medicine were included. All patients were staying in intensive care unit of Adana City Training and Research Hospital. Serum 25(OH)D concentration was measured for vitamin d deficiency. Serum 25(OH)D concentrations were measured by using commercially available enzymelinked immunosorbent kits (Minneapolis, USA). A questionnaire survey was used to investigate the nutritional status of patients (NRS 2002). MedCalc 18.2.1 (MedCalc Belgium) statistical software was used for statistical analysis.

RESULTS. The mean age was 71.3±13.3. There were 75 (53.6%) men and 65 (46.4%) women (p=0.398). The mean concentration of 25(OH)D was 15.9±16.9. There was no statistical significant difference between men and women (13.2±9.6 vs. 19.0±22.2, p=0.341). The mean score of NRS-2002 was 3.75±1.8. Both men and women were comparable (3.8±1.7 vs. 3.6±1.8, p=0.791). There was an inverse correlation between 25(OH)D and NRS 2002 score (p=0.03, r=-0.182).

CONCLUSION. Malnutrition is associated with poorer clinical outcomes in hospitalized patients. Low concentration of vitamin d may be associated with impaired nutritional status in patients in internal medicine intensive care unit. Patients should be supported with vitamin d. It is better to initiate early nutrition therapy as soon as feasible in critically ill patients requiring nutrition therapy, unless there are significant contraindications.

The refeeding syndrome in critical care patients: a challenge

Y. Rovira Valles, E. Mor Marco, L. Bielsa Berrocal, V. Philibert, O. Plans Galvany, I. Martínez de Lagran Zurbano, P. Marcos Neira, L. Bordejé Laguna
Hospital Universitari Germans Trias i Pujol, Intensive Care Unit, Badalona, Spain
Correspondence: Y. Rovira Valles
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0735

INTRODUCTION. Refeeding Syndrome (RS) is the ensemble of clinical and biochemical alterations due to the introduction of nutrition in a malnourished patient, being hypophosphatemia the most specific finding. Critical patients can be at risk of developing RS, and its complications are potentially severe.

OBJECTIVES. Descriptive analysis of critical care patients at risk of developing refeeding syndrome (RS).

METHODS. Observational study of a cohort of 300 patients followed up during the admission in an ICU (Hospital Germans Trias i Pujol) from July to November 2017. We detected 22 patients at risk of developing RS. We analysed demographic variables, gravity scores, prognostic factors for RS and their evolution. Descriptive analysis: quantitative variables are expressed in means (SD) and medians (min, max) and qualitative variables in proportions.

RESULTS. Accumulated incidence of patients at risk of RS is 1.6% each month. Mean age was 61.6 (SD 12) years, APACHE 25.5 (16-48) and BMI 25 (SD 5.7). Mean length of stay was 13.5 (2-52) days, with 8 (0-53) days of mechanical ventilation and 20.8% (CI 95%: 4.8-36.8%) of ICU mortality. Patients were selected because of both clinical suspect of RS (73%, CI 95%: 55-91%) and hypophosphatemia (27%, IC95%: 9-45%). We detected 16 hypophosphatemias (73%, CI 95%: 55-91%), with an mean phosphate value of 1.6mmol/L (SD 0.57). 37.5% of the patients included due to clinical suspicion, did not develop hypophosphatemia, given that 50% of them was in renal failure. Therapeutic adequacy (early/late/never) was analysed: artificial nutrition (AN) was adjusted in the 80% (55%, 25%, 20%); electrolytes were supplemented in the 86% (59%, 27%, 14%) and thiamine in the 90% (72%, 18%, 10%) of the patients.

CONCLUSIONS. Refeeding syndrome occurs in critical patients. Its identification is a challenge and its incidence is underestimated, so it is essential to develop a screening tool. Prevention of refeeding syndrome involves electrolyte monitoring, attentive supplementation of micronutrients and progressive nutritional intake.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0736

INTRODUCTION. Estimation of energy requirements of critically ill patients is essential for providing proper nutritional support. The effect of different sedative drugs on resting energy expenditure (REE) was not well investigated.

OBJECTIVES. The aim of this study is to compare the effect of dexmedetomidine (Dex) and midazolam on REE in critically ill patients.

METHODS. A randomized, double-blinded, controlled trial was conducted in a tertiary hospital including 30 critically-ill patients. Patients were randomized into either Dex Group (n= 15) (received DEX infusion at a starting dose of 0.15 µg/kg//hr), and midazolam group (n= 15) (received midazolam sedation at a starting dose of 1 mg/h). Both medications were infused for 24 hours and were titrated to maintain the Richmond Agitation and Sedation Scale (RASS) scores in a range of −3 to −1. REE was measured using indirect calorimetry. Hemodynamic variables were continuously measured. Serum epinephrine, and serum interleukin-1β were measured at the baseline and after the end the infusion period. Time to extubation, length of stay, and in-hospital mortality were also evaluated.

RESULTS. There was a significant decrease in each of REE, oxygen consumption (V02), carbon dioxide production (VC02), serum epinephrine, and serum IL-1β in the 24-hour reading compared to the baseline reading within the two study groups. However, there were no significant differences in REE between both groups. Arterial blood pressure and heart rate were lower in Dex group compared midazolam group. Time to extubation was shorter in Dex group compared to midazolam group.

CONCLUSIONS. In conclusion, infusing sedatives to target RASS score between -1and -3 in mechanically ventilated patients reduced the REE by ~ 15%. No difference was reported between the effect of Dex and midazolam on REE; however, Dex infusion shortened the time to extubation.

Differences in critically ill patients with severe acute pancreatitis between a district general hospital and a tertiary referral hospital in Scotland, UK

C. McCue[1], K. Millar[1], K. Puxty[1], R. Sundaram[2]
[1]Glasgow Royal Infirmary, Intensive Care, Glasgow, United Kingdom;
[2]Royal Alexandra Hospital, Intensive Care, Paisley, United Kingdom
Correspondence: C. McCue
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0737

INTRODUCTION. Severe acute pancreatitis (SAP) accounts for approximately 25% of patients with the disease and invariably requires critical care admission [1]. Overall hospital mortality for pancreatitis is 1% but climbs to 42% for SAP, with a 31% ICU mortality [2]. Disease specific scoring systems have sought to define outcome and severity in SAP, with APACHE II remaining one of the most discriminatory [3].

OBJECTIVES. We sought to review any characteristics or outcome differences between patient groups at both sites. Then to analyse all patients to assess any differences between patients divided into 3 outcome groups: early mortality (48 hours), in hospital mortality, and survivors.

METHODS. The study period covered admissions from 2009-2017. Royal Alexandra Hospital (RAH), Paisley has 7 Level 3 beds, and the tertiary referral hospital (Glasgow Royal Infirmary, GRI) 12 Level 3 and 8 Level 2. Data was obtained from the ICU clinical database, with search term 'acute pancreatitis' as diagnosis, with permission from the local administrator. Supplemental data was obtained from clinical information systems. Calculations were completed using Excel and Vasser Stats. Readmissions were excluded from data analysis.

RESULTS. Table 1 examines differences between all level 3 patients at both sites.

Between the three groups there were no significant differences in age, aetiology, APACHE II and organ support. The group of patients referred to the tertiary centre had a higher proportion of males and gallstone aetiology. Mortality was higher in the tertiary referral centre for primary admissions.

Table 2 describes differences between outcome groups in all level 3 patients excluding those referred from other sites to GRI.

CONCLUSIONS. From this dataset we can see a tendency towards increasing age and poorer outcome, and low RRT utilisation seen in the survivor group. Interestingly lower RRT use is seen in the early mortality group compared with in hospital mortality which may reflect resource rationing in clinical futility.The differences in mortality between sites are surprising and merit further interrogation of the cohorts. APACHE II remains a robust measure of severity scoring in pancreatitis with a possibility of further discrimination between early and later mortality.

Metabolic monitoring of patients in chronic critical illness after brain damage: a pilot study

I. Sergeev, M. Petrova, K. Krylov, A. Shestopalov, R. Yagubyan, A. Sergienko, A. Yakovleva
Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, Russian Federation
Correspondence: K. Krylov
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0738

INTRODUCTION. One of the main problems in chronically critically ill patients is development of protein-energy deficiency in the acute phase, which persists in the chronic phase. We did not find any unified recommendations on energy needs in this patients' population. Usage of indirect calorimetry to determine energy needs of patients in chronic critical illness remains controversial. The aim of the stud ywas to compare the energy needs of patients in chronic critical illness defined by indirect calorimetry according to international recommendations and by Harris-Benedict equation.

OBJECTIVES. In this prospective cohort pilot study there were included 10 patients in the intensive care unit who fulfilled the inclusion criteria (9 men, 1 woman) with brain damage present more than 30 days after the onset of the disease. The mean age in the study group was 47 ± 16 years. All patients were with tracheostomy placed. On the enrollment majority of patients (9) were self-breathing, and 1 was on ventilator. All patients included in the study were without exhaustion signs. Mean body mass index was 21.6 ± 4.8 kg/m². All patients received standard high-protein enteral nutrition 35 kcal/kg/day. There was no impairment of liver or kidney function and signs of dysfunction of the gastrointestinal tract in all patients during the study.

METHODS. The energy requirements were defined using either the Harris-Benedict equation or indirect calorimetry. The protein needs were defined by nitrogen loss in urine.

RESULTS. On average energy requirements determined by indirect calorimetry did not differ from those calculated by the Harris-Benedict equation ($p = 0.64$). Results for indirect calorimetry were 24.3 ± 6.1 kcal/kg/day (1506.7 ± 300,43 kcal/day) and 23,6 ± 2,8 kcal/kg/day (1474,7 ± 180,17 kcal/day) for Harris-Benedict equation. Although the energy requirements determined by indirect calorimetry were higher in 3 patients. Mean protein requirements were 0.7 ± 0.25 g/kg/day. Despite the fact that patients received more energy (30-35 kcal/kg/day) and protein (1.3-1.5 g/kg/day) than required, mean transferrin level remained rather low 128.6 ± 33, 62 mg/dL (reference: 200-400 mg/dL). Despite the fact that mean body mass index was within normal limits, the circumference of the shoulder muscles was reduced (mean 20.3 ± 1.8 cm).

CONCLUSIONS. Usage of indirect calorimetry only without taking into account functionality of the gastrointestinal tract and other factors that affect body composition is not enough to prescribe optimal nutritional support in this patients category. Indirect calorimetry is a good tool for determining the resting energy requirements level in chronically critically ill patients and allows one to specify the boundaries of the patient's energy needs. Further research is required.

Effect of glutamine supplementation in polytrauma patients

F. Marchese[1], A. Cotoia[2], M.T. Tucciariello[2], L. Mirabella[2], L. Tullo[2], G. Cinnella[2]
[1]O.O.R.R. di Foggia, Anestesia e Rianimazione, Foggia, Italy; [2]Università degli Studi di Foggia, Anestesia, Rianimazione, Terapia Intensiva e del Dolore, Foggia, Italy
Correspondence: F. Marchese
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0739

INTRODUCTION. Glutamine plays an important role under stress condition, and it is correlated with immunologic system response and outcome in critically ill patients. The glutamine is becoming formulated suitably in addiction to artificial nutrition.

OBJECTIVES. Aim of this study is to observe the immunologic effect of glutamine supplementation in polytrauma patients.

Methods In this prospective observational study we enrolled 42 polytraumatized patients (Injury Severity Score >15) admitted in Intensive Care Unit (ICU), University Hospital of Foggia.

Patients aged under 18 years, with renal failure, hepatic failure, IBD, with steroids treatment, patients undergoing abdominal surgery and pregnant were excluded.

Patients admitted in ICU were randomized to receive enteral nutrition alone (30 Kcal/Kg/die) (G1) or plus intravenous glutamine (0,5 g/kg of ideal body weight) (G2). Glutamine supplementation was given for 12 days.

Blood was drawn at baseline, 4, 8 and 12 days for measurement of of plasmatic CD3+ T Lynfocyties, CD3+/CD4+/CD45+ T Helper Lynfocyties, CD3+/CD8+ T suppressor Lynfocyties , CD19+/CD45+ B Lynfocyties, IL4, IL2, IgA.

P value of 0,05 was considered statistically significant.

RESULTS. Serum levels of T CD3+ Lynfocyties increased significantly at any time vs baseline in G2 (p< 0.003), while they remained stable over time in G1. Comparisons between groups showed similar T CD3+ Lynfocyties levels at baseline (p=0,7), whilst they significantly increased in G2 vs G1 at T2,T3 and T4 (p< 0.01).

In both groups CD3+/CD4+ T Helper Lynfocyties levels increased during the study period especially at T4, while CD3+/CD8+ T suppressor Lynfocyties increased significantly vs baseline only in G2 (p< 0.01) . CD19+/CD45+ B Lynfocyties significantly increased at T8-T12 only in G2.

IL2 was stable during the study period in both groups; IL 4 trend increased progressively only in G2 (p< 0.004). IgA level increased in G1 from T0 to T3 (P< 0.05).

No adverse reactions or oversensitiveness to glutammine supplement were observed.

CONCLUSIONS. The preliminary data show that glutamine increased IL4, CD3+/CD4+ T lymphocytes and CD19+/CD45+ B lymphocytes production. Glutamine supplementation may improve T-cell function in the poly-traumatized patients.

A comparative study of advantages of using separate bottle T.P.N. formulae and the 3-in-1 admixture of T.P.N. in critically ill pediatric patients

A. Wahdan
Cairo University, Anesthesia, SICU and Pain Management, Cairo, Egypt
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0740

INTRODUCTION. Total parenteral nutrition (T.P.N.) is an essential part in the management of patients with gastrointestinal surgeries, being an effective method for supplying energy and nutrients where oral or enteral feeding is impossible or contraindicated. T.P.N. admixtures are more convenient to the healthcare providers and to the patient. The aim of this work was to compare the outcome of separate bottles of T.P.N. formulae and 3-in-1 admixture of total parenteral nutrition in critically ill pediatric patients.

PATIENTS AND METHODS. This study was conducted in the Pediatric surgical intensive care unit, Abu EL Reesh Hospital, Cairo University.

Number of Patients (N=40). Age from 3 months to 12 years after major GIT surgery e.g. intestinal resection, biliary atresia correction, colon bypass surgeries, etc.

EXCLUSION CRITERIA. Major organ failure (e.g. Liver or Kidney), Sepsis and shock, associated cardiac disease, Associated juvenile diabetes and DIC.

Patients were randomly divided into 2 groups, each group is (20 patients), taking TPN for 10 days postoperatively.

· Group 1 (N=20), odd numbers of ICU admitted patients will be on separate bottles of TPN including macro and micro-nutrients, including: amino acids (Aminosteril KE,10% Fersenius Kabi), Carbohydrates (Glucose 25%), Lipids (Intralipid 10%), Trace elements and vitamins (Adamel, vitalipid and soluvit), Electrolytes (Potassium and Calcium), Albumin (if needed, according to patient's laboratory findings)

· Group 2 (N=20) even numbers of ICU patients will be on 3-in-1 bags, each bag contains the nutrients needed for the 24 hours for the patient. They will be infused over 24 hours via 1.2 micron filters in a central line connected to the central vein.

Preparation of the 3-in-1 admixtures were done using the laminar flow in the TPN Admixing Unit of the New Kasr El Aini Teaching Hospital according to admixing and stability ranges, based on the daily requirements prescribed by the clinical nutritionist.

Results showed that most of the cases were malnourished. For group 1 cases, body weight was below 3rd percentile in 70% of the cases, for TSF, 60% were below 10th percentile and 30% were between 15th and 25th percentiles, and their head circumference was below the 10th percentile in 60% of the cases. For group 2 body weight was below 10th percentile in 85% of cases, TSF measurement showed that 50% of cases were below the 10th percentile and their head circumference was below the 10th percentile in 60% of the cases.

Association of energy adequacy with 28-day mortality in mechanically ventilated critically ill patients

M. Haliloglu, B. Bilgili, I. Sayan, I. Cinel
Marmara University School of Medicine, Anesthesiology and Intensive Care, Istanbul, Turkey
Correspondence: B. Bilgili
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0741

INTRODUCTION. For mechanically ventilated critically ill patients, the effect of full feeding on mortality is still controversial.

OBJECTIVES. We aimed to investigate the relationship of energy intakes with 28-day mortality, and nutritional risk status influenced this relationship.

METHODS. This prospective observational study was conducted among adult patients admitted to ICU and required invasive mechanical ventilation (IMV) for more than 48 h. Data on baseline characteristics and the modified Nutritional Risk in Critically ill [mNUTRIC] score was collected on day 1. Energy intake and nutritional adequacy was recorded daily until death, discharge or until twelfth evaluable days. Patients were divided into 2 groups:

a) received < 75% of prescribed energy,

b) received ≥ 75% of prescribed energy.

RESULTS. 150 patients (65% male, mean age 51.0±15.3 years, mean body mass index 27.9±6.2 kg/m2, mean mNUTRICscore 5.8± 1.7) were included. In the univariate analysis, mNUTRIC score was associated with 28-day mortality. In the multivariable logistic regression analysis, mNUTRIC score(Odds ratio, OR 1.65, CI 1.20-1.70, P < O.OO1) was associated with 28-day mortality. Nutritional adequacy was assessed, median nutritional adequacy was 0.40 (0.17-0.75). In patients with high mNUTRIC score (5-9), received ≥ 75% of prescribed energy was associated with a lower predicted 28-day mortality; this was not observed in patients with low mNUTRIC score (0-4).

CONCLUSIONS. Nearly 60 % of IMV required patients admitted to ICU were at nutritional risk, mNUTRİC score is associated with 28-day mortality. Energy adequacy of ≥ 75% of prescribed amounts were associated with decreased mortality in patients with a high mNUTRİC score.

Correspondence: K. Gundogan
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0742

INTRODUCTION. Thiamine is an essential water soluble vitamin and a critical component of cellular metabolism. In intensive care unit (ICU) patients, blood thiamine concentrations may decrease due to decreased dietary intake, malabsorption, increased utilization for carbohydrate and amino acid metabolism, and/or urinary loss with diuresis.

OBJECTIVES. The purpose of this study was to determine serum thiamine concentrations in critically ill medical patients who required chronic diuretic drug treatment before admission to the intensive care unit.

METHODS. This prospective study was performed in a single medical ICU at Erciyes University Hospital, Kayseri, Turkey. Individuals above 18 years of age and required to stay in the ICU at least 48 hours were included. Subjects who received diuretic drug therapy for at least 6 months prior to ICU admission constituted the Diuretic Group. The Control Group were clinically matched adults admitted to the ICU without a history of diuretic therapy. Serum thiamine concentrations were measured using high-performance liquid chromatography (HLPC) within 48 hours of admission and serially on days 2, 5 and 10 after entry while in the ICU.

RESULTS. A total of 50 subjects were included (25 subjects in each of the Diuretic Group and Control Group). The mean age was 59±17 years and 48% were female. The mean Acute Physiology and Chronic Health Evaluation II score (APACHE II) was 15.7 ± 6.5 at entry to the ICU [Diuretic Group = 17.5 ± 7.2; Control Group = 14.2 ± 5.4 (p=0.14)]. The most common causes for ICU admission were acute respiratory failure (42%) and miscellaneous metabolic events (30%). Congestive heart failure and chronic liver diseases were the most frequent co-morbidities. The median daily dose of furosemide prior to admission was 40 mg (range = 20-160 mg/d), for 12 months (range = 6-120 mo) for the Diuretic Group. The baseline serum thiamine level was below the reference range of 35-99 ng/mL at 31.2 ± 27.1 ng/mL in all patients. The baseline thiamine level was significantly lower in the Diuretic Group compared to the Control Group (15.5 ± 10.7 vs. 46.8 ± 29.5 ng/mL; $p< 0.001$). On day 2 after entry, thiamine levels were 23.2 ± 15.4 ng/mL in the Diuretic Group and 49±38 ng/mL in the Control Group (p=0.003). In the Diuretic Group, serum thiamine concentrations were below the normal range in 24 of the 25 subjects (96%) at baseline, in 18 of 25 patients (72%) on day 2 after entry, in 8 of 15 subjects (53%) at day 5 after entry, and in 2 of the 4 patients (50%) remaining in the ICU on the 10th day after study entry.

CONCLUSIONS. Adults receiving chronic diuretic therapy and requiring medical ICU care exhibit a very high rate of thiamine depletion on admission to the ICU and during the initial days of ICU care. Larger, prospective, observational studies are needed to confirm the magnitude of thiamine deficiency in this ICU patient population in Turkey.

Comparison of the 'Malnutrition Universal Screening Tool' (MUST) and ´Nutritional Risk Screening 2002´ (NRS-2002) for prognosis in the intensive care unit

D. Ozates, H. Sungurtekin, S. Kiter, S. Serin
Pamukkale University, Denizli, Turkey
Correspondence: H. Sungurtekin
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0743

INTRODUCTION. Malnutrition is a clinical conditions that can affect all age groups in the world. It is an important problem that causes high hospital costs, long hospital stay, and associated widespread complications, high infection risk and mortality.

OBJECTIVE. It was aimed in our study to evaluate the NRS-2002 and MUST screening tests relations with mortality and morbidity.

METHODS. Following the approval of the Ethics Committee, 250 patients over 18 years of age between April 2014 and November 2016 were enrolled in this study in Pamukkale University Medical Faculty Hospital Anesthesiology and Reanimation Department Intensive Care Unit. The age, sex, height, weight, and BMI data of the patients were recorded during their admission to the intensive care unit. The causes of hospitalization, current comorbidity, malignancy and infection were determined. The duration of stay in intensive care and hospital, hospital discharge status were examined. APACHE II and SAPS II values were calculated using vital findings, laboratory values, GCS, urine volumes, chronic disease findings, age and organ failure values. Anthropometrically; skin fold thickness, middle circumference of upper arm was measured. The patients underwent NRS-2002 and MUST screening tests to assess nutritional status. NRS-2002 was grouped as malnutrition risk and expected risk, MUST was grouped as low malnutrition risk, moderate malnutrition risk, and high malnutrition risk.

RESULTS. Of the 250 patients included in the study, 101 were female, 149 were male, and the mean age was 63. When the discharge status of NRS-2002 risk groups is examined; of the alive patient 143 (57%) patients 47 (32%) was in the expected risk and 96 (67%) was in the malnutrition risk group; of the 107 (42%) patients with exitus, 17 (15%) was in the expected risk and 90 (84%) was in the malnutrition risk group. According to the MUST; out of the 143 (57%) alive, 50 (34%) were in the low risk group, 9 (0,06%) were in the medium risk group and 84 (57%) were in the high risk group. Out of the total 107 (42%) exitus patients, 5 (0.04%) were in the low risk group, 5 (0.04%) were in the moderate risk group and 97 (90%) were in the high risk group. There is a significant difference in survival in MUST risk groups were observed, while a significant difference was not found in NRS-2002 risk groups.

CONCLUSION. In conclusion, MUST screening test was more successful in determining malnutrition related mortality, while NRS-2002 was more unsuccessful. We suggest that MUST would be more effective in predicting mortality in patients that will be screened for malnutrition in intensive care units.

Risk factors for severe vitamin D deficiency in critically ill patient at ICU admission

A. Khaldi[1], D. Prevedello[2], J.-C. Preiser[2]
[1]Hopital Erasme, Anderlecht, Belgium; [2]Hopital Erasme, Intensive Care, Brussels, Belgium
Correspondence: A. Khaldi
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0744

INTRODUCTION. 25-OH vitamin D (25-OH) is the major circulating vitamin D metabolite, and reflects the stores of vitamin D (1). In the general population, endogenous vitamin D production is influenced by genetic predisposition, adiposity, age, season, exposure to sunlight and skin color (2). In critically ill patients, severe 25-OH deficiency is frequent but the risk factors for decreased 25-OH are currently not well characterized.

OBJECTIVES. The aim of this study was to assess whether patients with admission 25-OH $\leq$ 12 ng/ml differed from patients with higher 25-OH levels in terms of demographic variables, type of admission, preexisting co-morbidities, severity of disease, and length of stay (LOS) in the ICU and in the hospital.

METHODS. Consecutive patients admitted over a 4- month period in a medical/surgical 32-bed ICU were included. In these patients, 25-OH, demographic data, Charlson co-morbidity score, severity scores (SAPS II and SOFA) were collected at admission. ICU and hospital length of stay (LOS) were recorded. Patients were categorized according the 25-OH admission value ($\leq$ 12 ng/ml). A chi-square test was calculated to compare categorical variables, T-student test for age and non-parametrical tests for other variables.

RESULTS. 613 patients were included (age 60.1 $\pm$ 16.5 years, male gender 58%, medical admissions 40%, SAPS II 45.4±18.9, SOFA 3.3 ±4.2, Charlson 2.2±2.6). Mean 25-OH averaged 18.2±11.1 ng/ml, with a level $\leq$ 12 ng/ml in 251 patients (41%).

CONCLUSIONS. In the population studied, severe 25-OH deficiency was frequent. A systematic determination of 25-OH at the time of admission could be particularly valuable in younger males.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0745

INTRODUCTION. Patients in a state of serious stress from trauma, sepsis, burn so critical illness, exhibit an accelerated catabolism of bodyproteins, and increase the degradation and transamination of amino acids in skeletal muscle. Therefore, inadequate nutrition can alter immune responses, integrity of the intestinal mucosal barrier and protein synthesis thus contributing to significant morbidity and mortality. Therefore, nutrition is an important part of treatment in a severely ill patient.
OBJECTIVE. To establish the degree of compensation of malnutrition of the critically ill patient.
METHODS. An observational, descriptive, analytical and retrospective study will be carried out at Juarez of México Hospital, in a period from 01-January- 2016 to 31-January- 2017. Where patients with malnutrition, either malnutrition and / obesity and at the same time hospitalized in the intensive care unit area are considered, the purpose of the study is to establish the degree of compensation for malnutrition presented by the patients, through the correct caloric intake. Socio-demographic variables such as age, sex, weight, height, BMI, type of malnutrition, degree of obesity, type of diet received, caloric intake, nitrogen balance are considered. Statistical analysis will be done using frequencies and proportion for qualitative variables, an X 2 to determine the dependence between variables, a Student´s T for numerical variables, with a p 0.05 for the statistical significance.
RESULTS. The 2.38% of the patients had malnutrition, 23.81% had first-degree obesity, and finally, 7,14% had second-degree obesity, and only 4.76% of the patients had with morbid obesity.
CONCLUSIONS. The mean BMI of patients was 26.92 kg / m2, where it is established that patients are overweight. Only 2.38% of the patients had malnutrition, however, in the assessment of nutritional status, it was identified that 64.28% of the patients where over nourished.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0746

INTRODUCTION. Ionized calcium (iCa) and not total calcium (totCa) is the physologically relevant component of blood calcium. Hypoalbuminemia, acidemia, free fatty acids concentrations acute elevation may result in poor correlation of total calcium with direct measurements of iCa. Different type of calcium measurement (iCa, totCa with or without adjustment for albumin or total protein) may lead to misinterpretation of calcium disorders.
OBJECTIVES. To report the results of a practice study in critically ill patients.
METHODS. Online survey about calcium measurement in ICU patients consisting of eleven questions regarding frequency and indication of measurement, type of measurement (totCa or iCa), adjustment of totCa results.
RESULTS. 59 answers, mainly anesthesia critical care or critical care residents (residents 72.9%, senior physicians 27.1%).
76.3% of the responders systematically measured calcium on ICU admission.
Subsequent systematic measurements during ICU stay were performed in 71.2% of cases.
In first intention, iCa was tested in only 36.2% of cases and totCa in 63.8%. 69.2% of totCa values were adjusted, mainly on albumin (albumin 59.6%, total protein 28.8%).
CONCLUSIONS. Among the responders of this sample, measurement of calcemia is frequent.
However, practices are heterogeneous.
Total calcemia remains the most frequently used method, and one third of these results are not adjusted. Furthermore, robust data concerning the reliability of totCa adjustment are lacking in this specific population
Despite its widespread use, usfulness of routine calcium measurement is not warranted and may lead to misinterpretation of the concentration of calcium and hazardous diagnosis of dyscalcemia.
Complementary studies are probably needed to determine the usefulness of this this test and the accuracy of different sample methods.

INTRODUCTION. Treatment in the intensive care unit of patients with end-stage liver disease has been limited. Liver transplantation has been a major improvement in this and has become standard in the management of these patients. However, many patients die awaiting liver transplantation, mainly due to the scarcity of organ donors. The majority of endogenous toxins leading to organ failure and accumulating in the blood are bound to albumin. The Molecular Adsorbent Recirculating System (MARS), enables simultaneous liver and kidney detoxification and can improve the patient´s clinical condition to permit, the recovery from an acute episode and enhance the chances of survival while waiting for an available organ donor. We used the technic with this objective and describe our results.

OBJECTIVES. To describe the epidemiological characteristics of patients admitted to the ICU treated with MARS in a referral hospital.

METHODS. Observational, retrospective study, 2007-2014, of patients with hepatic failure (FH) treated with MARS in a medical ICU of 24 beds. The variables were analyzed: age, sex, etiology of liver failure, severity scores (MELD and CHILD), number of sessions applied, biochemical variables pre- and post-MARS and mortality.

RESULTS. N = 50 patients (72% males), Middle-aged 50 years old (39-59). The main etiology of hepatic failure was viral (52%), followed by alcohol (22%). Acute on chronic liver failure was the principal tipe of hepatic failure (46%), progression of Cirrhosis (32%) and acute liver failure (22%). 64% of patient were in Child-Pugh stage C and with MELD of 27 SD7. A median of 2 sessions per patient (2-4). Pruritus disappeared in 71.4% CI 95% (56.57 to 86.28). Liver transplant in 38%. The Mortality was 64% (81% < 90 days).

CONCLUSIONS. The most frequent etiology was HCV. In recent years, the implementation of MARS has decreased. The mortality remains high and precocious. One third of patients were transplanted. MARS significantly decreased bilirubin and this is possibly related to the disappearance of pruritus. One of the main indications of the technique at present.

INTRODUCTION. Antimicrobial resistance among Gram-negative rod (GNR) strains is a growing worldwide issue. Delayed appropriate antimicrobial therapy is associated with higher mortality. Because of this it is recommended to monitor flora to be able to choose the right antimicrobial treatment at the first option.

OBJECTIVES. To compare dynamics of pathogens and sensitivity of hospital-acquired (HA) GNR monobacteremia strains in 7 yrs period to antimicrobial drugs and risk factors of mortality in Intensive Care Units (ICUs).

METHODS. Ongoing comparative retrospective study of patients treated in ICUs of Kaunas Clinic's with positive blood culture for GNR taken after 72 hrs of hospitalisation during one yr and after 7yrs was carried out.

RESULTS. At the 1st study yr there were found 46 cases of HA bacteremia due to GNR: 32/46 (69.6%) Enterobacteriaceae spp. (P=0.04), 5/46 (10.9%) Acinetobacter spp., 38/46 (82.6%) multi-drug-resistant (MDR), 9/38 (19.6%) extensively-drug-resistant (XDR) strains. Sensitivity to carbapenems (n=43, 93.5%), amikacin (n=29, 63.0%) and cefoperazon/sulbactam (n=26, 56.5%) was found. Lethal outcome 78.3% (n=36) found in male gender (P=0.04, OR=3.40, CI95%=0.53-0.75), mechanical ventilation and septic shock (P=0.01, OR=11.55, CI95%=1.18-12.71), previous treatment in hospital (P=0.03, OR=7.52, CI95%=1.19-9.77), acute kidney injury (AKI) (P=0.04, OR=3.90, CI95%=1.91-16.80), higher SOFA score (P=0.04, RR=5.48).

After 7yrs there were found 32 cases: 16/32 (50.0%) Acinetobacter spp. (P>0.05), 13/32 (40.6%) Enterobacteriaceae spp. (P>0.05), 29/32 (90.6%) MDR, 14/29 (43.8%) XDR strains. Sensitivity to carbapenems (n=28, 87.5%), amikacin (n=22, 68.8%), cefoperazon/sulbactam (n=20, 62.5%) was found. Lethal outcome 78.1% (n=25) was found in patients with mechanical ventilation and septic shock (P=0.01, OR=6.80, CI95%=2.48-10.54), AKI (P=0.01, OR=10.23, CI95%=3.35-7.46), previous treatment in hospital (P=0.04, OR=4.21, CI95%=2.27-14.42), XDR strain (P=0.02, OR=4.77, CI95%=1.10-11.32), higher SOFA score (P=0.03, RR=8.41).

In multi-variate analysis lethal outcome in 1st yr and after 7yrs was found in patients with mechanical ventilation (P=0.001, OR=6.47, CI95%=1.56-10.32; P=0.01, OR=4.77, CI95%=1.10-11.32), septic shock (P=0.001, OR=3.27, CI95%=3.56-16.78; P=0.001, OR=4.77, CI95%=1.10-11.32), AKI (P=0.04, OR=4.77, CI95%=1.10-11.32; P=0.02, OR=7.27, CI95%=2.56-14.89), respectively.

CONCLUSIONS. Dynamics of predominant pathogen of HA bacteremia changed from Enterobacteriaceae spp. to Acinetobacter spp. during study period of 7yrs. High sensitivity to carbapenems has remained. Rate of XDR strains has doubled. High mortality rate remained and was associated with mechanical ventilation, septic shock and AKI.

INTRODUCTION. The hypothesis that bacterial translocation plays an important role in the development and perpetuation of systemic inflammation is well accepted. Scientific evidence to prove this hypothesis, however, is scarce.

OBJECTIVES. Quantification of bacterial translocation and correlation with markers of gut barrier failure, systemic inflammation and severity of illness in an ICU patient cohort with spontaneous intracerebral bleeding.

METHODS. Prospective monocentric observational cohort study (ethical approval Göttingen University 22/1/14) in 24 subsequent ICU patients with spontaneous intracerebral parenchymatous bleeding. Inclusion into the study was within eight hours after hospital admission. Quantification of Bacteroides and Enterococcus species DNA und surrogate parameters for altered epithelial permeability (iFABP, Claudin 3, sCD14) in patient blood and urine was performed on admission (d0), d1, d2, d3, d5, d7, d10, and d14 of ICU stay. Severity of disease scores were calculated on admission, organ failure scores were used repetitively in the further course of ICU stay.

RESULTS. Enterococcus or Bacteroides DNA was detected in 67% of patients with intracerebral bleeding and in 64% of those patients, who developed sepsis. Patients with bacterial translocation

developed sepsis in only 56% of cases. Neither disease severity scores nor organ failure scores differed between patients with or without bacterial translocation. iFABP concentration in urine was higher in patients with sepsis compared to patients without sepsis (509 [94; 2393] vs. 134 [94; 516] pg/mL, p=0.015). iFABP also was higher in patients with bacterial translocation (385 [94; 1788] vs. 96 [94; 400] pg/mL, p=0.012).

CONCLUSIONS. Bacterial translocation of gut-specific bacteria into the blood was present in the majority of patients with intracerebral bleeding. There was no association between bacterial translocation and the development of sepsis in this cohort of patients. A high urine concentration of iFABP, a surrogate marker for gut barrier failure, however, was associated with bacterial translocation and sepsis.

INTRODUCTION. Bacteria obtained from the lower respiratory tract of patients undergoing mechanical ventilation (MV) can be part of the resident microbiome or act as pathogenic microorganisms. Colonization may persist even when the clinical symptoms improve and thus to determine its role as causative agents of infection is still an unresolved issue.

Staphylococcus aureus (SA) remains as one of the main causes of respiratory infection, although clinical presentation may vary from asymptomatic carriage to severe invasive disease, demonstrating an adaptation and a switch in virulence. It is of paramount importance to distinguish bronchial colonization from infection to adequate antimicrobial treatment to the patient's needs.

OBJECTIVES. To identify host and microbial factors associated with persistent isolation of SA in the lower respiratory tract despite adjusted treatment to antibiotic susceptibility profile.

METHODS. This is a retrospective and observational study conducted during 2 years in a polyvalent ICU.

Patient's population were those who, at their admission in ICU required MV, had a *S. Aureus* positive culture in endotracheal aspirate (ETA) and received antimicrobial treatment adjusted to susceptibility profile. Isolation in ETA was considered persistent when it lasted more than 7 days despite treatment adjusted to susceptibility profile. ETA and blood cultures were performed when there was clinical suspicion of respiratory tract infection, not systematically. Nasal swabs were obtained to check MRSA carriage.

Study was performed according to confidentiality criteria.

Data from patients included epidemiological characteristics (Age, Sex), presence of comorbidities, Glasgow Coma Scale (GCS), central nervous system (CNS) involvement, score in the Clinical Pulmonary Infection Score (CPIS), severity of illness at admission assessed by Acute Physiology and Chronic Health Evaluation (APACHE-II), consecutive isolation of *Pseudomonas aeruginosa*, days on MV and ICU length of stay (ICU LOS). SA's phenotypic factors taken into account were cloxacillin resistance.

RESULTS. A total of 97 patients that received antimicrobial treatment adjusted to susceptibility profile were selected: 29 were bronchial colonized, 41 had tracheobronchitis and 27 had pneumonia.

Persistence at ≥7days was documented in 39 cases (40.2%), being 27 MSSA and 12 MRSA.

In the univariate analysis, persistence correlated with younger age (p=0.009), higher CPIS (p=0.041), ICU LOS (p< 0.001), days on MV (p< 0.001), cloxacillin resistance (p=0.016) and consecutive isolation of *P. aeruginosa* (p< 0.001).

CONCLUSIONS. Persistent isolation of SA in mechanically-ventilated patients despite adjusted antimicrobial treatment is frequent.

Persistent isolation of SA correlated with younger age, higher CPIS, ICU LOS and days on MV, cloxacillin resistance and consecutive isolation of *P. aeruginosa*.

Critically ill burn patient and invasive candidiasis: do not keep calm!

A. Agrifoglio, E. Herrero, L. Cachafeiro, P. Millán, M. Sánchez, A. García de Lorenzo
Hospital Universitario La Paz, Critical Care Medicine Service, Madrid, Spain
Correspondence: A. Agrifoglio
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0751

INTRODUCTION. Burned patients represents a population with high risk for opportunistic infections. Burns infections are mainly caused by bacterial pathogens (70%), followed by fungal infections (20-25%) and finally by viral infections (5-10%). These infections have been described as one of the main causes of increased mortality. *Candida* spp. represents the main cause of fungal colonization in burned patients. The data varies according to the series, but the incidence of invasive candidiasis occurs between 2 and 21% of burned patients, with an attributable mortality between 30-90%; 30-60% of burned patients have at least one culture positive for *Candida* spp. during admission and the incidence of candidemia is around 3-5%.

OBJECTIVES. To analyze the incidence, mortality and risk factors associated with the development of invasive candidiasis in a population of critically ill burned patients.

METHODS. We retrospectively collected all patients admitted to our Critical Care Burn Unit between 2012 and 2017 and had any microbiological isolation by any *Candida* species. We collected: demographic and epidemiological data, severity scores (ABSI, APACHE-II), mechanism, extension and depth of burns, risk factors, need for organic supports, days of hospital stay and mortality.

RESULTS. 368 burned patients were admitted. Five invasive candidiasis in the form of candidemia were diagnosed: three candidemias due to *Candida albicans*, one for *Candida parapsilosis* and one for *Candida tropicalis* and three patients were colonized by yeasts in their burns. The candidemias were treated empirically with echinocandins. In 80% of the patients the mechanism of the burn was the flame. The medians were: age 40.5 years; 4 men; total burn surface area: 46%; depth, 34%; ABSI: 8, APACHE-II 18. The average hospital stay in the ICU was 39 ± 11 days. 100% of the patients were on mechanical ventilation at the time of the diagnosis of candidemia, and all of them also required vasoactive drugs. One patient (candidemia due to *C. albicans*) needed continuous renal replacement techniques. All had a central venous catheter, a urinary catheter, complementary parenteral nutrition and were on broad-spectrum antibiotic therapy. Two patients died, both with candidemia due to *C. albicans*.

CONCLUSIONS. Although the incidence of candidemia in our population is very low, almost half of the patients who develop it die during admission in a situation of refractory septic shock. Total burn surface area > 30%, multiple colonization by *Candida* spp., parenteral nutrition and broad spectrum antibiotic therapy, as well as central venous catheter and urinary catheterization continue to be the main risk factors.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0752

INTRODUCTION. Invasive pneumococcal disease (IPD) is a life-threatening disease. The European Center for Disease Control (ECDC) reported a notification rate of 16,1 cases per 100.000 population aged 65 years and older in 2015. In Portugal, notification rate was 1,4/100.000 for the same time frame (all ages). IPD is not a common diagnosis in ICU patients, but is associated with high rates of organ failure and mortality. Prevalence of IPD in our ICU was felt to be unusually high over the last year.

OBJECTIVES. Characterization of IPD patients admitted to our ICU over the last 12 months.

METHODS. Retrospective study of IPD patients over 12 months. IPD was classified either as bacteremic pneumonia, meningitis or infection of other usually sterile environment.Age,gender,SAPS II,length of stay (LOS), pneumococcal serotype,antimicrobial susceptibility testing, prevalence of ARDS, acute kidney injury (AKI) and septic shock, unadjusted mortality and standardized mortality ratio (SMR) were analyzed. Groups were compared on the basis of serotype and clinical features. Results were expressed as medians (interquartil range in brackets) for continuous variables and frequencies for categorical variables.

RESULTS. n=15 patients (0,78% of all admissions). Males:66,7%. Median age,years: 62 (20,8). SAPS II: 48 (41). Clinical presentation: Bacteremic pneumonia 53,3%, meningitis 33,3%, both 6,7% and pericardial empyema 6,7%. LOS,days: 4,5 (13,2). Diagnosis was performed either by cultures or molecular methods. Serotype analysis: 55,5% of infections due to serotypes covered by the pneumococcal 13-valent conjugated vaccine and one case due to a serotype not covered by any of the available vaccines. Of all isolates, 76,9% were susceptible to penicillin. Rates of organ failure were as follows: ARDS 13,4%,septic shock 53,3%, maximal norepinephrine dose on day 1 of 0,51 µg/Kg/min (1,80), AKI 46,7%. Sixty percent of patients were submitted to invasive mechanical ventilation (median days on IMV:11; IQR 15,5) and 20% to noninvasive ventilation; 40% performed continuous renal replacement therapy. ICU mortality was 20,0%, hospital mortality 40,0% (SMR 0,96). There was no relation between serotypes and mortality or organ dysfunction rates.

CONCLUSIONS. IPD is a severe and resource-consuming entity. At our centre, patients were mainly admitted with bacteremic pneumonia and had high rates of organ dysfunction, namely septic shock and acute kidney injury. Hospital mortality was high. Serotype distribution in terms of vaccinal coverage was somewhat different from the annual ECDC report, although this finding must be interpreted with caution given the reduced sample size. According to national guidelines, anti-pneumococcal immunization was due in 66,6% of these patients, raising the issue whether some of these admissions could have been prevented by previous vaccination. Penicillin susceptibility is in line with previous reports published in the literature.

0753

Clinical, microbiological and metabolomics changes in oral samples of septic patients admitted to the intensive care unit: a preliminary analysis

M. Kallas[1], M. Dias[2], M.A. Mendes[2], L.C.P.d. Azevedo[1,3]
[1]Hospital Sirio-Libanes, Sao Paulo, Brazil; [2]Universidade de Sao Paulo, Escola Politécnica, Laboratorio de Espectrometria de Massa, Sao Paulo, Brazil; [3]Faculdade de Medicina, Universidade de Sao Paulo, Disciplina de Medicina de Emergencia, Sao Paulo, Brazil
Correspondence: L.C.P.d. Azevedo
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0753

INTRODUCTION. Oral diseases in critically ill patients may be related to infectious complications, especially in septic ones. Thus, it is important to understand the most common pathogens in oral flora of these patients, as well as their changes during Intensive Care Unit (ICU) permanence.

OBJECTIVE. To evaluate clinical, microbiological and metabolomics changes in oral samples of septic patients during their ICU stay.

METHODS. We studied adult septic patients with more than 3 days of expected length of stay, which were admitted to the ICU of Hospital Sirio-Libanes, São Paulo Brazil from June 2016 to May 2017. These patients had samples collected from saliva and dental or oral prosthesis biofilm on their first, third and seventh day of ICU stay, while dental indexes where registered. ICU has protocolized oral care consisting of oral hygiene made with chlorhexidine 3-4 times a day. Microorganisms were cultured and isolated using Brain Heart Infusion agar 37 g L^{-1}. Bacteria were identified by Biotyper 3.1 database. The identification cut-off values higher than 2 and 1.7 were used for species and genus identification. Mass spectrometry analyses were performed using an UltrafleXtreme MALDI-TOF mass spectrometer. Metabolomic analyses were performed using a Gas chromatography-mass spectrometer. Statistical analysis was performed by the MetaboAnalyst tools.

RESULTS. We studied 10 septic patients with SOFA score 6.8±4.0 and ICU length of stay of 9.9±13.9 days. Mucosal plaque score improved from 4.6±1 at baseline to 3.8±1 (p< 0.001) at 7th day and bedside oral care exam from 15±2 at baseline to 12.8±3.1 at 7th day (p< 0.001). The most prevalent microorganisms in the saliva samples were *C. albicans* (26%), *Staphylococcus haemolyticus* (17.6%), and *E. faecalis* (11.7%). In the biofilm, the most prevalent microorganisms were *C. albicans* (36%), *E. faecalis* (7.7%) and *S. hominis* (7.7%). During the first 7 days of ICU stay, *Candida* and *Pseudomonas* species found in the biofilm had reduction on their percentages (p=0.037 and 0.007 respectively). Metabolomic analysis found 10 metabolites in higher concentration and frequency in these patients. Within them, 76.8% were found in oral biofilm, consisting mostly of glucitol (13%), alpha-D-Galactopyranoside (19%), 3,5-Dimethylbenzaldehyde (13%), D-Fructose (10%) and Octadecanoic acid (12%). The metabolites more frequently found in saliva were urea (15%), glucitol (27%), glycerol (12%) and D-Fructose (11%). Temporal analysis showed an increase in the concentrations of urea, alpha-D-Galactopyranoside and D-Fructose during ICU stay .

CONCLUSION. Septic patients admitted to an ICU with protocolized oral hygiene improve their oral clinical indexes during ICU stay. Analysis of saliva and biofilm showed persistence of pathogenic microorganisms and also metabolites correlated with sepsis and alterations of glycemic metabolism.

Does maintenance of the Zero Resistance project in ICU improve rates?

M. Muñoz Garach, O. Moreno Romero, M.E.Y.O. Yuste Ossorio
Hospital Universitario San Cecilio Granada, Granada, Spain
Correspondence: M. Muñoz Garach
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0754

INTRODUCTION. The multiresistant bacteria (MRB) in ICU is rising Public Health problem especially in the intensive care units. The implementation of surveillance programs for patients at risk of harboring MRB (Zero Resistance), a fast diagnostic and isolation when they appear are needed in our units.

OBJECTIVE. Description of the rates of multiresistant bacteria (MRB), days of isolation
in ICU and antibiotics after the start of the Resistencia Zero (RZ) project and analysis of these.

METHODS. Descriptive retrospective study, using the ENVIN-HELICS database, of patients admitted to UCI H.U. San Cecilio with 18 beds, comparing rates for the year in which the project starts (2014) with subsequent periods (2015). Variables studied were: days of antibiotic, days of MRB, days of isolation, patients with MRB at admission and during stay in ICU the colonization ±

infection infection and type of MRB and its evolution in the subsequent year(next year?).

RESULTS. The two periods compared:

1. Year 2014 (project start): 46 of 1034 patients presented MRB with the following rates for every 1000 days of ICU stay: 10.8 days of ICU stay, 334.9 days of antibiotic, 72.4 days of MRB and 54.54 days of ICU stay. isolation. At admission, 1.84 / 1000 days of stay and during admission, 6.58 including infection and colonization. 26 of these were infection (9 at admission = 0.87 rate and 17 = 4 during ICU admission). 84.73% GNBand 15.25% MARSA(17 pseudomonal MDR = 28.8%, Acinetobacter RI 22 = 37.29% Enterobacteria BLEE 9 = 15.25%)

2. Year 2015 in which the recommendations of the RZ project were maintained. 47 of 1051 presented MRB with the following rates: 11.33 days of ICU stay, 517.84 days of AB, 136.45 days MRB and 113.55 days of isolation. At admission, it was 2.57 / 1000 days of stay and during admission 5 including infection and colonization. Of these, 31 were infection (19 at admission = 1.81 and 12 = 2.89 during admission to the ICU). 76.78% GNB and 21.43 MARSA (24 pseudomonal MDR = 42.86%, Acinetobacter RI 5 = 8.93%, BLEE 11 enterobacteria = 19.64%)

CONCLUSIONS.

- After 2 years of the RZ project, the rate of infection by MRB 27.75% has been reduced, although the rate has increased on admission (extra ICU patients)
- The RZ project associates increase of days of isolation and days of AB
- In our unit, although the most frequent MRBs are the GNB in the last year, the MARSA has increased, not following under the current trend

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0755

INTRODUCTION. Sepsis, a life threatening condition, requires immediate treatment with antibiotics without knowledge of blood culture results. Patients hospitalized for prolonged periods of time tend to get colonized with hospital's flora, which is a plausible sepsis agent. We investigated whether knowledge of colonization could provide vital information in septic patients.

OBJECTIVES. To evaluate importance of epidemiological swab on successfully predicting septic patients' outcomes.

METHODS. A retrospective study was conducted in Vilnius University Santaros Clinics including all patients who had sepsis confirmed by blood culture and swabs from perineum collected during 7 days period before and after during 2016. Patient general information, main disease, different drugs taken, cultures' results were collected. Multidrug resistance (MDR) was defined as being resistant to 3 or more groups of antibiotics. Statistical analysis was performed with IBM SPSS 21. Odds ratio and adjusted odds ratio were compared using Fisher's exact test and logistic regression method.

RESULTS. A total of 98 patients were included in the study. 56 (57%) of them male. Mean patient age - 55,44±16,16 yrs. 70 (71%) patients were diagnosed with hematological malignancy. On 41 cases (42%) drug resistant bacterial strain, identified from perineum swab, coincided with blood culture. Overall, colonization by MDR strain was not associated with sepsis, caused by the same strain (OR 2,75, 95% CI 0,715-10,584; p=0,129). However, after analyzing only colonization by ESBL strain, we found out that colonization with ESBL was associated with sepsis, caused by the same strain (OR 2,976, 95% CI

1,13-7,836; p=0,024). Hematologic malignancy, after adjusting for different chemotherapy protocol, was associated with a higher risk of colonization by VRE (aOR 5,044, 95% CI 1,369-18,587; p=0,015). After adjusting for different immunosuppressive drugs taken, consumption of glucocorticoids was associated with increased colonization by ESBL strain (aOR 4,926, 95% CI 1,57-15,453; p=0,006), whereas cytostatics alone were associated with lower risk of such colonization (aOR 0,189, 95% CI 0,045-0,786, p=0,022). Colonization with VRE, ESBL or all MDR bacterial strains as well as concordance between blood test and perineum swab cultures did not predict mortality due to sepsis during in-hospital stay (OR 0,458, 95% CI 0,154-1,366; p=0,155; OR 1,127, 95% CI 0,444-2,862; p=0,802; OR 0,47, 95% CI 0,097-2,267; p=0,338, OR 0,644, 95% CI 0,255-1,627; p=0,351, respectively).

CONCLUSIONS. Colonization with ESBL strains is associated with ESBL caused sepsis. Glucocorticoids were found out to be associated with ESBL strain colonization, while hematologic malignancy - colonization with VRE. Colonization with resistant strains or concordance between perineum swab and blood culture were not associated with increased mortality.

INTRODUCTION. The information of urinary tract infection(UTI) in patiens with a nephrostomy catheter is very poor. The objective of this study was analyze the epidemiological, clinical, microbiological factors and the prognosis of complicated high UTI in patients with nephrostomy catheter.

METHODS. A descriptive, prospective study with 988 patients with UTI during 18 years, from 1997 to 2015. A culture taken from nephrostomy catheter was considered positive with $\geq 10^3$ufc/ml. With few exceptions, after the diagnosis the catheter was replacement. All the patients received treatment, first empirically and subsequently for a period of $\geq$10 days. After the initial decriptive analysis of the most relevant variables of the global series, the differnt clinical epidemiogical variables and the prognosis were compared with the rest of the patients.

RESULTS. From 988 patients with UTI, 69 cases (7,5%) had nephrostomy catheter. The mean age was 61.36 +/- 11.47 years . 36 cases were male (52,2%). 41 cases (59,4%) had a history of ureteral obstruction, 40 cases (58%) presented structural bladder patholoy, 19 cases (27,5%) had suffered urinary instrumentation in the previous 15 days, 11 cses (15,9%) had doublé "J" catheter. 87% had underlying systemic pathology, 60,3% active neoplasia, 37,7% chronic renal failure, 30,4% Diabetes Mellitus and 27,5% were inmunosuppressed.Only 11 cases (16,2%) was the first episode. Clinical expression was: 28 cases (40,6%) of miccional síndrome, in 26 cases (54,2%) greater than grade II ectasia was observed in ultrasound and in 8 cases hydronephrosis in abdominal CT. 21,7% of the cases presented bacteriemia. Microbiology, Ecoli was the principal mo observed. 13,3% of the cases were produced by non-fermenting gram-negative bacilli and 6,7% by enterococcus spp. 21,2% were produced by ESBL producing microorganisms. The duration of symptoms was 2,84 + 2,37 days, 11 cases (15,9%) developed septic shock, 43 casaes (62,3%) acute renal failure and 16 cases (24,2%) superinfection. The hospital stay was 10,83 +/- 6,3 days. Attributable mortality was 50%. Patients with nephrostomy had more structural bladder pathology (OR 3.46, 95% CI 1.76-6.81), higher repeat ITUS rates (OR 2.08, 95% CI 1.02-4.22) , more history of neoplasia (OR 4.35, 95% CI 2.27-8.31), ureteral obstruction (OR 6.68, 95% CI 3.45-12.95), higher isolates of Enterococcus spp (OR) 4.18, 95% CI 1.20-13.29) as well as higher

rates of superinfection (OR 2.34, 95% CI 0.94-5.79), without differences in crude or attributable mortality.

CONCLUSIONS. The percentage of UTI in patients with a nephrostomy catheter is considerable. In a high proportion of cases there is a history of previous episodes of urinary infection. The proportion of microorganisms other than E. coli is significantly higher, which means that the initial empirical treatment must be changed more frequently. The rate of reinfection in this type of infection is significantly higher.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0757

INTRODUCTION. While *Legionella pneumophilia* infection is a known as a cause of respiratory distress, its impact on heart function has not been well reported. Therefore we evaluated the impact of myocardial depression in a series of critically ill patients with legionella infection.

METHODS. In this retrospective study, we collected data from our electronic record system information on all patients admitted to the ICU with *Legionella* infection between February 1, 2016 to March 31, 2018. Echocardiograph is routinely performed on admission in our unit, and repeated as needed according to the evolution of the patient. In addition to echocardiographic data, we also collected demographic, hemodynamic, biologic, and organ support data. Data are presented as mean ± SD.

RESULTS. Seven patients were identified with a mean age of 70 ± 8y. Most patients did not receive immunosuppressive agents.

Four patients had mild respiratory impairment and were supported by high flow oxygen therapy. Three patients had severe ARDS, one requiring only prone position while two received in addition veno-venous ECMO.

Left ventricular ejection fraction was 43 ± 18% on admission, and progressively recovered in a delay varying from 2 to 6 days. Two patients had cardiogenic shock due to severe alteration in left heart function on admission. Right ventricular dysfunction was also identified in 2 other patients, and rapidly recovered after initiation of veno-venous ECMO. Inotropic support was used in 2 patients (dobutamine in 1 patient with 3 mcg/kg.min during 4 days and milrinone in 2 patients with a mean dose of 9 ± 3 mg during 24 and 48h) and vasopressor support in 4 patients (norepinephrine 0,06 ± 0.04 mcg/kg.min for a mean duration of 7 days.

There was no relationship between the severity of respiratory disease and impairment of left ventricular function.

Renal replacement therapy was used in 2 pts.

ICU length of stay was 23 ± 18 days. All patients recovered and were discharged alive from the hospital.

CONCLUSIONS. We illustrated that myocardial depression can be severe in patients with *Legionella pneumophilia* infection and is unrelated to the severity of respiratory disease. In some patients, cardiogenic shock can be the predominant symptom on admission.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0758

INTRODUCTION. ICU patients are exposed to the emergence of MDR GNB enteral colonization. Previous work showed that the MDR GNB infection risk is related to the RA of MDR GNB (Log 10 concentration of MDR GNB - concentration of GNB) amongst the enteral microbiota, but the RA of MDR GNB in ICU patients had not been studied yet. (1)

OBJECTIVES. We aim to study the relationship between the digestive RA in MDR GNB and occurrence of invasive MDR GNB infections in ICU patients.

METHODS. During 2 months, every intubated patient admitted in Bichat medical-infectious diseases ICU (Paris, France) was prospectively included. We collected an average of 2 stools samples per week from the admission to the discharge or death. MDR GNB were detected by seeding stool samples on selective environment and identified by using matrix-assisted laser desorption/ionization-time of flight (MALDI-TOF).

In case of MDR GNB detection, a quantification of the MDR GNB colonies and of the whole GNB colonies was made, and MDR GNB digestive RA was calculated.

We also collected clinical and biological data (SOFA score, lymphocyte to neutrophil ratio, death). The occurrence of MDR GNB nosocomial infection was reported during the 7-day period following the stool sample collection, as well as active MDR GNB antibiotics exposure between the stool sample and the infection or until the 7th day. Results are expressed in median [Interquartile range] and the concentration in $\log_{10}$.

RESULTS. In 62 stool samples in 32 intubated ICU patients followed and able to emit stools, 19 (30.6%) were positive for MDR GNB. MDR GNB enteral colonization was followed by a MDR GNB nosocomial infection within 7 days in 7 cases (37%) (including Ventilator associated pneumonia (VAP) in 4 cases).

Neither quantitative culture of MDR BNG (8,48 vs 7,60, p= 0,27), quantitative culture of total GNB (8,6 vs 8,3, p= 0,42) and MDR GNB digestive RA (-0,18 vs -0,40, p= 0,46) were related to infection.

Infected patients tend to have a higher SOFA score at the time of sampling stools (8 vs 6, p=0,26) and a lower lymphocyte to neutrophil ratio (0,051 vs 0,083, p=0,24). Time of antibiotic exposure effective against MDR GNB during the 7 days following the sampling of stools did not differ between patients who developed MDR GNB infections and others (0 vs 0,5 days p= 0,48).

3 patients (9,3%) developed a MDR GNB infection without a MDR GNB enteral colonization (2 VAP and 1 bacteremia).

CONCLUSIONS. In a pilot study, we found that MDR GNB abundance and relative abundance in the stool is high in all intubated ICU patients. We were not able to unmask major differences in abundance and relative abundance of MDR GNB in the stool for predicting nosocomial infections in the next week. Further largest cohort using systematic swabs instead of stools and adjusted on immune status and antimicrobial exposure is ongoing.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0759

INTRODUCTION. Infections caused by Enterococcus spp. have been associated with an increase in mortality in critical care patients.The change in the resistance pattern of these germs has been established, with an increase in the prevalence of Vancomycin-resistant Enterococcus spp. (ERV). In the critical patient, the adequate choice of empirical antimicrobial therapy is essential to improve outcomes.

OBJECTIVES. To determine the risk factors associated with the development of VRE infection in patients with sepsis admitted to an intensive care unit in Latin America.

METHODS. We analyzed retrospective data and development observational study case-control from patients admitted to a polivalent ICU during a 2-year period. We analyzed those patients with an infection during their ICU stay and search for factors related to the isolation of Enterococcus from clinical samples.

RESULTS. We studied 1200 patients, 24 of them with E faecalis (78 %) and 8 E. Faecium (22 %) vancomycin resistance was found. Patients with Enterococcus Vancomicyn - resistant (VRE) isolation were young (53.2 vs 55 years) and more high scores for APACHE II (17.5 vs 15.1 OR: 1.1 p: 0.02), infections had been acquired in the hospital, were surgical patients in higher proportion (77 vs 54.3%) , with abdominal surgical in high percentage (44 vs 22% p: 0.005) and had longer ICU stay (77% vs 54.3 % and 18.9 (DE 13.2) vs 10 (DE 9) days OR: 1.2 p 0.005: respectively), had received parenteral nutrition (40.6 % v 4 % OR: 9.5 p 0.008).Renal disease (59.3 vs 54.1% OR: 1.2) and need of haemodialysis (37.5 VS 34.3% OR 1.1) are risk factors for VRE infections (Prior use of antibiotics carbapenemic are associated with more cases of infections VRE (34.2 vs 21.8% OR 1.8). Mortality rate was higher in patients with VRE infection (56.2 vs 27.8 % p: 0.0027). The strategies such as empirical appropriated antibiotic, in patients with VRE, show a tendence to have low mortality (47% vs 57% 0R: 0.6 p: 0.39); Unlike the need of escalonation antibiotic is associated with high mortality (OR: 4.O IC:1.5-10.8 P 0.23).

CONCLUSIONS. Infections with VRE are more score severity to admission of ICU and the mortality is twice as old, with patients are infectios for other bugs in ICU. Although the empirical appropriated therapy antibiotic its difficult in this infection, its use are associated with minor mortality. The importance of know the risk factors for VRE , are the patients with septic shock to admission of icu and surgical abdominal with request parenteral nutrition for set up the empirical management appropriated.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0760

INTRODUCTION. In sepsis, empiric antibiotics are initiated prior to the reporting of microbial cultures[1]. Yet antibiotic resistance is an increasing problem in intensive care units, particularly in the context of nosocomial infections[2]. Early diagnostic biomarkers and treatment efficacy biomarkers have shown promising results in sepsis. One of these is C-reactive protein (CRP), which can be used to monitor efficacy of antibiotic therapy[2].

In this study we examine whether serial CRP measurements in patients undergoing treatment for ventilator-associated pneumonia (VAP) and ventilator-associated tracheobronchitis (VATB) reflect antimicrobial sensitivity, as demonstrated by tracheal aspirate cultures.

METHODS. A retrospective chart review of patients with ventilator-associated pneumonia or tracheobronchitis in a large urban ICU from 2015-2017 was performed. Ventilated patients with positive tracheal aspirate cultures at least 5 days after ICU admission were included. Exclusion criteria included a decision by the attending physician not to treat and the presence of other ongoing infections. CRP levels were recorded for 8 days, starting on Day 1 of treatment for presumed VAP/VATB. Patients who received antibiotics to which the culture organism was resistant, but subsequently changed to an effective regimen, were included in the "resistant" group until the day of antibiotic change. Statistical analysis was based on evaluating direct correlation of CRP values, CRP variation during consecutive days, and CRP ratio analysis (current day CRP concentration/ CRP concentration on day 1).

RESULTS. 48 patients with positive tracheal aspirate cultures and treatment for presumed VAP/VATB were identified. Of these, 33 were empirically prescribed antibiotics to which the culture organism was sensitive and 14 were prescribed antibiotics to which the organism was resistant. Sex, age and length of ICU stay prior to initiation of antibiotics were similar for both groups.

The most commonly isolated microorganism was *Pseudomonas aeruginosa* (47,9%) in both groups. Mean CRP levels on initiation of antibiotics were 173 ± 109 in the sensitive group and 222 ± 111 in the resistant group. On Day 2 of antibiotic treatment mean CRP levels increased in both groups and subsequently decreased starting on Day 3. No significant difference was identified in the decline in CRP levels between groups.

CONCLUSIONS. CRP does not appear to be a useful indicator of antimicrobial resistance in ICU patients with culture-positive VAP or VATB.

Gastrointestinal motility disorders in patients with acute brain injury - a risk factor for sepsis?

J. Schäper, C. Köhncke, M. Quintel
University Hospital Göttingen, Anaesthesiology, Göttingen, Germany
Correspondence: J. Schäper
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0761

INTRODUCTION. The "gut as a motor of sepsis hypothesis" is an accepted hypothesis for the pathogenesis of systemic inflammation in critically ill patients. Impaired gastrointestinal motility may be a surrogate parameter for intestinal failure including gut barrier failure.
OBJECTIVES. This retrospective analysis in patients with traumatic brain injury tests different clinical variables of gastrointestinal motility as independent risk factors for sepsis and death on ICU.
METHODS. Retrospective data analysis of clinical variables from a patient data management system (IntelliSpace Critical Care & Anesthesia, ICCA™). Identification of 671 patients with traumatic brain injury treated on ICU in the years 2010-2015 using 9 search items. Chronologic analysis of 108 patients with respect to clinical variables of gastrointestinal motility (time until 50% of nutritional needs were achieved, gastric residual volume, time until first defecation) were analysed on days 0, 1, 2, 3, 5, 7, 10, and 14 as well as outcome parameters (sepsis, death on ICU). Statistics: multivariate analysis of prior evaluated variable-candidates for dichotomous outcome measures sepsis and death on ICU. Comparison of variables of patients with gastrointestinal motility disorders with and without sepsis. Group comparison with Mann-Whitney U test. Significance level at p< 0.05.
RESULTS. Risk factors for sepsis were female sex (p=0.016), detection of gram positive (p=0.033) or gram negative pathogens (). The only risk factor for death on ICU was the time until defecation (p =0.033). Patients who died on ICU had shorter times until defecation when compared to patients who survived ICU (58 [29;68] vs. 109 [58;159] h, p=0.032). In patients with sepsis as compared to patients without sepsis neither time until first defacation 130 [58;190] vs. 95 [53;154] h, median[quartiles], p=0.197) nor time until 50% of nutritional needs differed significantly (95 [56;130] vs. 60 [53;75] h, p=0.06).
CONCLUSIONS. In this ICU-cohort of patients with traumatic brain injury variables of gastrointestinal motility did not serve as risk factors for sepsis or death on ICU. Gastrointestinal motility disorders also were not significantly pronounced in patients with sepsis compared to patients without sepsis.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0762

INTRODUCTION. Growing antimicrobial resistance among Gram-negative rod (GNR) strains is a worldwide issue. Delayed appropriate antimicrobial therapy is associated with higher mortality, so flora monitoring impacts the right first choice of antibiotic.
OBJECTIVES. The aim of study was to analyze pathogens and their sensitivity of hospital-acquired (HA) GNR monobacteremia strains to antimicrobial drugs and risk factors of mortality in Intensive Care Units (ICUs).
METHODS. Ongoing retrospective cohort study of patients treated in ICUs of Kaunas Clinic's with positive blood culture for GNR taken after 72 hrs of hospitalisation during 7yrs period was carried out.
RESULTS. We've found 196 cases of HA bacteremia due to GNR: 72 (36.7%) caused by Acinetobacter spp. (P=0.03), 38 (19.4%) by Escherichia coli, 34 (17.3%) by Klebsiella spp., 19 (9.69%) by Serratia spp. and just few others. Sensitivity to carbapenems (n=182, 92.9%), amikacin (n=131, 66.8%) cefoperazon/sulbactam (n=116, 59.2%), and piperacillin/tazobactam (n=93, 47.4%) was found. There were found 151 (77%) multi-drug-resistant and among them 64 (42.4%) - extensively-drug-resistant (XDR) strains. Among Acinetobacter spp. there was found 61 (84.7%) multi-drug resistant strain (P=0.04). In general multi-drug-resistant strain was found in male gender (n=90/118, P=0.04, OR=4.56, CI95%=2.4-15.4), elderly (P=0.001, RR=13.3), acute kidney injury (AKI) (n=98/128, P=0.03, OR=2.84, CI95%=1.35-9.92). Lethal outcome 73.5% (n=144) was found in male gender (P=0.04, OR=2.70, CI95%=1.53-9.75), elderly (P=0.04, RR=7.84), previous treatment in hospital (P=0.018, OR=2.46, CI95%=1.24-7.88), higher SOFA score (P=0.002, RR=32.1), mechanical ventilation (P=0.001, OR=12.45, CI95%=1.67-34.5), septic shock, (P=0.001, OR=8.21, CI95%=2.84-27.54), AKI (P=0.001, OR=5.62, CI95%=2.84-11.13), ventilator-acquired pneumonia (P=0.004, OR=2.37, CI95%=1.178-7.76), multi-drug-resistant strain (P=0.001, OR=5.67, CI95%=1.18-27.26). In multi-variate analysis lethal outcome was found in male gender (P=0.04, OR=2.92, CI95%=1.98-8.67), mechanical ventilation (P=0.04, OR=4.125, CI95%=2.70-6.34), septic shock (P=0.001, OR=8.21, CI95%=1.33-6.26), AKI (P=0.02, OR=5.67, CI95%=1.18-27.25), multi-drug-resistant strain (P=0.01, OR=3.47, CI95%=2.46-7.56).
CONCLUSIONS. 7yrs study of hospital-acquired GNR bacteremia in ICUs revealed Acinetobacter spp. as predominant mostly multi-drug-resistant pathogen. 3/5 of hospital-acquired bacteremias were related with multi-drug-resistant, almost in half of cases XDR GNR strain. Hospital-acquired multi-drug-resistant GNR bacteremia was related with male gender, elderly and AKI. High sensitivity of GNR to carbapenems was found. High rate of mortality was associated with male gender, mechanical ventilation, septic shock, AKI and multi-drug-resistant strain.

Fig. 1 (abstract 0763). HDL particles size at day 1 (A) and day 7 (B)

INTRODUCTION. Sepsis is associated with systemic inflammation that may impact lipoprotein function. In particular, high-density lipoproteins (HDLs) that display pleiotropic protective functions may be dysfunctional in septic conditions (1,2,3).
OBJECTIVES. The aim of this study was to evaluate the HDL profile and the inflammatory context in septic shock patients admitted to our intensive care unit (ICU).
METHODS. In this study,20 septic shock patients and 20 controls (ICU patients without septic shock) were included. Plasma samples were collected on days 1, 2 and 7. Total cholesterol and lipoprotein concentrations were determined. HDL profiles were obtained using the Lipoprint® System (non-denaturing electrophoresis).HDL profile characterization was carried out in vitro using whole blood, plasma and isolated HDLsincubated with different bacterial strains.
RESULTS. HDL-cholesterolconcentration was statistically lower in septic shock patients than in controls (table 1). At days 1 and 2, septic patients had significantly more large-sized HDL than control patients (figure 1). Survivor patients recovered a normal lipid profile at day 7. More importantly, we provide *in vitro* evidence that bacteria and LPS are able to increase the size of HDL particles (figure 2).
CONCLUSIONS. Our results emphasize that HDL-cholesterol levels are dramatically decreased at the acute phase of septic shock. The shift towards large HDL particles observed during sepsis could be due to a direct action of bacteria and LPS on lipoproteins.

INTRODUCTION. Blood culture is central to the investigation of any critically ill patient with a serious infection, however results take up to 5 days and, in 90% of cases, they are unable to identify an organism. Earlier, negative results may aid clinical decision-making. Cognitor© Minus (CM) is designed to provide rapid, universal detection of viable organisms. It is performed on blood culture aspirates after 12 hours incubation, and employs Enzymatic Template Generation and Amplification technology to detect microbial DNA polymerase activity. It is designed as a rule out test to exclude

bacteraemia and fungaemia, and has a negative predictive value (NPV) of 99.5% when compared to culture at 5 days.

OBJECTIVES. Analyse the performance of Cognitor© Minus in critically ill patients being investigated for infection and assess the potential impact on antibiotic prescribing.

METHODS. This was a prospective, observational study in a single, adult Critical Care

Unit. Paired blood cultures (2 aerobic & 2 anaerobic) were taken from patients being investigated for potential infection, at the physicians discretion. Providing no growth was detected after 12 hours incubation, a total of 1ml of blood was aspirated from one set and the CM test performed. The CM test was performed only in office hours. Clinicians were blinded to the result but were asked a series of questions by the critical care microbiologist at 24 hours and 48 hours post culture. This included; if the CM test excluded a bacteraemia or fungaemia would it affect their decision to continue or stop antimicrobial treatment compared to current practice.

RESULTS. 125 patients (mean age 58 SD ± 18, 58% male) were enrolled over a 6 month period. 110 patients received antibiotics (574 doses). The median time to obtain a CM result was 27 hours (IQR 20-47h) and it obtained a NPV of 100% in this study. Clinicians reported, if they had this information they would have de-escalated/ stopped antibiotics in 12 patients (11%). This was a calculated saving of 119 doses.

CONCLUSIONS. The use of the CM test beyond office hours would have led to a reduction in average reporting times, however the CM test maintained a very high NPV and demonstrated potential for reducing antimicrobial prescribing. These results support a further interventional study to test whether this test can safely reduce antimicrobial prescribing.

The HME filter resistance after drug nebulisation, experimental study

V. Zvonicek[1,2], V. Sramek[1,2], M. Zimmer[1,2]

[1]St. Anna´s University Hospital in Brno, Departement of Anaesthesia and Intensive care Medicine, Brno, Czech Republic; [2]Masaryk´s University Brno, Faculty of Medicine, Brno, Czech Republic

Correspondence: V. Zvonicek

INTRODUCTION. Heat and moisture exchanger (HME) is commonly used device for humidification of artificial airway. The potential drawback of HME is its obstruction by the aerosolized drug when the nebulizer is simultaneously placed into the ventilator circuit (1). The amount of increase of filter resistance after drug inhalation and its relevance is not well known.

OBJECTIVES. The aim of this study was to measure the impact of the drug nebulization on HME resistance.

METHODS. In the experimental model active humidifiers (Fisher Paykel MR 730) were used to simulate humidification function of airways, (100% relative humidity and airflow temperature of 33° C).The model was connected to the ventilator (Avea, Cheiron) by two-way circuit and ventilated in volume control mode with tidal volume 500 ml, respiratory rate 14 breaths per minute, PEEP 5 cm H_2O, I:E 1:2, FiO_2 35% and square flow pattern.

The vibrating mesh nebulizer (Aeroneb Pro, Aerogen Limited, Galway, Ireland) was positioned between Y-piece of the ventilation circuit and HME filter (proximal) or between filter and patient´s airways (distal). Two types of HME filters were used (Medisize HME Filter or Medisize Hygrovent Filter/HME). Berodual (solution of ipratropium and fenoterol) was nebulised for 15 minutes.

Flow and pressure drop over the HME filter (dP) were recorded by bedside chart (differential pressure transducer Validyne DP45, Validyne Engineering) and resistance (dP/flow) were calculated.

Statistical significance were tested using T test with Bonferroni correction, p< 0.05 was considered significant, data as mean and SD.

RESULTS. Fourteen experimental procedures were performed, 6 in proximal and 8 in distal position.

The initial dP and resistance (basal) significantly increased during nebulisation (peak), the increase was observed after 8 (2) minute after the start of nebulisation and sustained 4 (2) minutes. After nebulisation (end) dP and R returned to normal values and remained low at 15 and 180 minutes after end of nebulisation (end +15, end +180).

Both types of HME filters did not differ significantly and therefore results are provided together (Table 1).

CONCLUSION. The resistance of HME was transiently doubled after nebulisation of the drug, but returned to initial values in minutes, both in proximally and distally placed nebulizer.

Standardization of a sampling technic for evaluating airway inflammation in mechanically ventilated patients

R. Stamatiou, V. Tsolaki, E. Zakynthinos, D. Makris

Intensive Care Unit, University of Thessaly Medical School, Larisa, Greece

Correspondence: R. Stamatiou

INTRODUCTION. Mechanically ventilated (MV) patients may present airway inflammation and increased secretion production. However, it is not known whether cellular profiles in bronchial samples may be useful to evaluate the clinical condition of patients and bronchial sampling for such purposes is not yet standardized. [1]

OBJECTIVES. Our aim was to evaluate homogenized and non-homogenized samples obtained bronchoscopically from different parts of the bronchial tree, in order to access the optimum material for cell counting and protein evaluation.

METHODS. Patients admitted in the Intensive Care Unit of the University Hospital of Larissa, Greece, were enrolled in the study if they were intubated and mechanically ventilated. 3 types of bronchial samples were collected via bronchoscopy (PENTAX FB-15X):

a) tracheo-bronchial secretions macroscopically visible at bronchoscopy (VS)

b) tracheo-bronchial aspirates from surfaces without macroscopically visible secretions (IS)

c) mini bronchial lavage after the instillation of 5 ml of sterile normal saline (miniBL) on surfaces without macroscopically visible secretions and

d) bronchial lavage (BL) after the instillation of 50 ml of sterile normal saline in subsegmental bronchi.

Samples were homogenized in a Heidolph Silent Crusher S. Homogenized and non-homogenized samples were used for cell count after Trypan Blue staining and for protein extraction. Total protein was measured using the Bradford method after treatment with Lysis buffer (20 mM Tris-Cl pH 8.0, 150 mM NaCl, 1% Triton X-100, 1 mM dithiothreitol, 100 mg/mL-1 PMSF). Cell extracts were cleared by centrifugation (1000g, 20min, 4°C) and optical density was measured photometrically in samples with or without cells.

RESULTS. There were no significant differences in both cell numbers and total protein concentration between homogenized and non-homogenized samples. Handling time- time to extract protein and create smears - was 35 min less compared to non-homogenized samples. Total cell number in homogenized samples of IS, VS and miniBL were statistically significantly lower than in BL [677.2*103±144.7*103, 2249*103±508.4*103, 964.2*103±221*103and 2492*103±792.7*103 respectively, (p< 0.05)]. Total protein measurements in IS, VS were statistically significantly higher than in BL [12.21±1.99 μg/ml, 17.61±2.17 μg/ml and 8.41±1.81 μg/ml, respectively, (p< 0.05)]; there was no statistically significant difference between samples with or without cells.

CONCLUSIONS. Homogenization of bronchial samples in MV patients does not seem to affect cell numbers and total protein concentration. Homogenized samples were easier to handle and therefore could represent a biomaterial useful for protein extraction and examination.

Respiratory PaO₂ oscillations and their relationship to dynamic atelectasis measured by CT during tidal ventilation in a surfactant depletion model of ARDS

D. Crockett[1], J. Cronin[2], N. Bommakanti[3], R. Chen[1], C. Hahn[1], G. Hedenstierna[4], A. Larsson[4], A. Farmery[1], F. Formenti[2]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0767

INTRODUCTION. It has been hypothesised that respiratory oscillations in PaO₂ (O₂Os) in the injured lung are caused by cyclical recruitment of atelectasis (CA)[1,2]. These phenomena have been observed independently using rapid PaO₂ measurement[3,4] and CT[5,6] respectively. Here we explore the hypothesised relationship between O₂Os and CA by contemporaneous measurement of PaO₂ and tidal lung density changes in a porcine surfactant-depletion model of lung injury.

OBJECTIVES. We hypothesised that the amplitude of O₂Os increases with increasing CA during tidal ventilation in a porcine, surfactant depletion model of Acute Respiratory Distress Syndrome (ARDS). The aim of this study was to establish the role of CA as a determinant of O₂Os.

METHODS. This study of n=5 domestic pigs (mean weight (±SD) = 29.6 (±1.7) kg) at the Hedenstierna Laboratory, Uppsala University, Sweden was approved by the local ethics committee and adhered to ARRIVE guidelines. Animals under general anaesthesia were studied after saline lavage during tidal ventilation with VCV & PCV at V_T 10 ml kg^{-1}, RR 12 min^{-1} and variable I:E ratios. Contemporaneous measurements of atelectasis and PaO₂ were recorded using single, juxtadiaphragmatic slice dCT (temporal resolution of 250ms) and a rapid intra-arterial, fluorescence-quenching PaO₂ sensor.

RESULTS. A total of n = 148 sections of 30 s O₂O data were analysed. Fig. 1(A) demonstrates there is no direct relationship between the change in atelectasis and the respiratory PaO₂ oscillation amplitude (R^2's = 0.06 - 0.18) across the group. Mean PaO₂ and respiratory PaO₂ oscillation amplitude for each ventilator condition are shown in Tab.1 & Fig.1(B).

CONCLUSIONS. This is the first study to contemporaneously use a dCT measurement of CA and dynamic measurement of PaO₂ in the injured lung. It demonstrates that the presence of CA is not the sole, main determinant of respiratory PaO₂ oscillation amplitude in a saline-lavage model of lung injury in pigs, and supports further investigations in the dynamic, often overlooked, role of pulmonary perfusion within the complex context of pulmonary responses to mechanical ventilation.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0768

INTRODUCTION. Nebulization is a widely used technique for delivering drugs to patients under mechanical ventilation (MV) in intensive care units (ICU). However, the effectiveness of this drug delivery and optimal conditions for implementation still remain poorly documented. Further clinical trials for MV patients are needed but in vivo human studies are scarce because of ethical restrictions due to imaging technique in nuclear medicine. Consequently, few in vivo trials are feasible and anatomical models remain controversial (1). Thus we need an easy to manage, cost-effective, reproducible and physiologically validated model.

OBJECTIVES. This study aim to validate the MV of an ex vivo chimeric lung model previously developed in our laboratory (2) for deposition pattern of inhaled particles.

METHODS. The intra-thoracic part of the respiratory tract was obtained from porcine slaughterhouses and arranged in a sealed enclosure. Data about wounds potentially leading to abnormal results were collected. Tracheal intubation respected physiological angulation. MV was achieved with an Evita 4 ventilator (Dräger, Germany). Ventilation parameters were set based on a recent epidemiological study of MV patients (3). They were as follows: volume controlled, heated humidifier, fraction of inspired oxygen: 21%, tidal volume: 540 mL, positive end expiratory pressure: 9 mbar, respiratory rate: 20 cycles per minute with an inspiratory / expiratory ratio of 1/2, inspiratory flow: 35 liters per minute (3, 4).

The first part of the study was dedicated to physiological measurements using a pneumotachograph and a differential pressure sensor.

The second part consisted in 81m Krypton scintigraphies to assess the homogeneity of ventilation. A manual count of total relative uptake corrected for background signal attenuation was made for each lung.

RESULTS. Twenty-three respiratory tracts were set for MV. Physiological measurements showed good coherence with human data.

Average values and their standard deviations (SD) are as follows: tidal volume, 479 mL SD 52 mL; minute volume, 9.6 L/min SD 1.1 L/min; leakage volume, 1.2 L/min SD 1.1 L/min; resistance, 3.1 cmH2O/L/sec SD 0.9 cmH2O/L/sec; compliance, 339.6 mL/cmH2O SD 195 mL/cmH2O. The 12 scintigraphies realized showed homogenous ventilation (Fig. 1) having an average of 52.3% and 47.7% of respectively right and left lung counts (SD, 3.7%) meaning great similarity with human studies (5, 6).

CONCLUSIONS. This preclinical model provides an easy to use, reproducible and cost-effective tool to later achieve larger aerosol studies under mechanical ventilation.

Not only pendelluft: multifold local inspiratory air-redistribution events continuously occur in collapsible lungs. An experimental study

M. Pellegrini[1,2], G. Hedenstierna[3], A. Larsson[1,2], G. Perchiazzi[1,2]

INTRODUCTION. Macroscopic air-redistribution events related to strong inspiratory efforts causes unpredictable overstretch in heterogeneous lungs during spontaneous breathing (SB). The micromechanics of air-redistribution in heterogeneous lungs has not been investigated and quantified before.

OBJECTIVES. To describe at the acinar level during both SB and mechanical ventilation (MV) the effects of positive end-expiratory pressure (PEEP) and external resistance (xRaw) on gas-redistribution during inspiration.

METHODS. SB and MV were compared in six pigs with collapsible lungs obtained by lung lavage. Dynamic CT images were acquired at two distances from the diaphragm dome, during the application of different combination of applied PEEP and xRaw. CT images were processed to obtain delta volume images (ΔVol), each subtending a time frame of 0.05 seconds.

Inspiration was studied as divided in two different functional phases: 1.the airway flow-independent phase of inspiration (classically defined as "pendelluft") and 2. the airway flow-dependent phase of inspiration (here defined as "gas-mingling").

For each inspiration, the first three ΔVol, characterized by zero flow at the airway opening, allowed the pendelluft analysis; the following ΔVol sequence allowed the analysis of air-redistribution during ongoing inspiration.

RESULTS. In the studied setup, pendelluft was detected only during SB: it developed along cranio-to-caudal and nondependent-to-dependent directions and was reduced or prevented by high PEEP.

During both SB and MV, multifold local inspiratory air-redistribution events continuously occurred.

Two patterns of gas mingling were identified during ongoing inspiration: 1. large and few areas, here defined as "gas-displacement", 2. small and numerous areas, here defined as "gas-scattering".

Patterns of gas-displacement, characterizing SB at low PEEP and high xRaw, turned into gas-scattering at high PEEP and low xRaw, mainly in peri-diaphragmatic regions. MV predominantly showed gas-displacement patterns.

CONCLUSIONS. Albeit pendelluft appears only in SB, both SB and MV are characterized by gas-mingling throughout the whole inspiration. Although not causing pendelluft, MV is more prone than SB in generating unstable patterns of air-redistribution.

INTRODUCTION. Modern ventilators consist of digitally controlled electromechanical devices and analogue systems driven by compressed gas sources[1]. Digital sensors and associated control software contribute to high cost, fragility and impracticality whilst pneumatic alternatives rely on a compressed gas source. A Robust, low cost and safe alternative technology is needed in many areas of critical care and in low resource environments[2].

OBJECTIVES. We present the invention, prototyping and evaluation of a simple, inexpensive mechanical ventilator that uses a novel design and pressure sensing approach. The technology relies solely on basic control algorithms and a disposable pressure sensitive 'on/off´ switch within the circuit. The resulting binary signal is interpreted and controls an impeller. The approach retains the ability to detect compliance, resistance and circuit leak changes using a novel timing metric. We hypothesize this design safely delivers effective ventilation and provides accurate monitoring at low cost thus overcoming many disadvantages of modern ventilators.

METHODS. A prototype was constructed and evaluated using a test lung. Algorithms recorded the time taken to reach peak pressure, 'TRP' (ms), during each breath indicated by 'tripping' of the pressure-sensitive switch. This data was used to investigate the identification of isolated variations in circuit leak, compliance and resistance at multiple peak pressures.

RESULTS. The prototype reliably measured pressure-time waveforms. At $20cmH_2O$ peak pressure, as circuit leak area increased to $6mm^2$, TRP values increased by 43ms. As leak increased further, TRP values breached a safely threshold resulting in automatic recalibration and adjustment to the leak. As compliance varied from $10ml/cmH_2O$ to $20ml/cmH_2O$, a TRP change of 98ms was recorded. Between $20ml/cmH_2O$ and $50ml/cmH_2O$ a change of approximately 48ms was recorded. As resistance varied between 0, 5 and $20cmH_2O/L/s$ the TRP varied by 124ms and 155ms respectively. Results were consistent across a range of peak pressures (16-$35cmH_2O$).

CONCLUSIONS. The results show this novel ventilator design is able to deliver pressure-controlled mechanical ventilation effectively and safely using simple, low cost, and robust technology. Data supports the reliable performance of the prototype in varied respiratory conditions without needing a compressed gas supply, complex digital sensors or software. We believe the findings make this an attractive prospect for providing short-term mechanical ventilation in remote environments, low resource settings, and during intra/inter-hospital transfers. Further in-vivo clinical testing is planned.

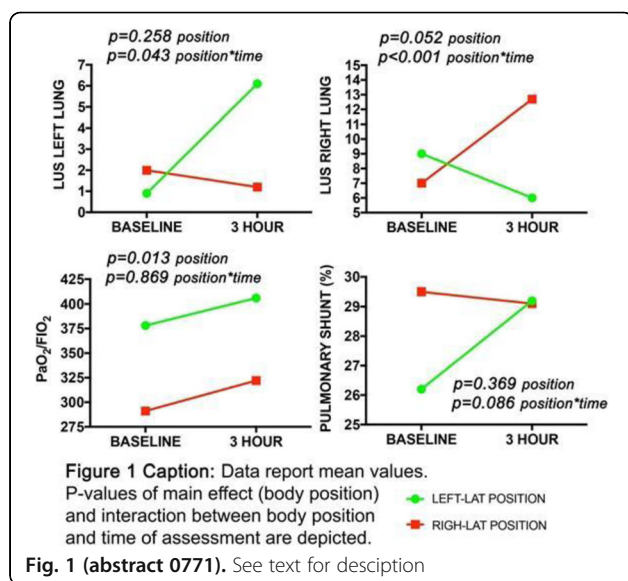
INTRODUCTION. Mechanically ventilated patients with mono-lateral pneumonia are commonly positioned in lateral decubitus, with the healthy lung in the dependent position, to ameliorate ventilation-perfusion coupling. The effects of this intervention on the dependent healthy lung are still elusive.

OBJECTIVES. To assess changes in lung ultrasound examination and gas exchanges, during right and left lateral decubitus, in an animal model of right-sided pneumonia.

METHODS. Eight pigs (32.4±1.2 Kg) were sedated, and mechanically ventilated. Right-sided pneumonia was induced with bronchoscopic instillation of *P. aeruginosa*. After 24h, animals were positioned in supine position. Then, a recruitment maneuver was carried out and animals were randomly positioned on the right or left side. Primary outcome was lung ultrasound score (LUS) of the dependent lung, computed upon lateral positioning (baseline), and three hours thereafter. Furthermore, at aforementioned times, oxygenation and pulmonary shunt were measured. After these evaluations, animals were repositioned supine, an additional recruitment maneuver was performed, and the effects of positioning on the contralateral side were tested. Two experts in lung ultrasound, blinded to the study interventions, calculated LUS of both lungs, based on a 4-level score (normal = 0, well-separated B-lines = 1, coalescent B-lines = 2, and consolidation = 3) of each of the 6 regions of assessment of both hemithorax (anterior, lateral, and posterior), which were further subdivided into a superior and inferior subsections [1]. Total LUS of right and left lungs was computed.


RESULTS. LUS of the left lung worsened in left lateral decubitus (Figure 1). In addition, LUS of the right lung slightly improved in the left lateral decubitus, but worsened to a greater extent in the right lateral decubitus. As expected, PaO_2/FIO_2 improved by approximately 100 mmHg in left lateral position, and ameliorated further during the 3-h study period in both positions. Irrespective of oxygenation

benefit, a slight increase in pulmonary shunt was found in left lateral decubitus. Linear regression analysis demonstrated slight correlation between PaO_2FIO_2 and LUS (p=0.055, r^2 =0.11).

CONCLUSIONS. In an animal model of right-sided pneumonia, left lateral position improved oxygenation, marginally ameliorated the diseased lung, while deteriorating the healthy lung. In contrast, right lateral position further collapsed the diseased lung, without affecting the healthy lung. Overall our data raises controversial points concerning the use of lateral position in mono-lateral pneumonia and calls for confirmatory clinical evaluations.

Positive end-expiratory pressure ventilation induces longitudinal atrophy in diaphragm fibers

INTRODUCTION. Critically ill patients often develop diaphragm weakness, which prolongs ventilator dependency, hospital stay, and increases mortality and health care costs. Mechanisms underlying diaphragm weakness include cross-sectional atrophy and contractile dysfunction of diaphragm muscle fibers, but whether shortening of these fibers *(i.e. longitudinal atrophy)* occurs is unknown.
OBJECTIVES. To study the hypotheses that:
(1) an increased end-expiratory lung volume during positive end-expiratory pressure (PEEP) ventilation causes caudal diaphragm displacement and acute shortening of diaphragm fibers;
(2) diaphragm fibers adapt to this acutely shortened position by reducing their contractile filament lengths or the number of serially-

linked sarcomeres - the smallest contractile units in the muscle - to maintain a maximum force generating capacity;
(3) adaptation is modulated by the giant mechanosensing protein titin.
METHODS. Diaphragm displacement, visualized by ultrasound, and diaphragm fiber shortening during different levels of PEEP ventilation were examined in critically ill patients and shortly mechanically ventilated wild type rats. Diaphragm fiber adaptation during long-term PEEP ventilation was studied in critically ill patients and 18h mechanically ventilated wild type rats. Modulatory effects of titin were assessed in 18h mechanically ventilated wild type rats and rats with a more compliant titin isoform (RBM20 deficient rats).
RESULTS. This study shows that (1) in patients PEEP ventilation results in 0.40±0.10cm and 0.89±0.17cm caudal diaphragm displacement at Δ5 and Δ10cmH$_2$O PEEP; in rats PEEP ventilation results in 0.24mm displacement per cmH$_2$O PEEP. In rats, acute displacement caused by 2.5 cmH$_2$O PEEP was accompanied by shorter full-length diaphragm fibers (18.0±0.5 vs. 19.9±0.4mm; p=0.01), and shorter sarcomere lengths (2.64±0.06 vs. 2.85±0.07µm; p=0.04) at end-expiration. (2) After long-term PEEP ventilation, diaphragm fibers in rats adapted to the shorter sarcomere length by reducing the number of serially-linked sarcomeres by 12% (5488±128 vs. 6250±170; p=0.004), whereas contractile filament lengths did not change. (3) RBM20 deficient rats did not show a reduced number of serially-linked sarcomeres after 18h of PEEP ventilation (PEEP vs. control: 7005±777 vs. 7155±424; p=0.70).
CONCLUSIONS. Diaphragm fibers show longitudinal atrophy during PEEP ventilation, which might be modulated by titin-borne elasticity. We postulate that longitudinal atrophy contributes to a lower force generating capacity of the diaphragm during spontaneous breathing trials in critically ill patients. During these trials PEEP and the end-expiratory lung volume are reduced, which stretches the shortened diaphragm fibers to excessive sarcomere lengths. At these long sarcomere lengths, muscle fibers generate less force and diaphragm weakness ensues.

Effect of invasive mechanical ventilation (IMV) on sleep architecture in intensive care unit (ICU) using 24 hour polysomnography

B. Prajapat, A.S. Sandhya, D. Chaudhry
PGIMS, Pulmonary and Critical Care Medicine, Rohtak, India
Correspondence: B. Prajapat
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0773

INTRODUCTION. Sleep in icu is not sound and restorative but disturbed and distorted. Survivors of critical illness reported their sleep to be of poor quality and a major stressor associated with their admission. Among several factors, use of mechanical ventilation has been reported as an important cause of disturbed sleep in ICU.
METHODS. 24 hour polysomnography (PSG) study was done in two groups of patients who were recovering from their critical illness:
group 1 - IMV group and
group 2 - spontaneously breathing group.
Frequency of nursing care activities were also recorded for both the groups. Quality of sleep in ICU was also assessed by using Richard Campbell sleep questionnaire (RCSQ) and sleep in ICU questionnaire (SICU). Mann- Whitney U test was used to assess the difference of means of both groups.
RESULTS. 26 patients completed the study (15 patients in group 1 and 11 patients in group2).Pressure support ventilation was the mode in all group 1 patients . Mean REM stage duration in those who received mechanically ventilation (IMV) and those who did not was 16.57 ± 21.12 mins (2.9%) and 31.47 ± 18.45 mins (5.9%) respectively (p = 0.018). The difference in means of N2 stage between the two groups was also significant (62.5% vs 57.2 %, p=

0.048). Mean arousal index (AI) in IMV and spontaneously breathing group were 27.02 ±11.58 and 16.7 ± 4.46 respectively (p = 0.015). Mean sleep duration without wake was more in spontaneous group (2.699 ± 1.36 mins, 3.83± 1.09 mins : p = 0.018). The difference in mean of other parameters of sleep like total sleep time (TST), wake after sleep onset (WASO), N1, N3, day time sleep and night time sleep did not reach statistical significance (Table 1). Nursing care activities in patients who received mechanical ventilation was more compared to spontaneously breathing patients (52.6 ± 6.78, 48.5 ± 5: p = 0.14) especially during day time (42.2 ± 5.75, 38.6± 4.5: p= 0.06) although the difference in mean did not reach the statistical significance. Mean RCSQ score difference was significant (group 1- 54.6 ± 7.69, group2- 60.19 ± 10.85: p= 0.04). Patient perceived their sleep as very poor in ICU and addressed nursing interventions and noise as major disrupting factors.

CONCLUSION. Sleep in icu is disturbed and fragmented. Mechanical ventilation is an important factor responsible for architectural distortion of sleep in ICU.

driving pressure increase (4,8±2 vs. 7±2, p< 0,05) with no difference in EELV/kg (28±6 vs. 29±7, p=n.s.).

Horowitz Index showed no difference in all three groups after 6 hours. The heart index decreased at PEEP 10 (6.4±0.8 vs. 4.9±0.7, p< 0.01) and PEEP 15 (4.4±1 vs. 3.6±0.5, p< 0,05). Comparing all groups driving pressure decreased and EELV/kg increased with increasing PEEP.

CONCLUSIONS. Higher PEEP can improve lung mechanics and gas exchange in moderate abdominal hypertension without lung injury in a swine model.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0774

INTRODUCTION. Intraabdominal hypertension is a well-known phenome in critically-ill patients. The elevated intraabdominal pressure (IAP) interacts with intrathoracic pressure and influence driving pressure, transpulmonary gradient (ΔP_L), end-expiratory lung volume (EELV), and pulmonary compliance (C_{stat}) and therefore lung mechanics. We analysed these parameters in swines with moderate intraabdominal hypertension of 10 mmHg.

OBJECTIVES. To compare the effect of different PEEP levels in lung mechanics, gas exchange, cardiocirculatory parameters at induced clinical picture.

METHODS. Swine's received general anaesthesia, were tracheotomized and supplied with an esophageal balloon, intraabdominal balloon to induce intraabdominal hypertension, central venous and PiCCO® lines and bladder catheter. Animals were randomised into 3 groups (Group A=PEEP 5cmH$_2$0, B=PEEP 10cmH$_2$0 and C=PEEP 15cmH$_2$0) and ventilated in pressure controlled/volume guaranteed mode with a tidal volume of 8ml/kg bodyweight for 6 hours. 10 mmHg IAP was generated and maintained in all groups at hour 0. EELV, C$_{stat}$, driving pressure, ΔP_L, IAP and circulatory parameters were measured at baseline, hour 0 and every 2 hours until hour 6.

RESULTS. 18 swine (N=18) were included in the study. There were no significant differences between groups at the baseline. In group A (PEEP 5) there was an increase in ΔP_L (11.2±1 vs. 17.2±1, p< 0,01) and driving pressure (5,7±1 vs. 10±3, p< 0,01) and a decrease of C$_{stat}$ (42±4 vs. 27±2, p< 0,01) and EELV/kg (27±4 vs. 16±3, p< 0,01) compared hours 0 and 6. In group B (PEEP 10) there was an increase in ΔP_L (11.2±1 vs. 14.5±1, p< 0,01) and driving pressure (5,2±1 vs. 6.7 ±1, p< 0,01) and a decrease in C$_{stat}$ (42±7 vs. 32±3, p< 0,01). EELV did not decreased with a PEEP 10 in group B (27±8 vs. 24±6, p=n.s.). In group C (PEEP 15) ΔP_L increase (10±1 vs. 12±1, p< 0,05) and

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0775

INTRODUCTION. Simulation in intensive care is an innovative method for teaching. Respiratory settings can be responsible for some asynchronies, which may increase mortality of our patients (1). For this reason we develop a simulator (SimVA) of spontaneous artificial ventilation with virtual breathing patients. Mathematical model resolved differential equations of chest and lung movements according to inspiratory effort in order to match with a clinical database.

OBJECTIVES. The goal of this study was to evaluate asynchrony index (AI) in virtual COPD patients according to pressure support (PS) level and Inspiratory time (Ti) and to compare the results to the study of Thille et al (2).

METHODS. Virtual case were COPD, defined by thoracic and pulmonar compliance, resistances, lung volumes, and inspiratory adaptive muscle pressure. Asynchrony Index was patient ineffective efforts (IE)/ (IE +Ventilator Respiratory Rate). Ventilatory protocols were Baseline-PS, Optimal-PS and Optimal-Ti (Optimal meant decreasing PS or Ti in order to reduce AI) as described by Thille et al (2). Each virtual case was titrated with each protocol. AI was recorded and compared to the results of Thille et al.

RESULTS. The optimal protocols titrated PS or Ti in order to reduce AI, the software simulates the corresponding values of tidal volume and respiratory frequency and its effect on intrinsic PEEP and gas trapping. The difference in settings and respiratory mechanic between virtual cases and patients were not significant (Table 1).

CONCLUSIONS. AI was able to change according to PS or Ti settings within the same range as the study from Thille et al. Simulation with the software SimVA is realistic and may help to teach interactively ventilatory settings and asynchronies in COPD patients under Pressure Support Ventilation anywhere without any risk for the patient.

Intensive Care Unit, University of Thessaly Medical School, Larisa, Greece
Correspondence: V. Tsolaki
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0776

INTRODUCTION. Cellular profiles in bronchial airways of mechanically ventilated patients are largely unknown although it may reflect airway inflammation and may be associated with ventilator associated infections. [1]
OBJECTIVES. The aim of the present study was to evaluate cellular profiles in different methods of bronchial sampling.
METHODS. Patients admitted in the Intensive Care Unit of the University Hospital of Larisa, Greece, were enrolled in the study if they were intubated and mechanically ventilated. Two types of bronchial samples were collected via bronchoscopy (PENTAX FB-15X): simple tracheo-bronchial aspirates from mucous membranes with macroscopically visible secretions (VS) and aspirates obtained with bronchial lavage (instillation of 60 ml of sterile normal saline in subsegmental bronchi - BLa). A subgroup analysis of patients without pneumonia was also performed. Samples were homonegized in a Heidolph Solent Crusher S (Heidolph Instruments GmbH &Co. KG, Germany) and cell counting was performed after Trypan Blue staining. Cell extracts were cleared by centrifugation (10000g for 20 min at 4o C) and optical density was measured photometrically.
RESULTS. Samples were obtained in 11 cases. VS samples had similar cellular profiles with Bla samples in terms of neutrophils, lymphocytes, macrophages (13.25%±1.58% vs 10.56%±2.96%, p=ns, 29.31%±1.82% vs 24.42%±2.56%, p=ns, 30.10%±2.35% vs 28.56%±3.31%, p=ns, respectively). Similar cellular profiles were observed in patients without pneumonia (n=6) (15.17%±2.27% vs 18.63%±3.15%, p=ns, 26.58%±1.75% vs 24.69%±2.54%, p=ns, 30.62%±3.51% vs 27.15%±4.54%, p=ns, respectively).
CONCLUSIONS. Bronchial samples obtained via bronchoscopy either with simple aspiration of macroscopically visible secretions or with bronchial lavage might have similar cellular profiles, irrespective of the presence of pneumonia or not.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0777

INTRODUCTION. CPAP is a technique widely used in acute respiratory failure, it's reduce work of breathing (WOB) and improve gas exchange. Various device are avaible, which could have different performance and load on respiratory effort of the patient.
OBJECTIVES. Testing of four CPAP systems based on air entrainment comparing its perfomance, in terms of work and effort of breathing (WOB) due to circuit, inspiratory debit, pressurization stability and resistance.
METHODS. Boussignac® CPAP valve (Vygon, France); Pulmodyne® (Linde, USA); Ventumask® High Flow (StarMed, Italy); and Caradyne Whiperflow2®(Philips), were evaluated in active lung model simulating spontaneous ventilation (Elastance 33 cmH$_2$O/L, Resistance 5cmH$_2$O/L/s, RR 22/min), with three effort level computer-generated (A: -5 cmH$_2$O, B: -10 cmH$_2$O, C: -15 cmH$_2$O), at three CPAP preset level (5, 10, 15 cmH$_2$O). Calibration was made by gas flow analyzer Vt-Mobile®, Fluke biomedical. Airway, pleural, alveolar pressure (Paw, Ppl, Palv), and Flow (V') were recording at sampling 560 Hz for subsequent analysis. Ten cycles were taken for each condition for measures. Measurement: Mechanic respiratory by multiple linear regression, respiratory pattern, effort and WOB, swing of pressurization as ΔPaw and ΔPalv. The distribution of variables was initially tested with the Shapiro-Wilk test for normality. Results are expressed as mean ± SD, or as median (25-75%). Comparisons were performed by analysis of variance (Bonferroni t-test) or on ranks test (Dunn's) when appropriate.
**RESULTS.**
CONCLUSIONS. The performance of CPAP device studied was different. For all levels of effort and pressurization Pulmodyne® represents the lowest breathing load imposed. In response to the effort, Boussignac® valve and Pulmodyne® provide the greatest difference in tidal volume, 2.96 and 2.82 times for CPAP 5 cmH$_2$O, 1.51 and 1.35 times for 10 cmH$_2$O, respectively.

The incidence of ICU-acquired swallowing disorders after prolonged intubation in the elderly: an endoscopic evaluation

M. Nakanishi
Kurashiki Central Hospital, Intensive Care Medicine, Kurashiki, Japan
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0778

INTRODUCTION. Critically ill elderly patients requiring prolonged intubations often develop ICU-acquired swallowing disorders (ICU-ASD), which related to the worse outcomes. However, few research has examined the incidence of ICU-ASD with using fiberoptic endoscopy.

OBJECTIVES. The aim of our study is to describe the incidence and clinical characteristics of ICU-ASD in the elderly patients using fiberoptic endoscopy.

METHODS. A cross-sectional study was conducted in our medical-surgical ICU from May 2016 to March 2018. The inclusion criteria were all consecutive patients aged ≥65 years old who required prolonged intubation (endotracheal intubation ≥48 hours).

Exclusion criteria were patients who had preexisting dysphasia, tracheostomy, and altered mental status (GCS < 13). All included patients were examined for ICU-ASD using fiberoptic endoscopy within 48 hours after extubations. The severity of ICU-ASD was evaluated using the Hyodo-Komagane score which consists of four categories (0: normal, 1: mild, 2: moderate, 3: severe) and assessed four findings (salivary pooling in the vallecular and piriform sinuses, response of the glottal closure reflex, swallowing reflex initiation, pharyngeal clearance after swallowing of test water). The primary outcome was incidence of ICU-ASD. The secondary outcomes were the length of ICU stay and hospital stay.

RESULTS. 104 patients were included in our study. Median age was 79.0 (73.8-83.5) years old and 52.9% were male. The median intubated days were 7.0 (5.0-8.0) days. Indications of intubations were sepsis (44.2%), respiratory failure (17.3%), trauma (15.4%), and others (23.1%). The median APACHE II score was 23 (18-30), and the median SOFA score was 9 (7-11). The incidence of ICU-ASD was 25 patients (24.0%). The severity of ICU-ASD was that the normal was 56 patients (53.8%), mild to moderate 40 patients (38.5%). And observed abnormal findings were as follows: 25 patients had aspiration, 12 patients had moderate to severe salivary pooling degree, 6 patients had that reduction of the glottal closure reflex, 27 patients had delayed time of the swallowing reflex, and 15 patients had reduction of pharyngeal clearance. The length of ICU stay and hospital stay were 8.0 (6.0-10.5) and 30.0(17.5-41.0) days.

CONCLUSIONS. The incidence of ICU-ASD was 24.0% in the elderly patients, which was lower than previous reports. Multivariate analysis is needed to find risk factors of developing ICU-ASD.

Lung aeration score and the role of lung ultrasound in patients with acute respiratory distress syndrome on veno-venous extracorporeal membrane oxygenation: a prospective observational study

S. Curry[1], L. Gargani[2], O. Ng[3], A. Roscoe[1], K. Salaunkey[1], B. Agrawal[4], A. Rubino[1]
[1]Royal Papworth Hospital NHS Foundation Trust, Department of Anaesthesia and Intensive Care, Papworth Everard, Cambridge, United Kingdom; [2]Institute of Clinical Physiology, Pisa, Italy; [3]Singapore General Hospital, Bukit Merah, Singapore; [4]Royal Papworth Hospital NHS Foundation Trust, Department of Radiology, Papworth Everard, Cambridge, United Kingdom
Correspondence: S. Curry
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0779

INTRODUCTION. Acute Respiratory Distress Syndrome (ARDS) is characterised by an acute inflammatory process, loss of lung aeration and impaired gas exchange. In its most severe form, ARDS carries a high rate of mortality and may require Veno-Venous Extracorporeal Membrane Oxygenation (VV-ECMO) to preserve adequate physiological parameters. For ARDS patients receiving VV-ECMO, strict imaging protocols are important for clinical management. Lung UltraSound (LUS) is an emerging bedside imaging technique used to support diagnosis and monitoring of acute lung conditions. A standardised protocol allows for repeated assessment for quantification of lung aeration and examination of pathological aspects of ARDS. The potential use of LUS as a tool to monitor ARDS pathology represents a significant opportunity to enhance patient care and optimise treatment delivery.

OBJECTIVES. To determine if lung aeration scores calculated using LUS correlate with the severity of lung injury identified on Computed Tomography (CT) and bedside Chest X-Ray (CXR) in patients with ARDS receiving VV-ECMO.

METHODS. This single-centre prospective, observational study investigated consecutive adult patients diagnosed with ARDS receiving VV-ECMO admitted to Royal Papworth Hospital between October 2017-February 2018. LUS assessments were conducted to examine 12-lung regions within 24-hours of patient admission and daily thereafter, until liberated from VV-ECMO. Lung aeration scores were

calculated according to appearance of four defined ultrasound patterns. Re-aeration scores were calculated as the total change of each lung region. CT and bedside CXR were conducted as per hospital protocol, with aeration and re-aeration scores calculated retrospectively by an independent consultant radiologist.

RESULTS. Consecutive adult patients (n=30) were prospectively screened for inclusion. Data were collected from 18 patients who met inclusion criteria. Full analysis of data is pending, awaiting interpretation of CT and CXR. Preliminary analysis of LUS data indicated good inter-observer reliability to quantify LUS aeration, with an agreement of K=.683 (95% CI .549-.797; p< 0.005). A moderate agreement for intra-observer reliability were identified for individual operators, K=.587 (95% CI .460 - .706; p< 0.005) and K=.582 (95% CI .490 - .668; p< 0.005).

CONCLUSIONS. Full statistical analysis is required to determine concordance of aeration scores between imaging modalities. If a significant degree of agreement is demonstrated, routine use of LUS for monitoring of lung aeration is appealing because it is non-invasive, low-risk and may provide more timely clinical assessment to optimise treatment delivery. In the current study LUS were performed by experienced operators, which may preclude extrapolation of intra and inter-observer results to all ICU settings. Limited sample size and specific population make it difficult to draw statistically significant conclusions across populations.

NTRODUCTION. IRobotic uro-gynecological pelvic surgery (UGpRS) requires pneumoperitoneum and Trendelenburg position, which may both affect intraoperative respiratory mechanics with a consequent impairment of oxygenation [1].

OBJECTIVES. IOur aim is comparing conventional ventilation (CV) and transpulmonary pressure (TP), obtained by subtracting esophageal pressure (Pes) from airway pressure, driven ventilation (TPV), as recently proposed in neurosurgical patients [2] on arterial oxygenation during UGpRS.

METHODS. IA dedicated nasogastric feeding tube equipped with an esophageal balloon (Nutrivent - Sidam) was inserted in nineteen patients receiving elective UGpSR. Pes was assessed after calibration of the esophageal balloon volume in each patient [3]. Calibration was repeated at every change of positive end-expiratory pressure (PEEP), of pneumoperitoneum level and body position. Patients were randomly assigned to CV or TPV. Controls (CV) received a PEEP value according to the current standards in our division, while in the intervention group (TPV) was set to maintain expiratory end-expiratory PT (PTexp) positive [4]. Arterial oxygen tension to inspired oxygen fraction ratio (PaO2/FiO2) was measured at specific time-points: after anesthesia induction (T0), at pneumoperitoneum and Trendelenburg application (T1), after 20 (T2), 60(T3) and 120(T4) minutes from PEEP application, at the end of surgery (T5), and at awakening (T6). PTexp was monitored from T0 to T5. Finally, lung ultrasound score (LusS) [5, 6] was computed before anesthesia induction (TA) and at T6.
RESULTS. TPexp was negative at each time points in controls, while increased above zero cmH2O after instituting TPV (figure 1). As shown in figure 2, PaO2/FiO2 increased from T1 to T6 (p< 0,0001) in

the TPV group, while no significant differences were detected in CV group. LusS significantly increased between TA and T6 in the CV group (p=0,0002), while increased slightly and not significantly in the TPV group (figure 3).

CONCLUSIONS. IThese preliminary results suggest that, compared to CV, TPV results in improved arterial oxygenation consequent to better lung aeration.

Incidence and risk factors for the occurrence of Expiratory Flow Limitation (EFL) in ICU patients

S. Spadaro[1], F. Dalla Corte[1], C. Rizzuto[2], V. Cricca[1], G. Montanari[1], A. Cavallari[1], V. Alvisi[1], D. Morri[1], E. Marangoni[1], C.A. Volta[1]

INTRODUCTION. EFL indicates that maximal expiratory flow is achieved during tidal expiration; this promotes dynamic hyperinflation, leading to an increase in work of breathing and adverse effects on hemodynamics [1]. Although EFL is associated with several different clinical conditions [2], no study has evaluated the prevalence and etiology of EFL in ICU.

OBJECTIVES. Aims of present study were:
1) to evaluate the prevalence and incidence of EFL in ICU;
2) to identify the risk factors for EFL development in ICU;
3) to investigate the possible role of fluid therapy on EFL development.

METHODS. In this prospective, observational study we enrolled patients admitted to the ICU with expected need for mechanical ventilation > 72 hours. Prevalence of EFL was evaluated by PEEP-test [2] at admission and daily. At 24 hours from ICU admission we performed respiratory mechanics tests. Fluid balance data were recorded during the first three days. Cumulative Fluid Overload (CFO) was calculated by dividing daily fluid balance by the weight of the patient at admission; severe fluid overload was defined by CFO>10% [3]. Mann-Whitney and Kruskall-Wallis tests were used for inter-group analysis. Logistic regression was performed to evaluate independent factors determining EFL at admission and association between CFO and incidence of EFL.

RESULTS. A total of 112 patients were enrolled; 53 patients had no EFL (NoEFL) during ICU stay, while 33 patients (30%) had EFL at admission (EFL), and 20 (18%) developed EFL (EFLin) during the first 72 hrs of ICU stay. NYHA class $\geq$ 2 (OR 10.1,CI 95% 1.8 - 57.1,p = 0.009) and COPD (OR 5.0 CI 95% 1.3-18.7 , p = 0.017) were found to be independent risk factors for the presence of EFL at ICU admission; EFL was associated with more deteriorate respiratory mechanics (Table 1).
Patients developing EFL while in ICU experienced a more pronounced positive fluid balance (Figure 1).
Moreover, a CFO $\geq$ 10% at 48 and 72 hrs was a determining factor for developing EFL in ICU (OR 3.9, CI 95% 1.3-11.6, p = 0.013 and OR 3.0, CI 95% 1.1-8.6, p = 0.038).

CONCLUSIONS. EFL is a common finding in patients admitted to the ICU. Interestingly, more patients than those with EFL at ICU admission developed EFL. This event seems to be related to fluid overload.

Establishing reliability in providing lung protective ventilation to all mandatory ventilated patients in a general ICU

C. McCue, L. Jarvie, M. Shaw, M. Daniel, M. Hughes, K. Puxty, GRI ICU QI Group
Glasgow Royal Infirmary, Intensive Care, Glasgow, United Kingdom
Correspondence: C. McCue

INTRODUCTION. The benefit of lung protective ventilation (LPV) using tidal volumes of 6 mls/kg of predicted body weight (PBW) in ICU patients with ARDS has been established since 2000 (1). Unfortunately, increasing evidence is demonstrating poor adherence to LPV. In 2012, Needham et al published a multi-centre cohort study of patients ventilated for ALI and found only 41% adherence to LPV (2). A recent analysis of LPV adherence from OSCAR, HARP-2 and BALTI-2 demonstrates LPV utilisation from 20-39% (3).

OBJECTIVES. We sought to implement and assess the effects of a quality improvement project to improve adherence with LPV for all mandatory ventilated patients in our ICU.

METHODS. We set up a quality improvement project with the aim to achieve 95% of mandatory tidal volumes set to ≤6mls/kg/PBW. Baseline data was gathered and from March 2016 a quality improvement project was initiated. We utilised weekly QI meetings to discuss the project and to plan interventions to improve adherence.

RESULTS. Over 17 months, 708 patients received mandatory ventilation of which 106 patients were excluded from LPV (53% for CO_2 control, 20% clinician decision, 27% not documented). Patient demographics are outlined in table 1.
Figure 1 demonstrates LPV adherence over time, with annotated interventions as part of the QI project. Proportion of patients receiving ≤6mls/kg/PBW (solid line), >8mls/kg/PBW (dotted line) and the median value (dashed line). Interventions as follows; mandatory ventilation was standardised using a pressure controlled, volume cycle mode (1), automated PBW calculation built in to electronic clinical information system (2), weekly QI meetings (3), discussion of 'failed patients' at weekly meetings (4), default tidal volume advice on ventilators at bedside (5), documentation of tidal volume on whiteboard at patient bedspace (6). Baseline adherence in March 2016 was 39%, improving to 56.5% after weekly meetings, 91% after discussion of progress and 'failing patients', and finally a median of 98% with the final interventions.

CONCLUSIONS. Implementation of a quality improvement project within our ICU has demonstrated significantly improved adherence with LPV in mandatory ventilated patients.

The effect of serum phosphate level and correction of hypophosphataemia on the duration of mechanical ventilation

K.C. Chan[1], P. Wu[1], H.P. Shum[2]
[1]Tuen Mun Hospital, Department of Anaesthesia and Intensive Care, Hong Kong, China, [2]Pamela Youde Nethersole Eastern Hospital, Department of Intensive Care, Hong Kong, China
Correspondence: P. Wu

INTRODUCTION. Low serum phosphate (PO4) level was found to be associated with a longer duration of mechanical ventilation and had been suggested as a useful prognostic factor to predict the need for ventilation. However, it is unclear whether the correction of hypophosphataemia would reverse the effect.

OBJECTIVES. To investigate the relationship between the serum PO4 level and the duration of mechanical ventilation in ICU.

METHODS. This was a retrospective cohort study that included all mechanically ventilated patients, who had unplanned ICU admission to adult ICUs of two tertiary hospitals in Hong Kong from 2014 to 2017. Patients were excluded if
1) they were excluded from APACHE IV evaluation for any other reasons,
2) they received renal replacement in ICU,
3) their PO4 level was high (> 1.5 mmol/L) at the beginning of their mechanical ventilation,
4) they had fewer than three PO4 measurements taken during their mechanical ventilation, or
5) they had a PO4 level greater than 2.0 mmol/L anytime during their mechanical ventilation.
General additive model with negative binomial distribution was used to explore the effect of the PO4 level on the duration of mechanical ventilation, adjusted to APACHE IV predicted length of stay (A4LOS), and the presence of chronic respiratory failure. The analysis was performed using SAS 9.4.

RESULTS. Among 7,345 unplanned ICU admissions during the study period, 1,294 admissions were recruited after considering the inclusion and exclusion criteria. The general additive model, factoring in the minimum PO4 level (Min_PO4) during mechanical ventilation, was shown in Table 1 Model 1. The additive effect of A4LOS and PO4 level was shown in Figure 1. A lower Min_PO4 was associated with a longer duration of mechanical ventilation (p< 0.0001). We modelled the effect of PO4 replacement by the change of PO4 level from the Min_PO4 after one day (Diff_Next_Day). Thus, the more the PO4 rises in one day, the greater the Diff_Next_Day. The effect of PO4 replacement on the duration of mechanical ventilation was not significant (p=0.6523, Table 1 Model 2 and Figure 2). When limiting the analysis to those with hypophosphataemia (Min_PO4 less than 0.75 mmol/L) (n=782), the effect of PO4 replacement on the duration of mechanical ventilation was again not significant (p=0.6761, Table 1 Model 3 and Figure 3).

CONCLUSIONS. After adjustment, a lower minimum of PO4 level was associated with a longer duration of mechanical ventilation. This effect may not be modifiable with phosphate replacement. Further prospective interventional study is warranted.

Addressing diaphragm dysfunction in cardiac surgery patients: successful therapeutic use with current technology and future prophylactic use of temporary diaphragm pacing utilizing intramuscular electrodes

R. Onders[1], M. Elmo[2], R. Schilz[2]
[1]University Hospitals Cleveland Medical Center, Surgery, Cleveland, United States; [2]University Hospitals Cleveland Medical Center, Cleveland, United States

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0784

INTRODUCTION. 1.6 to 60% of cardiac surgery patients experience phrenic nerve injury and diaphragm dysfunction (DD). Up to 5% require prolonged ventilator support. Invasive or non-invasive mechanical ventilation carries significant morbidity and potential mortality.

OBJECTIVE. Describe both therapeutic intramuscular Diaphragm Pacing (DP) for weaning and a feasibility trial of prophylactic capability in 4 patients.

METHODS. A retrospective review of compassionate off label use of an FDA approved device under IRB approval (#02-10-18). In this group, an electrical stimulus was delivered to the diaphragm via laparoscopically placed intramuscular electrodes to facilitate diaphragm strengthening and subsequent weaning from mechanical ventilation. A second group prospectively received two temporary DP electrodes placed

intramuscularly in each diaphragm at the motor point of where the phrenic nerve enters the muscle at the end of their primary cardiac procedure. (FDA IDE #G150040 and clinicaltrials.gov listing NCT 02410798). Serial diaphragmatic EMG´s were obtained. Safety and efficacy parameters for pacing and implantation are reported.

RESULTS. Eleven post cardiac surgery patients with prolonged ventilator support from DD were implanted. Ages ranged from 57-81 years old (average 68). Mean duration of positive pressure ventilation prior to DP was 20 days. All patients were successfully weaned with DP. (8 patients received invasive and 3 received noninvasive mechanical ventilation). The average survival is 32.6 months (1.67 to 76.8 months). There was 1 non DP related early death. Serial EMG's of the diaphragms measured through DP electrodes showed improved burst activity and was used to guide DP therapy. In the next phase, temporary DP electrodes were implanted in 4 patients who underwent median sternotomy. Subject ages ranged from 46-84 years (72 average). The temporary electrodes were successful in achieving ideal tidal volumes and exceeded ideal tidal volumes by 47%. Temporary electrodes successfully measured dEMG. There were no complications. There was complete intact removal of all electrodes at the bedside.

CONCLUSIONS. DP can be used successfully to treat DD from phrenic nerve injury. This trial also demonstrates safe placement, removal and functionality of temporary DP electrodes. Routine use of temporary DP electrodes at cardiac surgery followed by early DP use may mitigate prolonged mechanical ventilation and the need for tracheostomy.

Functional residual capacity, respiratory system compliance, and lung stress and strain recordings in a PEEP INview trial in mechanically ventilated children - a pilot study

E. Geromarkaki, S. Ilia, M. Miliaraki, P. Briassoulis, P. Bourbaki, E. Tavladaki, G. Briassoulis
University Hospital of Heraklion, Pediatric Intensive Care Unit, Heraklion, Greece
Correspondence: E. Geromarkaki
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0785

INTRODUCTION. Functional residual capacity (FRC) determines both oxygenation and respiratory system compliance (CRS). In ARDS, in which FRC is decreased, an optimal PEEP is anticipated to restore FRC; accordingly, application of different levels of PEEP might improve FRC and CRS and ameliorate possible ventilator-induced lung injury. In adult ARDS, it has been argued that PEEP should be titrated primarily by its impact on CRS.

OBJECTIVES. In this longitudinal study, we sought to detect the changes of FRC, CRS, driving pressure (ΔPrs), and lung stress and strain when applying incremental PEEP levels (PEEP INview) in mechanically ventilated (MV) children with or without ARDS and to correlate admission lung mechanics to length of stay (LOS) or MV-days (MVD).

METHODS. Mechanically ventilated children were deeply sedated, paralyzed and ventilated in volume-control mode or PRVC with a tidal volume of 6 mL/kg BW throughout the study protocol. Based on their PaO_2/FIO_2 ratios, patients were divided in ARDS (< 300) and control groups (>300). Using spirometry of the Engström Carestation and the PEEP INview tool, end-expiratory lung volume (EELV), FRC, and CRS were tested longitudinally (0-12-24hours). Vt was measured at mouth level. At each PEEP level, FRC and CRS measurements were recorded using the nitrogen washout process. Airway driving pressure was calculated as the airway pressure changes from total PEEP to end-inspiratory plateau pressure.

RESULTS. Seventeen critically ill mechanically ventilated children (4 girls) were included in the study. At 0-hrs, increasing PEEP from 4 to 10 cmH$_2$O increased EELV (64±22 to 246±42 ml, p< 0.05) and Global strain (0.17±0.6 to 0.58±14, p< 0.05) in the control group only. At 12-hrs, PEEP incremental changes (4 to 10 cmH$_2$O) increased FRC (54±26 to 180 ±28 ml, p< 0.05 and CRS 0.57±0.1 to 0.88±0.1 mL/cmH$_2$O, p< 0.05) in ARDS and EELV (54±22 to 246±42 ml, p< 0.01) and Static strain (0.17 ±0.06 to 0.58±0.14, p< 0.05) in controls. At 24-hrs, PEEP-induced lung volume recruitment did not significantly change in ARDS patients but increased EELV in the control group (28±42 to 228±28 ml, p< 0.005). LOS and MVD correlated inversely to FRC (rs=-0.7 and -0.88, respectively, p< 0.005) and CRS (rs=-0.79 and -0.87, respectively, p< 0.001); MVD also related with Dynamic strain (rs=0.71, p< 0.02).

CONCLUSIONS. PEEP INview might represent a promising tool for optimizing PEEP in mechanically ventilated children. Further studies are needed to ascertain if this PEEP strategy could help guide optimizing various aspects of lung mechanics in individual patients with ARDS.

Identifying patients at risk of pulmonary complications post cardiac surgery using static compliance and clinical risk factors

H. Burns, F. Elwin, M. Ahmed
St Georges Hospital, CTICU, London, United Kingdom
Correspondence: H. Burns
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0786

INTRODUCTION. Pulmonary complications post-cardiac surgery are an important cause of morbidity and mortality, influencing length of stay (LOS) and total cost (1) reportedly affecting 7.5% of patients (2). Cardiac surgery and perioperative recovery alters pulmonary mechanics, which influences these outcomes (1).

OBJECTIVES. This proof of concept study aims to investigate the extent of derecruitment post-cardiac surgery, using static compliance as a surrogate marker, and its association with pulmonary morbidity. We aim to use the data to determine whether high-risk groups may benefit from individualised care.

METHODS. Convenience sampling was used to collect data from post-op cardiac cases in a two-month period. Demographic data was collected along with calculation of Static Compliance (Cst) and P/F ratios on arrival to intensive care. Follow up data of hospital length of stay (LOS), respiratory support and clinical decision to treat for a post-op pneumonia was collected.

High risk variables chosen were BMI >35, history of COPD or asthma, recent smoking history, length of surgery > 4 hours and cardiopulmonary bypass time > 120 minutes.

Statistical analysis was done with two-tailed student's T-test or Chi-Squared test.

RESULTS. Our study included 50 patients, 27(54%) had coronary artery bypass grafting.

Higher risk patients had a significantly lower compliance and P/F ratio, and a trend towards longer hospital LOS and time on supplemental oxygen. The overall risk of being treated for pneumonia was 36%, with a positive sputum culture in 10% of patients.

Grouping patients using static compliance we found that there was a trend of increased incidence of respiratory complications 42% with Cst under 50 and 16% over, although these did not reach significance p=0.11.

CONCLUSIONS. This data adds to the body of evidence showing that post cardiac surgery patients are at high risk of pulmonary complications. With evidence that patients at increased risk can be easily identified. This can be used for future studies to introduce bundles of care to those at higher risk with the aim of reducing pulmonary complications and hospital length of stay and provide more individualized care.

Esophageal pressure guided PEEP optimization significantly improves oxygenation and intra-pulmonary shunt without increasing driving pressure in obese and pregnant patients

E. Rohrs[1,2], S. Reynolds[3,4]
[1]Simon Fraser University, Biomedical, Kinesiology and Physiology, Burnaby, Canada; [2]Fraser Health Authority, Respiratory Therapy, New Westminster, Canada; [3]Simon Fraser University, Biomedical, Kinesiology and Physiology, New Wesminster, Canada; [4]Fraser Health Authority, Critical Care, New Westminster, Canada
Correspondence: E. Rohrs
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0787

INTRODUCTION. Obese and pregnant patients admitted to the ICU are challenging to ventilate because of increased chest wall and abdominal pressures. This decreases lung compliance and exacerbates atelectasis, contributing to lung injury. While optimizing PEEP is one of the cornerstones of lung protective ventilation, the higher pressures needed in these patient populations creates a challenge for ventilation management. Esophageal pressure is demonstrated to be a good measure of pleural pressure and can be used to determine the amount of pressure directly transmitted to the alveoli.

OBJECTIVES. The objective of this study was to evaluate the effect of PEEP optimization using esophageal pressures on oxygenation and intrapulmonary shunt in an obese or pregnant patient.

METHODS. This is a retrospective case series of 18 obese and pregnant ICU patients. P (A-a) O$_2$ gradient and PaO$_2$/FiO$_2$ ratios on

admission to the ICU were compared before and after PEEP optimization using esophageal pressure manometry.

RESULTS. PEEP is significantly higher after esophageal pressure PEEP optimization (p=0.000) with no resultant increase in driving pressures (p=0.38). The PaO_2/FiO_2 ratio is significantly improved (p=0.031). FiO_2 and P(A-a) O_2 gradient also improve after PEEP optimization (p=0.000, p=0.016).

CONCLUSIONS. Esophageal pressure guided PEEP optimization significantly improves oxygenation and intra-pulmonary shunt in obese and pregnant ICU patients without increasing driving pressure. Further study is needed to investigate the levels of lung injury and inflammation present in obese and pregnant population in the face of high PEEPs being used to ventilate these patients.

INTRODUCTION. The pulmonary artery occlusion pressure (wcp) in mechanically ventilated patients can reflect changes in lung pressure. We theorize about the relationship between pulmonary elastic pressure and variations of wcp during the respiratory cycle. As well as, there could be some relationship between pulmonary elastance postoperatively and prognosis.

OBJECTIVES. Assess the mechanics of lung and chest wall after of postoperative lung transplant (LT), the relationship between transpulmonary pressure (Ptp) and wcp, and its association with prognosis.

METHODS. Prospectively collected data from 56 patients undergoing LT from December 2016-March 2018, on first day post-transplant. During controlled mechanical ventilation we recorded the flow signals (V´), airway pressure (Paw), esophageal pressure (Pes). Of these, 35 were available pulmonary artery. We calculate by multiple linear regression the mechanics of the respiratory system (Ers, Rrs), pulmonary (Eptp) and chest wall (Ecw). Using the same method we calculated another factor related to pulmonary elastance using the wcp signal (Ewcp). Data were

analyzed by the Fisher exact test, Mann-Whitney test or t-test as appropriate. We use linear regression and Bland-Altman analysis for the relationship between ptp and wcp, Relative Risks (RR) using 95% confidence intervals.

RESULTS.

Global respiratory components: Rrs 13.32±4.94 cmH2O/L/s, Ers 32.17±9.83cmH2O/L, Eptp 22.69±9.15 cmH2O/L, PEEP 6.12±2.13 cmH2O, V' 0.77±0.42 L/s, Vt 0,493±0,11L, RR 20.90±2.81/min.

Single vs double LT: Rrs 14.68±5.39 vs 11.24±3.28 cmH2O/L/s, p=0.01; Eptp 24.45±9.68 vs 19.85±7.58 cmH2O/L, p=0.055.

Emphysema vs fibrosis: Eptp 20.04±6.13 vs 25.86±11.11 cmH2O/L, p=0.025;

Death: Eptp 30.15±8.41 vs 20.61±8,29cmH2O/L, p=0.001. Rrs 16.03 ±7.23 vs 12.59±3.90, p=0.03.

Txp_uni: Eptp 32.57±9.98 vs 22.71± 8.85 cmH2O/L, p=0.021. Txp_bi: 27.73±6.49 vs 16.69± 5.46, p=0.001.

Stay< > 10d: Eptp 19.21(16.03-27.12) vs 21.80 (18.69-29.11) cmH2O/L, p=0.143.

Days of mechanical ventilation < > 12d: Eptp 21.49±8.43 vs 27.49 ±10.59 cmH2O/L, p=0,051. The resistances and the elastance of the chest wall were irrelevant to the prognosis.

Relationships between Eptp vs Ewcp: 21.21±6.63 vs 19.96 ±5.78cmH2O/L, p=0.480. R: 0.88. Concordance analysis: Difference means -1.25±2.98; limits of agreement CI 95% -7.22 to 4.72.

Ewcp according to death: 24.15±7.18 vs 16.74±4.37cmH2O/L, p=0.034.

Patients who had lung elastance greater than 20 cmH2O/L had a higher risk of mortality. According to Eptp, RR 6.32, 95% CI (1.23-32.33), p=0.016; and for Ewcp

RR 6.56, 95% CI (1.05-40.94), p=0.044.

CONCLUSIONS. The analysis of Lung elastance provides prognostic value, and invites us to try to reduce the perioperative factors associated with its increase (fluids, Vt..). The elastic pressure of lung has a good fit with variations of pulmonary artery occlusion pressure, and therefore in patients who have this measure would not require pleural pressure.

The impact of using Echinacea as a complementary modality with use of ventilator care bundle to prevent ventilator-associated pneumonia

A. Wahdan
Cairo University, Anesthesia, SICU and Pain Management, Cairo, Egypt
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0789

INTRODUCTION. Echinacea has been utilized for its medicinal properties for over 400 years by Native Americans to treat infections and general illnesses. Echinacea strengthens the body's innate resistance and, if indeed the hyaluronidase enzyme inhibiting action is a factor, inhibits the proliferation of bacteria by increasing phagocytic activity.

OBJECTIVES. The study will be designed to establish the effect of implementation of ventilator care bundle combined with Echinacea on VAP rate in mechanically ventilated patients.

METHOD. Population of study & disease condition . The study will be conducted in 5-bed surgical intensive care unit (SICU) in Kasr-Alainy teaching hospital where patients are admitted from general surgery and trauma unit to receiving mechanical ventilation.

Eighty patients will be divided randomly into two groups:

Group (A): 40 patients will have ventilator bundle measures as well as Echinacea capsules.

Group (B): Another 40 patients will have ventilator bundle measures only. Capsules will be taken by oral route (in patients who cannot swallow, it can be taken by opening capsules prior to flushing down enteral tubes with no hazards on gastric mucosa.

OUTCOME PARAMETER. Rates of VAP will be defined as the number of VAP cases per 1000 ventilator days. Cases of VAP will be identified by the attending intensivists during routine daily round using Centers for Disease Control and Prevention criteria. According to CDC criteria, VAP can be diagnosed in a patient receiving mechanical ventilation who has a new radiographic opacity, a change in

pulmonary secretions along with evidence of impaired gas exchange, and either fever or an abnormal WBC count. A lower respiratory tract specimen with positive quantitative culture results is an optional additional CDC criterion for the diagnosis of VAP. Ventilator days will be counted daily by a well trained nurse. A ventilator day is defined as a calendar day for which the patient is charged for mechanical ventilation.

RESULTS. In Group B VAP rate is 3.9/1000 ventilator day in Group A, and 5.3/1000 ventilator day in Group B with a P value 0.08 that was not significant. Monthly VAP rate in both groups .Total number of patients acquired VAP were 33 (41.3%), fourteen patients in Group A, and ninteen patients in Group B (P value = 0.256)

CONCLUSION. In this study, VCP components were applied in 80 ICU ventilated patients, with providing 40 patients of them Immulant capsules, 2 capsules three times daily for five days decrease inflammatory reactions promoting faster improvement and that may decrease VAP associated mortality.

Additional inspiratory load of breathing imposed by endotracheal tubes. Dynamic study in patient during pressure support ventilation

P. Carmona Sánchez[1], J.A. Benítez Lozano[2], M. Delgado Amaya[2], J.M. Serrano Simón[1]
[1]Hospital Universitario Reína Sofía, Intensive Care Medicine, Córdoba, Spain; [2]Hospital Universitario Regional Málaga, Intensive Care Unit, Málaga, Spain
Correspondence: P. Carmona Sánchez
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0790

INTRODUCTION. It is widely accepted that tube resistance can highly increase the work of breathing. This has been proven in vitro and tracheostomized spontaneously breathing patient, however it been not enough studied in tracheally intubated patients during spontaneously ventilatory modes.

OBJECTIVES. To determine the relationship between total effort (Effort$_{tot}$) and tube-related additional inspiratory effort of breathing (Effort$_{add}$) in critically ill patients, mechanically ventilated during different assistances on pressure support ventilation (PSV).

METHODS. Prospective, clinical study. Fourteen consecutive patients receiving PSV through endotracheal tube (ETT) were studied, under level of assistance applied by your attending physician. We recorded the flow signals (V'), airway pressure (Paw), esophageal pressure (Pes), tracheal pressure (Ptrach), at 560 Hz during 30 min, for a posterior analysis of ten regular cycles. Ptrach was measure using Intratracheal Pressure Sensor®, REF M1045564, CareFusion, Finland. Clinical and demographics data was recording. Measurements: Total Distending Pressure (Ptot) = Paw + Muscle pressure+ (Pmus$_+$). Pmus = Pes - V'*Elastance chest wall. Pressure drop across the ETT (ΔPETT) was obtained by subtraction of Ptrach to Paw. The ratio ΔPETT change to the corresponding change in flow was computed as the resistance tube-related, as well inspiratory and expiratory resistance (ETTi, ETTe) were calculated, using linear and polynomial quadratic regression. The respiratory effort of the patient (Effort$_{pat}$) was calculated as pressure-time product/min (PTP/min) by subtraction of Paw to Ptot at inspiratory time. Effort add tube-related (ETT$_{add}$) as PTP based on ΔPETT. The fraction of Effort$_{add}$ to Effort$_{tot}$ was obtained. The results are expressed, mean ± standard desviation, median (25-75%), or percentage. The comparisons were made by t-student test or analysis of variance on ranks, as appropiate.

RESULTS.

Age: 59.71±8.32 y. Male 85.71%. PaO$_2$/FiO$_2$ 275.15±96.6.

Diagnosis : Lung Transplantation 42.85%. Pneumoniae 35.71%.

Thoracic surgery 21.42%. Duration ventilation 5d (1-7.5). Tube: I.D: 8.35±0.23 mm. Inspiratory pressure support 16.76±5.67 cmH$_2$O. PEEP 7.01±1.55 cmH$_2$O.

Resistances computed as 70-75% of the total (cmH$_2$O/L/s). Linear regression: Resistances respiratory system (Rrs): 12.81 (10.09-16.93), ETT$_{tot}$ 8.46 (7.35-13.57), P = 0.063. ETTi 9.04 (6.58-14.49), ETTe 8.71 (6.37-11.96), P = 0.713. Polynomial regression ETT$_{tot}$ 8.33 (7.02-13.29) versus (vs) linear, P=0.713. Among groups P value = 0.573.

Effort, (cmH$_2$O.s/min): Effort$_{tot}$: 391.465±118.575. Effort$_{paw}$: 305.269 ±110.701. Effort$_{pat}$: 86.196±62.723. ETT$_{add}$: 105.043±65.048. ETT/Total(%): 25.821±10.37.

CONCLUSIONS. The resistance of tube-relate, can represent to 25% of mechanical load in intubated patients during PSV. We not find differences between inspiratory and expiratory resistances, neither of the results of resistances calculated by linear vs polynomial regression.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0791

INTRODUCTION. Beside its role as lifesaving treatment for the acute respiratory distress syndrome (ARDS), mechanical ventilation (MV) can determine additional ventilator-induced lung injury (VILI). Among the multiplicity of MV settings, the effects of inspiratory airflow on determining VILI have largely been neglected (1).

OBJECTIVES. We focused on effects of inspiratory airflow on transpulmonary pressure measured by esophageal pressure (Pes) and ventilation heterogeneity measured by electrical impedance tomography (EIT) (2, 3). Study hypothesis was that lower flow rates could result in lower lung stress and heterogeneity.

METHODS. We conducted a prospective interventional randomized cross-over study on 7 sedated and paralyzed patients with mild and moderate ARDS (Berlin definition) undergoing volume-controlled ventilation (VCV, S1 ventilator, Hamilton Medical, Bonaduz, Switzerland). Informed consent was obtained following local regulations.

We randomly set two PEEP levels (5 and 15 cmH$_2$O), while keeping Vt of 6-8 ml/kg PBW and clinical FiO$_2$, and we set the ventilator I:E ratio, without end-inspiratory pause, to obtain inspiratory airflow of 401±34 ml/sec, 842±69 ml/sec and 1254±51 ml/sec at each PEEP level (10 minutes per airflow).

Pes, airway pressure (Paw), airflow and EIT data were continuously monitored. By offline analysis, we measured at each step: Vt; peak pressure (Ppeak); end-inspiratory Paw after 2-3 seconds of occlusion (Pplat); Paw at zero flow during end-inspiratory occlusion (P1); transpulmonary pressure (P$_L$ = Paw - Pes) at P1, Ppeak and Pplat. EIT data were analyzed to measure Vt distending non-dependent and dependent lung regions and lung heterogeneity (i.e., number of ventilated pixels in the non-dependent lung region divided by ventilated pixels of the dependent region).

RESULTS. Patient were 64 [56-68] yo, undergoing mechanical ventilation since 2 [2-4] days. On the day of the study, PaO$_2$/FiO$_2$ was 190 [188-239] and 3 patients (42%) had moderate ARDS. Table 1 summarizes study results: Pplat wasn't affected by modification of inspiratory airflow while Ppeak and P1 increased significantly. At Ppeak and P1, inspiratory P$_L$ was significantly higher at increasing airflow. Moreover, the difference between P1 and Pplat (i.e., a classic sign of aeration heterogeneity and pendelluft) increased at higher airflows. The lung heterogeneity measured by EIT showed a trend towards increase at different airflows, too.

CONCLUSIONS. Although preliminary, the present results might suggest that higher inspiratory airflow could yield higher transpulmonary pressure and heterogeneity, two possible determinants of VILI.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0792

INTRODUCTION. Despite the Pressure Volume curve (PV) have been suggested as a bedside tool to set mechanical ventilation[1], in heterogeneous lung diseases - like Acute Respiratory Distress Syndrome (ARDS) - it expresses the average behaviour of the lung, possibly under or overestimating regional pressures. Regional PV (PVr) derived from Electrical Impedance Tomography (EIT) can add valuable local information at the bedside but the only available data are on animal models[2].

OBJECTIVES. To evaluate the feasibility of a PVr-based method to set mechanical ventilation in patients affected by Acute Hypoxic Respiratory Failure (AHRF) and ARDS.

METHODS. Slow inflation PV maneuvers[3] were simultaneously recorded with a pneumotacograph and EIT (Swisstom BB2, Swisstom, Landquart) in patients with AHRF/ARDS. From each maneuver, a global PV curve (PVg) and 16 to 19 (depending on lung dimension) cranio-caudal regional PV curves (PVr) were obtained, each one corresponding to a pixel row coming from the EIT image[2]. PVg and PVr were fitted into a sigmoidal equation and the upper (UIP) and lower (LIP) inflection points were calculated[4]. LIP and UIP from PVg were called respectively LIPg and UIPg. For each measurement, the regional highest LIP (LIPr$_{MAX}$) and lowest UIP (UIPr$_{MIN}$) were found (fig1). The pressure between those two points falls in the linear part of each PVr and was defined ΔP$_{lin}$. A paired t-test (α=0.05) was used to compare inflection points from PVr and PVg.

RESULTS. We successfully analysed 38/41 maneuvers. A statistically significant difference (p< 0.05) was found between LIPr$_{MAX}$ (15±7.1 cmH$_2$O) and LIPg (4.6±5.2 cmH$_2$O); in all measurements, the LIPr$_{MAX}$ was higher than the corresponding LIPg. We also found significant difference (p< 0.005) between UIPr$_{MIN}$ (30±8.9 cmH$_2$O) and UIPg (42 ±12 cmH$_2$O), being the UIPr$_{MIN}$ lower than the corresponding UIPg in all the analysed PV. The average ΔP$_{lin}$ was 15±8.6 cmH$_2$O.

CONCLUSIONS. The regional PV curves give different information compared to the PVg. A safe pressure boundary on the linear part of

each PVr can be easily found in patients undergoing mechanical ventilation. Wheatear this can be used to improve lung protection has still to be explored.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0793

INTRODUCTION. Red blood cells (RBCs) have important roles in tissue oxygen delivery. Previous studies showed changes of morphology and rheological behavior of RBCs in various clinical conditions of ischemia/reperfusion injury such as sepsis, severe trauma, and critically ill patients. Global I/R injury also has important roles in the pathophysiology of cardiac arrest victims. However, few studies evaluated about RBCs of postcardiac arrest.
OBJECTIVES. We wanted to evaluate the morphologic and functional status of the RBC during post-cardiac arrest care.
METHODS. After successful resuscitation in the emergency department, patients were enrolled after informed consents. Blood samples were taken immediate after ROSC and daily during ICU admission. Morphological, biochemical and mechanical properties of RBCs were retrieved from the cDOT microscopy. All the parameters are measured within 1 hours after collections of samples.

RESULTS. Total 40 patients were enrolled. Survival was observed in 26 (65%). Favorable neurologic outcome (Cerebral Performance Category 1 or 2) at 28-day after cardiac arrest was 10 (25%).
Membrane fluctuations of day 3 (59.12 vs. 55.61 nm, $p < 0.001$) and day 5 (59.28 vs. 55.68 nm, $p = 0.027$) higher in survivors. SI(sphericity index)s of day 3 (0.61 vs 0.68, $p < 0.001$) and day 5 (0.62 vs. 0.64, $p = 0.044$) were lower in survivor. With generalized mixed Linear models analysis, functional outcome of 28-day after cardiac arrest failed to show meaningful correlation to membrane fluctuation nor SI.
CONCLUSIONS. Morphologic and functional differences of RBCs were present in 3 and 5 days after cardiac arrest between survivors and non-survivors.

CPR guidance by an emergency physician via video call

S.M. Park, D. Lee
Seoul National University Bundang Hospital, Emergency Department, Anyang si, Korea, Republic of
Correspondence: S.M. Park
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0794

INTRODUCTION. In South Korea, the prehospital treatment of cardiac arrest is generally led by an emergency medical technician-paramedic (EMT-P) and defibrillation is delivered by the automatic external defibrillator (AED).

OBJECTIVES. This study aimed at examining the effects of direct medical guidance by an emergency physician through a video call which enabled prompt manual defibrillation.

METHODS. Two hundred eighty eight paramedics based in **Gyeonggi** Province were studied for four months, from July to November 2015. The participants were divided into 96 teams, and the teams were randomly divided into either a conventional group using the AED or a Video call guidance group using manual defibrillators, with 48 teams in each group. The time to first defibrillation, total hands-off time, and hands-off ratio were compared between the two groups.

RESULTS. The median value of the time to first defibrillation was significantly shorter in the video call guidance group (56 s) than in the conventional group (73 s) (p< 0.001). The median value of the total hands-off time was also significantly shorter (228 vs. 285.5 s) (p< 0.001), and the hands-off ratio, defined as the proportion of hands-off time out of the total CPR time, was significantly shorter in the video call guidance group (0.32 vs. 0.41) (p< 0.001).

CONCLUSIONS. Medical direction by video call enabled prompt manual defibrillation and significantly shorten the time required for first defibrillation, hands-off time, hands-off ratio in simulated cases of prehospital cardiac arrest

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0795

INTRODUCTION/ OBJECTIVES. The 2015 European resuscitation council (ERC) guidelines recommend advanced airway management (AAM) over bag mask ventilation (BMV) for provision of sufficient ventilation and prevention of aspiration during advanced cardiac life support (ACLS). However, there is conflicting data on the superiority of AAM compared to BMV. It was our aim to investigate the influence of airway management on overall adherence to ACLS algorithm in a simulated CPR model.

METHODS. One hundred and fifty-four teams, each consisting of three to five physicians, were randomized to perform ACLS with the instruction to perform either AAM or BMV. Data analysis was performed using video-recordings obtained during simulations. Primary endpoints were adherence to guidelines with regard to respiratory recommendations (BMV 2 breaths/ cycle, not longer than 4 seconds; AAM respiratory rate 8-12/ min) and overall hands-on time. Secondary outcome measure was the impact of ventilation on hands-off times.

RESULTS. Advanced airway management was provided by 71/76 (93,4%) teams during ACLS, whereas all BMV (n=78) teams complied with their target ventilation. Adherence to guidelines with regard to respiratory recommendations was reached by 6/ 71 AAM groups (8,5%) and 14/ 78 BMV (17,9%) groups (p = 0.0893). Groups allocated to AAM ventilated 19±8/ min, whereas BMV groups ventilated 7±6 /min (p < 0.0001). BMV groups had higher overall hands-off times than AAM Groups (22±7% vs. 14±6, p < 0.0001). Adjusted for ventilation-associated hands-off times, BMV groups still had 9±4% vs. 3±3% in the AAM groups (p < 0.0001

CONCLUSIONS. This simulator based trial found that insertion of an advanced airway leads to significant hyperventilation but is associated with more hands-on time, indicating that reducing complexity of an algorithm makes it easier to follow.

How comfortable are residents with CPR?

C. Salmon[1], N. Din[1], D. Kim[1], N. Ahmad[2]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0796

INTRODUCTION. Cardio pulmonary resuscitation (CPR) is an event that medical professionals encounter frequently during their training time. Residents at our institution are the engine that runs this hectic end of life moment.

OBJECTIVES. The objective of the study is to assess the relation between resident comfort level and time to terminate cardiopulmonary resuscitation. We hypothesize that third year medical residents vary in their comfort level of running code as team leader from the beginning to the end of residency year. These may result in "longer codes" earlier in their leader role without better outcomes compared to the national average.

METHODS. Third year residents were given a questionnaire of ten questions comparing their comfort levels, number of "code blue" encountered, knowing when to terminate resuscitative efforts and emotional reactions during the first semester and during the second semester of their third year.

Charts from patients who underwent cardiac arrest with CPR were reviewed in a period of one year and identified by a unique code to each patient. Data was divided within a six month period corresponding to the first six months of third year vs the last six months of third year, July to December and January to June, respectively.

Data was collected in excel sheet and was analyzed with SPSS using Wilcoxon singed rank test.

RESULTS. Data analysis showed no significance (*p0.377*) between the "code blue" in the first semester vs the last semester in regards of duration of CPR, 19.55±*8.18* minutes vs 16.57±*10.01* minutes in patients who expired, in cases were the resident had to decide when to terminate CPR. Analysis of questionnaire data was mostly significant on seven out of ten questions answered subjectively by residents, including feeling prepared to lead the cardiac arrest team (*p0.011*), supervising the team (*p0.004*), being worried about making mistakes (*p0.038*), knowing proper time to terminate CPR and feeling comfortable terminating these efforts (*p0.023*). The data that did not show significance was emotional reaction (*p0.059*), proper indications to terminate CPR (*p0.055*) and comfort delegating tasks (*p0.059*), however the average answers in both semester fell between "agreeing" or "neither", but did not show a negative response when evaluated with the scale of the questionnaire.

CONCLUSIONS. In hospital setting, residents who are in training are responsible for supervising CPR and it is fairly challenging as they will be making the decisions on when to terminate resuscitative efforts on a patient who did not achieved return of spontaneous circulation. CPR is often stopped within 30 minutes after cardiac arrest. The size of our sample was small and the questionnaire was subjectively answered. We believe that a larger sample could be collected and could potentially show significant change on results when comparing both semesters.

INTRODUCTION. Candida peritonitis occurs frequently in patients undergoing urgent abdominal surgery. Rates ranges 30-40% and carries a high mortality. The latest ESCMID clinical guidelines recommend empirical treatment with echinocandins for the treatment of intra-abdominal infections caused by fungi.

OBJECTIVES. To evaluate the diffusion of micafungin into peritoneal fluid (PF) used in the usual therapeutic dosage (100 mg/day) and to establish the correlation between concentrations in the PF and MIC, to show the potential therapeutic effectiveness.

METHODS. A prospective study in two centers' ICUs during one year period was conducted. Correlative 20 patients were validated. Two groups were studied, one naïve (before first dose) with 12 patients and a second on day 3 (8 patients) at steady state. Blood and peritoneal samples were drawn at hours 0,1,3,5,8, 18 and 24 h after drug administration to obtain a Pk/Pd profile.

RESULTS. 11 patients (55%) were men and a mean (SD) aged 65.5 (18.6) year. APACHE II and SOFA scores were 17.5 (7.1) and 7.0 (3.6) points. Candida Score was 4 (3-4) and in 2 (10%) patients Candida albicans was isolated in the PF so empiric treatment resulted in the remaining 18 (90%) cases. Clinical cure was reached in 12 (60%) with a crude in-

hospital mortality of 11 (55%). Plasma concentrations in group 1, Cmax (achieved at the end of 1-hour intravenous infusion) was 5.4 (2.2) mg / L, Cmin was 0.0 (0.0) mg/L, whilst in those at steady-state (group 2) Cmin was 1.9 (1.2) mg / L , and Cmax 8.4 (3.6) mg / L. Levels in PF, group 1, Cmax was 0.7 (0.5) mg / L and was reached at 8 hours, Cmin 0.1 (0.1) mg/L. In patients at steady state (group 2), Cmin at pre-dose time was 0.2 (0.3) mg / L and Cmax 1.2 (1.0) mg / L (reached 5 h after infusion). Pharmacokinetic data observed in group 1 mean plasma AUC 0-24 h (mg*h/L) 54,3 (21,9); in group 2 (steady state) AUC 0-24 h 91,8 (48,0). Data from PF in group 1 AUC 0-24 h 12,98 (8,63); in group 2 AUC 0-24 h 7,42 (4,99). We also found a lower micafungin plasma concentration on day 3 in non survivors compared to survivors (0.92 SD 0.96 vs 2.85mg/L SD 0.10; p< 0.05) and additionally on day 1 for PF 0.03 SD 0.09 vs 0.22 mg/L SD 0.27; p< 0.05).

CONCLUSIONS. A high interindividual levels in plasma and PF variability was observed and could be related to variations in extracellular volume and alteration in distribution, metabolism and elimination. Our results show a moderate penetration of micafungin into PF in patients with intra-abdominal infections, with a mean AUC0-24 peritoneal fluid/plasma ratio of 24% (0.2390; SD 0,09) on day 1 after the first dose and 26% (0,2557; SD 0,12) at steady-state. Data also suggest a correlation between low micafungin levels and poorer prognosis observed even earlier in PF than in plasma.

Correspondence: T. Guo
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0798

INTRODUCTION. Cefotaxime is a widely used against life threatening infections in the critically ill including community acquired pneumonia. In addition, many ICUs use it as the intravenous component of selective decontamination of the digestive tract strategies. Adequate plasma concentrations are crucial for efficacy. However, the pharmacokinetic (PK) profile of cefotaxime in critically ill patients has been rarely reported.

OBJECTIVES. Our aim is to establish a population PK model identifying the dose exposure relationship of cefotaxime to facilitate individualised clinical therapy in critically ill patients.

METHODS. Data from 50 adult patients from a retrospective study conducted in 2010 in the ICU of the OLVG hospital in Amsterdam was collected. All patients were scheduled to receive 1000mg cefotaxime every 6 hours. The data includes patients' plasma level of cefotaxime and demographic characteristics, clinical diagnostics. 4 blood samples of each patient were collected. Population PK analysis was carried out with non-linear mixed effects modelling (NONMEM) software. Inter-individual variability of PK parameters was modelled by a full block matrix. A combined error statistical model was used to account for the residual error.

RESULTS. A one compartment model was established to describe the PK profile of cefotaxime. Typical value of the clearance (CL) and volume of distribution (V) is 12 L/h and 41.4 L, respectively. Serum creatinine

(SCR), albumin (ALB) and sequential organ failure assessment (SOFA) score showed significant associations on CL (P< 0.001). Patients with higher SCR or lower ALB, or higher SOFA exhibit lower clearance.

CONCLUSIONS. A one compartment population PK model was established to depict the PK profile of cefotaxime in critically ill patients. Because of the data limitation, more complex model structure as Urien et al reported, cannot be well established. Serum creatinine, albumin, and SOFA score were identified as the main covariates influencing CL of cefotaxime. No covariate effect was found in V.

Vancomycin therapy - indications and the influence of renal dysfunction on serum levels

J. Hruda, L. Bauer, A. Papiez, V. Sramek, P. Suk
St. Anne's University Hospital Brno, Brno, Czech Republic
Correspondence: J. Hruda
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0800

INTRODUCTION. Vancomycin is the drug of choice for treatment of β-lactam antibiotic resistant Gram positive bacterial infections (βLR-GPB). However, its broad empiric use might be excessive in countries with low prevalence of βLR-GPB. Since vancomycin has renal elimination, kidney dysfunction increases the risk of inappropriate dosing.

OBJECTIVES. To determine, whether empiric use of vancomycin was supported by subsequent microbiological cultures and whether renal dysfunction or renal replacement therapy influences the reaching of target serum concentrations.

METHODS. In this retrospective study, all the patients admitted to the general ICU between January 2015 and December 2016 receiving intravenous vancomycin were included. Dosing, renal functions and replacement therapy, vancomycin levels and microbiological results were analysed. Data are presented as median (IQR).

RESULTS. 64 patients and 347 vancomycin therapy days were analysed. The indication was based on βLR-GPB cultures in 16 patients (25%), administered empirically in 27 patients (42%), the other 21 patients have recent history of βLR-GPB or any Gram positive bacteria in samples. In the empirical group, βLR-GPB were cultured in 9 patients (34%). Intermittent haemodialysis (IHD) was used 22 days, continuous renal replacement therapy (CVVHD) in 41 days. Loading dose was 13 (11-14) mg/kg and the daily maintenance dose varied between 21 (13-32) mg/kg in patients with serum creatinine < 100 µmol/l and 10 (7-13) mg/kg on CVVHD or 6 (4-9) mg/kg on IHD.

There was no dependence between maintenance dose and subsequent vancomycin level. Vancomycin levels (243 values) were 13.7 (10.5 - 16.5) µmol/l. The target therapeutic level 10 - 17.5 µmol/l was reached in 68% in days without RRT, 56% in days with CVVHD and 68% in days with IHD (p=0.63).

CONCLUSIONS. Microbiological cultures justified only minority of empirical vancomycin therapies. Renal dysfunction or renal replacement therapy significantly influenced the maintenance dose but did not alter the proportion of reaching the therapeutic levels. Therefore, these data suggest that vancomycin can be safely used in patients with various degree of renal dysfunction. From the current point of view, the target therapeutic levels were lower than the present recommendation (14-21 µmol/l) and, concordantly, vancomycin doses would be higher to reach the current goal.

Does the income level of the residential area impact the incidence of ICU admission and demographics of acute poisonings?

L. Koskela[1], L. Raatiniemi[1,2], T. Ala-Kokko[1,3], J. Liisanantti[1,3]
[1]Oulu University Medical Research Center, Study Group of Surgery, Anesthesiology and Intensive Care, Oulu, Finland; [2]Oulu University Hospital, Centre for Pre-Hospital Emergency Care, Oulu, Finland; [3]Oulu University Hospital, Department of Anesthesiology, Division of Intensive Care Medicine, Oulu, Finland
Correspondence: L. Koskela
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0801

INTRODUCTION. There are significant regional differences in the use intensive care resources depending on the income of the neighborhood: in the highest income areas the incidence of ICU admission is significantly lower compared to areas with inhabitants with lower income. In the low income areas, the poisonings are more frequent compared to other areas. (1) We have previously reported regional differences in trauma and poisoning mortality in Northern Finland, but the regional differences in the need of ICU admission due to poisonings are not well studied. (2,3)

OBJECTIVES. We determined to examine differences in the incidence of ICU admitted poisonings and in the patient demographics between postal code areas with different median annual income in Northern Finland.

METHODS. We conducted a retrospective analysis of all adult patients admitted to hospital due to poisoning in the County of Northern Ostrobothnia in Finland during 2013-2016. Patients were divided into three (low-middle-high) patient groups based on median income in their residential postal code areas.

RESULTS. A total of 140 (7.3 %) of all 1909 hospitalized adult patients were admitted to intensive care during study period and of these 57.9 % were males. The proportion of ICU admissions from emergency ward did not differ between the areas. Proportion of males and patient median age did not differ significantly between patient groups. Overall incidence of intensive care treated poisoning was 12.2/100,000 (CI 95% 10.3-14.4). Incidences of intensive care treated poisoning in different income areas were following: 18.9/100,000 (CI 95% 14.0-25.1) in low income, 12.1/100,000 (CI 95% 9.1-15.7) in middle income and 8.8/100,000 (CI 95% 6.5-11.8) in high income area. Proportion of mixed substance poisonings was 36.4 % and there were only few differences in the causes of poisonings between the groups. [Table 1]

CONCLUSIONS. Incidence of intensive care treated poisoning is significantly higher in the lowest earning residential areas compared to the highest earning residential areas. The overall incidence of ICU-treated poisoning was low and the admittance rate of all hospital-treated poisonings to ICU was also low.

Imidacloprid poisoning: an Indian experience

J. Nikhilesh[1], T. Apurv[1], J. Vivek[2], G. Ankur[3]
[1]CHL Hospital, Dept of Critical Care Services, Indore, India; [2]Shalby Hospitals, Dept of Critical Care Services, Indore, India; [3]Apollo Hospital, Dept of Critical Care Services, Indore, India
Correspondence: J. Nikhilesh
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0802

BACKGROUND. Imidacloprid is among newer insecticides in chloronicotinyl nitroguanidine category. It acts on postsynaptic nicotinic acetylcholine receptors in the nervous system.it is known to be effective by contact/ingestion. This communication delineates epidemiological characteristics and outcomes in India over a course of three year duration.
OBJECTIVE. To assess epidemiological patterns and outcomes of Imidacloprid poisoning.
SETING. Three tertiary care ICUs of multidisciplinary pattern.
STUDY MODULE. Consecutive patients presenting with imidacloprid poisoning were included and data was collected with a focus on demographics, SOFA scores, neuropsychiatric symptoms, rhabdomyolysis, requirement of RRT, deranged liver function tests[LFT] (defined as ALT/AST elevations three times above normal),GI symptoms (nausea / vomiting/diarrhea), cardiac arrhythmias and length of stay (LOS) in days. Discharge from ICU/death was considered as end points.
RESULTS. Fifty four patients were included (n=54,M:F-36:18).Age of the cohort was 27.7+5.1 years. SOFA scores for the cohort were 6.5 +1.6.Incidence of neuropsychiatric symptoms, rhabdomyolysis, requirement of RRT, deranged LFTs, GI symptoms and cardiac arrhythmias was 53.7%(n=29),38.9%(n=21),24%(n=13),42.6%(n=23),48.1%(n=26) and 37%(n=20) respectively.LOS was 2.9+1.2 days. On applying a chi square test with relevance to SOFA scores none of the variables achieved statistical significance. Methhemoglobinemia was reported in one of the cases.

CONCLUSION. Imidacloprid poisoning remains a nonlethal poisoning with increasing prevalence owing to shift in the compounds used as insecticides in Asian countries. In view of changing patterns of use we need more data to define subsets at risk of requiring major interventions in ICU/propensity to develop MODS.

0803

Anaphylaxis: study of epidemiological and therapeutic characteristics

B.J. Amira[1,2], I. Sedghiani[1], A. M'Rad[1], H. Maamouri[1], N. Brahmi[1]
[1]CAMU, Intensive Care Unit, Tunis, Tunisia; [2]Tunis Manar, Toxicology, Tunis, Tunisia
Correspondence: B.J. Amira
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0803

INTRODUCTION. Certain studies dealing with anaphylaxis from emergency departments suggest that it remains misdiagnosed and under-treated, with behaviors often diverging from international recommendations.
OBJECTIVES. To study the epidemiologic, therapeutic and evolutionary characteristics of patients admitted to ED for anaphylaxis.
METHODS. Prospective, observational study including patients over the age of 14 who visited a single emergency and toxicological intensiv care department between 2007 and 2016 for anaphylaxis. Collection of epidemiological, clinical and therapeutic parameters.
RESULTS. Inclusion of 105 patients. Average age = 42.52 ± 17.42 years. Sex ratio = (1.29). History of anaphylaxis: 80 %(n=84). Clinical signs n (%): cutaneous manifestations 80% (n =85) cardiovascular signs 37 (35), respiratory signs 38% (40), digestive signs 15 % (n=16) and neurological signs 13% (n=14). Allergens incriminated: medicated 58 %, food 14 % and bites of Hymenoptera 28 %. Anaphylactic shock state noted in 35 patients (35%) Adrenaline was used in 40 % of cases by by direct intravenous injection in 31% of cases . Corticosteroids and antihistamines were prescribed respectively in 88% and 80% of patients. Three patients had recurrences. Two patients had cardiac arrest and one death was recorded.
CONCLUSION. The prevalence of anaphylaxis in our study was low. This shows that this is a situation that remains so far underestimated. It is therefore imperative to conduct prospective multicentre studies in emergency departments to better determine its incidence and risk factors.

Cyroheptadin intoxication: analytical study

A. Ben Jazia, I. Sedghiani, A. M'rad, H. Maamouri, N. Brahmi
CAMU, Toxicology, Tunis, Tunisia
Correspondence: A. Ben Jazia
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0804

INTRODUCTION. Acute poisoning with Cyroheptadine (CPT) has become frequent and potentially serious through neurological complications.
Despite the increase in the incidence of intoxication and the severity of this intoxication in Tunisia or the world, few studies have been interested in this molecule.
The purpose of this study was to identify epidemiologic characteristics and clinical outcomes in patients who were through CPT and to investigate any association between ingested dose and reported adverse events.
METHODS. We conducted a retrospective study at CAMU´s intensive care unit over a period from February 2006 to March 2017. For each patient we collected the anamnestic data (age, sex, antecedents, the ISD and the delay between ingestion and management), clinical

(mainly neurological and hemodynamic), biological (transaminases, arterial blood gases), therapeutic and progressive.

RESULTS. We collected 47 patients (4 men / 43 women). The median age was 22 years [18; 33]. Pathological antecedents were psychiatric in 12% of cases (n = 6). All intoxications were voluntary. The median CPT ISD was 100 [40; 750] mg. The median consultation time was 3 h [1; 14].The IGS II score ranged from 6 to 38 with a median of 6.Metabolic acidosis was observed in 8.5% of cases (n = 4).The main clinical manifestations were impaired state of consciousness with Glasgow score (GCS) $\leq$ 11 in 4.3% of cases (n = 2), anti-cholinergic syndrome in 47% of cases (n = 22) and one sedative syndrome in 21% of cases (n = 10).For GCS comatose patients < = 8 there is a correlation between coma and the supposedly ingested dose of (CPT) with p = 0.03 .ASC = 0.91 and p = 0.01. The corresponding dose is 140 mg.There is a correlation between the dose of ingested antihistamine and obnubilation with p = 0.005 with AUC 0.83.There is a correlation between the dose assumed to be ingested and the tremor with a p = 0.008 AUC = 0.84.For a dose equal to 117 mg p = 0.003.

CONCLUSION. Cyproheptadine is a widely available drug. Medical staff and parents should take special care in the management of cyproheptadine because it can be used in suicide attempts, especially by adolescents.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0805

INTRODUCTION. Severe trauma patients are frequently exposed to antibiotic therapy at the initial phase of their management : open fractures, inhalation, digestive wound ...
ATB is however a major risk factor favoring the emergence of MRB acquired during the stay. This study investigates the emergence of 3GCephalosporin-resistant bacteria in the respiratory area in these patients.

METHODS. All of the serious trauma patients (ISS> 15) hospitalized in intensive care for more than 10 days between 2010 and 2015 were retrospectively included. The patients were divided in 3 groups according to the initial ATB (ATBi) they received: No-ATBi, Short-ATBi ($\leq$72h) and Extended-ATBi (> 72h). In addition to demographic and lesion severity data, early respiratory (D2 to D5) and late (from D6) ecology were specifically collected: early modified (EME) and late (LME) ecology were defined as emergence of a C3G-resistant bacterium on respiratory samples. These samples were taken in case of clinical suspicion of pneumonia. The statistical association between ATBi and the occurrence of EME and LME was tested by comparison of the 3 groups and by logistic regression models.

RESULTS. A total of 507 patients were studied (mean age 43.7 ± 19.7, 78% male, mean ISS 30.0 ± 11.5): 444 patients (88%) were ventilated more than 48 hours, with an average duration of ventilation of 15.3 ± 12.6 days. The distribution of the 3 groups was as follows : 114 (22%) No-ATBi, 95 (19%) Short-ATBi, 299 (59%) Extended-ATBi. The groups differed significantly on admission (ISS, AIS head injury, AIS thorax, AIS abdominal, AIS bones, ventilation duration, Table1). The characteristics of antibiotherapy (ATBi and secondary antibiotherapy, defined as an antibiotic therapy started at least 48h after the end of ATBi) are shown in Table2. The rate of EME observed in the cohort (5,5%, 28/508) did not differ significantly between the 3 groups. In contrast, the LME rate differed significantly between these 3 groups: 10.5% (95% CI 6.1-17.5%) in the No-ATBi

group, 19.0% (95% CI 12,3-28.0%) in the Short-ATBi group, 22.1% (95% CI 17.8-27.1%) in the Extended-ATBi group (P = 0.027) (Graph1). The median time to LME (D10, EQ D8-D13) did not differ significantly between the groups. Logistic regression analysis showed that the ATBi-short and ATBi-prolonged groups had a odds ratio of 2.0 (95% CI 0.9-4.4%, P = 0.088) and 2.4 (95% CI 1.4-4.7%, P = 0.009) to predict the occurrence of LME. After adjusting for multivariate analysis, these statistical associations were not influenced by the following variables of lesional severity: ISS score, AIS brain, AIS thorax, AIS abdomen, complex orthopedic lesions.

CONCLUSIONS. EME are rare regardless of the type of ATBi, close to one trauma patient out of 20. LME occur preferentially in the presence of an ATBi (2 times more often), whatever its duration.

Table1 (abstract 0805). See text for desciption

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0806

INTRODUCTION. Ventilator-associated pneumonia (VAP) is a frequent complication of invasive mechanical ventilation (IMV), with an impact on mortality and costs. Exposure to antibiotics may alter bacterial colonization and promote infection by multiresistant bacteria. Prophylactic antibiotics are routinely administered after major trauma.
OBJECTIVES. We aimed to evaluate the association between the administration of prophylactic antimicrobials and VAP characteristics in patients with traumatic brain injury (TBI).
METHODS. This was a retrospective cohort of adult TBI victims with a Glasgow Coma Scale (GCS) score ≤12, admitted to an emergency and trauma Intensive Care Unit under IMV. Early VAP (eVAP) was defined as occurring between 48 to 96 hours of IMV. Patients were divided in two groups: Group ≤24h, patients who did not use or used prophylactic antibiotics for less or equal than 24h; and Group >24h, patients who used prophylactic antibiotics for more than 24h.
RESULTS. From 01/Jan to 30/Aug/2016, 907 patients were admitted in the ICU and 231 consecutive patients were included, 108 (46.8%) to the Group ≤24h and 123 (53.2%) to the Group>24h. On average, VAP was diagnosed 6.35 (2.97) days after admission, and multiresistant bacteria were responsible for 35.1% VAP episodes. Group >24h had less eVAP (19,4% vs. 36,6% p=0.004), shorter hospitalization (34 days vs. 61 days p=0.035) and a higher occurrence of multiresistant bacteria in the first episode of VAP in 14 days (48.6% vs. 27.4%, p=0.036) compared to Group ≤24h. In a multivariate analysis, Group> 24h was the only variable associated to a lower occurrence of eVAP (OR 0.47 IC95% 0.25; 0.87 p=0.016). Among patients admitted with a GCS 3 to 8, Group >24h had less eVAP (p = 0.006) and fewer tracheostomies (p = 0.033). Group >24h patients with a GCS 8 to 12 had more multiresistant bacteria as an etiological agent of VAP (p = 0.016).
CONCLUSIONS. In this population of TBI victims, a higher exposure to prophylactic antibiotics was associated with lower occurrence of eVAP, shorter hospital length of stay and with multiresistant bacteria in the first episode of VAP.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0807

INTRODUCTION. Hypoalbuminemia after severe burn injury is mainly related to capillary leak syndrome and is associated with multiple organ failure (MOF) [1].
OBJECTIVES. To assess if very early hypoalbuminemia (< 6h after burn injury), as a potential modifiable variable, is associated with 28-day mortality.
METHODS. Retrospective cohort study including severely burned patients (Total Body Surface Area burn (TBSA) ≥20 % and/or mechanically ventilated) admitted to the burn unit of the Saint Louis Hospital, Paris between January 2013 and March 2017. The primary outcome was the association between serum albumin levels in the first 24 hours after burn injury and 28-day mortality. Initial albumin administration was defined by a local resuscitation protocol (After the 6th hour after injury, target albuminemia = 25-30 g/L) [2]. Non parametric tests, ROC curves, univariate and multiple regression analyses were perfomed (p< 0.05).
RESULTS. We enrolled 73 severely burned patients with a median (interquartile range) delay of admission of 3 (2-4) hours. The median TBSA, Full Thickness BSA, Abbreviated Burn Severity Index (ABSI) and Simplified Acute Physiology Score II (SAPSII) were respectively 40 (26-57)%, 20 (10-44)%, 8(7-11) and 37(24-52) respectively. 28-day mortality was 19%. On admission albuminemia (AlbH0) and H4 albuminemia (AlbH4) were significantly lower in deceased patients at day 28 (respectively 34(29-37) vs 27(22-30) g/L, p=0.009; 27 (22-30) vs 20 (17-25) g/L, p=0.02) whereas H24 albuminemia (AlbH24) was not (28(26-31) vs 27(25-31) g/L, p=0.79). The median infused crystalloids and human 20% albumin in the first 24 hours (survivors vs non-survivors at day 28) were respectively 3,4 (2,1-4,6) ml/kg/TBSA% vs 3,5 (2,3-4,5) ml/kg/TBSA% ; p = 0.90 and 77 (3-120) g vs 85 (46-140) g; p=0.28. ROC curves assessing the ability of AlbH0 and AlbH4 to discriminate 28-day mortality showed areas under curves of respectively 0.76[CI95% 0.60-0.92] (p=0.011) and 0.80[CI95% 0.64-0.96] (p=0.004). The best threshold value of AlbH4 was 23 g/L (Youden index, sensitivity=0.81, specificity=0.70). ABSI, SAPSII, Full Thickness BSA and inhalation injury were also significantly associated with 28-day mortality. Mulltiple logistic regression analysis revealed a significant association between AlbH4 and 28-day mortality (Adjusted odds ratio=0.88 [0.78-1.00]), p=0.04) independently of inhalation injury and TBSA. Kaplan-Meier curves of 28-day survival according to AlbH4 (< 23 g/L versus ≥ 23g/L) are shown in the Figure.
CONCLUSIONS. Very early hypoalbuminemia (< 6h) was associated with higher mortality in critically ill burn patients whereas AlbH24 was not. Early Albumin infusion from the 6th hour after thermal injury in order to improve outcome should be assessed in large randomized controlled trials.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0808

INTRODUCTION. Critical burns represent a pathology with great morbidity and mortality. The skin damaged by burns is characterized by the presence of a necrotic eschar of denatured proteins that generate an inflammatory reaction. The application of proteolytic enzymes such as bromelain is an easy process which allows a faster, more effective and selective debridement of the denatured tissue by heat, avoiding the healthy areas and therefore preserving the vital tissues around and under the burn. This therapeutic approach can improve treatment in burned patients in comparison with the standard care.

OBJECTIVES. To describe our experience using enzymatic debridement in our Critical Burn Unit, taking under consideration both advantages and disadvantages of its use.

METHODS. Retrospective observational study performed in the Critical Burn Unit (March 2016 to September 2017) including 27 patients >18 years old with a total body surface area (TBSA) burned >15% and < 75%, or >65years old with a TBSA burned >10% who underwent enzymatic debridement. Mean and standard deviation were used for normal quantitative variables and median and interquartile range in the opposite case. Qualitative variables were presented by absolute and relative frequencies.

RESULTS. Mean age was 47.6years (±17.8years), 74% were males, the most frequent injury mechanism was direct contact with fire, mean APACHE II was 11 (IQR 5-18), ABSI 7 (IQR 5-9). Median TBSA was 29% (IQR 18-50%), 21% (IQR 16-39) were deep dermal or full thickness. Time until debridement was 21 hours (IQR 8-35). 7.4% (n=2) of patients had incomplete debridement after first application, requiring tangential debridement. 33% (n=9) received regional anesthesia, 91% (n=25) didn't need blood transfusion. 25% of patients who didn't have vasopressors prior debridement needed the use of it after with a mean dose of 0,6mcg/Kg/min. 25% of patients with vasopressors prior treatment required an increase of dose by a mean of 0.9mcg/Kg/min. Median ICU stay was 19 days. Mortality was 22%, being the sepsis secondary to infection of the burns the most frequent cause of mortality.

CONCLUSIONS. Topical bromelain allows a fast start of tissue debridement with a low rate of failure. The spontaneous epithelialization rate seems to be higher compared to the standard of care, which decreases the need of surgery. The need for fasciotomy and blood transfusion was very low. Topical treatment involved a fast and simultaneous debridement of the TBSA generating an inflammatory response that in some cases required vasopressors. A rigorous control of analgesic treatment is required.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0809

INTRODUCTION. Postoperative infections (POI) are one of the most common complications in thoracic and digestive cancer surgery. Therefore, identifying risk factor for POI is important from a public health perspective. Former studies have demonstrated that inflammatory response is altered during perioperative period causing a lymphopenia. It has been suggested that lymphopenia may contribute to POI. To date, this was not proved by multivariate analysis integrating other known factors of POI.

OBJECTIVES. The aim of our study was to determine whether lymphopenia is a factor associated with POI in thoracic and digestive cancer surgery.

METHODS. Multicentric French cohort study. This study was approved by our local ethic comity (ethic comity for research in anaesthesia and critical care IRB 00010254 - 2016 - 024). Lymphocytes counts were obtained from patients undergoing pulmonary or digestive cancer surgery before surgery (day-0) and 1, 3, 5 and 8 days after surgery. Risks factors of POI and information's related to anesthesia and surgical procedure were collected as well

as clinical and biological signs of POI. A univariate analysis was performed to identify the risks factors for POI. Variables with p≤0.20 were integrated in a multivariate analysis. A factor analysis was used to identify the factors related to patient, anaesthesia or surgery which could explain post-operative lymphopenia.

RESULTS. 1306 patients were included. 216 patients (16 %) had a POI including postoperative pneumonia, secondary peritonitis and surgical site infection. The time to nadir for lymphopenia was day 1 after the surgery (mean $1.2.10^9$ cells.l^{-1} ± 0.7). Lymphocyte count at post-operative day 1 (HR 1.48 CI 95 % [1.09 - 2.02] p=0.01), open surgery (HR 1.68 IC 95 % [0.76 - 1.93] p=0.01), ASA score >3 (HR 2.75 IC 95 % [1.02 - 7.43] p=0.05), COPD (HR 1.53 IC 95 % [1.02 - 2.30] p=0.04) and the length of surgery (HR 1.83 IC 95 % [1.26 - 2.66] p=0.001) were identified as risks factors for POI in the multivariate analysis (table). Epidural analgesia did not reduce the risk of infection (table). No variable related to patient, anaesthesia or surgery was identified to explain the lymphopenia observed at post-operative day (data not shown). The development of POI was not associated with absolute or percentage decrease in lymphocyte count after surgery (data not shown). This result suggests that there may be a threshold value of lymphocyte count for risk of POI.

CONCLUSIONS. Post-operative day 1 lymphopenia was a risk factor for POI. This study does not allow determining lymphopenia mechanisms and suggesting prophylactic measures.

Table 1 (abstract 0809). Risks factors for post-operative infection in multivariate analysis

Variable	Hazard ratio	Standard error	p	95 % CI
Lymphocyte count at Post Operative Day 1	1.48	0.23	0.01	1.09 - 2.02
Open surgery	1.68	0.35	0.01	1.11 - 2.55
ASA Score 4	2.75	1.39	0.05	1.02 - 7.43
Radiotherapy	1.42	0.38	0.16	0 .86 - 2.40
COPD	1.53	0.32	0.04	1.02 - 2.30
Epidural analgesia	1.21	0.21	0.28	0.86 - 1.69
Length of surgery	1.83	0.35	0.001	1.26 - 2.66

INTRODUCTION. MicroRANs are small noncoding RNA sequences that control de expression of genes involved in many different cell functions. Their expression can be measured in different body fluids. This measurement can be useful for biomarker identification and for a better understanding of the pathogenesis of different conditions.

OBJETIVE. To study the effect of sepsis and volume resuscitation on the serum expression of different microRNAs (miRNAs) involved in the inflammatory response in an animal model

METHODS. Adult pigs (sus scrofa) sedated (thiopental, fentanyl iv), tracheostomized, subjected to mechanical ventilation and monitored by a pulmonary artery and femoral arterial catheter. One group of animals was observed without any treatment (group C,n = 15) and another group (S) received at t=0 an iv dose in 30 min of live E. coli (108 * 2 ml / kg).The animals in group S were randomized to receive from t = 0 to t = 300min different rhythms of resuscitation fluids (saline 0.9% at 4 ml/kg/h,10ml/kg/h and 17ml/kg/h)(groups S4, S10, S17, respectively) (n = 8 each group). The serum expression was quantified at t=300min of different microRNAs by RT-PCR (Qiagen, Hilden, Germany).The studies were carried out with the authorization of the Animal Research Committee.

RESULTS. Sepsis induced a state of decreased blood pressure, cardiac output and systemic vascular resistance (data not shown), which was attenuated by administration of fluids. The serum expression levels of miR 155-5p, miR 146-5p , miR 150-5p, miR 21a-5p, miR 34a-5p, but not those of miR 486a-5p and miR 133 increased significantly (p < 0.05) in animals with sepsis compared to the control group. The expression of miR 146-5p (C: 0.01 [0.006-0.05]; S4: 13.8 [6.8-23.8]; S10: 0.63 [0.34-0.75] ; S17: 1.67 [0.18-3.16], p = 0.026) was lower in animals resuscitated with fluids.

CONCLUSIONS.
(i) miRNA expression assessed in serum can be useful for biomarker identification.
(ii) Resuscitation in sepsis is accompanied by an anti-inflammatory effect.
(iii) Certain miRNA could be therapeutic targets in sepsis.

INTRODUCTION. Sepsis is a highly heterogeneous clinical syndrome characterised by a dysregulated response to an infectious insult, leading to systemic inflammation. Understanding the mechanisms underpinning this variability will help develop novel therapeutic approaches and personalised treatment. Due to their immunomodulatory properties, lipoproteins represent an interesting potential target for intervention.

OBJECTIVES. To identify patterns of lipoprotein metabolism and evaluate their role in patients with septic shock.

METHODS. A panel of 105 lipoprotein subclasses were measured using nuclear magnetic resonance spectroscopy (NMR) from the serum of a prospective cohort of 174 ICU patients who had septic shock and were enrolled in the VANISH trial (1). Samples were collected at 24-48 hour intervals to generate four discrete time-points. Unsupervised multivariate analysis with principle component analysis (PCA) was used to identify natural clusters. Orthogonal partial least squares discriminant analysis (OPLS-DA) and univariate statistics were then applied to separate out the most influential lipoproteins.

RESULTS. There was a significant change in lipoprotein profiles over time between enrolment in the study and when the final sample was taken (R^2 0.26 Q^2 0.20, p< 0.001). The metabolic changes were driven predominantly by an increase in triglycerides bound to low-density lipoprotein subclasses. Total LDL triglycerides increased from 34.1mg/dL to 56.2mg/dL (p< 0.001). There was also a significant increase in total apolipoprotein A-2 (25.4 to 33.7mg/dL, p< 0.001), the second most abundant protein on HDL. Overall lipoproteins that changed significantly increased over time with the exception of HDL-1 cholesterol (20.6 to 12.3mg/dL, p< 0.001) and LDL-6 free cholesterol (4.0 to 0.2mg/dL, p< 0.001) both of which decreased.

Contrary to previously published work (2), we found no significant relationship between total cholesterol levels at baseline and mortality (*p*=0.45).

CONCLUSIONS. The lipoprotein profiles of patients with septic shock evolve substantially throughout their clinical course. Further work is needed to elucidate how these may correlate with outcomes and response to treatment.

INTRODUCTION. Hemophagocytic lymphohistiocytosis (HLH) is an inflammatory devastating syndrome, caused by impaired downregulation of activated macrophages and lymphocytes. Sepsis usually overlaps with HLH, rendering the diagnosis of the syndrome challenging, since the two conditions might be life-threatening.

OBJECTIVES. The aim of the present study was to retrospectively investigate the incidence of HLH in septic patients. We studied the clinical and pathophysiologic characteristics paralleling the two syndromes (sepsis and HLH) and the subsequent morbidity and mortality.

METHODS. For six years period,septic patients, treated in ICU,were included in this retrospective observational study.Diagnosis of sepsis was based on the criteria included in the Third International Consensus definition on Sepsis and Septic shock. HLH diagnosis was based on five out of the following eight HLH criteria: persistent fever, splenomegaly, peripheral blood cytopenia,hypofibrinogenemia and/or hypertriglyceridemia, hemophagocytosis in bone marrow, low NK cells activity, hyperferritinemia and high concentration of sCD25. Multivariated analysis was used, to evaluate the risk factors associated with mortality.

RESULTS. During the study period, fifteen (15) fulfilled the HLH diagnostic criteria. Septic shock was present in seven patients (46%). Bloodstream infection was present in nine patients (60%): The responsible isolated pathogens were *Klebsiella pneumoniae* (3 patients), methicillin sensitive *Staphylococcusaureus* (1 patient), *Acinetobacter baumannii* (2 patients), *Candida albicans* (1 patient), *Pseudomonas aeruginosa* (1 patient) and Cytomegalovirus (1 patient). Ventilator associated pneumonia was the cause of sepsis in 3 patients (20%), while one patient suffered from diverticulitis. In two patients the cause of sepsis was not identified. Concerning the possible triggering factors of HLH, lymphoid malignancy was present in six patients (40%), while CMV infection was observed in one patient and connective tissue disease in three patients as well. Hemophagocytosis on bone marrow aspirates was found in nine patients (60%), whereas ferritin levels were high in the whole sample. Intravenous immunoglobulins were administered in thirteen patients, while one patient received dexamethasone and etoposide. The mean (±SD) ICU stay was 25±17 days, while the observed ICU mortality was 60%.Multivariated analysis showed that ICU mortality was significantly associated with SOFA score (p=0.001) and advanced age (p=0.04).

CONCLUSIONS. HLH might be associated with sepsis and septic shock. Future research will elucidate the possible pathophysiologic mechanisms connecting the tissue injury in sepsis, with the hyperinflammatory state leading to HLH, to identify the subset of patients who might take benefit of immunosuppressive therapy.

INTRODUCTION. Pneumonia sepsis cannot be overlooked because of high mortality and morbidity rate.However, none has sufficient accuracy to serve as a prognostic indicator about pneumonia sepsis. It is well known that immature granulocyte are an indicator of increased myeloid cell production and are associated with infection or systemic inflammation.

OBJECTIVES. The data, however, are limited and little is known about the clinical usefulness of DNI in assessing mortality risk in patients with pneumonia sepsis. Therefore, this study evaluated the clinical utility of DNI as a prognostic indicator of mortality of pneumonia sepsis patients.

METHODS. We conducted a retrospective study from January 2013 to March 2015. The study was carried out in Kangdong Sacred Heart Hospital Medical Intensive Care Unit on patients with pneumonia sepsis. The DNI was measured in 3 consecutive days for pneumonia sepsis patients admitting to ICU. Primary outcome of this study was 28-day mortality.

RESULTS. A total of 89 patients with pneumonia sepsis were included in this study. Septic shock patients were 48(53.9%). In multivariate Cox proportional analysis, septic shock (Hazard ratio

4.373; 95% confidence interval (CI) 1.55-12.302; P=0.005), DNI at 72 hours of admission (DNI 3) (Hazard ratio 2.993; 95% CI 1.193-7.504; P=0.019) and ECMO (Hazard ratio 4.831; 95% CI 1.449-16.107; P=0.10) were significantly related to 28-day mortality. In the higher DNI 3 group (≥3), 53.8% (14/26) of the patients died to 28 day, whereas in the lower DNI 3 group (< 3), 15.7 % (8/51) died during 28 days (P=0.000)

CONCLUSIONS. DNI of 72 hours after ICU admission is a promising prognostic marker of 28-day mortality in patients with pneumonia sepsis.

INTRODUCTION. Neutrophil-to-lymphocyte ratio (NLR) is a representative index of systemic inflammation and a prognostic inflammatory biomarker in various diseases, especially various cancers[1]. NLR was recently reported to be associated with mortality in patients with acute respiratory distress syndrome[2, 3]. Sepsis induces a systemic inflammatory response.

OBJECTIVES. In this retrospective study, we sought to explore whether NLR is a prognostic factor in patients with sepsis.

METHODS. The study cohort comprised patients diagnosed as having sepsis and admitted to our intensive care unit (ICU). We calculated NLR by dividing the neutrophil by the lymphocyte count on admission to the ICU and categorized patients into two groups based on NLR values. Primary outcome was ICU stay. The relationship between NLR and ICU-stay was assessed using Kaplan-Meier plots and multivariable Cox regression. Secondary outcomes were weaning from administered norepinephrine, 28-day mortality, and 90-day mortality.

RESULTS. We divided the 58 patients in the final analysis into two groups with NLR ≤15 and >15. The median (interquartile range) NLR in the low NLR (S) and high NLR groups (L) were 7.8 (5.9-11.3) and 30.8 (21.8-45.9), respectively. The ICU stay was 12 (8.5-15.5) and 8.5 (6-15) days, respectively. Cox regression analysis showed that NLR is not a significant predictor of ICU stay (adjusted hazard ratio (HR) = 1.674, 95% confidence interval (CI), 0.462 to 6.063, p = 0.432). NLR was also not a significant risk factor for weaning from administered norepinephrine (HR = 1.049, CI, 0.542 to 2.03, p = 0.887). The 28-day mortality was 6.9% and 22.2% (p = 0.185), respectively and the 90-day mortality 22.2% and 35.7% (p = 0.453), respectively.

CONCLUSIONS. In this preliminary study, we found no association between high NLR and duration of ICU stay or weaning from norepinephrine administration in critically ill patients with sepsis.

Association between soluble Toll-like receptor 2 levels and sepsis on admission to the ICU: results of a case-control study

Y. Lim[1], A.-C. Raby[2], M.O. Labéta[2], T. Szakmany[3]
[1]Cardiff University, School of Medicine, Cardiff, United Kingdom; [2]Cardiff University, Division of Infection and Immunity, Cardiff, United Kingdom; [3]Cardiff University, Division of Population Medicine, School of Medicine, Cardiff, United Kingdom

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0815

INTRODUCTION. There is an ongoing need for better, more reliable early detection of sepsis. The soluble form of Toll-like receptor 2 (sTLR2) has previously been shown to be elevated in patients with infective and inflammatory conditions (1). In our previous pilot study, plasma sTLR2 levels were preferentially raised in patients with sepsis and organ failure compared to patients with sterile inflammatory response syndrome (2).

OBJECTIVES. The present study aimed to confirm and validate our previous findings in a larger and independent population.

METHODS. We performed a retrospective case-control study in 172 patients with either confirmed sepsis according to Sepsis-3 criteria (n=138) or out-of-hospital cardiac arrest (OOHCA) (n=34). Plasma levels of sTLR2 obtained from samples within 24 hours of admission to the ICU were determined by ELISA, performed blind to patient group. Demographic, organ dysfunction severity and mortality data were collected. For statistical analysis Mann-Whitney-U, Chi-square test and ROC analysis was used.

RESULTS. sTLR2 levels were significantly higher in the sepsis group: median sTLR2 levels were 2713 pg/mL (IQR 1457-5248) in sepsis and 661 pg/mL (IQR 380-1377) in the OOHCA group (p< 0.001; Figure). Clinical characteristics on admission were similar in the sepsis and OOHCA groups: Age median 68 years (IQR 59-76) vs 62 (IQR 52-72),
SOFA scores median 17 (IQR 15-19) vs 16 (15-18) and APACHE II scores median 32 (IQR 23-38) vs 30 (IQR 26-34) did not differ significantly. ICU mortality was 21.3% in the sepsis and 35% in the OOHCA group (p=0.102).

Using ROC analysis, sTLR2 showed discriminatory power for sepsis: AUC 0.827 95%CI 0.751-0.904 p< 0.001 on admission to the ICU. Our previously identified cut-off of 1000 ng/mL had 85.7% sensitivity and 75% specificity for diagnosing sepsis. sTLR2 levels below 500 ng/mL had 93% specificity and 35% sensitivity to rule out organ dysfunction secondary to infection.

CONCLUSIONS. This study confirms our previously observed association between elevated sTLR2 levels and the diagnosis of sepsis early in the clinical course. Our previously identified cut-off of 1000 ng/mL was confirmed to have appropriate discriminatory power. We also identified that lower sTLR-2 levels can confidently rule out infection induced organ dysfunction. Further work is required to identify the time-course of sTLR-2 levels, whether an optimum diagnostic cut-off exists and if sTLR2 levels can be used effectively in a multivariable prediction model.

INTRODUCTION. Sepsis is a progressive state from a local infection to systemic response. Neutrophils and monocytes are critical cellular components of the innate immune system. There have been controversial results of monocyte counts and its impact in sepsis. The reduction in monocyte counts has been reported to be correlated with the severity of sepsis in some studies, but not in all.

OBJECTIVES. This study was performed to evaluate the association of monocyte counts with mortality, the rate of bacteremia and organ dysfunction and to evaluate whether the change in monocyte counts

from the premorbid state to sepsis would differ between survivors and non-survivors in patients with severe sepsis or septic shock.

METHODS. A retrospective analysis of patients with severe sepsis or septic shock was performed. Monocyte counts were categorized into < 250, 250 - 500, 500 - 750 and ≥ 750 cells/μL; in addition, 28-day mortality, the rate of bacteremia and organ dysfunction were compared between the groups. Multivariate logistic regression analyses were performed to evaluate the independent association of initial blood cell counts with 28-day mortality. Subgroup analyses of patients who had premorbid data of blood cell counts were performed to evaluate the difference in the change in monocyte counts between survivors and non-survivors.

RESULTS. During the study period, 2012 patients were included. Neutrophil and monocyte counts were significantly different between survivors and non-survivors. However, only monocyte counts were independently associated with mortality in the multivariate logistic regression analyses. Patients with initial monocyte counts < 250 cells/μL showed the highest mortality, rate of bacteremia and organ dysfunction. In patients who had premorbid blood cell counts, the monocyte counts increased in survivors but decreased in non-survivors from the premorbid to sepsis.

CONCLUSIONS. In conclusion, monocyte counts were associated with mortality, the rate of bacteremia and organ dysfunction in patients with sepsis, possibly due to the relative lack of monocytopoiesis related with septic insults in non-survivors.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0817

INTRODUCTION. Sepsis is a complicated process including several pathophysiological events with a high mortality rate and problematic therapy. Altough there are many experimental studies on multimodal immunological cascade resulting from the sepsis, there is not any research evaluating the relation between proinflammatory and inflammatory cytokines, procalcitonin levels and mortality and morbidity in sepsis in human yet.

OBJECTIVES. This study aims to investigate the correlation between the mortality and levels of leukocyte, TNF-α, IL-10, IL-4 and procalcitonin in sepsis.

METHODS. This prospective study was performed with 45 patients diagnosed with sepsis, severe sepsis and septic shock and stayed more than 24 hours in Intensive Care Unit of Anestesiology and Reanimation Clinic of Health Science University Derince Education and Research Hospital. As a control group, 20 patients who were not diagnosed with sepsis but stayed in intensive care unit for more than 24 hours were accepted. The patients with sepsis were assigned as Group 2 (n:14), severe sepsis patients were Group 3 (n:15) and septic shock patients were Group 4 (n:16). These groups were also divided into two groups as alive and mortal after care and treatment. Descriptive data as age, sex, diagnosis, hospitalization duration,

APACHE II scores, underlying diseases of the patients were recorded. Leukocyte levels of the blood samples of patients were determined ath the moment of diagnosis for sepsis, at 7th day of hospitalization and at the discharge moment from the clinic or at time of death. Moreover, proinflammatory cytokine levels of TNF-α, IL-4, IL-10 and PCT levels were measured from the blood samples.

RESULTS. The findings of study showed the demographic characteristics of patients were statistically similar. There were significant differences when the mortality rate and the severity of sepsis were compared with hospitalization duration, acute renal damage, leukocyte levels, some IL-10 levels and procalcitonin amount in the patients. However, any relation between mortality rate and levels of the cytokine levels for TNF-α and IL-14 could not be detected.

CONCLUSIONS. This study concluded that there may be a correlation between the mortality rate and hospitalization duration of sepsis, severe sepsis and septic shock patients and their levels of leukocytes, IL-10 and PCT. However, unrelated correlation between TNF-α and IL-4 levels and the mortality rate in sepsis may indicate that the patient range should be enlarged to a larger multicentered study.

INTRODUCTION. Community-acquired pneumonia (CAP) is considered an important cause of mortality and morbidity worldwide. There is a constant need to explore novel prognostic markers. Dynamic changes in immune cells response to sepsis sourced markers like the Neutrophil-to-Lymphocyte Ratio (NLR), that has shown potential usefulness in sepsis and septic shock.

OBJECTIVES. To evaluate the ability of NLR in the prognosis of outcome in CAP.

METHODS. A prospective cohort of consecutive patients admitted to Intensive Care Unit (ICU) or Internal Medicine (IM) with diagnose of CAP, in the absence of hematological disease, immunosupression, chemotherapy, myelotoxic agents, hemotransfusion or liver damage. Clinical-demographic information, co-morbidity and laboratory data were obtained from medical records. The NLR was calculated from the hemogram at admission and during 3, 5 and 7 days of follow-up. Severity scores (SOFA), its modification during evolution [DSOFA]) and the clinical outcome (unfavorable outcome: use of vasopressors, invasive ventilation and mortality) were evaluated; as well as the hospitalization time. In addition, we explored apoptotic trends in neutrophils and lymphocytes (Western blot, Anexin V). The study population was grouped according to outcome. Mortality was analyzed separately. Student's t-tests, ROC curve, Odds ratio and Pearson's correlation were used. Statistical significance, p-value < 0.05.

RESULTS. Fifty nine patients (31 males, 28 females), mean age 65.4 ±18.8 years old, constituted the study population. We observed the following baseline values: CURB-65 2.06±1.04; SOFA 6.10±3.04, and NLR 14.78±11.06. Interestingly, the higher NLR, the higher CURB-65 score (p< 0.05), and negative related with DSOFA, during time course analysis. Baseline data from groups with favorable and unfavorable outcomes were: CURB-65 score 1.64±0.78 vs 2.45±1.12 (p< 0.05), SOFA 4.57±1.95 vs 7.58±3.05 (p< 0.05) and NLR 11.25± 8.7 vs 17.21

±10.75 (p< 0.05), respectively. Regarding latter comparison, NLR value was higher in subpopulation with unfavorable outcome, who were admitted directly to ICU 16.30±8.9 compared to those admitted to IM 11.81±10.31 (p< 0.05); as well as cases who showed in-hospital death 17.61±8.4 (p< 0.05).

NLR cut-off (14) was calculated based in the discriminatory ability to predict unfavorable outcome, SE 0.68, SP 0.64, AUC=0.41 (p< 0.05); OR 3.1 (CI95= 1.07 to 13.08, p< 0.05). Furthermore, baseline NLR< 14 associated shorter hospitalization time and significant correlation (Pearson's r=0.66 (CI 95=0.21-0.88, p< 0.01). A decreased expression of Anexin V in neutrophils was observed patients with unfavorable outcomes.

CONCLUSIONS. The NLR showed prognostic ability of unfavorable outcome in patients with CAP.

INTRODUCTION. Sepsis is a maladaptive inflammatory process in response to infectious agents, related to immune dysfunctions and devastating complications. Recently, interest has been shifted towards apoptotic and anti-apoptotic pathobiology, which might bring to light attractive therapeutic interventions for septic intensive care unit (ICU) patients. Apoptosis is regulated through the activation of a number of anti-apoptotic proteins, such as survivin, with different biological functions (pro-apoptotic or anti-apoptotic), depending on the expression of its different splice variants (wild type-WT, ΔEx3, 2B, 3B). The importance of these complicated pathways in sepsis has not yet been elucidated.

OBJECTIVES. The present study seeks to ascertain whether sepsis is associated with an upregulation of certain anti-apoptotic biomolecules, such as survivin, as well as to assess the prognostic value of the expression of the survivin transcript isoforms -WT, -ΔE3x, -2B and -3B, in ICU patients with sepsis and trauma-related SIRS.

METHODS. This prospective observational study was performed in a sample of critically ill adult (n=257) patients with sepsis or SIRS, compared to healthy controls (n=116). The expression of survivin transcript variants was analyzed by real-time quantitative PCR in peripheral blood leukocytes, whereas measuring the activity of survivin, through ELISA in serum samples, specified anti-apoptotic tendency.

RESULTS. Serum levels of the survivin protein as well as WT transcriptional levels for survivin were found significantly elevated in septic patients, compared to SIRS and control individuals (p< 0.05). The main survivin splice variants (ΔEx3, 2B), showed an escalated increase in SIRS and sepsis, except 3B, which appeared to be elevated in the SIRS group, while being significantly depressed in septic patients (p< 0.05). All survivin isoforms showed an upward slope among non-survivors, with survivin protein, -ΔEx3, and -2B differing significantly (p< 0.05). For predicting sepsis, splice variants 2B and ΔEx3 achieved a receiver operating characteristic curve (AUROC) >0.90 (95% CI 0,85-0,98, p< 0.05). In predicting mortality among critically ill patients, isoforms 2B and ΔE3x achieved an AUROC >0.82 (95% CI 0,76-0,98, p< 0.05).

CONCLUSIONS. The survivin apoptotic and anti-apoptotic pathways might represent attractive targets for future research in the clarification of sepsis. The mRNA expression of survivin variants and protein activity quantification could predict outcome and provide additional information about clinical management of patients suffering from sepsis.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0820

INTRODUCTION. Sepsis remains a leading cause of mortality worldwide.[1] Impaired circulating monocyte function has been linked to the pathogenesis of sepsis, specifically relating to HLA-DR expression[2] and Tyro3-Axl-MerTK family of receptor tyrosine kinases.[3] Further examination of this relationship could therefore guide novel treatment discovery.

OBJECTIVES. We sought to investigate monocyte immunotypes in sepsis patients, to elicit functional relevance of any impaired immune response.

METHODS. Plasma from septic patients was obtained from the LeoPARDS trial.[4] CD14[+] bead-isolated healthy control (HC) monocytes were preconditioned for 24 hrs in the presence of either HC or septic patient plasma. Phenotypic analyses of these monocytes, focused on activation/pro-repair markers, were performed using flow cytometry. Preconditioned monocyte migratory characteristics were assessed utilising an *in vitro* trans-endothelial migration assay, recently described,[5] allowing analysis of migratory characteristics of monocytes into the subendothelial space, and back across the endothelium (reverse migration), thus mimicking their *in vivo* transit patterns, e.g. when returning to the circulation.

RESULTS. Compared to HC, baseline MerTK, CCR2 and CCR5 expression levels were significantly increased in CD14+ 'septic' monocytes whereas HLA-DR, Axl and PD-L1 levels were decreased (Table 1). They also exhibited reduced Axl and CD86 expression following migration into the sub-endothelial space. Of note, reverse-migrated 'septic' monocytes were characterised by increased MerTK and lower CD86 and PD-L1 expression, in contrast to HC (Fig 1).

CONCLUSIONS. We describe a pro-repair yet immunosuppressive HLA-DR[low] MerTK[high] phenotype in monocytes conditioned with septic patient plasma, in line with previous findings.[2-3] We also report a reduction in Axl, part of the same tyrosine kinase family as MerTK, at baseline and sub-endothelially, which may indicate activation-induced receptor shedding. Furthermore, adaptive co-stimulatory molecules (CD86/PD-L1) were down-regulated in migrating monocyte populations conditioned with septic plasma.

Together, our data indicate that 'pro-repair/immune-inhibitory' monocytes may suppress tissue-specific immune responses, accounting for the dysregulated host immune responses observed in sepsis. Future work will characterise functionally 'septic' monocytes including comparison between survivors/non-survivors, to elucidate the key mechanisms involved in the pathogenesis of sepsis.

Resistin exerts differential immunomodulatory effects on neutrophils and macrophages in sepsis

A. Bonavia[1], L. Miller[1], K. Singbartl[2]

[1]Penn State Milton S. Hershey Medical Center, Anesthesiology and Perioperative Medicine, Hershey, United States; [2]Mayo Clinic, Critical Care Medicine, Phoenix, United States

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0821

INTRODUCTION. Mounting evidence suggests that sepsis-induced morbidity and mortality are due to both immune activation and immunosuppression. Resistin is a 12.5kDa uremic cytokine, and septic hyperresistinemia(HR) has been associated with greater disease severity and worse outcome in critically-ill patients. Normal serum resistin levels are < 20 ng/ml, and levels in septic shock with acute kidney injury may be as high as 90-120 ng/mL. Resistin has been reported to block the LPS-Toll-like receptor (TLR)-4 interaction in monocytes/macrophages, thus exerting a protective, anti-inflammatory effect in endotoxic shock. However, we have reported that at concentrations above 20 ng/ml, resistin also impairs polymorphonuclear neutrophil (PMN) migration, intracellular bacterial killing and generation of reactive oxygen species (ROS) in a dose-dependent manner when PMN are challenged with *P. aeruginosa*, a nosocomial Gram-negative organism.

OBJECTIVES. Our central hypothesis is that the intracellular signaling mechanism following resistin exposure differs between PMN and macrophages. We hypothesize that (1) the effects of resistin on PMN are not TLR4-mediated as evidenced by persistent impaired killing of Gram positive organisms, which do not release endotoxin/LPS, and (2) the intracellular effects of resistin on PMN are mediated by G proteins.

METHODS. Intracellular bacterial killing of *S. aureus* (Gram positive) and *P. aeruginosa* (Gram negative) were assessed separately in neutrophil (NB4) and macrophage (THP-1) cell lines exposed to resistin (100 ng/mL). To study whether resistin's effects in PMN were mediated by G proteins, we performed Ca^{2+} influx assays using fMLP (a $G_{i/o}$ receptor agonist) as the stimulus in the presence or absence of 100 ng/mL resistin.

RESULTS. Resistin significantly impaired intracellular bacterial killing of *P. aeruginosa* in both macrophages and PMN. Resistin did not impair intracellular bacterial killing of *S. aureus*, while PMN exposed to resistin demonstrated markedly impaired intracellular bacterial killing of this organism within 30 minutes of exposure to the cytokine. This indicates that resistin signaling in PMN is not TLR4-mediated. Resistin did not alter the fMLP-mediated Ca^{2+} influx in PMN, arguing against a $G_{i/o}$ receptor signaling mechanism for impaired phagocytosis and killing.

CONCLUSIONS. While HR may exert a protective, anti-inflammatory effects in monocytes during endotoxic shock via a TLR-mediated mechanism, it likely also causes PMN dysfunction. The resistin signaling mechanism in PMN appears to be neither TLR nor G protein-mediated.

Inflammation promotes coagulation by activation of the extrinsic pathway through endothelial cells in-vitro

A.K. Brandtner, G.F. Lehner, M. Joannidis

Innsbruck Medical University, Department of Internal Medicine, Division of Intensive Care and Emergency Medicine, Innsbruck, Austria

Correspondence: A.K. Brandtner

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0822

INTRODUCTION. Septic patients often present with deranged coagulation. Parameters of an activated coagulation, such as D-dimer and thrombin-antithrombin complexes are elevated within hours after onset of sepsis[1]. The role of the endothelium in this reaction and determining the sepsis phenotype is recognized to be major. As tissue factor (TF) and negatively charged phospholipids are expressed by endothelial cells (EC) upon inflammation, both the extrinsic and the intrinsic coagulation cascades may be activated[2]. To support our understanding of the interaction between the endothelium and the coagulation system in sepsis, we established an in-vitro system to test TF-dependent factor X (FX) versus prothrombin (FII) activation by negatively charged phospholipids on endothelial cell surface to evaluate their relative contribution to coagulation activation upon inflammatory stimulation.

OBJECTIVES. Our aim is to evaluate the relative contribution of TF and negatively charged phospholipids expressed on the surface of endothelial cells to coagulation activation in inflammation.

METHODS. Primary human umbilical vein cells (HUVEC) were incubated with ascending concentrations of tissue necrosis factor alpha (TNFa, 50, 5 and 0.5 ng/mL), lipopolysaccharide (LPS 1000,100 and 10 µg/mL) and interleukin-1 beta (IL-1b 1, 0.5 and 0.1 nmol/L) for 3 hours in a 96-well plate at standard cell culture conditions. FX and FII activation were measured by specific cleavage of a chromogenic substrate after addition of FX and FVIIa or FII and FVa respectively. Absorbance was measured after acid quenching of the reaction. Results are expressed as fold change to untreated controls and were analyzed by linear reg ression.

RESULTS. TNFa and IL-1b induced a significant increase of FXa even between the lowest concentration and untreated control (mean 0.1869 vs. 0.1089, p = 0.01; mean 0.3828 vs. 0.129, p = 0.01, respectively). A dose-depend increase of FX activation by endothelial cells was observed for each of the three pro-inflammatory agents, with TNFa showing the strongest relation to a dose-dependent linear increase in this bivariate model (mean 4.4-fold increase, SD 1.66; R^2 = 0.773, df = 14;). leavage of FII was elevated, but did not exhibit a significant or dose-dependent increase upon pro-inflammatory stimulation.

CONCLUSIONS. These experiments propose a predominant role of TF for coagulation activation on the surface of HUVEC upon pro-inflammatory stimulation with TNFa.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0823

INTRODUCTION. Ventilator-associated pneumonia (VAP) is a frequent intensive care unit (ICU)-acquired infection with worse consequences. Critically ill patients, especially septic patients, have depressed immune system. Transcriptomic analysis of circulating peripheral blood leucocytes has demonstrated to be a valuable approach to evaluate immunity in different infectious diseases and to identify new molecular markers for diagnosis proposes.

OBJECTIVES. The evaluation of the systemic immune dysfunction of VAP patients could be useful to understand the pathological events of this disease and to detect it early. In order to study these immune alterations in VAP we decided to use a molecular method, transcriptome microarrays.

METHODS. An observational prospective cohort study enrolling immunecompetent adults with VAP, and no infection patients in seven medical ICU. A blood sample was collected in the first 24 hours following diagnosis of VAP by using PaxGene tubes. In the MV control group, the sample was collected at 6th7th day under MV (median day

for diagnosis of infection in the VAP group). Clinical data also was collected; including medical history, physical examination and hematological, biochemical, radiological and microbiological data.

RESULTS. 41 mechanical ventilated (MV) patients (24 VAP and 17 control MV). ICU-admission reason, patient baseline characteristics are in Figure 1.

Both comparable in age, gender and comorbidities. The main reason for orotracheal intubation was low-consciousness level (72,5%). VAP group showed a lower PaO2/FiO2 ratio and higher CPIS score compared with non-infected patients. VAP patients stayed longer under mechanical ventilation (20 vs 12 days) and showed a longer ICU and hospital stay. Finally, no differences in terms of mortality were evidenced between both, control and pneumonia group.

1231 genes were identified whose expression levels were significantly different between the two groups. 680 genes were over-expressed in VAP patients and 551 genes showed lower transcript levels in this group. A large proportion of the implicated genes were down-regulated in patients with VAP. The molecules codified by these genes are related to immunological synapse, it`s suggested a depression of the antigen presentation in these patients.

CONCLUSIONS. These results support the idea of being able to be used the gene expression as biomarkers in the early diagnosis of ventilator adquired pneumonia.

INTRODUCTION. Cardiac surgery with the use of cardio-pulmonary bypass is commonly associated with the development of systemic inflammatory response syndrome (SIRS) due to exposure of blood to artificial surfaces, myocardial and pulmonary ischemia/reperfusion and surgery itself. Currently used biomarkers including white blood cell count (WBC), C-reactive protein and procalcitonin (PCT) have limitations in the differential diagnosis of sepsis versus SIRS given by their low specificity in the surgical patients. There has been recently a renewed interest in the immature granulocyte (IG) count as an infection predictor. The occurrence of IG in the blood indicates increased activation of bone marrow in sepsis. Several recent studies including general surgical patients presented usefulness of this parameter in predicting sepsis however, data from a population of cardiac surgical patients are lacking.

OBJECTIVES. The usefulness of immature granulocyte percentage (IG%) to discriminate between postoperative non-infective SIRS and sepsis was tested in cardiac surgical patients.

METHODS. A retrospective analysis of 124 patients who developed non-infective SIRS and sepsis after elective cardiac surgery with the use of cardiopulmonary bypass from January 2015 through December 2015 was performed. The diagnosis was made by a clinician in charge based on Sepsis-2 criteria and available clinical, radiographic and microbiological parameters. Predictive ability of IG% to predict sepsis was compared to PCT, WBC and temperature using receiver operator characteristic (ROC). The Liu method was used for calculation of optimal cut-off points. The diagnosis sensitivity, specificity, and positive (PPV) and negative predictive values (NPV) were calculated for each parameter. Using logistic regression analysis the composites scores were created combining the individual biomarkers. Their discriminative power was subsequently evaluated and compared by linear discriminative analysis (LDA).

RESULTS. There were 44 patients diagnosed with sepsis and 80 with non-infective SIRS. In ROC analysis, area under curve (AUC) was higher for IG% and PCT compared to WBC and temperature (0.71, 0.72, 0.62 and 0.58 respectively). The best cut-off value for IG% was 1.45% (sensitivity, specificity, PPV and NPV of 70.5%, 60%, 49.2% and 78.7% respectively) and 1.43 µg/l for PCT (sensitivity, specificity, PPV and NPV of 65.9%, 75%, 59.2% and 80 respectively). The predictive ability was significantly improved by constructing a composite score combining IG% and PCT (AUC of 0.8 in ROC analysis, sensitivity, specificity, PPV and NPV of 63.6%, 88.8%, 75.7% and 81.6% respectively).

CONCLUSIONS. In cardiac surgical patients IG% is a helpful marker with moderate ability to discriminate between sepsis and non-infective SIRS, comparable to serum PCT. The combination of these two biomarkers in a composite score increased test´s overall predictive ability mainly by improving its specificity.

Patients' characteristics influence ICU results, or do they?

Quality of life after ICU discharge: a prospective observational study from a tertiary care centre in North India

A. Azim, R. Rai, A. Aggarwal

Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Correspondence: A. Azim

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0825

INTRODUCTION. Advances in medical and interventional management has increased survival of critically ill patients. This has led to the need for outcome measures other than survival.
OBJECTIVES. The aim of this study was to assess quality of life after ICU discharge using 6 months prospective follow up and to analyze risk factors affecting health quality parameters.
METHODS. After obtaining institutional ethical committee approval and written informed consent from patient or next of kin, we conducted a prospective observational cohort study on patients who got discharged from Intensive Care Unit (ICU) after more than 7 days stay (January 2017-October 2017) and survived for 6 months Post-ICU discharge. Patients less than 18 yrs age, those getting discharged for end of life care and patients with pre-existing neurological illness, patients lost to follow up were excluded from the study. Follow up was done at 1 month and 6 month using SF-36 questionnaire. For comparison purpose, SF-36 was also filled for each patient to know pre ICU status. Data collection included patient demographics, SOFA Score, APACHE II Score, NYHA classification, and ICU stay details. Telephonic interview was conducted for patients who could not report for follow up. Appropriate statistical tests were used for quantitative and qualitative data. Correlation between various parameters was done using Pearson's correlation. P value of < 0.05 was taken as significant.
RESULTS. 100 patients met inclusion criteria (M=60, F=40). Respiratory infection was the most common cause for ICU admission. Diabetes and hypertension were the most common co-morbidities. Mean ICU stay was 13.6 days, mean days of mechanical ventilation were 7.93 days, mean admission APACHE II was 18.88 and mean SOFA was 7.73. Comparison of SF-36 parameters showed Physical Component Summary Score (PCS) and Mental Component Summary Score (MCS) at pre-ICU as 55.12 and 55.09 which deteriorated to 39.59 and 35.49 (p< 0.05) at 1 month post discharge and 47.93 and 37.46 at 6 months. Multivariate analysis showed Age, Admission APACHE II, and SOFA score as significant factors affecting PCS and MCS. Length of ICU stay and duration of mechanical ventilation significantly affected Physical Functioning (PF) at 6 months and Bodily Pain (BP) at 1 month. When compared with general population norm both PCS and MCS showed significant deterioration at 6 months.
CONCLUSIONS. Post ICU discharge patients have significant functional impairment and compromised health related quality of life. Age, severity of illness, length of ICU stay and duration of mechanical ventilation significantly affect health quality parameters.

INTRODUCTION. Prolonged stays in ICU have been repeatedly associated with high rate of resource consumption, but little is known about their epidemiology and prognosis.
OBJECTIVES. To describe the epidemiology and events during the stay of patients hospitalized 30 days or more (long stay patients - LSP) in an medical ICU and to identify early predictors of prolonged hospitalization.
METHODS. We conducted a monocentric retrospective observational study, in a medical ICU of a teaching hospital. Data regarding preadmission and admission characteristics as well as evolution during the ICU stay were collected. Univariate and multivariate analyses using logistic regression were conducted to find predictors of mortality among LSP and to compare LSP with patients hospitalized less than 30 days (short stay patients - SSP).
RESULTS. Among 8906 patients hospitalized in the ICU between july 2000 and december 2013, 417 were hospitalized 30 days or more. Median length of stay (LOS) was 39.0 [34.0 ; 52.0] days. LSP were mostly men (sex ratio 2.0) and inpatients (61.1%) admitted for respiratory (55.6%) or infectious (25.2%) disease with a median SAPSII of 50.0 [38.0; 64.0]. Organ support was frequent: mechanical ventilation in 99.7%, vasoactive drugs (VD) in 75.8%, renal replacement therapy (RRT) in 33.1%. 382 (91.6%) patients presented at least one complication during their ICU stay: admission-disease related in 271 (65.0%), intercurrent infectious in 319 (76.5%) and intercurrent non-infectious in 251 (60.2%). In-ICU and in-hospital mortality were respectively 39.1% and 47.7% with no difference of LOS between the deceased and the survivors. An older age (OR 1.02 [1.00; 1.04], p=0.044), the requirement of VD at any time during the stay (OR 3.3 [1.6; 6.9], p=0.001) and the occurrence of admission-disease related or intercurrent infectious complication (OR 2.06 [1.2; 3.6], p=0.009 and OR 4.3 [2.0; 10.0], p< 0.001 respectively) were independently associated with mortality whereas RRT was the only protective factor (OR 0.5 [0.3; 0.9], p=0.020). Multivariate comparison to SSP yielded male sex (OR 1.4 [1.1; 1.7], p< 0.001), transfer from another ICU (OR 2.7 [1.7; 4.2], p< 0.001) and hospitalization for a respiratory (OR 2.9 [1.8; 4.7], p< 0.001) or an infectious disease (OR 2.0 [1.2; 3.5], p 0.01) as independent factors associated with long stays while being an outpatient (OR 0.5 [0.4; 0.6], p< 0.001) and being hospitalized for a cardiovascular (OR 0.4 [0.2; 0.7], p< 0.001) or endocrine/metabolic disease (OR 0.2 [0.1; 0.6], p =0.01) were associated with short stays.
CONCLUSIONS. Prolonged ICU stays were associated with a high rate of complications but the majority of patients were discharged alive from the hospital. Early identification and prediction of mortality of long stay patients seems difficult as most predictors are related to events occurring during the stay and not to preadmission and admission characteristics.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0827

INTRODUCTION. Quality of life (QoL) after an Intensive Care Unit (ICU) stay can be compromised. The factors, which influence quality of life

are numerous and still poorly understood. Determining major contributors may help prevent deterioration of QoL after ICU stay.

OBJECTIVES. To evaluate QoL after ICU discharge and to identify major associations with clinical factors.

METHODS. Prospective cohort study of all patients discharged from a mixed ICU between 1st January of 2015 and 31stDecember 2016, observed at the follow-up clinic, and evaluated in terms of QoL and functional status (respectively by the EQ-5D and Karnofsky performance status scale).

RESULTS. A total of 222 patients were observed at the follow-up clinic and were evaluated in terms of QoL and functional status. The EQ-5D is a descriptive system used as a measure of health-related QoL, which records the patient's self-rated health. The Karnofsky performance scale is allows for the appraisal of functional impairment. The relationship between quality of life and functional status wasn't statistically significate in terms of sedation, mechanical ventilation, neuromuscular blockage, delirium, agitation, length of stay, time until the appointment, acute neurologic non-traumatic condition, psychiatric pathology and post-cardiac arrest. However, Cranioencephalic trauma (CET) had statistically significate impact in functional status (p=0.007), as well as, return to usual activity (p=0.001) and decrease in functional ability (p=0.043) - see figure 1. The most affected dimension of the EQ-5D in patients with CET and in patients with a decrease in functional ability was difficulty in usual activities (mild to severe in 54% and 67%, respectively) and in patients having returned to usual activity the most altered dimension was walking difficulties (mild to severe in 43%; see Figure 2).

CONCLUSION. QoL is a multidimensional concept, which is crucial in evaluating long-term outcomes in ICU and is compromised after discharge. The influencing factors of QoL post-ICU are still poorly understood, but a statistically significate association was found with CET, return to usual activity and decrease in functional ability.

Elderly donor and gender impact on cumulative survival rates of liver graft recipient in 20 years of experience in Santiago de Compostela, Spain

J.R. Fernández Villanueva[1], R. Fernández Garda[1], R. Hernández Vaquero[1], I. Granja Gómez[1], E. R. Ruiz[1], C. Galbán Rodríguez[1], E. Varo Pérez[2]
[1]Complexo Hospitalario Universitario de Santiago de Compostela, Intensive Care Unit, Santiago de Compostela, Spain; [2]Complexo Hospitalario Universitario de Santiago de Compostela, Abdominal Transplant Unit, Santiago de Compostela, Spain
Correspondence: R. Fernández Garda

809 Liver Transplants (LT) were made at Hospital Clínico Universitario of Santiago de Compostela (Spain) in the period 1994-2014, accounting 4.25% of all LT performed in Spain. Review of the impact of the Donor´s Age on the Survival of Graft and Recipient in 20 years of experience in our center.

MATERIALS AND METHODS. Retrospective and descriptive review of 809 cases of liver transplantation performed in the 1994-2014 period at the Hospital Clínico Universitario of Santiago de Compostela (Spain) acording to the Local Registry and the Spanish Registry of Liver Transplantation (RETH).

RESULTS. 809 cases, 12 cases were Hepato-renal transplantation, 3 requeried Re- transplant. Media of Donors: 33 cases/year. 79.35% Men and 20.64% Women with Recipeint Mean Age: 51 years old. Predomintaly Blood group A (49%). Most frequent LT indication: Alcoholic Cirrhosis (43,%), Idiopathic (43.01%) and Fulminant Liver Failure (6.18%). Cumulative Survival at 20 years in our serie: 47% higher than the comparison with the global data provided by RETH (37% applying Kaplan-Meier curve p < 0.01) and in the last 5 years (2008- 2013): 77% compared to RETH data for the same period (70% with p < 0.05). The Mean Age of the Donor in Brain Death: 53.5 years, increasing exponentially from the beginning of the program with a Median of 35 years (1994) to 68 years (2014). Impact of Survival Rate of the Graft based in Elder Age and Gender of the Donor (>60 years old): 55% to Elder Male Donors and 38% to Elder Women Donors (*p< 0,07*) at 20 years. And the group LT indication for Hepatitis C Virus Cirrhosis (HCV), the Impact of Survival Rate of the Graft in Elder Donors form 60-69 years: 32% and >70 years: 30% (*p< 0,05*) at 20 years of study.

CONCLUSIONS. Elderly Age Donors, as a surrogate marker, affects the Survival Rates of the Recipient, but it is necessary to adjust other co-variables of the Donor to correctly assess this finding. Donor's Elder Age affects negatively Survival Rates of the HVC Receptors, something that will undoubtedly change in future studies regards introduction of Antiretroviral Therapy to treat it.

Changing practices - impact in outcome concerning intra-abdominal infections after ICU reorganization

E. Campôa[1], B. Sarmento Banheiro[2], I. Jesus Pereira[3], G. Campello[2]
[1]Centro Hospitalar Universitário do Algarve, Serviço de Oncologia Médica, Faro, Portugal; [2]Centro Hospitalar Universitário do Algarve, Departamento de Emergência, Urgência e Cuidados Intensivos, Portimão, Portugal; [3]Centro Hospitalar Universitário do Algarve, CriticalMed Investigator, CINTESIS - Center for Health Technology and Services Research, Faculty of Medicine, University of Porto, Faro, Portugal
Correspondence: G. Campello
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0829

INTRODUCTION. Intra-abdominal infections (IAI) often lead to Intensive Care Units (ICU) admission and are associated with high mortality rates.
OBJECTIVES. To understand the impact in outcomes of IAI comparing two distinct moments of clinical practices under different leadership and expertise.
METHODS. Retrospective analysis of patients admitted in an ICU from January to September 2016 compared to the same period in 2015. Clinical and therapeutic variables were analyzed using the SPSS statistical program v. 25.0. The significance level used was 0,05. T test for independent sample, Mann Whitney test, chi-squared test and Fisher's exact test were used.
Logistic regression modeling was used to understand factors associated with mortality.
RESULTS. We reviewed 111 patients, 61.3% were males and the global mean age was 67.1 years. In the total group of patients, the APACHE II was 18.5 (SD ± 9.2) and the SAPS II was 45.5 (SD ± 20.4), there were no differences between both subgroups. ICU mortality was 27.0%, with no differences between the two periods. Acute abdominal surgery was performed in 61.3% of the cases, and in 34.3% of the cases a second surgical intervention was required with no differences between groups when reviewing the causes for reintervention. The main etiologies for IAI were intestinal occlusion/ischemia (47.5%) and intestinal perforation (33.3%). The total hospital LOS was similar between subgroups but when analyzing the ICU LOS between the two subgroups, it was significantly longer in 2015 with a median of 6 days (IQR 16) and 3 days (IQR 6) in 2016. The need for ICU readmission was similar between subgroups (one in 2015 and 2 in 2016). The number of IMV days was also significantly higher in 2015 with 3 days (Med; IQR 13) and 1 day (Med; IQR 4) in 2016. There was no difference concerning the duration or tapering off of antibiotic therapy even though the number of blood cultures collected was significantly higher in 2016 (24 in 2015 and 41 in 2016, p=0,013). Among the schemes used we found significant differences between the two periods, a predominance of schemes containing 3rd generation cephalosporins with metronidazole in 2016 and carbapenems in 2015, these results were not associated with differences in antibiotic resistance between groups. We found a statistically significant influence of age, severity scores and number of IVM in mortality.
CONCLUSIONS. The consequences of changing organizational procedures are obvious when analyzing the two-time frames, even though we could not find differences in mortality, we found significant differences in other outcome variables: ICU length of stay, days of IMV and antimicrobial strategy. Even thought we did not analyze costs, we consider that health care cost reduction is probably another positive outcome of the ICU reorganization. This shows us that resource reorganization may have major healthcare system implications.

Mortality of patients discharged in-hours and out-of-hours from a British ICU: are functional ICU practices to blame?

J. Cumberworth, I. Francis, M. Chequers, R. Gray, O. Boyd
Royal Sussex County Hospital, Department of Intensive Care Medicine, Brighton, United Kingdom
Correspondence: J. Cumberworth
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0830

INTRODUCTION. ICU patients discharged out-of-hours have been demonstrated to have a higher in-hospital mortality rate. A recent systematic meta-analysis has reported a pooled OR of 1.31 (95% CI 1.25-1.38) for hospital mortality following ICU discharge out-of-hours compared to in-hours.[1]
It is frequently assumed that the increased mortality is a reflection of ward practices such as reduced staffing; we explore the possibility that factors within the ICU or ICU discharge influence results. Here we present preliminary data on a retrospective cohort study of post-ICU mortality in our unit for those discharged in-hours and out-of-hours.
OBJECTIVES.
1. Is the mortality rate of patients discharged out-of-hours higher than mortality rate of patients discharged in-hours from our unit?
2. Are there other factors influencing differences in reported mortality rates that may not have been previously considered?
METHODS. Data were collected retrospectively on all patients admitted to, and discharged from, our unit between 1st January 2017 and 30th June 2017. Readmissions, elective surgical patients and those with ICU stay < 8 hours were excluded. Data were collected on age, sex, length of stay, APACHE II score, nature of admission (medical or surgical), time from unit to hospital discharge or death, and final outcome. In-hours was defined as 07:01 to 21:59 and out-of-hours was defined as 22:00 to 07:00. Data were compared by Chi-squared test or Mann-Whitney U test as appropriate.
ICU admission and discharge summaries were reviewed for patients discharged from the ICU who did not survive to hospital discharge, as were medical certificates of cause of death. Patients discharged from the ICU for organ donation or end-of-life-care were identified and excluded. Comparisons of those discharged in-hours and out-of-hours were then repeated.
RESULTS. The study population initially contained 613 subjects, the majority discharged in-hours. The mortality rate after ICU discharge was 5.37% for those discharged in-hours and 13.64% for those discharged out-of-hours. After removal of those discharged for end-of-life care or organ donation (n=19), however, corresponding mortality rates were 3.25% and 6.86% respectively (*p*=0.0854) as shown in Table 1.
CONCLUSIONS. The prognoses of patients discharged from the ICU following clinical improvement will contrast with those discharged for organ donation or to a ward-based environment for end-of-life care, as mortality in these groups will be 100%. Small numbers of patients in this group being discharged at differing times may, therefore, lead to striking differences in reported mortality rates. If these discharges frequently occur out-of-hours the effect could be even greater and skew out-of-hours discharge mortality rates.

Risk factors for one-year mortality at ICU discharge in patients with free flap reconstruction due to cancer of the head and neck

S. Lahtinen[1], T. Ala-Kokko[2], P. Koivunen[3], J.H. Liisanantti[2]
[1]Oulu University Hospital, Anesthesia and Intensive Care, Oulu, Finland; [2]Oulu University Hospital, Anesthesia and Intensive Care, Division of Intensive Care Medicine, Oulu, Finland; [3]Oulu University Hospital, Otorhinolaryngology and Head and Neck Surgery, Oulu, Finland

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0831

INTRODUCTION. Free flap transfer is a standard method in reconstruction of large defects in head and neck cancer surgery with frequent postoperative complications and high long-term mortality; 5-year survival is approximately 50-60% but a high rate of patients dies within one year from the operation. Risk factors for short-term mortality in immediate postoperative phase and within one year from the operation in this patient group are not well studied.
OBJECTIVES. The aim of this study was to evaluate the risk factors for one year mortality in patients operated due to cancer of the head and neck with free flap repair at ICU discharge.
METHODS. Retrospective analysis of 146 patients that underwent head and neck cancer surgery with free flap repair in Oulu University Hospital in 2008-2016.
RESULTS. Of the 146 patients, there were 27 patients (18.5%) who died within one year from the operation and 10 of them within 180 days. The median ICU stay was 0.9 days [0.8-1.7]. Most of the one-year non-survivors were males (21(77.7%), p=0.008) and more often recorded as ASA 3-4 (22 (81.5%) vs 59 (49.6%), p=0.003) compared to the one-year survivors. There were no differences in the intraoperative course. Among the one-year non-survivors the preoperative albumin level was lower (42 [37-44] vs 43 [41-45], p=0.032) and the SOFA admission score was higher (4 [3-59] vs 3 [2-4], p=0.013) compared to the one-year survivors. The levels of CRP (87 [67-112] vs 61 [51-89], p=0.019) and leukocytes (11.7 [9.1-15.2] vs 8.9 [7.3-12.2], p=0.001) of the one-year non-survivors were higher on the first postoperative day compared to the survivors.
CONCLUSIONS. One-year non-survivors had higher ASA classification, and lower preoperative albumin levels. The postoperative inflammatory markers were higher in non-survivors.

A single centre retrospective study: can lactate be used to predict increased length of stay in post-operative surgical patients admitted to the intensive care unit (ICU)?

E. Ahmad, A. Myers, T. Samuels
East Surrey Hospital, Intensive Care Unit, Redhill, United Kingdom
Correspondence: E. Ahmad
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0832

INTRODUCTION. Lactate is considered to be a useful prognostic biomarker in patients with conditions such as sepsis.[1] However, the significance of lactate in surgical patients remains unclear.[2]
OBJECTIVES. This study aims to assess whether raised admission lactate in surgical patients is associated with an increased ICU length of stay (LOS).
**METHODS.** Retrospective review was carried out on patients admitted post-operatively to an adult ICU during the period 1st January to 1st October 2017. The highest lactate level measured for each patient within the first 24 hours of admission was recorded. LOS was then analysed according to whether lactate was less than 2.5mmol/l (group A) or greater than 2.5mmol/l (group B). Statistical analysis was performed using the Wilcoxon rank sum test.
RESULTS. 265 patients were admitted post-operatively (mean ages: 67.4 and 73.1 years in groups A and B respectively); 34 patients were excluded from analysis since no lactate was recorded within the first 24 hours. Median LOS for groups A and B were 2.5 days [IQR 1.1 - 4.7 days] and 3.5 days [IQR 2 - 5.8 days] respectively (p = 0.0292)..
CONCLUSIONS. In our cohort of surgical patients, lactate greater than 2.5mmol/l measured on admission to ICU is associated with an increased length of stay.

INTRODUCTION. Chronic Critical illness (CCI) is a devastating syndrome of prolonged dependence on mechanical ventilation and other intensive care therapies. The influence of age on decision making in Intensive care unit is well established, but its influence on Chronic Critical Illness is yet poor explored. [1,2]

OBJECTIVES. The aim of this study was to compare outcomes (mortality, ICU resource use, quality of life) between older (≥ 60 years) and younger (< 60 years) patients with chronic critical illness while in the intensive care unit of a low-resource public hospital and in a high-resource tertiary private hospital in São Paulo, Brazil.

METHODS. A prospective study was conducted in two hospitals of different social levels. Patients were defined as CCI after a stay of at least 8 days in the ICU plus one of the six eligible clinical conditions: mechanical ventilation for at least 96 hours; tracheotomy; sepsis; severe wounds; stroke; traumatic brain injury [1]. Patients were classified into groups A and B based on age [(< 60, n = 25) and (≥ 60, n = 75) years old, from high-resource hospital] and C and D [(< 60, n = 45) and (≥ 60, n = 41) years old, from low-resource hospital].

RESULTS. Group A had a median age of 39 [30-46] years; group B 75 [68-83] years; group C 47 [35-54] years and group D 67 [64-72] years, p< 0.0001 for all. Although they had different SAPS 3, (p< 0.0001, for all), ICU mortality had no difference between groups (28.8% versus 36.6%, p=0.298, for low-resource hospital) and (8.3% versus 20.0%, p=0.280, for high-resource hospital) and no difference in advanced life support needs (mechanical ventilation, tracheotomy, renal replacement therapy, blood transfusion) were observed. Interestingly, older patients had worst health at baseline according to EuroQol 5D-5L score (< 0.005 for all), but there was no difference at 30- and 90-days after ICU. Older patients presented more delirium (p=0.011) and dementia (0.042) only in high-resource hospital, in which the hospital mortality rate was higher in the elderly groups (42% versus 13%, p=0.023). However it was similar in the low-resource hospital (41.4% versus 34.8%, p=0.456). The age category had no impact on symptoms of anxiety and depression neither on Quality of life of family members (p>0.05 for all). We found that, in the case of younger patients, those family members with higher scores for anxiety and depression, had a lower quality of life, only in high-resource hospital (p< 0.005 and R>0.7).

CONCLUSIONS. The great influence of the chronically critically ill patient´s age was on emotional disorders of family members when their loved ones were younger.

INTRODUCTION. "Post- intensive care syndrome" (PICS) describes a constellation of complications enduring well past the ICU stay, which include loss of strength, cognitive impairment, and mental illness including depression, posttraumatic stress syndrome and anxiety. PICS likely contributes to adverse effects on the individual's quality of life and long-term survival.

OBJECTIVES. In February 2016, we initiated a multidisciplinary follow up clinic in our tertiary academic hospital that has a 33-bed medical/surgical/trauma ICU. The present study describes the cohort of ICU patients seen in the first year. We aimed to characterize the phenotype of ICU survivorship, and to identify ICU experiences that contribute to post-ICU psychological and cognitive dysfunction.

METHODS. In this retrospective cohort study, charts were reviewed to collect information on clinical course during ICU admission and ICU follow-up clinic visits. Information recorded included: delirium score, days of mechanical ventilation, and results of ICU follow-up assessments. Patients were considered eligible for follow-up assessments if they met at least 1 of the following characteristics:
1) >4 days of mechanical ventilation,
2) received tracheostomy,
3) were delirious during their ICU stay,
4) had other reason intensivist wished follow up (e.g. no primary care physician).

Follow up occurred at least 3 months after ICU discharge. Patients were screened for: cognitive impairment (Montreal Cognitive Assessment [MoCA]), mood (anxiety and depression: hospital anxiety/depression scale [HADS], Post Traumatic Stress Syndrome [PTSS]-14) and quality of life (SF-36).

RESULTS. To-date, 19 patients have been seen through the follow-up clinic. Patients were 58% female (mean age ± SE = 62 ± 4 yrs; male, 61 ± 6 yrs). Approximately 63% (12/19) of patients received an average of 20 ± 7.5 days of mechanical ventilation. ICU-associated delirium was reported in 42% (8/19) of patients. Of the patients that completed the MoCA, 42% (5/12) were deemed cognitively impaired (scoring lower than 22 on the MoCA). HADS screening indicated that an 18% (3/17) prevalence of mild depressive symptoms, 12% (2/17) moderate and 6% (1/17) severe. The PTSS scores indicated that 24% (4/17) patients had symptoms of PTSD. Anxiety and depression subset scores on the HADS as well as PTSS-14 significantly correlated with quality of life (SF-36), with more mood symptoms correlating significantly with lower reported quality of life (HADS-A and SF-36: n=15, r= -.81, p< 0.001; HADS-D and SF-36: n= 15, r=-0.83, p< 0.001; PTSS-14 and SF-36: n=15, r=-0.70, p = 0.004). Neither age, mood (HADS or PTSS-14) or quality of life (SF-36) correlated with cognition (MoCA).

CONCLUSIONS. These preliminary findings corroborate prior work indicating impaired cognition and mood that contribute to reduced quality of life in patients following ICU discharge.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0835

INTRODUCTION. A frequent dilemma for intensivists is to decide whether a critically ill patient will benefit from ICU admission. If the patient's pre-morbid general condition was good and the patient suffers from a potentially reversible condition, almost every intensivist will consider ICU admission and inherent intensive treatment modalities as medically appropriate.

OBJECTIVES. We hypothesized that pre-morbid physical reserve is a predictor of survival status in critically ill patients.

METHODS. We conducted a long-term prospective cohort study in a university-affiliated teaching hospital. Between February 2013 until

February 2014 we included all patients within 72 hours on a first ICU admission. We evaluated item response based assessment of physical functioning tailored to a patient's individual capacities (Academic Medical Center Linear Disability Score; ALDS), and Health-related quality of life (HRQOL) (Short-form-12; SF-12, general health item; SF-1) before admission by patients themselves or, by close proxies within 72 hours after ICU admission.

RESULTS. We developed four logistic regression models to predict 1 year mortality using the predictors age, APACHE-II score, ALDS, SF-1, and PCS-12. We validated the models using the bootstrap method on the AUC, Brier Score, and Net reclassification improvement (NRI). We also inspected the calibration graphs of the models. A total of 510 patients were included. Twelve months after ICU discharge,110 patients (22%) had died. The pre-admission ALDS, significantly improved a model with age (p= 0.0012) showing an NRI with 19% improvement in predictions for non-survivors, and 22% for survivors. Adding the ALDS score to a model with the APACHE II score improved the model (p=0.0117) and NRI showed a 21% improvement in predictions for survivors and 19% for non-survivors. Adding the SF-1 to a model with age (p=0.007) or APACHE II score (p=0.024) also improved the models although a bit inferior to ALDS. PCS-12 showed no significant association with mortality. Practical nomograms were generated to estimate the risk of mortality for individual patients.

CONCLUSIONS. Both pre-admission physical functioning measured with the item- response based ALDS as well as the SF-1 improve the predictive performance of age and the APACHE II model. Since the ALDS score is more time-consuming to administer, the use of the SF-1 may be preferred.

The patient experience of recovery from critical illness: a systematic review and meta-synthesis of qualitative studies across the continuum of recovery

B. Connolly[1], J. Mortimore[1], C. Apps[1], C. Crowley[2], E. Corner[3], N. Pattison[4]

Correspondence: B. Connolly
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0836

INTRODUCTION. Survivorship is increasingly mirroring, if not surpassing, survival as a central tenet in managing patients experiencing critical illness. Protracted impairment and symptomology in patients surviving an admission to the intensive care unit (ICU), and their family/caregivers, is progressively more recognised. However the qualitative experience of recovery from critical illness has not been systematically explored.

OBJECTIVES. To systematically review and meta-synthesise qualitative literature to determine patient experience measures for critically ill patients throughout the recovery continuum, including in relation to receipt of physical rehabilitation.

METHODS. A systematic review and meta-synthesis (PROSPERO, CRD42017078549). Five electronic databases (CINAHL, EMBASE, Medline, CENTRAL, PsychInfo) were searched from inception to 21st Nov 2017. Primary studies with qualitative methodologies, published from 2000 onwards, were included. Systematic reviews, meta-syntheses, editorials, opinion pieces, auto-ethnographies, and non-English-language papers were excluded. Studies focused on adult (aged ≥18years) patients who had experienced critical illness necessitating ICU admission for ≥48hours, or their family/caregivers, and reported experience of recovery including receipt of physical rehabilitation interventions, at any time-point of the recovery continuum i.e. within ICU, following ward transfer, following hospital discharge. Screening for eligibility and data extraction were performed independently and in duplicate. Data were descriptively reported and summarised. Meta-synthesis was performed using thematic analysis, discussion and consensus by two reviewers.

RESULTS. Preliminary results are presented. Twenty-three articles were included, of which 3 focused specifically on physical rehabilitation during recovery. Eighteen studies involved patients alone, 4 involved patients and family/caregivers, and 1 involved family/caregivers alone. The majority (n=22) examined post-ICU discharge stages of recovery. In total studies reported 86 major- and 77 sub-themes describing patient experience of recovery. Meta-synthesis reveals potential over-arching themes of adaptation, transitioning between recovery stages, dynamics with healthcare professionals, enabling recovery with healthcare infrastructure, persistent multi-domain impairment, recollecting and interpreting the critical illness experience, shifting interpersonal dynamics, and the role of rehabilitation in directing recovery.

CONCLUSIONS. Experience of recovery following critical illness is multi-faceted for patients and family/caregivers. Further analysis of findings will confirm over-arching themes characterising this recovery.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0837

INTRODUCTION. Few studies have evaluated the incidence and magnitude of discomfort, a multifactorial experience reflecting physical, psychological symptoms and environmental factors. It is an important indicator of ICU quality of care.

OBJECTIVE. To adapt a French multifaceted discomfort questionnaire (IPREA[1]) to our ICU setting and identify and quantify predictors of discomfort perceived by ICU survivors.

METHODS. Eligible patients (>18 years, GCS 15, length of stay ³ 48 hours) admitted to ICU from April to September 2017 were surveyed within 48 hours of ICU discharge. Ethics committee approval was obtained. We translated IPREA (a questionnaire validated in French ICU's) and measured patient perceived discomfort.(1) Patients scored their recalled ICU discomfort for each of 16 items on a visual analogue scale of 0 (no discomfort) to 100 (maximum discomfort). Overall score was computed as the mean of the 16 items.

RESULTS. 168/172 survivors participated (58% males, mean age 60.1 ± 14.8 years, mean APACHE II 13.8 ± 5.6). The questionnaire had good internal consistency (Cronbach alpha: 0.82), good content and construct validity (average inter item correlation 0.23). Mean overall discomfort score was 18.4±12.5 and did not differ by gender and type of ICU (general ICU, cardiothoracic ICU, high dependency unit). Items associated with maximum discomfort were noise, sleep, pain, lines and tubes. On multivariate analysis, increasing age was an independent predictor of low discomfort score (β = - 0.26, 95% CI: -0.42 to - 0.11, P=0.001) after adjusting for sex, marital status, employment status, APACHE II and type of ICU.

CONCLUSIONS. The French IPREA discomfort questionnaire performed well in an Australian ICU setting. Overall discomfort was low. There was an inverse relationship between age and discomfort.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0838

INTRODUCTION. Circulatory shock is a common condition in critical care, which can lead to multiple organ dysfunction and potentially death. The most recognizable clinical sign of shock is hypotension. In surgical patients, both the intensity and duration of hypotension increase the risk of organ dysfunctions[1]. Early intensive hemodynamic management strategies, which involve fluid resuscitation and vasopressors, are described as beneficial in this population[2]. However, there is a lack of studies evaluating the risk factors associated with need of vasopressor in orthopedic surgical patients admitted to the intensive care unit.

OBJECTIVES. We aimed to evaluate the risk factors associated with vasopressor use in the first 48h of Intensive Care Unit (ICU) stay in patients undergoing major orthopedic surgery.

METHODS. A single-center retrospective cohort study of patients admitted to the ICU of a tertiary hospital in São Paulo, Brazil. Inclusion criteria were: adult patients undergoing major orthopedic surgery (total or partial knee/hip arthroplasty, femur fracture repair, and spine arthrodesis) from 2012-2017, who needed continuous infusion of vasopressors (adrenaline, dopamine, noradrenaline, or vasopressin). Exclusion criteria were: vasopressor use before surgery and patients with advanced directives. Univariate and multivariate logistic regressions were used to estimate the association of risk factors and vasopressor use. Variables with p-value< 0.2 in the univariate regression analysis were used to build a model with the backward elimination technique. The model's goodness-of-fit and calibration were accessed with the Hosmer-Lemeshow statistic, and its performance with the area under the Receiver Operating Characteristic curve (AUC).

RESULTS. Of the 388 patients included, 96 (24.74%) experienced the primary outcome. Patients' characteristics according to vasopressor use and significant risk factors in the univariate analysis are shown in table 1. Independent risk factors for vasopressor use after surgery were: age (OR 1.021, 95% CI 0.99-1.04 ,p = 0.078), SOFA score (OR 2.29, 95% CI 1.86-2.83 ,p < 0.001), Shock Index [dichotomized at 0.7 (OR 2.47, 95% CI 1.27-4.79 ,p = 0.007)], and blood transfusion during surgery (OR 1.9, 95% CI 0.93-3.85 ,p = 0.075), with an AUC = 0.8626.

DISCUSSION. Patients who required vasopressors in the first 48h of ICU admission are older, had higher rates of acute kidney injury, longer ICU and Hospital length of stay, and have higher in-hospital mortality. Age, SOFA score, Shock Index, and blood transfusion during surgery were associated with vasopressor use. The adoption of a model to predict vasopressors requirement might be able to identify the patients at risk, increase awareness and might help the ICU team in taking preemptive therapeutic actions, as well as can help planning resource allocation.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0839

INTRODUCTION. The lack of sleep-related slow-wave activity (SWA) may be associated with ICU delirium. The SWA is considered to be essential for the recovery of the brain and may be disturbed in the intensive care environment. The activity can be monitored quantitatively with electroencephalogram (EEG).

OBJECTIVES. In this pilot study, we investigated the association between nighttime SWA and recovery from delirium during standard treatment in the ICU.

METHODS. We performed an overnight (from 9 pm to 7 am) recording of EEG for seven patients diagnosed with hyperactive delirium. The delirium was diagnosed with an Intensive Care Delirium Screening Checklist (ICDSC) score higher than three. During the EEG recording, the administration of dexmedetomidine was carried out following the ICUs standard protocol to keep the patients moderately sedated. The amount of nighttime SWA was estimated by calculating the low-frequency (less than 1 Hz) power of EEG during the recording. The level of sedation was assessed using Richmond Agitation-Sedation Scale (RASS). In the following morning, the delirium was evaluated using

ICDSC and the quality of sleep using Richards-Campbell Sleep Questionnaire (RCSQ) filled by the intensive care nurse.

RESULTS. For five of the patients, the morning ICDSC score was less than four not fulfilling the criteria for ICU delirium. The cumulative duration of nighttime SWA for these patients was 204 ± 91 min (mean ± std). For two of the patients, the morning ICDSC score exceeded the threshold for delirium and the cumulative duration of SWA for these patients was 31 ± 11 min. The average RASS during the EEG recording was -1.2 ± 2.1 and -1.3 ± 1.2 for the patients with and without delirium in the following morning, respectively. Average RCSQ value for the patients with delirium was 70.3 ± 14.6 and for the patients without delirium 74.8 ± 18.1.

CONCLUSIONS. In the presented pilot study, the lack of nighttime SWA was associated with delirium in the following morning. This association, which will be further investigated in a larger patient group, could offer new possibilities for the assessment, prediction and treatment of ICU delirium.

Impact of a multifaceted nursing engagement intervention on pain, agitation, and delirium assessment in a community intensive care unit

C.M. Tan[1], M. Camargo[2,3], F. Miller[1], K. Ross[2], R. Maximous[2], P. Yung[1], C. Marshall[1], D. Fleming[2], R. D'Sa[2,4], M. Law[3], J.L. Tsang[1,2,4]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0840

INTRODUCTION. Delirium affects up to 80% of patients in the intensive care unit (ICU) and is associated with multiple adverse outcomes[1]. In 2013, ICU pain, agitation, and delirium (PAD) guidelines were published. Despite the well-established advantages of implementing PAD guidelines, adoption and adherence remain suboptimal[2]. Educational interventions have been shown to address barriers to guideline implementation[3]. However, the impact of multifaceted nurse engagement interventions in a community ICU is unknown.

OBJECTIVES. The purpose of this prospective interventional study is to evaluate the effect of a Multifaceted Nurse Engagement Intervention on PAD assessment in a community ICU.

METHODS. All patients admitted to our community ICU for over 24 hours were included. A 20-week baseline audit was performed, followed by implementation of the intervention, and a 20-week post-intervention audit. The Nurse Engagement Intervention consisted of a survey, focus groups, and education sessions. Primary outcomes included rates of daily pain, agitation, and delirium assessment using validated scoring tools.

RESULTS. There were significant improvements in the proportion of patients with at least one assessment per day of pain (67.5±11.9% v. 59.3±12.2%, p=0.04), agitation (93.1±4.3% v. 78.7±8.2%, p< 0.001), and delirium (54.2±10.2% v. 39.4±11.6%, p< 0.001) (Figure 1), as well as number of patients with target RASS ordered (63.1±15.8% v. 46.8±15.6%, p=0.002) (Figure 1). There was a significant decrease in rate of physical restraint use (10.0±7.2% v. 30.9±15.9%, p< 0.001) and no change in rate of self-extubation (0.9±1.9% v. 2.5±5.2%, p=0.2) (Figure 1).

CONCLUSIONS. The implementation of a Multifaceted Nurse Engagement Intervention has the potential to improve rates of PAD assessment in community ICUs. Screening rates in our ICU remain suboptimal despite these improvements. We plan to implement multidisciplinary interventions targeting physicians, nurses, and family members to close the observed care gap.

Incidence and risk factors of postoperative delirium in adult patients after elective craniotomy: a prospective cohort study

C.-M. Wang, H.-W. Huang, J.-X. Zhou
Beijing Tiantan Hospital, Capital Medical University, Critical Care Medicine, Beijing, China
Correspondence: J.-X. Zhou
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0841

INTRODUCTION. Postoperative delirium (POD), as an important complication, occurs in 11-51% of patients after major surgery. However, in the majority of cohort studies and randomised controlled trials investigating POD, patients after intracranial operations were usually excluded.

OBJECTIVES. We aimed to determine the incidence of POD and its associated risk factors in adult patients admitted to the ICU after elective craniotomy under general anaesthesia.

METHODS. This prospective cohort study was conducted in a neurosurgical ICU of University affiliated hospital. The local IRB approved the protocol, and written informed consents were obtained. Adult patients after elective craniotomy under general anaesthesia were included. The exclusion criteria are shown in figure 1.

Delirium was evaluated by the Confusion Assessment Method for Intensive Care Unit (CAM-ICU) at three time points: (1) at the ICU admission; (2) at 08:00 to 10:00 on postoperative day one in the ICU; and (3) at 08:00 to 10:00 on postoperative day three in the ICU or in the neurosurgical ward. The assessment at the ICU admission was used to diagnose emergence delirium. The assessments on postoperative day one and day three were used to diagnose POD. Thus patients were classified as POD group if delirium was diagnosed on postoperative day one and/or day three, otherwise non-POD group.

Baseline and preoperative data, anaesthesia- and surgery-related data, and data during the ICU stay before the delirium assessment on postoperative day one were collected. The incidence of POD and 95% confidential interval (CI) were calculated. Univariate and multivariate logistic analyses were performed to determine the risk factors for POD.

RESULTS. During the study, 800 patients were included for final analysis (figure 1). POD was diagnosed in 157 (19.6%, 95% CI: 16.9%-22.4%) patients, of whom 97 (61.8%), 33 (21.0%), and 27 (17.2%) were classified as hypoactive, hyperactive, and mixed subtypes, respectively.

Independent risk factors for POD included: age, type of lesion, frontal approach of operation, duration of operation, episode of $SpO_2 < 90\%$ at the ICU admission, occurrence of emergence delirium, presence of ischemia on the first postoperative CT scan, and external delirium risk factor score (figure 2).

Compared with the non-POD group, less patients in the POD group were discharged from ICU at postoperative day one, and more accidental removal of tubes and catheters, higher hospital mortality, longer postoperative length of stay in hospital, and higher costs were found in the POD group.

CONCLUSIONS. POD was prevalent among adult patients after elective craniotomy, and was associated with adverse outcomes. Identifying the disease-specified and preventable risk factors could help to facilitate the early warning and prevention of POD.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0842

INTRODUCTION. Delirium is present in more than 50% of ventilated patients, and it may delay extubation (1). Dexmedetomidine has been shown to be effective for hyperactive delirium (HD) but there is no evidence whether this has an impact on the time to extubation.

OBJECTIVES. The aim of this study was to evaluate the impact of Dexmedetomidine on the time to extubation of critically ill patients who developed HD during the weaning period of mechanical ventilation (MV).

METHODS. We conducted a prospective observational study in adult patients who required MV for more than 48 h and, who presented HD during weaning (defined as CAM-ICU (+) or SAS score 5-7, plus asynchrony, minute ventilation >200 ml/Kg/min, or tachycardia / hypertension).

Patient demographics were collected at enrolment. Data on sedatives, analgesics and neuromuscular blockers were collected during the first 3 days after admission, and for 3 days after the onset of HD. Two groups of patients were defined, according if they received or not Dexmedetomidine during the first 24 hs after HD.

Main outcome was time to extubation (from HD onset to successful extubation). Secondary outcomes were time on MV, MV-free days at day 28, ICU stay and in-hospital mortality.

RESULTS. Twenty-three patients, 57 (39-75) y.o., 15 male, APACHE II 20 (15-23), SOFA 10 (7-11), met HD criteria 4 (3-7) days after connection to MV. In 18 (78%) patients HD occurred promptly after sedative interruption (4 (2-9) hours).

Dexmedetomidine was used in 13 patients (57%, Dexmedetomidine group) as the primary sedative to control HD. Propofol (91%), Fentanyl (60%) and antipsychotics (70%) were used in both groups. More patients in Dexmedetomidine group used Quetiapine (85% vs 20%, p=0.003).

Patients in the Dexmedetomidine group had the same time to extubation than patients who did not (5 (2-12.5) vs 6.5 (2.8-15, p=0.7). Time on MV, MV-free days and mortality for the full cohort were 11 (7-23) days, 16 (0-20) days, and 30%, respectively, without differences between groups.

CONCLUSIONS. Dexmedetomidine was frequently used for the control of HD, but showed no impact on the time to extubation. Propofol, antipsychotics, and Fentanyl are also used to treat HD.

Effects of nocturnal dexmedetomidine on sleep quality in critically ill patients equipped with high flow nasal cannula

Y. Ueno, J. Oto
Tokushima University Hospital, Critical Care and Emergency Medicine, Tokushima, Japan
Correspondence: Y. Ueno
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0843

INTRODUCTION. Sleep quality of critically ill patients is extremely poor and nocturnal infusions of dexmedetomidine have been increasingly utilized in non-intubated patients. Previous study revealed nocturnal dexmedetomidine infusion improved sleep quality and quantity in patients with and without mechanical ventilation. High flow nasal cannula (HFNC) is relatively acceptable, however, effectiveness of dexmedetomidine on sleep quality in patients undergoing HFNC is unknown.

OBJECTIVES. We investigated if dexmedetomidine infusion could improve sleep quality in patients with HFNC.

METHODS. Adult patients with HFNC were randomly assigned to receive nocturnal dexmedetomidine (DEX group) or not (Control group). Dexmedetomidine infusion rate was controlled from 0.2 µg/kg/h to 0.7 µg/kg/h. We recorded polysomnography (PSG) during nighttime (9:00 p.m. to 6:00 a.m.). We collected the values of sleep efficiency, total sleep time, percentage of each sleep stage: stage 1 (N1), stage 2 (N2), stage 3 (N3), and rapid eye movement (REM), and arousal index. Sleep efficiency was calculated as the value of total sleep time / the observation time (9 hrs). Arousal index was defined as the value of arousals /h.

RESULTS. Twenty patients were studied (10 in DEX group and 10 in Control group). There were no significant difference in sleep efficiency of median: 57% (IQR: inter quartile range 32-75) vs. 33 %(12-66) (p=0.22), total sleep time of 310 min (172-404) vs. 177 min (62-357) (p=0.22), N1: 26 % (18-47) vs. 51 % (30-76) (p=0.34), N2: 69 % (34-78) vs. 49 % (20-58) (p=0.50), N3: 0 % (0-0) vs. 0 % (0-0) (p=0.47), REM: 1 % (0-2) vs. 0 % (0-3) (p=0.47), and arousal index: 21 /h (16-34) vs. 37 /h (28-47) (p=0.08).

CONCLUSIONS. Although HFNC is generally comfortable device, sleep time was very short and highly disrupted. Dexmedetomidine infusion did not significantly improve sleep quality and quantity in patients under HFNC.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0844

INTRODUCTION. Various strategies to promote light sedation are highly recommended in recent guidelines, as deep sedation is associated with suboptimum patient outcomes[1,2]. Yet, the quality of sedation and analgesia provided is rarely addressed. In a cluster-randomised quality improvement trial in eight Scottish ICUs we evaluated the effectiveness of three interventions for improving sedation-analgesia quality in mechanically ventilated patients[3] (Development and Evaluation of Strategies to Improve Sedation Quality in Intensive Care- DESIST trial, ClinicalTrials.gov NCT01634451).

OBJECTIVES. As part of the trial evaluation, we aimed to understand the challenges and barriers to optimising sedation in the Scottish ICU settings.

METHODS. We conducted focus groups (FG) with clinicians during the pre-intervention period in all participating ICUs. Clinicians volunteered to participate. FG were recorded and verbatim transcribed and inserted in NViVo for analysis. Qualitative thematic analysis was undertaken in order to develop emergent themes from the patterns identified in relation to sedation practice. Ethical approval was secured prior to the study.

RESULTS. Three themes emerged from the inductive analysis: a) the meaning of optimum and suboptimum sedation, including the clinicians' perceived quality of sedation; b) a shift in sedation practice, including a change in the agents used, a change from strictly protocolised care to patient-focused care, and a consideration of sleep promotion; and c) multifactorial challenges in managing sedation, including the uncertainty of difficult to sedate patients, the lack of appropriate assessment tools, the ICU environment, organisational factors and gaps in education.

CONCLUSIONS. The current sedation literature lacks recognition of the various challenges when mandating less sedation. An emphasis should be placed on the need for novel sedation-analgesia strategies that allow a systematic approach and ongoing monitoring of sedation-analgesia quality.

Serum noradrenaline levels can predict the occurrence of delirium in the ICU in catecholamine-free patients

M. Nishikimi, A. Numaguchi, Y. Yasuda, N. Matsuda
Nagoya University Graduate School of Medicine, Nagoya, Japan
Correspondence: M. Nishikimi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0845

INTRODUCTION. Abnormal secretion of neurotransmitters such as catecholamines has been known to be associated with the occurrence of delirium, and the secretion is seriously disturbed in critical care patients.

OBJECTIVES. The aim of this study was to evaluate the correlation between the serum levels of catecholamines and the occurrence of delirium in critical care patients.

METHODS. We retrospectively analyzed the data of the patients enrolled in our previous randomized clinical trial (Melatonin Evaluation of Lowered Inflammation in ICU Trial; UMIN000016541)

(1). The serum levels of catecholamines (adrenaline, noradrenaline and dopamine) were measured in 79 patients at the time of their admission to the ICU. Using the data of 50 of these subjects who had not received catecholamines before their admission to the ICU, we conducted univariate and multivariate logistic regression analyses to evaluate the correlations between the serum levels of catecholamines and the occurrence of delirium. We also analyzed the data of all 79 subjects to examine the interactions between the serum levels of catecholamines and use/non-use of catecholamines prior to ICU admission in the occurrence of delirium. Delirium was assessed every 4 hours during the ICU stay of the patients (the assessment was skipped if the patients were sleeping) by trained ICU nurses using the Confusion Assessment Method for the ICU (CAM-ICU), and by the ICU doctors as needed.

RESULTS. Among the 50 subjects, 34 developeddelirium during their ICU stay. The results of the univariate and multivariate analyses revealed that the serum levels of noradrenaline, but not those of adrenaline or dopamine, were associated with an increased odds ratio for the occurrence of delirium (univariate: OR 2.81, 95% CI 1.17-6.79, p=0.021; multivariate: OR 2.73, 95% CI 1.02-7.31, p=0.046).Furthermore, the analysis revealed a statistically significant interaction between the serum levels of noradrenaline and the use/non-use of catecholamines in the occurrence of deliriumin patients admitted to the ICU(p=0.047).

CONCLUSIONS. In patients who had not received catecholamines prior to their admission to the ICU, the serum levels of noradrenaline, but not those of adrenaline or dopamine, were correlated with the occurrence of delirium in the ICU.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0846

INTRODUCTION. Delirium is a severely underestimated condition in the critical patient. It constitutes a medical emergency and it is associated with an increased mean length of stay in the ICU and higher morbidity and mortality. Three different subtypes of delirium have been described (hypoactive, hyperactive and mixed) according to clinical presentation. Current recommendations emphasize the importance of accurate screening of delirium in the ICU so that treatment and management of its complications can be initiated at an earlier stage.

OBJECTIVES. To identify the incidence of delirium and its subtypes in our context, and to compare demographical and clinical characteristics of patients with and without delirium.

DESIGN. Prospective observational study.

PARTICIPANTS. Non-consecutive day data collection of all adult patients admitted to the ICU during a 50-day period.

METHODS. Detection of delirium with the Confusion Assessment Method for Intensive Care Unit (CAM-ICU) in its Spanish version. Classification into hyperactive, hypoactive and mixed subtypes. CAM-ICU is considered to be non-valuable in patients with stroke, cranial trauma or RASS -4/-5. Demographical and clinical data such as reason for admission, APACHE-II score, artificial airway, intravenous sedation or presence of predisposing factors for delirium were recorded.

RESULTS. 79 patients were included in the study, 25 (31.6%) whom developed delirium. The most common subtype was hypoactive (49.0%), followed by mixed (40.8%) and hyperactive (10.2%). The Kaplan-Meier test to compare the development of delirium among the different groups shows that there are no differences according to sex, but there are significant differences according to the presence of artificial airway (p=0.023), intravenous sedation (p=0.003), medical condition (p=0.004), >1 predisposing factor (p=0.003) and APACHE-II score >20 (p=0.011). These same factors are also associated with an increased risk of delirium as observed in the univariate analysis. Nevertheless, the multivariate analysis found that only medical condition [HR 4.53 (CI 95% 1.31-15.7)] and presenting >1 predisposing factor [HR 1.60 (CI 95% 1.20-2.12)] are independent risk factors for presenting delirium. The CART model categorizes different groups of patients combining logical decision rules with different factors, showing that the group with >1 predisposing factor and medical condition has a higher incidence of delirium of 83.3%.

CONCLUSIONS. More than 3/10 patients in our ICU develop delirium, the hypoactive subtype being the most frequent form of presentation. Artificial airway, intravenous sedation, medical condition, >1 predisposing factor and APACHE-II score >20 increase the risk of delirium, but only the medical condition and presenting >1 predisposing factor for delirium are independent risk factors for presenting delirium. The group with >1 predisposing factor and medical condition has the highest incidence of delirium (83.3%).

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0847

INTRODUCTION. In recent years, it has been proposed to change not only the sedation objectives of the critical patient, but also the drugs used for that purpose. Several benefits have been postulated regarding days of mechanical ventilation, delirium, and stay in critical care, however; the impact in economic terms of the implementation of these programs has not been analyzed even though the recommended drugs are more expensive. This can represent a significant difficulty at the management level, especially in intensive care units in developing countries.

The objectives were to compare the results of the implementation of a sedation protocol through the combined end point: mortality, prolonged stay in intensive care or prolonged mechanical ventilation and total costs of sedation before and after the implementation of the protocol.

METHODS. A sedation protocol was designed based on maintaining the minimum level of sedation necessary according to the patient´s illness and the evolving moment in which they were passing. Propofol and fentanyl were used as drugs of choice for deep sedation, and fentanyl or fentanyl plus dexmedetomidine in case of superficial sedation. It was indicated to maintain deep sedation for the shortest possible time. The drugs used before the implementation of the protocol were midazolam and fentanyl. All patients requiring mechanical ventilation and sedation for at least 48 hours were included.We included all the patients for a period of four months before and after the implementation of the protocol. The variables recorded were sex, age, diagnosis, history, APACHE II, sedation scheme used and total costs, days of mechanical ventilation, stay in critical care, mortality.

RESULTS. We included 78 patients in the study, 45 before and 33 after the implementation of the protocol. The median age of the patients was 69 years, with a 25-75 percentile between 60 and 75 years. The median of Apache II was 23, with a 25-75 percentile

ranging from 18-27. Regarding the days of mechanical ventilation, the median was 4 days with 25-75 percentiles ranging from 2 to 7 days. The stay in intensive therapy ranged between 3 and 11 days with a median of 6 days. The mortality was 24 patients in the group without protocol and 22 in the group with protocol. No variable was independently associated to the primary endpoint in a multivariate analysis. After adjust by APACHE II the protocol reduces 75% of the end point of death, stay in UTI and ARM (p = 0.03). There were no statistically significant differences in the costs (p = 0.5) nor in the delirium rate (p = 0.3).

CONCLUSIONS. Since the implementation of a sedation protocol with non-benzodiazepine drugs the death end point, stay in critical care and days of mechanical ventilation were reduced by 75%. In addition, sedation costs were not increased.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0848

INTRODUCTION. Insomnia, which could increase ICU delirium, is a common problem for the ICU patients, because of a lot of disturbance. Insomnia after discharge is one of the post intensive care syndrome, and it's reported to be associated with daytime sleepiness, depression and physical performance. But, sleeping drug prescription after ICU discharge is unknown.

OBJECTIVES. The aim of this study is to investigated whether benzodiazepine use during ICU stay is associated with benzodiazepine prescription at 6 months after discharge.

METHODS. We conducted retrospective cohort study in our hospital between Janurary 2014 and December 2016. All adult patients (18 years or older) who were consecutively admitted in the ICU, department of cardiac surgery is in charge of, and who were alive 6 months after discharge from hospital were included. Exclusion criteria is prior use of sleeping drugs, transfer to another hospital, post cardiopulmonary arrest, stroke, cognitive dysfunction, swallowing disorder, liver cirrhosis. We compared the patient who used oral benzodiazepine during ICU stay (BZ group) to the patients who didn't use (non BZ group). We investigated benzodiazepine prescription at discharge from hospital and 6 months after discharge. We performed logistic regression analysis for benzodiazepine prescription at 6 months after discharge.

RESULTS. 407 patients were included and 249 patients were analyzed. Age, sex, APACHE 2 score and SOFA score were not different between two groups, but ICU length of stay and ventilator days were longer in BZ group. Benzodiazepine prescription was more in BZ group; 30/81(37.0%) vs. 25/168(14.9%) at discharge, 18/81(22.2%) vs. 16/168(9.5%) at 6 months after discharge. Age ≥ 75 (OR 2.56, 95%CI 1.20-5.50), SOFA score ≥ 5 (OR 2. 76, 95%CI 1.01-8.91) and benzodiazepine use during ICU stay (OR 2.57, 95%CI 1.19-5.58) were risk for benzodiazepine prescription at 6 months after discharge independently.

CONCLUSIONS. Intravenous benzodiazepine is risk for ICU delirium and should be avoided, but oral benzodiazepine is unclear. In this study, oral benzodiazepine use during ICU stay might increase benzodiazepine prescription after discharge. Long-term use of benzodiazepine is associated with adverse events, including delirium, cognitive dysfunction and fracture. We should not prescribe benzodiazepine during ICU stay to avoid long-term use. Benzodiazepine use during ICU stay may increase benzodiazepine prescription after discharge.

INTRODUCTION AND OBJECTIVES. Difficult Sedation(DS) includes situations of therapeutic failure(inability to achieve the desired level of sedation at the maximum dose), tolerance(higher doses required to achieve the same level of sedation) or deprivation(symptoms appear after abrupt discontinuation or decreased dose) of sedatives being administered. This paper aims to characterize DS clinical picture and its effects on critically ill patients during their stay in the Intensive Care Unit.

MATERIAL AND METHODS. During 2015-17 all patients consecutively admitted to a 14 bed medical-surgical ICU and undergoing mechanical ventilation(MV) and sedation for more than 48h were prospectively followed until discharge or death. Complications and prognosis of patients presenting with DS were compared with those who did not develop it. Epidemiological data, type, duration and complications of sedoanalgesia practices and clinical outcome during ICU stay were analyzed. Significance p< 0.05, SPSSv21©.

RESULTS. 667 patients were admitted to the ICU during the study period, 327(49.0%) of whom were included in the study (71.3% male, 60.8 ±14.8 years old, admitted mostly due to a medical cause (58.7%); APACHE II (25,7± 9,2). Seventy-nine patients (24.1%) developed DS. DS patients were younger(55.9±17.7 vs 62.4±14.2 y/o;p=0.001) and less severely ill(APACHEII 23±9.5 vs 26.6±9.0;p=0.003) than no DS group. More patients in DS group had smoking (p=0.045) alcohol(p< 0.001) and psychotropic use(p=0.001) history than no DS group.

DS group patients were sedated during longer periods (Median 274h(min-max 32;1709) vs 77h(10;1467); p< 0.001) than no DS groups and required higher doses of Midazolam (0.21 ±0.71vs 0.18 ±0.12 mg/kg/h; p< 036), Propofol (2.3±0.9 vs1.9 ±1.0 mg/kg/h;p=0.023) and remifenatnil (10.9±10.3 vs 4.5±1.6 mcg/kg/h p=0.026). The percentage of DS patients requiring the use of more than one sedatives simultaneously doubled that of the no DS group (68.8% vs 31.1%;p< 0.001). DS patients presented more periods of oversedation (p=0.031) / undersedation (p=0.024) in relation to the desired level of sedation. More patients in the SD group suffered pain as measured by median time with EVN/ESCID scale > 3 (20(1;204) vs 14 (1;110) hours; p< 001). .

DS patients had prolonged mechanical ventilation times (16.2±13.1 vs 10.6±9.9 days;p < 0,001) than no DS patients. More patients in the DS group suffered injuries arising from dependence (46.8% vs 22.2%;p< 0.001), ventilator associated pneumonias (VAP)(11.4% vs4.4%;p=0.025) and underwent tracheotomies(40.5% vs 16.5%;p=0.001 patients not developing DS.

CONCLUSIONS. DS develops in one out of every four critically ill patients and affects negatively their outcome. Early identification and active prevention are essential strategies to minimize its impact.

The prevalence, risk factors and outcomes of ICU delirium among Chinese patients in an intensive care unit in Hong Kong

C.Y.Y. Lee, W.L. Tong, H.H. Tsang

Kwong Wah Hospital, Intensive Care Unit, Hong Kong, Hong Kong, China

Correspondence: C.Y.Y. Lee

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0850

INTRODUCTION. Intensive Care Unit (ICU) delirium is extremely common among critically ill patients and is associated with adverse outcomes including increased mortality, ventilator days and length of stay. ICU delirium is likely to be multifactorial and multiple risk factors have been identified. While the prevalence of ICU delirium has been reported to range from 30 to 80% (1-3), most studies were carried out in Europe and Northern American. Data concerning ICU delirium among Chinese patients are lacking.

OBJECTIVES. This study aims to determine the prevalence of ICU delirium among Chinese patients in an ICU in Hong Kong over a 3-month period, and to evaluate the risk factors and outcomes associated with this condition.

METHODS. This is a retrospective, observational study conducted during the period of November 2017 to January 2018. Patients admitted to the Kwong Wah Hospital ICU during the study period were evaluated for the presence of delirium by means of the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU) (Traditional Chinese version) and the Richmond Agitation-Sedation Scale (RASS) two times per day. The period prevalence of ICU delirium was determined. Clinical data were correlated with the presence of ICU delirium and the independent risk factors were identified. The outcomes associated with ICU delirium were also evaluated.

RESULTS. The period prevalence of ICU delirium during the study period was found to be 30.5%. Five independent risk factors for ICU delirium were identified with multivariate analysis, namely old age (≥65), presence of at least one chronic disease, comatose state during ICU stay, exposure to benzodiazepine, and the duration of sedation. ICU delirium was linked to higher ICU and 30-day mortality, longer ICU length of stay, hospital length of stay, and ventilator days in the bivariate analysis, but not in the multivariate analysis.

CONCLUSIONS. This study revealed that the prevalence of ICU delirium in the Hong Kong Chinese patient population is comparable to the figures quoted in the literature. The independent risk factors identified are in keeping with other studies. Although a linkage to adverse outcomes is found, a larger sample size is needed to determine a definite association.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0851

INTRODUCTION. Evidence suggests that routine assessment and monitoring of sedation, pain and delirium may improve patient outcomes. Nevertheless, surveys carried out in different ICUs have shown that frequently these aspects go unmonitored.

OBJECTIVES. To analyze the routine use of scales and protocols for analgesia, sedation and delirium in a group of health professionals who attended a multidisciplinary simulation course focused on this area of knowledge and to evaluate the course impact on their daily practices.

METHODS. Descriptive study analyzing the three editions of an analgesia, sedation and delirium course performed at the Simulation Unit of Puerta de Hierro Hospital in Majadahonda during 2016. This course was aimed at intensive care professionals (nurses and doctors). The course consisted of a theoretical introduction followed by three workshops that included real-life simulations in which the students had to assess the patient, apply analgesia, sedation and delirium scales [behavioral pain scales, Richmond Agitation Sedation Scale (RASS), the Confusion Assessment Method for the ICU (CAM-ICU)] and decide subsequent treatments. At the end of the course they were asked to fill out a survey enquiring about scale use and protocols in their hospitals and the usefulness and impact that learning through simulation had had in their training.

RESULTS. Sixty students completed the course: 33 doctors (55%) and 27 nurses (45%), coming from 28 different hospitals throughout Spain and one in Portugal.

Forty-one (68%) routinely used analgesia scales in communicative patients (analogue and/or numeric) and only 16 out of these 41 used behavioral pain scales in non-communicative patients. Sedation scales were used in 49 (82%) of the cases, Riker Sedation Agitation Scale and the RASS being the most commonly reported (43;72%). Strategies to identify delirium were reported by 12 students (20%), in all cases by the CAM-ICU. Twenty-nine (48%) had protocols for pain and sedation management in their hospitals and eight (13%) for delirium management.

When asked about the usefulness of learning through simulation: 51 (85%) evaluated this tool as helpful to clarify their previous knowledge, 48 (80%) became aware of the importance of the patient adapting to an unfriendly environment, 54 (90%) considered that the course had helped them to understand the importance of using scales in critically ill patients and 56 (93%) answered that training through simulation made the strategies to identify and manage delirium easier. All students would recommend this course to their colleagues.

CONCLUSIONS. In our series we identified a lack of use of scales oriented at identifying pain, sedation and delirium in the critically ill, most of all when we look at analgesia scales for non-communicative patients and delirium identification.

Training through simulation was well accepted by the students and helped them understand the use of pain, sedation and delirium scales in ICU patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0852

INTRODUCTION. Delirium is a complex neuropsychiatric disorder commonly encountered in critically ill patients and associated with adverse outcomes including increased length of ICU stay, mortality and long-term cognitive impairment. However, delirium is often mis-diagnosed, detected late or missed.

OBJECTIVES. To determine the incidence, risk factors and outcomes of delirium in a Tunisian ICU.

METHODS. A prospective cohort observational study conducted over six months duration from October 2017 to March 2018 including all patients admitted in a 9-bed medical ICU for more than 24 hours. Patients who were deaf or unable to speak or understand were excluded. All included patients were screened by psychiatrist for delirium using DSM-V (Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition) criteria. Predictors investigated included underlying condition, severity, diagnostic at admission, invasive interventions, electrolyte disorders and medications used. Variables found to be statistically significant in univariate analysis were introduced into a multivariate regression model to identify factors independently associated to delirium.

RESULTS. During the study period, 125 patients were assessed and 104(83.2%) met the inclusion criteria. Patients' characteristics were : mean age, 59.32±15.78 years ; age >65 years, 44(42.3%) ; female, 29(27.9%) ; median Charlson index, 3[2-5] ; mean SAPSII, 27.77±9.57 ; invasive mechanical ventilation (IMV), 59(56.7%) and vasopressors use, 41(39.4%).

Using DSM-V criteria, 37(35.6%) had delirium. The most common subtype of delirium seen in the present study was hypoactive type, 24(64.86%), followed by hyperactive subtype, 11(29.7%) and few patients had mixed subtype of delirium, 2(5.4%).

Patients who were diagnosed with delirium had significantly longer duration of IMV (13.94±11.1 vs 8.15±10.7days, p=0.024), longer length of ICU stay (18.86±12.8 vs 12.03±11.14days, p= 0.006) and higher mortality rate (40.45% vs 20.89%, p=0.032).

Univariate analysis revealed the following factors to be associated to delirium respectively for delirium and controls : age≥65years, (56.8% vs 34.3%, p=0.027) ; smoking, (59.5% vs 37.3%, p=0.03) ; alcoholism, (16.2% vs 3%, p=0.023) ; SAPSII, (31.5±10.7 vs 25.6±8.2, p=0.002) ; IMV (81.1% vs 43.3%, p=0.00) ; vasopressors use (67.6% vs 23.9%, p=0.00) ; use of narcotic analgesics, (64.9% vs 35.8%, p=0.004), use of Propofol (48.6% vs 14.9%, p=0.00) and physical restraint, (56.8% vs 25.4%, p=0.001).

Multivariate regression model identified the following factors as independently associated to delirium: use of vasopressors, (OR, 5.5 ; 95%CI, [2.17-13.9] ; p=0.00) and use of Propofol (OR, 4.1 ; 95%CI, [1.51- 11.3] ; p=0.00).

CONCLUSIONS. Delirium seems to be common in ICU. In the present study, vasopressors and propofol were the only independent predictors of delirium.

Correspondence: J.G. Boyd
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0853

INTRODUCTION. Delirium, defined as an acute change in level of consciousness that is characterized by impaired attention and disorganized thinking, occurs commonly in critically ill patients. Patients that develop delirium have increased risk of prolonged mechanical ventilation, long term cognitive dysfunction, and mortality. However, the cause of delirium is unknown, which significantly limits our ability to design rational therapeutic interventions. Poor cerebral oxygenation, as measured by near-infrared spectroscopy (NIRS), may be related to post-operative neurological dysfunction (e.g. delirium and long-term cognitive impairment). However, the relationship between NIRS derived cerebral oxygenation and neurological outcomes in critically ill patients is unclear.

OBJECTIVES. The purpose of this systematic review was to assess the utilization of NIRS-derived cerebral oxygenation in critically ill patients outside of the operating theatre. We aimed to examine the relationship between cerebral oxygenation and neurological outcomes.

METHODS. In collaboration with a librarian with expertise in systematic reviews (A. R-W), the following databases were searched from inception to August 14th, 2017, Ovid MedLine, Embase, Cochrane Library, and Web of Science. Conference proceedings, abstracts, and articles published in languages other than English were not considered. Two of the authors (ON, NB) independently reviewed each title and abstract for relevance, and articles deemed relevant were selected for full text review. In the case of disagreement, a third reviewer (JGB) resolved the conflict. The bibliographies from each selected article were searched for additional relevant articles. The selected papers were assessed for quality using the modified Downs and Black checklist for observational studies. Relevant data was abstracted from each article, and authors were contacted to provide missing data if required.

RESULTS. Of 1410 articles identified by the search strategy, 8 were ultimately selected for final review. Most (7 of 8) were published since 2013. These studies included a total of 213 patients primarily with shock or respiratory failure. A variety of devices were used to measure cerebral oxygenation, including the INVOS device and the FORESIGHT NIRS monitor. The duration of recording varied from 5 minutes to 72 hours. Four of the 8 studies reported on neurological outcomes. In all 4 studies, cerebral oxygenation was lower in critically ill patients that were delirious compared to controls, but this was only statistically significant in 2 of the studies. The heterogeneity in devices and duration of recording precluded a meta-analysis of this data.

CONCLUSIONS. NIRS is being studied outside of the operating room more commonly over the past 5 years. More study is needed to explore the relationship between cerebral oxygenation and delirium.

Assessment and documentation of delirium in a single district general hospital intensive care unit (ICU) using the Confusion Assessment Method in ICU (CAM-ICU)

C. Fleming, P. Morgan, A. Myers, S. Ranjan, T. Samuels
East Surrey Hospital, Intensive Care Unit, Redhill, United Kingdom
Correspondence: C. Fleming
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0854

INTRODUCTION. Delirium is a common clinical condition which is associated with poor outcomes, but that is preventable and treatable[1,2]. National Institute for Health and Clinical Excellence (NICE) guidelines recommend assessing for delirium if indicators of delirium are present[1]. American College of Critical Care Medicine (ACCM) guidelines recommend routinely monitoring patients for delirium, at least once per nursing shift, if they are at moderate to high risk of delirium[3].

OBJECTIVES. The aim of this project was to quantify the incidence of delirium in our ICU population. We investigated whether this is being adequately assessed and documented, in line with national and international guidelines[1,3].

METHODS. The medical and nursing notes and the observation charts for a random sample of ICU patients in a single District General Hospital were reviewed. It was recorded whether patients had been assessed for the presence of delirium using CAM-ICU or any other valid tool, within the previous seven days. CAM-ICU was then performed on each patient to determine whether delirium was in fact present. If delirium was present, it was characterised as either hyper- or hypoactive. Data was collected between 8th and 23rd February 2018.

RESULTS. 28 patient records were reviewed. In 11% of patients (n=3), CAM-ICU had been performed and the result documented during the preceding 7 days. 25% of patients (n=7) were found to be

delirious, 6 having hypoactive delirium and 1 hyperactive. Of these, none had been documented as having delirium. 50% of patients (n=14) were CAM-ICU negative. 25% of patients (n=7) could not be assessed due to their low conscious level.

CONCLUSIONS. Assessment and documentation of delirium in our ICU population needs to be improved. It is notable that hypoactive delirium has been particularly overlooked in this study population. This may be due to the insidious nature of hypoactive delirium. It is important for healthcare staff working in critical care to be alert to the potentially harmful effects of delirium and understand the methods to diagnose and manage it. Education sessions are being held for both doctors and nurses involved in the care of patients in ICU, to improve knowledge of CAM-ICU and the guidelines on delirium, and to encourage regular assessment for delirium. This will be re-audited in the next 6 months.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0855

INTRODUCTION. Tumor lysis syndrome (TLS) is a life-threatening complication in patients with haematological malignancies.TLS-induced acute kidney injury (AKI) is associated with high morbidity and mortality rates (1,2).The mechanisms underlying TLS-induced AKI are not well defined owing to a paucity of studies consisting mainly in case reports. During TLS, cells release their contents, including histones and DNA. Patients with TLS have drastically increased plasmatic levels of extracellular histones compared with patients experiencing post renal AKI, or with patients with acute leukemia without TLS.

OBJECTIVES. We aim to evaluate the toxicity of extracellular histones on endothelial function.

METHODS. Endothelial cells (human microvascular endothelial cells) were exposed to recombinant histones for different durations (from two hours to 24 hours). Cytokines released by endothelial cells (Interleukin-6 (IL-6), IL-8) were measured by enzyme-linked immunosorbent assay (ELISA). Expression of intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1), E-selectin and apoptosis/necrosis were measured by flow cytometry. Expressions of IL-6, ICAM-1 and tissue factor were also quantified by quantitative polymerase chain reaction. We assessed peritubular capillary flow and vascular permeability by intravital microscopy in mice injected with extracellular histones.

RESULTS. *In vitro*, high doses (40μg/ml) of extracellular histones induced endothelial cell necrosis. At 24 hours, intermediate doses (20μg/ml) of extracellular histones increased the secretion of IL-6 (p=0.02) and IL-8 (p< 0.001) by endothelial cells, and increased surface expression of ICAM-1 (p< 0.001), but not VCAM-1, nor E-selectin. At two hours, recombinant histones induced a significant increase of IL-6 and tissue factor transcription (114.5±6.8 fold increase normalized to control p=0.005,and 10.9 ±1.45 fold increase normalized to control p=0.006, respectively). At four hours, recombinant histones induced a significant increase of ICAM-1 transcription (117±51.7 fold

increase normalized to control p< 0.01). *In vivo*, histones exposure significantly increased Evans blue dye leakage from peritubular capillaries to the interstitial compartment. Moreover, four hours after histones administration, the percentage of capillaries with continuous perfusion was reduced by 57 +/- 6.2% and the percentage of capillaries with no perfusion was increased by 21+/-4.6%.

CONCLUSIONS. Circulating histones induce *in vitro* endothelial toxicity and renal microvascular dysfunction in mice. Extracellular histones may be involved in the pathophysiology of TLS-induced AKI. The exploration of signaling pathways activated by histones will offer the opportunity for new therapeutic strategies during TLS.

Intensive care patients with haematological malignancy - why are they dying?

L. Russell[1,2], A. Perner[1]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Intensive Care 4131, Copenhagen, Denmark; [2]Zealand University Hospital, Roskilde, Denmark
Correspondence: L. Russell
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0856

INTRODUCTION. Intensive care patients with haematological malignancy have a high mortality[1,2], but during the last decades, survival in this group of patients has improved, both short-term[1,3]and long-term[4]and increasingly, earlier ICU admission is suggested.[5]Therefore, the number of haematological patients in ICUs is likely to increase in the future. Due to their haematological malignancy, they have an increased risk of severe and potentially lethal complications, such as sepsis, respiratory failure and bleeding.[2,3,6-8]

OBJECTIVES. The objective of this study was to elucidate the immediate cause of death a population of critically ill haematological ICU patients.

MATERIAL AND METHODS. Retrospective observational study of patients with acute myeloid leukaemia (AML), acute lymphoblastic leukaemia (ALL) and myelodysplastic syndrome (MDS) admitted to the general ICU at Copenhagen University Hospital, Rigshospitalet, between 1st of January 2008 and 31st of December 2012. The follow-up time was two years. The electronic patient files including autopsy reports when present were reviewed and the cause of death according to the treating intensive care and haematologist consultants at the time were obtained.

RESULTS. 116 patients were included; the majority were mechanically ventilated (87%) and received vasopressor (82%) and 64 patients (55%) died in the ICU. The 1-year mortality was 86 % and the 2-year mortality was 91%. The most common cause of death in the ICU was septic shock (Table 1); 16 patients died from rapidly progressing septic shock despite maximal treatment, in the remaining 6 patients therapy was withdrawn. The second most common cause of death in the ICU was progressive hypoxemic respiratory failure, causing the death in 10 patients (16%). Two of these patients received ECMO. In 9 patients (14%) active treatment was stopped while in the ICU due to progression of haematological malignancy without possible cure.

The main cause of death in patients discharged alive from the ICU was progression of their haematological malignancy (Table 2). The second most common reason was respiratory insufficiency/pulmonary failure. In this group, 3 patients declined further treatment or readmission to the ICU.

CONCLUSION. The most common cause of death in the ICU was septic shock and hypoxemic respiratory failure. The most common reason cause of death in patients who was discharged from the ICU alive was progression in their haematological malignancy where no cure was possible.

Status performance at hospital discharge in critically ill cancer patients who survive after ICU admission

D. Díaz Díaz, M. Villanova Martinez, E. Palencia Herrejon
Hospital Universitario Infanta Leonor, Madrid, Spain
Correspondence: D. Díaz Díaz
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0857

INTRODUCTION. It has been pointed out a high mortality rate of cancer patients admitted to the intensive care unit (ICU), being the main factors associated with in-hospital mortality: age, acute respiratory failure, the need for mechanical ventilation, late admission to the ICU, the presence of comorbidities, the status performance at admission and tumours in advanced stages. However, it hasn´t been evaluated the status performance at hospital discharge in cancer critically ill patients who survive after ICU admission neither than its predictive factors.

OBJECTIVES. To analyse the baseline clinical factors associated to a good status performance at hospital discharge in critically ill cancer patients admitted to an ICU of a community hospital.

METHODS. Retrospective observational study including adults with diagnosis of cancer admitted to the ICU, excluding those with previous dependence performance measured by the Eastern Cooperative Oncology Group (ECOG) at admission (scores 3-4), palliative life support decision at UCI, in-hospital death, or no available data from the ECOG score at hospital discharge. We recorded demographic data, department of origin and length of stay prior ICU admission, type of tumour and extent, ECOG score prior to hospitalization and at hospital discharge, reason for ICU admission and severity (SOFA, APACHE-II and SAPS-II) as well as the types of therapies received at ICU.

RESULTS. A total of 100 patients (mean age 70.2 years, 64% male) were included. Of them, 64 patients were independent at hospital discharge (ECOG 0-2). They had higher frequency of prior diagnosis of DM (35.1% vs 19.4%; $P=0.034$), better pre-hospital ECOG scores (ECOG 0-1: 73.4% vs. 36.1%; $P< 0.001$), lower frequency of metastatic disease (22.2% vs. 47.1%; $P=0.011$) and of metabolic derangement at ICU admission (4.7% vs. 19.4%; $P=0.012$) and a trend of lower SAPS-III score (median 64 vs. 72; $P=0.096$) without significant differences in sex, age, comorbidity and type of solid or haematological tumour. Neither chemotherapy or radiotherapy prior to admission to the ICU, nor the presence of neutropenia had any significant influence in the status performance at the hospital discharge. The frequency of ICU treatments such as mechanical ventilation, hemodynamic support and kidney replacement therapy was similar in both groups. Logistic regression showed that good prior status performance (ECOG 0-1) (OR 5.2; 95%CI 1.9-13.5; $P=0.001$), non-metastatic tumour (OR 3.0; 95%CI 1.1-8.3) and SAPS-III score at ICU admission (OR 0.9;95%CI 0.92-0.99) were independently related with the odds of good status performance at hospital discharge.

CONCLUSIONS. Up to 64% of the critically ill cancer patients who survive after ICU admission at discharge from hospital with good status performance, being the main influencing factors prior good status performance, non-metastatic tumour and SAPS-III score.

The choice of central venous catheters (CVCs) in patients (pts) undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT)

M. Spirin, P. Makarova, G. Galstyan, M.Y. Drokov
National Research Centre for Hematology, Moscow, Russian Federation
Correspondence: P. Makarova
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0858

INTRODUCTION. CVCs are essential in the treatment of pts undergoing allo-HSCT. There are three main types of CVCs: common CVCs (cCVC), antimicrobial-coated CVC (a-cCVCs) and tunneled-cuffed CVC (t-cCVC).

OBJECTIVES. The aim of the study was the comparison of three CVC types in allo-HSCT pts.

METHODS. 184 allo-HSCT pts were included in retrospective study. The pts suffered from acute myeloid leukemia (105), acute lymphoblastic leukemia (32), non-Hodgkin lymphoma (14), chronic myeloproliferative diseases (8), aplastic anemia (7), chronic lymphocytic leukemia (1), multiple myeloma (1). Before allo-HSCT cCVCs (Certofix Duo 7F, BBraun) were inserted in 35 pts, a-cCVCs (Certofix Protect Duo 7F, BBraun) were inserted in 103 pts and t-cCVCs (Hickman catheters 12 F, BARD Access) were inserted in 46 pts. The indwelling time, the number of the replaced CVCs and the incidences of complications were analyzed. Kaplan-Meier survival analysis curves were used to estimate the probability of CVC removal.

RESULTS. The median indwelling times of inserted before allo-HSCT CVCs were: 38 (11-111) days for cCVCs, 36 (8-110) days for c-aCVCs and 104 (18-414) days for t-cCVCs. During 6 months after allo-HSCT for the treatment of the complications (graft-versus-host disease (GVHD), infections, hemorrhage, etc) several of pts needed repeat

insers. Incidences of CVC related bloodstream infections (CRBSI) were: 6.3 per 1000 catheter days for cCVCs, 5.3 per 1000 catheter days for a-cCVCs, and 2.4 per 1000 catheter days for t-cCVCs. Incidences of CVC associated thrombosis (CAT) were: 0.97 per 1000 catheter days for cCVCs, 1.9 per 1000 catheter days for a-cCVCs, and 0.49 per 1000 catheter days for t-cCVCs. The reasons for the removal of CVCs were the treatment completion, patient death, CRBSI, CAT and malfunctions.
CONCLUSIONS. There were no any advantages of use of a-cCVCs in comparisson with cCVCs. The catheters of choice for allo-HSCT are t-cCVCs.

Fig. 1 (abstract 0858). The t-cCVCs resulted in significantly better survival as compared with other CVC types (P value<0,5)

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0859

INTRODUCTION. Induction of the remission of AML patients (pts) often leads to development of life-threating complications requiring ICU admission. Many of these pts have a number of unfavorable prognostic factors related to patient and tumor Moreover, after treatment of complications many pts can not receive a chemotherapy in the complete doses and need its modification need modification of a chemotherapy.
OBJECTIVES. To compare the overall and the disease free survival in AML pts who required and did not require ICU admission during a remission induction.
METHODS. All *de novo* AML pts (n=80) younger than 60 y.o. admitted in the National Research Center for Hematology from 2013 to 2016 years were enrolled in the study. Patients were divided into 2 groups: pts who were required ICU admission during remission induction (ICU-pts) (n=26) and pts who did not require ICU admission and received chemotherapy only in hematology ward (non-ICU pts) (n=54). The reasons for ICU admissions and results of life support were analyzed. Overall survival (OS) and decease free survival (DFS) were assessed by the Kaplan - Meier method, long rank value p< 0.05 consider as significant. Univariate analysis was performed with χ 2 tests or Fisher's exact tests for categorical variables to find an independent ICU mortality predictor.
RESULTS. The admission to ICU was required to 26 (32.5%) of 80 AML pts. ICU pts had more advanced disease than non-ICU pts: median LDH 1056 U/l vs 689 U/l; cytogenetic adverse risk category in 35% of pts vs 18% of pts, hyperleukocytosis in 23% of pts vs 10% of

pts. The reasons for ICU admissions were acute respiratory failure (ARF) (50%), intracranial hemorrhage (19.2%), septic shock (SS) (11.5%); caesarian section (11.5%), cardiac arrhythmia (7.8%). Survival rate of pts with ARF who required respiratory support was 53%. Survival rate of SS pts was 25%. Need for mechanical ventilation, vasopressors, ≥ 2 organ dysfunction were predictors of ICU mortality (p< 0.05). Overall ICU survival rate was 69.5%. Among non-ICU pts no one died during first 30 days. A landmark analysis for OS was performed for patients who survived the first 30 days of treatment. After the first 30 days there were no significant differences in OS and DFS between the groups. 3 years survival rate was 53% in non ICU group and 51.9% in ICU group (n.s. p=0.946)
CONCLUSIONS. 32.5% of de novo AML patients needed intensive care during remission induction. ICU survival rate was 69.5%. After discharging from ICU the long-term prognosis of ICU-pts is not worse, than non-ICU pts.

Correspondence: R. López
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0860

Acute respiratory failure (ARF) is the first reason for admission to ICU in immunocompromised patients and although survival improved markedly in recent years, when need invasive mechanical ventilation remain having significant mortality. Extracorporeal life support (ECLS) depicts one of the ultimate therapies in intensive care and may possibly be beneficial in patients with acute respiratory distress syndrome in general ICU population. Nevertheless, the immunocompromised state has been described as most common relative contraindication to ECLS [1].
Recently, novel data has emerged about ECLS in patients with hematological malignancies [2] and AIDS-related pneumocystis jirovecii [3]. However, limited data is available about the type of ECLS according if the purpose was oxygenation or extracorporeal CO_2 removal (ECCO2R).
OBJECTIVES. Describe cohort immunocompromised patients on ECLS referral to immunocompetent patients.

METHODS. Analysis of cohort of patients supported with respiratory ECLS, with focus on immune status and type of ECLS. Respiratory ECLS was delivered as veno-venous extracorporeal membrane oxygenation (VV-ECMO) if catastrophic respiratory failure, or as extracorporeal CO2 removal (ECCO2R) if ventilation is impaired and could not be optimized keeping protective ventilation. Immunocompetent patients with influenza A H1N1 (H1N1) related ARDS supported with ECLS were considered as reference population to compare both immunocompetent (without H1N1) and immunocompromised patients supported with ECLS.

When was possible, mortality proportions were compared with chi-square.

RESULTS. We identified 45 patients with respiratory support, twelve of them (27%) were immunocompromised: hematology malignancies (5), AIDS (1), pulse of steroids and other drugs (6). On other hand, 15 patients were positive to H1N1and the group of patients non-immunocompromised (without H1N1) were 18 patients (60%). Demographic and ECLS support details of immunocompromised patients in table 1 and table 2.

Four patients were diagnosed with pneumocystis pneumonia, two of them died.

We found difference on inhospital mortality only between patients immunocompetent H1N1 versus immunocompetent non-H1N1 on ECLS, 58% vs 20% respectively (p=0.028). Inhospital mortality according to ECLS and ECLS types are showed in figure 1.

CONCLUSIONS. A similar survival between immunocompromised and non-immunocompromised patients supported with ECLS was watched. Probably, with more data, immunocompromised state as contraindication to ECLS could be reconsidered. More data about immunocompromised patients on ECLS is required.

INTRODUCTION. Hematopoietic stem cell transplantation-recipients (HSCT-R) are a population with a high risk of developing severe complications that require admission to an intensive care unit (ICU), which is related to a high mortality. So, efforts are needed in order to improve their prognosis.

OBJECTIVES. Our aim was to describe the cohort of HSCT-R admitted to a tertiary hospital ICU and analyze factors that are likely to affect their survival.

METHODS. Retrospective study, including adult (+18 years) patients who received an HSCT and required admission to ICU between 1st January 2010 and 28th February 2018. X-Square, Fisher´s test, T test, U Mann-Whitney and logistic regression were employed as required. Quantitative variables are reported as median (IQR) and categorical as frequency (%).

RESULTS. Seventy-nine patients were included, 41 (64.1%) men, with a median age of 52 (39-62) years. The underlying leading conditions were leukaemia, with 33 (42%) patients, and lymphoma with 29 (37%). Allotransplant was done in 65 (82%). Seventeen (24%) had received a previous HSCT. APACHE score was 23 (17-28). SOFA score on admission was 9 (7-11). Organ failure, defined as a SOFA score >2, were present as follow: respiratory in 39 (50%), hemodynamic in 37 (47%), haematological in 46 (59%), renal in 12 (15%), liver in 9 (12%) and neurologic in 6 (8%).The most frequent diagnosis at admission were septic shock (45; 57%), pneumonia (35; 44%), and sinusoidal occlusive syndrome (7; 9%). Neutropenia was present in 40 (51%). Sixty (73%) required vasoactive drugs, 49 (62%) mechanical ventilation (MV), 42 (53%) high flow nasal cannula, and 23 (29%) renal replacement therapy (RRT). ICU mortality affected to 46 (58%) and hospital mortality to 59 (75%). APACHE score (OR 1.1, IC95% 1-1.2, p=0.006), SOFA score on admission (OR 1.3 IC 95%:1.-1.5, p= 0.014) and no improvement in SOFA score at 5th day (OR 1.8, IC95% 1.3-2.4, p< 0,0001) were related to mortality. No improvement in SOFA score at 3rd day was not related to mortality (1.6, IC95% 0.5-5.3, p=0.483). Patients with SOFA score > 11 or with more than three organ failures at admission had 100% mortality. Another variables related to mortality were MV (OR=8.8, IC95%:2.7-28.3, p< 0.0001) and RRT (OR 11.3 IC95%: 1.4-90.3, p= 0.022). We did not find any differences related to the type of HSCT or to the presence of neutropenia. In the multivariate analysis, SOFA score on admission (OR1.4 IC95%:1-1.9: p=0.024) and no improvement of SOFA score at 5th day (OR 28.3 IC95% 4-198.8, p=0.001) maintained statistical significance.

CONCLUSIONS. SOFA score on admission in HSCT-R admitted to ICU is related to hospital mortality, arriving to 100% in patients on multi-organic failure or SOFA score > 11, so earlier admission is advised. No improvement in SOFA score at 5th day, but not at 3rd day, is related to mortality, which can be an useful tool in the decision making process during an ICU trial.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0862

INTRODUCTION. The number of patients with cancer who receive intensive care treatment is growing. The new therapeutic armamentarium, based on targeted agents and inmunotherapy, have demonstrated to improve patient outcomes but has implied a change in the toxicity profile and a higher rate of complications that require potential ICU admission. However, the prognosis of these patients remains poor with a mortality after ICU admission of around 50%. So efforts are needed in order to improve their outcome.

OBJECTIVES. Our aim was to describe the cohort of patients with solid organ cancer admitted to a tertiary hospital ICU and analyze factors that are likely to affect their survival.

METHODS. Retrospective study, including adult (+18 years) patients with solid organ cancer who required admission to ICU between 1st January 2010 and 31th December 2017. X-Square, Fisher´s test, T test, U Mann-Whitney and logistic regression were employed as required. Quantitative variables are reported as median (IQR) and categorical as frequency (%).

RESULTS. Two hundred and nine patients were included, 110 (52.6%) men, with a median age of 61 (52-69) years. Lung cancer was the most frequent one, being present in 54 (26%), followed by colon 24 (12%), breast (19; 9%) and ovary (15; 7%). The functional status was ECOG 1 in 104 (50%) and ECOG 2 in 83 (40%). The indication for ICU admission was respiratory failure in 80 (39%), septic shock in 74 (36%), post urgent surgery in 18 (9%) and central nervous system involvement in 15 (7%). APACHE score was 20 (17-27) and SOFA

score at admission 6 (4-9) Neutropenia was present in 38 (19%). One hundred and thirteen (55%) required vasoactive drugs, 72 (35%) high flow nasal cannula, 102 (49%) mechanical ventilation (MV), and 17 (8%) renal replacement therapy (RRT). ICU mortality affected to 68 (33%) patients and hospital mortality to 96 (46%). Eighty (39%) patients were alive six months after hospital discharge. We identified the following factors related to mortality in the univariate analysis: APACHE score (OR 1.1, IC95% 1-1.2, p=0.001), SOFA SCORE on admission (OR 1.2, IC95% 1.1-1.3, p< 0.0001), MV (OR=2.9, IC95%:1.7-5.2, p< 0.0001), vasoactive drugs (OR=1.9, IC95%:1.1-3.4, p=0.02) and RRT (OR 4.3 IC95%: 1.3-13.5, p= 0.014). We did not find any differences in mortality according to the ECOG status or the presence of neutropenia. In the multivariate analysis, APACHE score (OR=1.1. IC95%:1-1.2, p=0.001), and SOFA score on admission (OR 1.28 IC95%:1.102-1.361: p< 0.001=0.035) maintained statistical significance.

CONCLUSIONS. Despite improvement in cancer therapies and critical care management, mortality is still high in oncologic patients admitted to ICU. APACHE score and SOFA score on admission are related to mortality. We did not find that ECOG status or neutropenia influence the hospital outcome of this patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0863

INTRODUCTION. In many health systems, patients with active haematological malignancies that become acutely unwell are denied admission to intensive care due to the perceived dismal mortality outcomes of critical illness in this patient group. However, in the light of recent therapeutic breakthroughs in the field of onco-haematology, it is worth revisiting the morbidity and mortality outcomes of ICU admission of this type of patient to inform future decision making.

OBJECTIVES. To describe the mortality and morbidity outcomes of intensive care admission in patients with active haematological malignancies in our healthcare network.

METHODS. We prospectively collected data on patients with active haematological malignancies admitted to our university hospital ICU network over a three year period. We specifically focused on: baseline patient demographics, presence of bacteriemia, degree of organ failure, need for mechanical ventilation and renal replacement therapy, need for vasopressor support, ICU length of stay, ICU, 30 day and 60 day mortality.

RESULTS. A total of 148 patients were included in the statistical analysis. Average age was 55 (+/- 16) years and 54% of patients were male. Average ICU length of stay was 7,4 (+/- 4) days and average APACHE II score was 22.2. Regarding baseline disease, 43% of patients had leukemia, 36% had lymphoma, 12% had a plasma cell dyscracia and 9% had myelodysplastic syndrome.

Regarding advanced organ support, 41% of patients required vasopressor support; 57% of patients required mechanical ventilation, and only 15% of patients required renal replacement therapy. Overall ICU mortality was 47%, gross 30-day mortality was 51% and gross 60-day mortality was 52%. Further analysis in pre-established subgroups revealed a higher mortality in the subsets of patients admitted with neutropenic sepsis and respiratory failure.

We conducted a retrospective multivariate analysis searching for variables associated with increased risk of death: variables that reached statistical significance were: APACHE score greater than 22, need for renal replacement therapy, need for vasopressor support and mechanical ventilation.

CONCLUSIONS. Although the outlook for critically ill patients with underlying haematological malignant disease remains poor, the updated results we here present suggest an improved global outcome compared to earlier studies. We hope these results will help

inform bedside management decisions for this challenging patient group.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0864

OBJECTIVES. To identify mortality associated factors in solid cancer patients admitted to the Intensive Care Unit and to evaluate the utility of severity of illness scores at ICU admission predicting outcome.

METHODS. We performed a retrospective study including consecutive patients diagnosed of solid tumour admitted to a polyvalent ICU of a Tertiary University Hospital from January 2010 to November 2016.

We collected demographic, clinical and cancer related data, organ failures, life-supporting therapies and three severity scores: Acute Physiology and Chronic Health Evaluation II (APACHE II), Sequential Organ Failure Assessment (SOFA) and ICU Cancer Mortality Model (ICMM).

RESULTS. One hundred and thirty-two patients were included. The patient characteristics and cancer related data are summarized in Table 1. The ICU and hospital mortality rate were 12.9% and 19.7% respectively. The overall ICU mortality rate during the study period was 12.2%. Among demographical and cancer characteristics, the univariate analyses revealed that previous treatment with antineoplastic therapy (radiotherapy and chemotherapy) was related with a worse prognosis (p < 0.05). Regarding clinical variables on admission to the ICU, medical reason for admission, 3 or more organ failures and the necessity of life supporting therapies (mechanical ventilation and vasopressors) were significantly associated with hospital mortality (p < 0.001). (Table 2)

The median value of APACHE II, SOFA and ICMM was significantly higher (p < 0.001) in patients who died than in patients who survived. In a logistic regression analysis, the severity scores APACHE II OR 1.18 (95% CI 1.09 - 1.27), SOFA OR 1.3 (95% IC 1.14 - 148), ICMM OR 1.04 (95% CI 1.02 - 10.7) were independently associated with a higher mortality (p< 0.01).

To evaluate the discrimination of the severity scores the Areas Under the Receiver Operating Characteristics Curves (AUC ROC) were calculated: APACHE II: 0.795 (95% CI: 0.690; 0.900), SOFA: 0.77 (95% CI: 0.690; 0.864) and ICMM: 0.794 (95% CI: 0.697; 0.891) showing a good discrimination. The comparison of AUC ROC of the three severity scores after DeLong's test showed no difference between them: AUC ROC SOFA vs APACHE II: 0.56, AUC ROC SOFA vs ICMM: 0.41, AUC ROC APACHE II vs ICMM: 0.78. In the Akaike information criterion (AIC) analysis APACHE II was 108.4, SOFA 112.5 and ICCM 108.5. The one with the lower AIC was the model that represented the prognosis better.

CONCLUSIONS. ICU mortality rate in cancer patients is similar to the overall ICU mortality. Hospital mortality was associated with the type of antineoplastic therapy and the type and severity of acute illness. The three severity scores were useful to assess outcome and accurate in the discrimination but we did not find a significant difference between them.

INTRODUCTION. In patients with hematologic malignancies, acute respiratory failure requiring mechanical ventilation is a severe and frequent complication. Recent studies have shown that the outcome of mechanically ventilated patients with hematologic malignancies over the last decade [1-3].

OBJECTIVES. This study conducted to clarify if percutaneous dilatational tracheostomy (PDT) is safe in this group of patients and to report the outcome of patients with hematologic malignancies requiring long-term mechanical ventilation.

METHODS. To evaluate the safety of PDT in patients with hematologic malignancies, we retrospectively analyzed the clinical characteristics of patients who underwent PDT in medical ICU from January 2012 to January 2017.

RESULTS. PDT was safely performed in all 55 patients. Although 5 (9.1 %) patients developed major bleeding that required electric coagulation, fatal complications were not observed. Of the 55 patients in this study, 21 (38.2 %) could be weaned from ventilator, and 19 (34.6%) survived the intensive care unit stay. There was no other complication such as pneumothorax, subcutaneous emphysema, infection of the stoma, paratracheal insertion or tracheal injuries. No significant differences between survivors and non-survivors were found, except for platelet counts; median platelet counts of non-survivors were significantly lower than those of survivors [48000.0 (30000.0 - 89000.0) vs. 95000.0 (39000.0 - 155500.0), p = 0.028]. No differences were observed in the demographics or laboratory findings between patients with bleeding complication and those with none.

CONCLUSIONS. PDT can be safely performed on patients with hematologic malignancies. The procedure did not result fatal complications in this study.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0866

INTRODUCTION. The aim of this study is to asses the impact of infection as a cause of admission in the intensive care, the mortality related with the infection origin and the microorganism isolated at admission of patients with haematological disease.

METHODS. An observational and retrospective study was conducted, which reviewed all patients were admitted into the Intensive Care Unit (ICU) of a University Hospital, with haematological diseases between May 2013 to March 2018.

We analysed with Chi square (X^2) the following variables: age, SOFA, APACHE II; SAPS II; haematological disease, cause of admission, focus of infection and microorganism isolated in the samples taken at the admission and their relation with ICU mortality.

RESULTS. A total of 207 patients met inclusion criteria, with an average age of 55.82±14.75 years. 59% were male and 41% were female. ICU mortality rate was 39.6% (82 patients).

160 patients (77%) the admission was related to an infection, 61 patients were community-acquired infections (38.12%) and 48.3% (99 patients) health care-associated infection, with mean severity score SOFA: 9.54±4.35, APACHE II 23.21±9.76 y SAPS II 52.59±21.17.

Respiratory infection was the most frequent (40.6%), followed by bacteraemia without an identified focus 13.12%, bacterial translocation from gastrointestinal tract (BT-GIT) 10.62%, urinary tract infection (UTI) 8.12% and catheter related infection 6.87%. In 14.37% of cases it was not possible to determine the infectious focus.

After evaluation of common sources of sepsis with the samples taken at the admission, we found that the microorganism most frequently involved was bacterial in 70 samples (43.75%), virus in 25 samples (15.62%) and fungal in 8 samples (5%). Five patients had multiple isolates. In 62 patients (30%) a microorganism wasn´t isolated.

Using X^2 we found relation between ICU-mortality and admission by infectious disease (p≤-0.001) equal as health care-associated infection (p=0.004) and respiratory infection (p≤-0.0001).

Applying the same test, we didn´t found increased risk of mortality with community-acquired infections (p=0.757), bacteraemia without an identified focus (p=1), catheter related infection (p=0.11), UTI (p=0.08), BT-GIT (p=0.8), and sepsis without identified focus (p=0.82). Analysing microorganisms, we found only a strong trend in viral infection (p=0.08) and no correlation with bacterial infection (p=1), and fungal infection (p=0.26), including in the cases in which there was no possible to isolate a microorganism (p=0.21).

CONCLUSIONS.

- There is no increase in mortality with community-acquired infection in patients with a haematological disease.
- Although infection related to health care increases mortality, no significant relationship was found when the focus of the infection or the microorganism of the infection could not be located.
- There is no increased risk of mortality at bacterial infection aetiology.

Infection impact as cause of admission in intensive care in patients with bone marrow transplant in a university hospital

G. Narváez Chávez, S. Gallego, J. Higuera, A. Caballero, D. Cabestrero, C. Soriano, L. Jaramillo, M. López, R. De Pablo

Ramon y Cajal University Hospital, Intensive Care Medicine, Madrid, Spain

Correspondence: G. Narváez Chávez

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0867

INTRODUCTION. The aim of this study is to evaluate the factors that increase mortality in patients who received a bone marrow transplant (BMT) when are admitted to Intensive Care (ICU) due an infectious pathology and their relation with ICU mortality and 30-day and 60 day mortality.

METHODS. We reviewed all the patients with BMT who required admission to the Intensive Care between May 2013 to March 2018.

The variables analysed: type of BMT, severity scores: SOFA; SAPS II and APACHE II, presence and type of infection objectified, microorganism isolated, neutropenia and mortality during ICU stay and mortality at 30 days and 60 days.

RESULTS. 79 patients (pts) were admitted to the ICU during the observational period. 52% were men and 48% were female, with average age 51.32 ± 12.27 years. Mean severity scores were SOFA: 10.51±4.22, APACHE II 23.63±9.4 y SAPS II 52.07±1.26.

68 pts (86%) had received an allogenic transplant and 11 patients (14%) had received an autologous transplant. 30 pts (38%) had neutropenia (< 500 cells) at admission. 29 pts (36.70%) were admitted to the ICU in the first 30th days after BMT.

71 pts (90%) were admitted due an infection disease, health care-associated infections were present in 51 pts (72%). UCI mortality was 46.8% (37 pts), 30 days mortality was 14% (6 pts) and 60-day mortality was 8% (3 pts).

Respiratory infection was the most frequent in 35.4% (28 pts) followed by bacteraemia without an identified focus 15%, catheter related infection 9%, bacterial translocation from gastrointestinal tract (BT-GIT) 6.3%, and urinary tract infection (UTI) 6.3%, We couldn´t determinate the infectious focus in 11.4%.

The microorganism isolated in the samples taken at admission were: bacterial in 31 samples (39%), virus in 17 samples (22%) and fungal in 2 samples (2.5%). Two patients had multiple isolates. In 23pts (30%) a microorganism wasn´t isolated.

Using Chi square (X^2) we found a significant relation between ICU-mortality and respiratory infection (p=0.002). When we analysed the relation between neutropenia and the others variables, there was only significant relation with respiratory infection ((p=0.02).

There wasn´t significant relation between ICU-mortality and health care-associated infection (p=0.35), admission in the first 30-day after BMT (p=0.35), neutropenia (p=0.58), sepsis without identified focus (p=0.58), bacterial infection (p=0.82), viral infection (p=0.19) and fungal infection (p=0.21) and sepsis without isolated microorganism (p=0.44).

CONCLUSIONS.

- The infectious disease is the most common cause of admission in the ICU after a BMT.
- BMT ICU patients and Neutropenia are related with respiratory infection.
- There is significant relation between respiratory infection and ICU-mortality.
- Although the antibiotic prophylaxis used in patient with BMT, there is no increase mortality in those patient with sepsis without focus and in those cases of sepsis without a microorganism isolated.

Predictive factors for mortality in cancer patients undergoing chemotherapy in the intensive care unit: an analysis of 222 cases

N.C. Santos Neto, G. Oliveira, S. Rizk, C. Park, A.P. Slovinski, R. Nakamura, M. Mourao, J.T. Fukushima, P.S. Toledo, L.A. Torres, A.C. Barrera, J.P. Almeida, L.A. Hajjar
Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil
Correspondence: L.A. Hajjar
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0868

BACKGROUND. Over the last years, advances in cancer treatment resulted in increased rates of intensive care unit (ICU) admission. In many cases, due to extensive disease and related complications, chemotherapy is prescribed during ICU stay in critically ill cancer patients. Literature is controversy about the efficacy of chemotherapy in these patients, mainly because of the related high rates of mortality.

OBJECTIVES. The aim of this study is to analyze predictors of hospital mortality in cancer patients receiving chemotherapy during ICU stay.

METHODS. From November 2012 to December 2017, 19,500 patients were admitted to the ICU of Cancer Institute of State of Sao Paulo, a 84-bed ICU of a tertiary referral center linked to University of Sao Paulo. Medical records were retrospectively reviewed by a group of 4 experienced physicians in critical oncology, using a specific database.

RESULTS. A total of 222 patients received chemotherapy and were included in the study. The median age was 47 years (31-62). There

were 160 (72%) patients with hematological malignancy and 62 (28%) with solid tumors. Most patients had metastatic disease (89%) and 35% of patients have received previous chemotherapy. Septic shock was the main cause of admission, diagnosed in 79 patients (35%). Hospital mortality was 43%. Most patients received chemotherapy in the first 48 hours of ICU admission. The most frequently prescribed chemotherapy drug was doxorubicin. A univariate analysis showed that among non-survivors, the incidence of vasoplegic shock as cause of admission was significantly higher when compared to survivors (53% vs. 22%, P< .001), the requirement for norepinephrine was greater (40% vs. 12%, P< .001) such as the requirement for mechanical ventilation (15.7% vs. 8.9%, P=0.04), SOFA was higher [4 (2-6) vs. 2 (0-4), P< .001]. Creatinine, C-reactive protein and lactate were higher in non-survivors [(1.49 mg/dL vs. 1.09, P=0.03), (42 mg/dL vs. 85, P=0,03), (23 mg/dL vs. 18, P=0.002). The platelets count (132500 vs. 206500, P=0.004) and the ratio PaO2/FiO2 (300 vs. 400, P< 0.001) were lower in non-survivors. In the multivariate analysis, the presence of vasoplegic shock [OR 1.6 (95% CI 1.04-2.45), P=0.01], higher levels of creatinine [OR 1.14 (1.03-1.27), P=0.01], lactate [OR 1.00 (1.0001-1.004), P< 0.001], C-reactive protein [OR 1.02 (1.01-1.03), P< 0.00], and lower levels of platelets [OR 0.97 (0.96-0.99), P=0.003], and PaO2/FiO2 [OR 0.99 (0.98-0.99), P< 0.001] were identified as risk factors for hospital mortality.

CONCLUSIONS. Chemotherapy in the ICU is usually prescribed in high risk patients with life-threatening disease. However, to decrease mortality rates, we should consider not prescribing chemotherapy during ICU stay in patients with vasoplegic shock, or presenting with higher levels of creatinine, lactate and C-reactive protein or with decreased levels of platelets and of PaO2/FiO2.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0869

INTRODUCTION. Cancer patients have an increased risk for hospital-acquired infections including severe sepsis, which is a frequent cause of ICU admission and of high mortality.

OBJECTIVES. To identify the most frequent type of infection as well as clinical and microbiological characteristics in critically ill oncological patients.

METHODS. Retrospective observational study (2011-2016) including adult cancer patients who were admitted to the ICU at a community hospital due to suspected infection and who stayed at the ICU for more than 24 hours. We reviewed clinical charts and collected the following data: age, sex, department of origin and length of stay prior the admission to the ICU, type of tumour, extent, score at the Eastern Cooperative Oncology Group (ECOG) scale, type of infection suspected, microbiological data, type of therapy received at ICU and factors associated to in-hospital mortality.

RESULTS. A total of 167 cancer patients were admitted to the ICU during the study period and 94 of them ICU admission was due to clinical suspicion of infection. The average age was 70.6 (SD 10.2), male sex 61.7%. Up to 76,6% presented a solid tumour and 23,4 an hematologic cancer. The 44,7% had metastases at ICU admission, 39.4% were in progression of the active tumour, 23.4% were in partial or complete remission, 19.1% were in diagnostic or induction phase and only 18.1% were in stable condition. They had received chemotherapy in 57.4% of the cases, radiotherapy 23.4%, hormone therapy 5.3%, bone marrow transplantation 2.1% and immunotherapy 1.1%. The severity scores at ICU admission were: SOFA (median 7; Interquartile range-IQR 5-9), APACHE II (median 20; IQR16-25), SAPS II (median 73.5; IQR 64,75-81). The most frequent sites of infection were

the lungs (35,1%), intraabdominal region (31,9%), urinary tract (11,7%), bloodstream as primary infection (9,6%), and in up to 6.4% no infectious focus was found. The main microorganisms involved were Gram-negative bacilli (27.7%), followed by Gram-positive cocos (11.7%), polymicrobial flora (11.7%) and fungi (7.4%). Pathogens were not isolated up to 28.7%. Up to 75.5% developed septic shock and invasive mechanical ventilation was necessary in 37,2% of the cases. In-hospital mortality was 43.6%, being the associated factors the status performance at admission (ECOG 0-1: 35%, ECOG 2: 42.9%, ECOG 3-4: 75%, P=0.049), extent of tumour (metastatic 54% vs. 35.5% locoregional extension, P=0.047) severity scores (SAPS III: P=0.013; APACHE II: P=0,039; SOFA: P< 0.001), the development of septic shock (P=0.039) and the need for invasive mechanical ventilation (P< 0.001).

CONCLUSIONS. Infection is a common cause of critical illness in patients with cancer and remains associated with high mortality. The main factors related with in-hospital mortality were the status performance to admission, extent of tumour, severity scores at ICU admission, the development of septic shock and the need for invasive mechanical ventilation.

Bacterial infection in cirrhotics: comparison of diagnostic and prognostic values of some biomarkers

N. Foudhaili, S. Khedher, A. Khaled, C. Abdennebi, M. Salem
Charles Nicolle Hospital, Digestive Intensive Care Unit, Tunis, Tunisia
Correspondence: N. Foudhaili

INTRODUCTION. Bacterial infections are very common and represent a major cause of mortality in patients with cirrhosis and major challenge for physicians.

OBJECTIVES. The aim of this study was to compare diagnostic and prognostic value of White blood cells count (WBC) , c-reactive protein (CRP) and procalcitonin (PCT) serum levels, platelet to lymphocyte and neutrophil to lymphocyte ratios (PLR and NLR) in cirrhotics with bacterial infection.

METHODS. It was a 1-year prospective study from January 2017 to December 2017. We enrolled patients with decompensated cirrhosis. Biological markers were obtained upon admission (one year). They were analyzed in terms of diagnosis performance and prediction of intrahospital mortality using the Receiver Operating Characteristic (ROC) curves analysis.

RESULTS. Eighty-seven patients were included with a sex-ratio at 0.95 and a mean age of 62±13 years (16-87). The main comorbidities were diabetes mellitus (38%) and hypertension (32%). Hepatitis C was the most common etiology of cirrhosis (39%). Child-Pugh score was mainly C (70%). Bacterial infection was diagnosed in 58 patients (66%). Identified types of infections included pneumonia (52%), spontaneous bacterial peritonitis (18%), urinary tract infection (13%), bacteremia (11%) and soft tissue infection (6%). Sepsis was diagnosed in 40 patients (46%) and septic choc in 7 patients (8%). Among 18 isolated germs, 14 were gram-negative bacteria, and 4 gram-positive bacteria. The most frequently isolated germ was Escherichia coli (11/18). Resistant organisms were isolated in 13 patients and mulitresistant organisms in 3 patients. Patients with bacterial infection had significantly higher neutrophile count (p=0.003), higher serum CRP level (p< .001), higher serum PCT level (p=0.029) and similar PLR (p= 0,799) and NLR (p = 0.055). ROC analysis of CRP serum level showed the highest AUC with a value of 0.858 (95%CI 0.766-0.949, p < .001). Infected patients with and without unfavorable outcome (death) had similar demographics characteristics. Mortality in patients with bacterial infection was 17.2%. They had significantly higher WBC count (p=0.033) and higher neutrophile count (p=0.045). ROC analysis of WBC count showed the highest AUC with a value of 0.694 (95%CI 0.532-0.856, p=046).

CONCLUSIONS. In cirrhotics with bacterial infection, CRP shows higher diagnostic accuracy than other biomarquers while WBC count has much stronger prognostic value.

Are antibiotics a cause of sepsis-induced immunosuppression?

M. Khpal, N. Arulkumaran, M. Singer
UCL, Bloomsbury Institute of Intensive Care Medicine, London, United Kingdom
Correspondence: M. Khpal

INTRODUCTION. Patients who recover from sepsis develop immunosuppression and are at risk of opportunistic infections[1.] These are relatively common in patients with more severe sepsis and/or win those with a transcriptomic profile consistent with immune suppression at the onset of secondary infection[2]. Factors well known to induce immune cell dysfunction include sedatives and antibiotics[3.] While antibiotics are necessary for the management of infection, prolonged use may result in immunosuppression. The underlying mechanisms of antibiotics-induced immune suppression in sepsis has not been elucidated.

OBJECTIVES. To determine whether commonly used classes of antibiotics alter cytokine release of immune cells ex vivo.

METHODS. Whole blood assays were performed on fresh samples taken from healthy male volunteers (n=4-7, aged 20-37 years). A range of commonly used antibiotics (Figure 1) were incubated with the blood at clinically relevant doses (minimum inhibitory concentrations; MIC, 5 mcg/ml), and simultaneously spiked with 10 mcg/ml Klebsiella pneumoniaelipopolysaccharide. At 6 and 24 hours, serum was isolated and assessed for cytokine release using ELISAs (Fig 1). Data are presented as ratio of cytokines from LPS + antibiotic-treated blood relative to LPS-treated blood alone. The Kruskal-Wallis test was used to assess differences in cytokine ratios between groups. Statistical analysis was performed using Prism software.

RESULTS. At 6 hours, TNF-alpha was suppressed by most antibiotic groups (p< 0.001). The reduction in IL-6 production did not reach statistical significance (p=0.12). There was no change in the anti-inflammatory cytokine, IL-10 at 24 hours (p=0.64) (Fig 1c); none was measurable at 6 hours.
CONCLUSIONS. Commonly used classes of antibiotics demonstrated direct effect on cytokine release in immune cells incubated with LPS. Pro-inflammatory TNF-alpha release was significantly reduced, but no effect was seen in anti-inflammatory IL-10. Further work is required to clarify the underlying mechanisms and its clinical relevance to septic patients.

The effect of vitamin C on mechanically ventilated patients with severe sepsis and septic shock: a retrospective cohort study

J.H. Ahn, D.K. Oh, J.W. Huh, C.-M. Lim, Y. Koh, S.-B. Hong
University of Ulsan College of Medicine, Asan Medical Center, Department of Pulmonary and Critical Care Medicine, Seoul, Korea, Republic of
Correspondence: J.H. Ahn
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0872

INTRODUCTION. Vitamin C has been shown to have several beneficial effects against sepsis in pre-clinical studies. It could help ameliorate sepsis-induced endothelial dysfunction, synthesize vasopressin and catecholamines, and modulate immune function [1]. However, clinical data supporting efficacy of vitamin C by itself in patients with sepsis are scarce.

OBJECTIVES. The aim of this study was to evaluate therapeutic effects of intravenous vitamin C on mechanically ventilated patients with severe sepsis and septic shock.

METHODS. Adjuvant intravenous vitamin C therapy has been applied to some patients with sepsis in our institution at an attending physician´s discretion since 2015. For this retrospective cohort study, consecutive patients with severe sepsis or septic shock who were admitted to the medical ICU and required mechanical ventilation from January to July 2017 were screened. Eligible patients were classified into a vitamin C or control group depending on the administration of intravenous vitamin C (2 g per 8 hours for 2 or more days). The primary outcome was hospital mortality. The secondary outcomes included ICU mortality, time to shock reversal, duration of initial mechanical ventilation, ICU length of stay, and changes in sequential organ failure assessment (SOFA) score over the first 72 hours.

RESULTS. Among 102 patients admitted to the ICU with sepsis, 75 mechanically ventilated patients with severe sepsis or septic shock (35 in the vitamin C group and 40 in the control group) were included. Baseline characteristics of both groups were similar except the positive rate of blood culture (20% versus 50%, $P = 0.03$). The hospital mortality in the vitamin C group was 46% (16 of 35), which was not significantly different from 40% (16 of 40) in the control group (odd ratio, 1.26; 95% CI, 0.50 to 3.30; $P = 0.62$). The median time to the reversal of shock was 3 days (interquartile range, 2 to 5) in both groups ($P = 0.28$). In the vitamin C group, the SOFA score was decreased by 1.4 ± 3.3 over the first 72 hours, compared to 1.4 ± 3.0 in the control group ($P = 0.96$). In terms of ICU mortality (34% versus 30%, $P = 0.69$), ICU length of stay (median 10 days [interquartile range, 6 to 19] versus 11 days [interquartile range, 7 to 35], $P = 0.13$), and duration of initial mechanical ventilation (median 8 days [interquartile range, 5 to 17] versus 8 days [interquartile range, 4 to 19], $P = 0.30$), there were no significant differences between vitamin C and control groups.

CONCLUSIONS. In this study, the adjuvant use of intravenous vitamin C in patients with severe sepsis or septic shock requiring mechanical ventilation neither reduced hospital mortality nor improved other ICU outcomes.

The effect of magnesium sulphate on cerebral perfusion in patients with sepsis-associated encephalopathy

N. Adel Shaban, T. Abdullah Helmy, S. Mohammed Al-Awady, D. Hassan Zidan
Faculty of Medicine, Alexandria University, Department of Critical Care, Alexandria, Egypt
Correspondence: N. Adel Shaban
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0873

INTRODUCTION. Magnesium sulphate has been shown to exhibit neuroprotective effects on the brain in experimental models of sepsis.

OBJECTIVES. To assess the effect of an intravenous bolus dose of magnesium sulphate on cerebral perfusion using flow velocities in the middle cerebral artery in patients presenting with sepsis-associated encephalopathy, and correlate between these findings and the neurological outcome.

METHODS. 46 patients with sepsis-associated encephalopathy were assessed. All patients presented with a Glasgow Coma Score (GCS) less than 15 and a positive score for delirium as evaluated using the Confusion Assessment Method for ICU (CAM-ICU). These patients weredivided into two groups (Group A= Magnesium group and Group B= Control group). The mean flow velocity in the Middle Cerebral Artery (VmMCA , cm/sec) was assessed with transcranial Doppler ultrasonography (TCD) and the pulsatility index (PI) and resistive index (RI) were calculated for both groups during the first 6 hours following admission, as well as 24 hours afterwards. For group A, additional TCD readings were also obtained 30 minutes after a 6 gram intravenous dose of magnesium sulphate. Results were correlated with the neurological status of the patients 24 hours after admission.

RESULTS. After 24 hours, the pulsatility index was significantly reduced in the Group A (1.09 ± 0.22 p < 0.001) as well as the resistive index (0.62 ± 0.07 p < 0.001). Mean flow velocity was significantly higher in the magnesium group after 24 hours (49.81 ± 16.24 p < 0.001). Group A displayed a significant improvement in the mean GCS (11.65 ± 1.99 p=0.048) and CAM-ICU score (negative CAM-ICU = 16/23 patients, p =< 0.001)

CONCLUSIONS. Results suggest that the administration of magnesium sulphate during the first 24 hours of the onset of sepsis seems to improve cerebral perfusion in patients with sepsis-associated encephalopathy and possibly correlates with better neurological outcomes in these patients.

Administration of chemotherapy to patients with hematologic malignancies admitted to the ICU with sepsis

D. Shaz, S. Pastores, N. Kostelecky, W. Zhou, N. Halpern
Memorial Sloan Kettering Cancer Center, Anesthesia Critical Care, New York, United States
Correspondence: D. Shaz
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0874

INTRODUCTION. Administration of chemotherapy to a patient with sepsis or septic shock is expected to yield a high risk for mortality.
OBJECTIVES. Identify risk factors for mortality among patients receiving chemotherapy for hematologic malignancies who were admitted to the intensive care unit (ICU) with sepsis.
METHODS. Retrospective single institution analysis of patients who were admitted to an oncologic ICU from 2010 to 2015 with a diagnosis of sepsis and received chemotherapy during their ICU stay. This is a subgroup analysis of prior work focusing on the patients with sepsis (ref.). Demographic (age, gender) and clinical data were collected including type of hematologic malignancy, severity of illness on ICU admission, Sequential Organ Failure Assessment (SOFA) score (on chemotherapy administration day), timing of chemotherapy in relation to ICU admission, source of infection, microbiologic data, use of mechanical ventilation, vasopressors and renal replacement therapy and ICU, hospital and 12-month outcomes.
RESULTS. Of 181 hematologic cancer patients who received chemotherapy in the ICU, 60 patients (33%) were admitted with sepsis as the primary or secondary diagnosis. ICU mortality was 35% and Hospital mortality was 58%. The mean time of chemotherapy administration from day of ICU admission was 2.2 days, which was similar among survivors and non-survivors. Risk factors for mortality were SOFA score on day of chemotherapy administration (p< 0.001), use of mechanical ventilation (p=0.004) and vasopressors (p=0.007) for ICU mortality.
CONCLUSIONS. Higher SOFA score on day of chemotherapy administration, use of mechanical ventilation and vasopressors are major risk factors for mortality among hematologic cancer patients admitted to the ICU with sepsis and receiving chemotherapy.

Clinical outcomes of septic patients with elevated cardiac troponin in Manila Doctors Hospital

O.F. Listanco[1], J.V. Galang[1], G. Mercado[1], K. Panugayan[1], F.E. Punzalan[2]
[1]Manila Doctors Hospital, Department of Internal Medicine, Manila, Philippines; [2]Philippine General Hospital, Department of Internal Medicine, Manila, Philippines
Correspondence: K. Panugayan
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0875

INTRODUCTION. The role of troponin I in risk stratification of sepsis is still debated. The study aims to determine the incidence of elevated troponin I among septic patients and its association with clinical outcomes and complications.
OBJECTIVES. To determine the association of levels of troponin I and clinical outcome among patients admitted for sepsis. Specific objectives are the following:

(1) to determine the incidence of elevated troponin I among septic patients;
(2) to determine the association between elevated troponin I and clinical outcomes among septic patients in terms of: a. mortality, b. use of inotropes and vasopressors, c. initiation of hemodialysis and d. use of mechanical ventilation

METHODS. The study includes all admitted septic patients with Troponin I levels determinations within 48 hours of admission from January 2014 to December 2016 in Manila Doctors Hospital. The charts were reviewed using questionnaires for sepsis, general characteristics, secondary outcomes and mortality.
RESULTS. The incidence of elevated troponin I was 65.670%. Patients with elevated troponin I levels were older (p0.042), have chronic kidney disease (p0.039), higher qSOFA score (p0.001), higher APACHE score (p0.0), and lower eGFR (p0.003). Using multivariate regression analysis, age (p0.045), presence of CKD (p0.033), qSOFA (p0.001) and APACHE scores (p0.0) were significantly associated elevated Troponin I levels. There was significant difference in mortality rate between elevated and non-elevated troponin I (p0.020) and in elevated troponin I, the likelihood of use of inotropes (p0.038) and mechanical ventilator (p0.049) were higher.
CONCLUSIONS. Elevated troponin I level is common among septic patients. The sensitive Troponin I in all septic patients is associated with increase in mortality.

Effect of fluid resuscitation with Ringer lactate versus acetate solution on correction of metabolic acidosis in critically ill patients

N. Rawat, N. Sahni, L. Yaddanapudi
Postgraduate Institute of Medical Education and Research, Anaesthesia & Intensive Care, Chandigarh, India
Correspondence: N. Sahni
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0876

INTRODUCTION. Normal saline is being considered harmful in critically ill patients and commercially prepared balanced salt solutions (acetate solution, AC) are being advocated.[1,2] However, there is paucity of studies comparing balanced salt solutions with widely available ringer lactate solution (RL).

OBJECTIVE. The objective was to compare time to correction of metabolic acidosis during initial period of fluid resuscitation with AC or RL in critically ill patients. Secondary outcome was the extent of correction of metabolic acidosis, volume and total cost of fluid used.
METHODS. A randomized controlled trial was conducted during July 2016 to December 2017 in which all adult patients admitted to intensive care unit with metabolic acidosis were included. The patients were randomized into group AC or group RL. Fluid resuscitation (AC or RL) was initiated at the rate of 20ml/Kg/hr for the first hour and arterial samples were taken 15 minutes apart. In the second hour, patients received fluid at the rate of 10ml/Kg/hr and arterial samples were drawn 15 minutes apart. The time to correction of metabolic acidosis and the extent of correction of metabolic acidosis (change in pH, lactate, standard bicarbonate, base excess) was noted. The fluid resuscitation was carried out for maximum of two hours and stopped earlier if pH got corrected to 7.3. The total volume used and cost of each fluid was noted.
RESULT. Out of total fifty patients, 25 patients in group AC and 24 in group RL were included. The demographic and baseline parameters (APACHE II score, hemoglobin, platelet count, leucocyte count, sodium, potassium, urea, creatinine, baseline blood gas parameters, time to randomization) were comparable. The metabolic acidosis got corrected in 12 patients in group AC and 10 patients in group RL (p=0.66).

The mean time for correction of metabolic acidosis was 56.25 minutes in group AC and 57 minutes in group RL (p=0.95). The extent of correction of metabolic acidosis and total volume of fluid used were also comparable (p.0.05). However, the cost of fluid used was significantly higher in group AC than group RL (p< 0.01).
CONCLUSION. Administration of two balanced salt solutions, AC or RL to critically ill patients with metabolic acidosis did not confer any advantage in time to or extent of correction of metabolic acidosis. The use of commercially prepared balanced solution (AC) increased the overall cost.

The Impact of hydrocortisone therapy on noradrenaline requirement and haemodynamics derived from transpulmonary thermodilution (TPTD) in patients with septic shock: an observational study

L. Fahrenkrog-Petersen, U. Mayr, T. Lahmer, A. Herner, G. Batres-Baires, S. Rasch, J. Wiessner, I. Hartter, R. Schmid, W. Huber
Klinikum rechts der Isar; Technical University of Munich, Medizinische Klinik und Poliklinik II, Munich, Germany
Correspondence: W. Huber
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0877

INTRODUCTION. The recommendations on the use of hydrocortisone in sepsis still are controversial . Resolution of septic shock is one of the most important outcome measures in sepsis studies. Despite several hints on an overall improvement of circulation by hydrocortisone, there is a lack of data on mechanisms and velocity of circulatory improvement.
OBJECTIVES. We investigated potential short term effects of hydrocortisone therapy (200mg i.v. bolus, followed by continuous infusion of 300mg/24h) in 20 patients with septic shock equipped with PiCCO monitoring.

METHODS. TPTD (PiCCO; Pulsion; Germany) was performed immediately before as well as 2h, 8h, 16h and 24h after the initiation of hydrocortisone therapy. Furthermore, cardiac power index CPI [W/m²]) (=0.0022 * cardiac index * MAP) and vasopressor dosage were recorded. Primary endpoint: changes in the ratio CPI/noradrenaline. Statistics: Wilcoxon-test; SPSS 24.
RESULTS. n=20 (14m; 6f); 65±14 years; APACHE-II 25±8; SOFA 12±8. Mechanical ventilation 17/20 (85%); vasopressor therapy 20/20 (100%). Baseline values: noradrenaline 1570±1232µg/h (no other vasopressors were used); MAP 73.9±9.2mmHg; heart rate 105±18/min; CVP 16±6mmHg; global end-diastolic volume index GEDVI 833 ±166mL/m²; cardiac index CI 4.77±1.35L/min/m²; global ejection fraction GEF 22.7±6.5%; dPmax 1606±485mmHg/s; extravascular lung water index EVLWI 12.0±4.3mL/kg; pulmonary vascular permeability index PVPI 1.95±0.73; CPI 0.83±0.25W/m²; CPI/noradrenaline 0.090 ±0.091W/m²/µg. After 2h, 8h, 16h and 24h there were no significant changes in CVP or GEDVI. Neither MAP nor SVRI changed over time. Among the parameters of cardiac performance, GEF slightly increased (Delta-GEF +1.3±2.7%; p=0.042) after 2h. Furthermore, dPmax decreased after 8h (-264±412mmHg/s; p=0.036), 16h (-326±478mmHg/s; p=0.016) and 24h (-344±522mmHg/s; p=0.046). By contrast, CI and CPI did not change after the onset of hydrocortisone.
Both markers of pulmonary oedema EVLWI (-1.3±2.3; p=0.044 and -1.8±2.9mL/kg; p=0.036) and PVPI (-0.27±0.34; p=0.007 and -0.36 ±0.62; p=0.054) decreased after 16h and 24h.
>The most pronounced changes were found regarding the primary endpoint CPI/noradrenaline: This ratio increased after 8h (+0.065±0.066; p=0.001), 16h (+; p=0.116±0.146; p=0.003) and 24h (+0.132±0.117 W/m²/µg; p=0.003). The increase after 2h slightly failed significance h (+0.011±0.034 W/m²/µg; p=0.053). The noradrenaline dosage decreased by 16%, 41%, 46% and 63% after 2h, 8h, 16h and 24h.
CONCLUSIONS. Our data suggest that hydrocortisone results in a fast and substantial improvement of the ratio CPI/noradrenaline without incraesing preload. Despite the absence of a control group, the fast onset of all relevant haemodynamic changes within 2-8h after the start of hydrocortisone suggests an association of haemodynamic improvement with steroid therapy. Finally, we observed a decrease in pulmonary oedema which might be related to hydrocortisone.

Is there a role for early administration of fixed low dose terlipressin in adult septic shock?

R. Etomi, A. Khan, T. Prabhahar
North Middlesex University Hospital, Critical Care, London, United Kingdom
Correspondence: R. Etomi
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0878

INTRODUCTION. Fluids and catecholamines are the cornerstones of management in sepsis induced hypotension. However to administer catecholamines there is a need for central venous access and continuous invasive arterial blood pressure monitor. Moreover catecholamines cause increase myocardial oxygen consumption, peripheral ischaemia and arrhythmias. Terlipressin is a synthetic long acting analogue of vasopressin. Vasopressin is being used at a fixed lower dose to reduce the catecholamine requirements in severe septic shock. There is some evidence that continuous fixed dose infusion of low dose Terlipressin when given as a first line vasopressor agent for hypotension in septic shock has reversed the hypotension.
OBJECTIVES. Objective of this small retrospective survey was to assess the impact of fixed low dose Terlipressin infusion when used as a sole agent in sepsis induced hypotension.
METHODS. Retrospective search was undertaken in the electronic (Acubase®) patient records of all admissions for three years from 2015 to 2017 using clinical intervention fixed low dose Terlipressin (30µg/hour) infusion. 120 patients were identified by this search. Electronic medical notes (Acubase®) were further searched manually

and patients who were not septic or Terlipressin was used with another vasopressor were excluded, 17 patients fulfilled the inclusion criteria. Manual search was undertaken on 14 patient observation and infusion charts, as three charts were unable to be obtained. We assessed the mortality of 17 patients. Of those who survived critical care admission nine were assessed for the improvement in their mean arterial blood pressure (MAP) at 12 and 24 hours, urine output (UOP) and serum creatinine after 24 hours.

RESULTS. 12 out of 17 patients survived the critical care admission. Three patients´ MAP at 12 hours were still less than 65 mmHg, and two remained less than 65 mmHg at 24 hours. All nine patients were either anuric or oilguric at the beginning of the infusion. Seven out of nine patients UOP improved to normal after 24 hours. Six out of nine patients' serum Creatinine improved significantly after 24 hours.

CONCLUSIONS. Fixed low dose Terlipressin as a sole agent vasopressor for sepsis induced hypotension improved the cardiovascular function, renal function and improved survival rate (70%) in this sample.

Since the data was limited we suggest a large prospective randomised control study analysing the effects of early fixed low dose Terlipressin infusion as a single agent for patients with sepsis induced hypotension.

Hypotension in septic patients after intubation and sedation - shock or adverse effects from sedatives?

J.E. Larsson, T. Skovsgaard Itenov, C. Dalby Sørensen, M. Heiberg Bestle
Nordsjællands Hospital, University of Copenhagen, Department of Anesthesiology and Intensive Care, Hilleroed, Denmark

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0879

INTRODUCTION. Respiratory failure is a common complication in septic patients mandating mechanical ventilation. Anesthetics used to facilitate endotracheal intubation and sedation have known hemodynamic adverse effects and may cause hypotension. It is unclear, whether hypotension in septic patients after induction and sedation can be solely attributed to pharmacological adverse effects, or if the anesthetics exacerbates the underlying disease.

OBJECTIVES. The aim of this study is to compare the mortality rate, fluid therapy, anesthetic agents and vasopressor usage in septic patients who develops hypotension after intubation and sedation, with septic patients who are hypotensive prior to intubation.

METHODS. In this single-center, retrospective observational cohort study, we included septic patients who were intubated in the intensive care unit (ICU) during 2014 and 2015, and had hypotension prior to, or after the procedure. We stratified the patients according to whether they met criteria for hypotension within the last six hours before intubation or during the first hour after intubation. Hypotension was defined as a systolic blood pressure < 90 mmHg; a middle arterial blood pressure (MAP) < 65 mmHg or the need for vasopressors to sustain a MAP > 65 mmHg. The primary outcome measure was mortality at 90 days post intubation.

RESULTS. Of the 427 admissions screened, 130 patients were included in the study. Among these, 53 patients had hypotension before intubation and sedation (HBI) and 77 patients had hypotension after intubation and sedation (HAI). At 90-days after intubation, 30 of 53 patients (57%) in the HBI group had died as compared with 34 of 77 patients (44%) in the HAI group (P=0.224). Survival curves and the results from the multivariate analysis are presented in Figure 1 and Table 1 respectively. During the first 24 hours after intubation, the HBI group received more noradrenaline (median

[IQR] 8957 µg/kg/24 hours [5515 to 12470] as compared with 3766 µg/kg/24 hours [2002 to 5954]; P< 0.001]), and higher volumes of resuscitation fluids (median [IQR] 71.4 ml/kg/24 hours [40.0, 112.9] vs. 50.0 ml/kg/24 hours [26.7, 73.0]; P=0.01).

CONCLUSIONS. The mortality of septic patients with hypotension following intubation and sedation was high and these patients should be considered as patients in early septic shock.

INTRODUCTION. Cellular therapy with mesenchymal stem cells (MSCs) represents emerging therapeutic strategy in sepsis. However, the encouraging results of experiments with MSC in rodent models of sepsis have not yet been confirmed in large animal models with better relevance to human sepsis.

OBJECTIVES. To assess safety and efficacy of bone-marrow derived MSCs in a clinically relevant porcine model of progressive peritonitis-induced sepsis.

MATERIAL AND METHODS. 32 anesthetized, mechanically ventilated and instrumented pigs were randomly assigned into four groups: 1) sham operated group (CONTROL, n=8); 2) sham operated group treated with Bone-marrow derived MSCs (MSC-CONTROL, n=8), 3) sepsis group with standard supportive care (SEPSIS, n=8); 4) sepsis group treated with MSCs in addition to standard supportive care (MSC-SEPSIS, n=8, MSCs administered i.v. at 6 h after sepsis induction). Before, 12, 18 and 24 h after the induction of peritonitis we measured, in addition to systemic, regional (renal) and microvacular (gut mucosal) hemodynamics, oxygen kinetics (DO2/VO2), organ function (lung, kidney, liver, heart), energy metabolism (lactate kinetics, acid base balance), systemic inflammation (cytokines), nitrosative/oxidative stress (isoprostanes) and tissue immunohistochemistry.

RESULTS. Administration of MSCs in the MSC-CONTROL group did not affect hemodynamics, organ functions nor the levels of systemic cytokines. Treatment of septic animals with MSCs did not attenuate sepsis-induced hyperdynamic circulation nor the development of vasopressor-requiring hypotension. The application of MSCs did not blunt sepsis-induced alterations in microvascular perfusion, cellular energetics and multiorgan functions. Finally, sepsis was associated with progressively increased levels of pro-inflammatory cytokines in both group, without intergroup differences. Analyses of oxidative stress and tissue immunohistochemistry are ongoing.

CONCLUSIONS. This is the first report to evaluate the safety and efficacy of MSCs in a clinically relevant, large animal, long-term model of progressive sepsis induced by diffuse peritonitis. Administration of MSCs to healthy animals was well tolerated without any measurable acute hemodynamic or organ toxicity. However, in sharp contrast to recent rodent studies, MSCs failed to attenuate sepsis-induced disturbances at multiple levels. Thus, the decision to move from experiments to clinical studies must be preceded by further and careful pre-clinical evaluation with high translational potential.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0881

INTRODUCTION. Sepsis is an extreme inflammatory response mediated by cytokines that can induce acute lung injury and multiorganic dysfunction. Sepsis remains one of the leading causes of mortality in the intensive care units and there is not a specific treatment for this disease. Nowadays, we have to focus in new therapeutic strategies. Mesenchymal stem cells (MSC) have shown anti-inflammatory, antimicrobial, anti-apoptotic and regulatory properties, MSC could be an interesting therapy for sepsis however with the new molecular technic of genetically modification the beneficial effects of MSC therapy could be enhanced.

HYPOTHESIS. Genetically modified MSC overexpressing IL10 and IL7 reduces the damage in a murine model of sepsis, modulating the inflammatory systemic response and diminishing the lung injury.

METHODS. Sepsis was induced by a cecal ligation and puncture (CLP) in Sprague-Dawley rats (225-300 g). 6 hours later we did a surgical source control and administered antibiotics (Meropenem 20 mg/kg), fluids (10 ml/kg) and analgesics (Buprenorphine 0.025 mg/Kg). In addition, we administered $2.5*10^6$ MSC genetically modified to overexpress Interleukin 10 and 7. 48 h later the animals were sacrificed and samples of lung tissue, bronchoalveolar lavage and blood were collected. We did control groups, rats were submitted to the same process but no CLP was performed. We analysed neutrophils, macrophages and lymphocytes in bronchoalveolar lavage; blood and spleen bacterial counts and expression of inflammatory cytokines in lung tissue.

RESULTS. Modified MSC compared to control MSC reduced number of neutrophils and proteins infiltrated into the alveolar space. Modified MSC also reduced the number of circulating bacteria in blood, increase the pO_2 and reduce the concentration of creatinine in plasma. In addition, modified MSC significantly reduced the expression of TNFα, iNOS, IL1β and CCL2 in lung tissue in the septic animals. Regardless the beneficial effects of the modified MSC there is no differences in survival compared with the non-modified MSC.

CONCLUSION. Genetically modified MSC modulates the proinflammatory cytokine production during sepsis, increase the bacterial clearance and the O_2 exchange in a murine model of sepsis.

INTRODUCTION. Sepsis, a life-threatening organ dysfunction caused by a dysregulated host response to infections, is a global burden with limited therapeutic options. In recent studies, combination of hydrocortisone (HC) and ascorbic acid (vitC) dramatically improves endothelial barrier function and mortality in patients with sepsis.

OBJECTIVES. The aim of the study was to investigate the effects of combined HC and vitC on cecal ligation and puncture (CLP)-induced sepsis in mice, and to elucidate its underlying molecular mechanisms.

METHODS. Experiments were performed on male C578L/6 mice. Sepsis was induced by CLP. Mice were randomly assigned to control group, HC group, vitC group, combination low-dose group and combination high-dose group (each n = 20). Mice in control group were treated with saline vehicle. Mice in HC group and vitC group were treated with HC (2.5mg/kg of body weight) or vitC (100mg/kg of body weight). Combination low-dose group and combination high-dose group were treated with HC (2.5mg/kg of body weight) plus vitC (100mg/kg of body weight) and HC (5.0mg/kg of body weight) plus vitC (200mg/kg of body weight) intravenously at 0, 12, 24, 36, and 48 h after CLP. Survival rate, cytokine and septic biomarkers were compared among these groups. Additionally, human umbilical vein endothelial cells (HUVECs) were exposed to LPS (1μg/ml) or high mobility group box 1 (HMGB1) protein (1μg/ml). Barrier protective effects and antiseptic activity of HC and vitC were examined.

RESULTS. There was significant difference in survival rate between control group and combination high-dose group at 140h (0% [20/20] vs. 60% [12/20], p< 0.001). LPS induced profound hyperpermeability,

as reflected in pulmonary microvascular albumin leak. Combination high-dose HC and vitC significantly reversed LPS-induced barrier dysfunction. The barrier-protective effects of HC and vitC were associated with dephosphorylation and cleavage of ocludin-1 and activation of transcription factor such as NF-κB p65 and glucocorticoid response element (GRE). The antiseptic activity of combination of HC and vitC was determined from the measurements of LPS-mediated HMGB1 release, expression of HMGB1 receptor, and leukocyte adhesion and migration in LPS/CLS-activated HUVECs and mice.

CONCLUSIONS. Our results indicated that HC and vitC might be useful in the treatment of sepsis. In addition, these data provide a novel mechanism of vascular barrier integrity protection and suggest that combination administration predicts synergistic therapeutic effects in septic patients rather than single administration.

Inhibition of uncoupling protein 2 exacerbates mitochondrial oxidative stress in the proximal tubular epithelial cells of a live kidney slice exposed to septic serum

S. Pollen[1], N. Arulkumaran[1], M. Duchen[2], M. Singer[1]

INTRODUCTION. We have previously found that exposure of naïve kidney slices to septic serum increases generation of reactive oxygen species (ROS) and decreases mitochondrial membrane potential (MMP) and NADH fluorescence. Scavenging ROS with the use of mitochondrial-targeted antioxidants reversed these changes.[1] A decrease in both MMP and NADH fluorescence suggests mitochondrial uncoupling as the underlying mechanism, which may provide a physiological mechanism to reduce the generation of mitochondrial reactive oxygen species (ROS)[2].

OBJECTIVES. To determine whether this observed change in mitochondrial function is mediated by activation of mitochondrial uncoupling proteins UCP2[3], in turn stimulated by ROS on exposure to septic serum[4], and whether inhibition of UCP2 by genipin, an inhibitor of UCP2 alters ROS generation.

METHODS. Live kidney slices (200 μm thick) were exposed to serum from 24-hour sham operated or septic rats and imaged with multiphoton confocal microscopy using fluorescent dyes to detect dynamic changes in mitochondrial function. MMP (measured with tetramethylrhodamine methyl ester, TMRM), ROS generation (dihydroethidium, HEt) and redox state (NADH autofluorescence) were all probed over 90 minutes, with or without co-incubation with the rapidly-acting, cell-permeant, UCP2 inhibitor genipin.[5] Experimental results were expressed as the median (n=4, ±IQR) percentage relative fluorescence intensity (RFI) at 90 minutes compared to the baseline RFI at time zero.

RESULTS. The decreases in MMP and NADH following exposure to septic serum were partially prevented by co-incubation with genipin (63% vs 80% Fig.1a and 77% vs 96% Fig.1c, p< 0.05).

The increase in ROS generation on exposure to septic serum was however enhanced by genipin (50 μM) co-incubation (146% vs 167% Fig1b, p< 0.05). In sham serum exposed slices, co-incubation with genipin also increased MMP (98% vs 123%) and ROS generation (86% vs 112%) (p< 0.05), but not NADH. [Figure notation: *=p< 0.05 vs sham serum, †=p< 0.05 vs septic serum, ‡=p< 0.05 vs sham serum + genipin].

CONCLUSIONS. UCP2 is a key regulator of MMP in an *in vitro* model of sepsis-induced renal tubular cell mitochondrial dysfunction. While inhibiting its action protects the MMP from the depolarisation seen on exposure to septic serum, the concomitant increase in ROS is potentially deleterious. Indeed, decreasing the MMP through uncoupling may be an intrinsic protective mechanism that reduces mitochondrial ROS generation in septic AKI [2,4].

INTRODUCTION. The Surviving Sepsis Campaign (SCC) guideline recommends transfusion of blood in sepsis when the haemoglobin concentration drops below 7.0 g/dL (1). Blood transfusion in septic shock is thus generally reserved as a later-stage treatment option after administration of crystalloids, colloids, vasopressors and inotropic agents. In the ProCESS trial, more patients in the early goal-directed therapy (EGDT) group receiving packed red blood cell (PRBCs) transfusion than in those in the protocol-based standard-therapy or the usual-care groups, without any apparent differences in the overall outcomes evaluated (2,3).

OBJECTIVES. We therefore conducted a randomised pre-clinical trial evaluating whether early administration of blood transfusion has a role in haemodynamic and volume resuscitation for endotoxaemic shock by comparing effects of fresh versus stored blood transfusion in a validated ovine model of hyperdynamic endotoxaemic shock(4).

METHODS. Endotoxaemic shock was induced in sixteen anaesthetised and mechanically ventilated merino ewes by infusing an escalating dose of lipopolysaccharide, LPS (*E.coli 055:B5*) over 4 hours (total LPS dose 11.25mcg/kg). During the last hour of LPS, 10mls/kg of either fresh (≤5 days); n=8 or stored (≥30 days); n=8 ovine PRBCs was administered followed by a 12-hour monitoring period. Blood samples were taken for measurement of inflammatory cytokines and coagulation profile.

RESULTS. Compared to fresh PRBC, transfusion of stored PRBC in ovine endotoxaemic shock was associated with haemodynamic changes including increased central venous (p< 0.0001) and pulmonary artery (p< 0.0001) pressures; decreased mixed venous oxygen saturation (p=0.0036) and cardiac index (p=0.0007). Additionally, there was an increase in pro-inflammatory cytokines (IL-6, p=0.0053; IL-8, p=0.0332), a decrease in the anti-inflammatory IL-10 (p=0.0215), and a decrease in the fibrinogen concentration (p=0.0036).

CONCLUSIONS. There were significant changes in the haemodynamics, inflammatory response and coagulation profile with stored ovine PRBC transfusion. These results indicate that a longer storage duration of PRBCs prior to transfusion could be associated with systemic effects that predispose septic shock patients to poor clinical outcomes.

Effects of platelet-activating factor and quinidine in the isolated perfused rat small intestine are related to similar MAPK pathways

N. Beckers[1], I. Lautenschläger[1], Y.L. Wong[1], K. Zitta[1], C. Schildhauer[1], K. Parczany[1], S. Krüger[2], C. Röcken[2], M. Albrecht[1], I. Frerichs[1], N. Weiler[1]

INTRODUCTION. Sepsis-induced endothelial dysfunction critically affects the gastrointestinal tract leading to intestinal failure. In the model of the isolated perfused small intestine, a bolus of 0.5 nmol platelet-activating factor (PAF) mimics this pathology[1,2,3]. We have recently shown that quinidine (QD) protects the gut in this setting[3].

OBJECTIVES. We aimed (I) to check if continuous PAF infusion (2.26 nM) leads to a persistent barrier dysfunction with organ failure, (II) to investigate if QD (100 μM) protects against organ dysfunctions and (III) to screen for adaptive intracellular pathways associated with the PAF-induced intestinal failure and the QD-mediated protection.

METHODS. An established model of the isolated perfused rat small intestine[1,2,3]. Group 1 (G1): PAF (n=6), G2: QD (n=5), G3: PAF+QD (n=5) and G4: control (n=6). Fluid shifts, macromolecular transfer of FITC-labelled dextran and compartment pressures were recorded. Venous galactose derived from luminal lactose was assessed as a measure of intestinal function. Tissue samples were taken to analyze morphology. A phospho-MAPK array (ARY002B, R&D Systems) was used to determine the status of intracellular signalling pathways.

RESULTS. PAF infusion led to an inflammatory pressure response, an endo- and epithelial leakage and a loss of the resorptive function followed by an adaptive process. The area under the pressure response curve (15-min intervals) was significantly elevated in the PAF group (G1) for 60 min when compared with G4 (p=0.0002). The peak value for PAF-induced FITC dextran transfer (mg·15min^{-1}) to the lumen was 0.076 (control: 0.0027) and to the lymphatics 0.205 (control: 0.015). Within the first 15 min after PAF infusion 12% of volume flow was lost from the mesenteric vascular bed into the other compartments. The galactose uptake dropped significantly in the PAF group (G1). When QD was administered before and during the PAF infusion, PAF-induced effects were abolished. Light microscopy revealed no changes in histological stability score (all groups). Nevertheless, edema formation was more pronounced in the PAF group than in the others. Phospho-MAPK arrays revealed that PAF increased the phosphorylation of 13 proteins with strongest effects on ERK2, GSK-3ab and JNK2. QD also increased the phosphorylation of 13 proteins with strongest effects on ERK2, JNK2, JNKpan and p38d. The combination of PAF and QD led to a pronounced relative increase of p-AKT3, p-CREB, p-ERK2, p-GSK-3ab and p-JNK2.

CONCLUSIONS. PAF infusion leads to a persistent intestinal barrier dysfunction with organ failure. QD infusion almost completely abolishes these effects. Both substances are related to similar signalling pathways, especially the ERK and JNK pathways.

Pentoxyphylline inhibits M1 polarization and favors M2 of murine macrophages treated with TLR4 agonist

M.C. Montero[1], J. Guerrero[2,3,4]
[1]Universidad de Chile, Facultad Medicina, Programa Disciplinario Fisiologia y Biofisica, Santiago, Chile; [2]Universidad de Chile, Facultad Medicina, Programa Disciplinario Fisiología y Biofisica, Santiago, Chile; [3]Universidad de Chile, Hospital Clínico, Departamento Medicina Interna, Santiago, Chile; [4]Clinica Alemana de Santiago, Departamento Paciente Critico, Santiago, Chile

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0886

INTRODUCTION. Pentoxyphylline (PTX) is a phosphodiesterase inhibitor that increases intracellular cAMP. Recently, PTX has been recognized as a pharmacological modulator of inflammation that may improve outcomes in septic patients (1). In neonatal sepsis, the use of PTX as an adjunct to antibiotics therapy decreased all-cause mortality and the length of hospital stays, without significant adverse effects (2). Authors had proposed its effect may be mediated by adenosine-dependent pathways for polymorphonuclear leukocytes and T cells (3). Results of studies in whole new born umbilical blood showed that PTX inhibited the inflammatory cytokine response induced by Toll-like receptors (TLR) agonists, TLR4, TLR7 and TLR8 (4). Considering that peripheral blood macrophages can reprogram their phenotype and orchestrate the inflammatory response, we tested if PTX modifies inflammatory cytokines profile in response to a TLR-4 agonist in a macrophage cell line.

OBJETIVE. To assess if PTX modulates macrophage TLR4-dependent polarization in vitro.

METHODS. Murine macrophages (Raw 264.7 cells) were cultured in Dulbecco's Modified Eagle's Medium (DMEM) (control), or in the presence of lipopolysaccharide (LPS, Sigma -Aldrich Chemie®, Germany[LM1]) 25ng/mL, LPS + PTX (dose-response curve; Sigma-Aldrich Chemie®, Germany) or PTX alone. We analyzed cell viability by trypan blue exclusion assay and the time-course of changes in TNF-alpha and IL-10 mRNA content (as surrogate markers of M1 or M2 polarization, respectively) in the presence or absence of LPS, PTX or LPS plus PTX by real-time qPCR.

RESULTS. PTX (100-250-500 and 1000mg/ml by 1-1.5 or 2h) had no effect on cell viability or TNF-alpha mRNA abundance. LPS induced TNF-alpha mRNA (3 times of control level; n= 4, p< 0,05) and PTX inhibited TNF-alpha mRNA induced by LPS (p< 0,05). The inhibitory effect of PTX on LPS-dependent TNF-alpha mRNA induction was greater with 250 mg /ml and over 1h of exposition. Interestingly, after 1.5 h of exposure, PTX+ LPS significantly increased the cellular content of IL-10 mRNA.

CONCLUSIONS. PTX modulates macrophage inflammatory cytokines response induced by a TLR-4 agonist. We postulate that PTX modifies the polarization profile of macrophages (M1 to M2). In the context of TLR4 activation, the increase of cAMP induced by PTX may activates PKA, stabilize the IκB inhibitor and suppress NF-κB nuclear translocation. Besides, cAMP-PKA-dependent CREB phosphorylation may explain the induction of IL-10 mRNA at a transcriptional level.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0887

INTRODUCTION. Sepsis is responsible of both an immune hyperactivity damage from inflammation and immune suppression and paralysis. A few studies support the role of IgM enriched immunoglobulins G as adjunctive of antimicrobial treatment

OBJECTIVES. To assess the efficacy of IgM enriched IgG as adjuvant therapy in treating sepsis in the critically ill.

METHODS. Case-control prospective study. Since 12/2016 to 01/04/2018, patients experiencing a septic shock - admitted with a first 24h SAPS II > 25, associated with a SOFA-score > 4 - underwent treatment with IgM-e-IG, given for three days at the total dosage of 500 mg/kg. The therapy response was based on clinical, microbiological and rheological data. All cases were 1:1 matched with analogous controls.

RESULTS. During the study period 25 patients were recruited and matched with 20 controls; no differences were found in median age [61 (55-78) vs. 63 (58-77) p=0.662], ICU length of stay [14 (5-19) vs. 15 (6-18) p=0.462]; duration of mechanical ventilation [7 (5-8) vs. 8 (5-9) p=0.348] and antimicrobial treatment [9 (8-11) vs. 11 (12-14) p=0.552]. PCT, CRP, WBC, Lactates and SOFA score were daily measured and computed the differences between day of stopping and starting IM-enriched IgG (For the controls such parameters ware considered over the same 72 hrs period. No differences were found in the trend of all parameters but SOFA [3.5 (2-5) vs. 0.5 (0-2) p=0.015], indicating a quicker and more timely recovery from sepis related organ failure in the treated patient group. The VLAD computed on the basis of SMR in the two group showed a higher number of saved lives in the treatment group (4.5 vs. 0.7). No differences in survival was found by Kaplan Meier analysis although at 28 days all patients of the treatment group were still alive.

CONCLUSIONS. IgM enriched immunoglobulins G as adjunctive of antimicrobial treatment may have a role in improving patient outcome, however PRCT are warranted to produce clear hints.

Hydrocortisone, vitamin C, low dose norepinephrine and thiamine for the treatment of severe sepsis and septic shock: a retrospective before-after study

A.W. Ahmadzai[1,2]
[1]Nangarhar Reagional Hospital, G ICU, Jalalabad, Afghanistan; [2]Nangarhar Madical Faculty, Intensive Care, Jalalabad, Afghanistan
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0888

INTRODUCTION. The global burden of sepsis is estimated as 15 to 19 million cases annually, with a mortality rate approaching 60% in low-income countries.

METHODS. In this retrospective before-after clinical study, we compared the outcome and clinical course of consecutive septic patients treated with intravenous vitamin C,low dose hydrocortisone,low dose

norepinehrine and thiamine during a 6-month period (treatment group) with a control group treated in our ICU during the preceding 6months. The primary outcome was hospital survival.

RESULTS. There were 45 patients in both treatment and control groups, with no significant differences in baseline characteristics between the two groups. The hospital mortality was 10.6% (5of 47) in the treatment group compared with 40.4% (19 of 47) in the control group (P < .001). The propensity adjusted odds of mortality in the patients treated with the vitamin C protocol was 0.13 (95% CI, 0.04-0.48; P = .002). The Sepsis-Related Organ Failure Assessment score decreased in all patients in the treatment group, with none developing progressive organ failure. All patients in the treatment group were weaned off vasopressors, a mean of 18.3 ± 9.8 h after starting treatment with the vitamin C protocol. The mean duration of vasopressor use was 54.9 ± 28.4 h in the control group (P < .001).

CONCLUSIONS. Our results suggest that the early use of intravenous vitamin C, together with low dose corticosteroids, low dose nor epinehrine and thiamine, are effective in preventing progressive organ dysfunction, including acute kidney injury, and in reducing the mortality of patients with severe sepsis and septic shock. Additional studies are required to confirm these preliminary findings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0889

INTRODUCTION. Non-invasive ventilation (NIV) is frequently used to treat pneumonia associated acute hypoxemic respiratory failure, although some data suggest high failure rates. In last years, high flow nasal cannula oxgenation (HFNO) has appeared as a new therapy for hypoxemic patients.

OBJECTIVES. To compare clinical outcomes of patients admitted due to severe pneumonia and treated with NIV and HFNO.

METHODS. We retrospectively studied patients admitted to our polivalent ICU in which NIV or HFNO were used as first line respiratory support for acute respiratory failure associated pneumonia. We compared baseline characteristics and clinical evolution of patients according to the therapy used. For statistical analysis we used t-Student, U-Mann-Whitney, Chi-square or Fisher test as appropriate.

RESULTS. During the study period 274 patients were admitted to our ICU due to severe pneumonia. For the present analysis we excluded those patients with do not resuscitate order status and those early intubated at admission, resulting in 110 patients, 71 treated with NIV and 39 with HFNO.

Patients in NIV group were older (62.7 (59.3-66.2) vs 53.5 (47.8-59.1) years, p 0.006) and had higher APACHE II (18.8 (17.4-20.2) vs 14.3 (12.9-15.7), p < 0.001). Comorbidities were similar, with a trend to higher proportion of chronic kidney disease and COPD in NIV group. Need of inotrope support was similar in both groups but renal replacement was more frequently used in NIV group (7 v 0 %, p 0.043).

Nosocomial pneumonia was more frequent in NIV Group (32.4 vs 10.3 %, p 0.01) and time to ICU admission was longer in NIV group (1 (0-5) vs 0 (0-1), p 0.041) No differences in microbiological aetiology was observed.

At admission, patients in HFNO group had lower pO2 (76.7 (68.3-85.2) vs 91.4 (79.3-103.5), p 0.048) and lower pCO2 (36.8 (35.2-38.4) vs 43 (39.5-46.6), p 0.013), with no differences in respiratory rate, FiO2 and pO2/FiO2 rate. Radiological involvement was greater in HFNO group (2 (IQR 1-4) vs 1 (1-3) quadrants, p 0.007).

No differences in length of ICU or hospital stay were observed. Mortality, both ICU and hospital, were higher in NIV Group (28.2 vs 7.7 %, p 0.012 and 35.2 vs 12.8 %, p 0.012 respectively)

More patients in NIV group required intubation (52 vs 41 %), but it did not reach statistical significance.

CONCLUSIONS. Our results suggest benefit of HFNO over NIV as first line therapy in severe pneumonia. However, differences in baseline characteristics and severity of pneumonia limit our findings.

Application of the ROX index as a predictior of response to high-flow nasal cannula in patients with acute hypoxemic respiratory failure

M. Magret Iglesias, N. Guasch Boqué, F. Esteban Reboll, A. Rodriguez Oviedo, M. Bodí Saera
Hospital Joan XXIII, Intensive Care Unit, Tarragona, Spain
Correspondence: M. Magret Iglesias
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0890

INTRODUCTION. High-flow nasal cannula (HFNC) have been defined as safe and useful therapy in patients with acute hypoxemic respiratory failure (AHRF), demonstrating a decrease in the need for mechanical ventilation (MV). However, one of the most challenging decisions in the management of AHRF patients is to decide when to move to invasive MV. In this regard, although HFNC may avoid further need for MV in some patients with AHRF, it may unduly delay initiation of MV in others and worsen their outcome. Therefore, to identify and describe accurate early predictors of the need for MV in spontaneously breathing patients with AHRF are of special interest. The literature shows that the ROX index (Respiratory rate OXygen) can be an early and non-invasive tool, predicting failure of HFNC.

OBJECTIVE. To apply the ROX index as a predictor of response to HFNC in our sample of patients with AHRF.

METHODS. .Retrospective study in a general ICU with 30 beds in a 12-month period. Adult patients with AHRF were included. Excluded patients were < 18, with hypercapnia or immediate MV criteria.The data were analyzed using median, interquartile range (IQR), mean and standard deviation (SD) for continuous variables. Absolute frequency and percentage for categorical variables. Through the Classification and Regression Trees (CART) we got a cut-off point for the continuous variables and the significance of the nominal or categorical variables. The ROX index was analyzed at 0, 12 and 24 hours, calculated from respiratory variables that allow the evaluation of respiratory failure: in the numerator, the variables correlated with the oxygenation and success of HFNC ($SatO_2$/ FiO_2) and in the denominator those that display inverse association (respiratory rate). The literature determines the cut-off point at 12 hours at 4.88.

RESULTS. 40 patients with AHRF were included. The most common cause was community-acquired pneumonia (CAP) (50%), followed by interstitial lung disease (15%). 17 patients were intubated (42.5%), 4 of them before 12 hours and 6 with diagnosis of CAP. There were no significant differences in sex, comorbidities, cause of AHRF or APACHE II between intubated and non-intubated patients. Using the CART system we obtained a cut-off point of 3.9 in the ROX index at 12 hours. At this time, patients with a ROX index < or equal to 3.9 were intubated in 71,4% compared to patients with a ROX index > 3,9 who were intubated in 29.6% (p< 0.05).

CONCLUSIONS. In our sample, the ROX index at 12 hours with a cut value of 3.9 allows us to predict the response to HFNC. Therefore, it may be an early non-invasive parameter to predict the need for intubation.

INTRODUCTION. Percutaneous dilatational tracheostomy (PDT) is an easy and safe procedure performed in intensive care units.
OBJECTIVES. The aim of this study was to compare the efficacy and safety of PDT with bronchoscopic guidance with those of PDT without bronchoscopic guidance.
METHODS. We reviewed retrospectively the clinical data of 121 patients who underwent PDT at Chonnam National University Hospital between March 2013 and November 2016.
RESULTS. The median age of the patients was 72.0 years (interquartile range, 61.5-78.0), and 80 (66.1%) were men. Of all the patients, 44 (36.4%) underwent PDT with bronchoscopic guidance, which was unsuccessful in one patient, thereby the overall success rate of PDT being 99.2% (120/121). The number of complications was higher in patients who underwent PDT without bronchoscopic guidance than in those who underwent bronchoscopy-guided PDT, but the difference was not statistically significant (12 vs 3, p=0.251). All the complications were bleeding during or after the procedure and were easily controlled, except for a major bleeding in one patient who underwent PDT without bronchoscopic guidance and required cardiopulmonary resuscitation because of airway obstruction.
CONCLUSIONS. PDT has a high success rate and a low complication rate when performed with or without bronchoscopic guidance.

Multidisciplinary airway training for intensive care staff in the workplace using the 'Bath Tea Trolley' approach

A. Serrano-Ruiz, G. Ball, S. Spencer, J. Chai, M. Charlton, F. Kelly
Royal United Hospital of Bath, Intensive Care Unit, Bath, United Kingdom
Correspondence: A. Serrano-Ruiz
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0893

INTRODUCTION. Intubation on the intensive care unit (ICU) is high risk,[1,2] with serious airway complications 55 times more likely to occur in ICU than in operating theatres.[3] Airway training for ICU nurses is challenging: ICU nurses often lack anaesthetic airway experience;[2] there are limited low risk cases for training;[2] nurses receive infrequent exposure to airway management especially advanced and rescue techniques;[2] and 'skill decay' is an issue which affects senior and junior staff alike.[4]
OBJECTIVES. Our aim was to design and deliver an airway training programme using the 'Bath Tea Trolley' method,[5] teaching ICU staff to use a bougie and apply cricoid pressure during a rapid sequence induction.
METHODS. We ran a month of concentrated airway training named 'Janu-airway,' using a trolley with airway training equipment on the top and pot of tea on the bottom. A trainer and the trolley travelled around the ICU, providing 10-15 minute teaching sessions for ICU staff at the bedside during their normal working shifts (both day and night shifts.) Cricoid pressure application was practiced and its effect on the view at laryngoscopy was demonstrated using a manikin and a C-MAC[TM] videolaryngoscope (Karl Storz GmbH, Tuttlingen, Germany), and assisting intubation using a bougie was practised. Posters were distributed via email/closed social media groups, and handouts were given to participants to facilitate reflective learning. Feedback was collected with staff self-rating confidence before/after training using a five point Likert scale, followed by a cup of tea!
RESULTS. 81 members of staff received training: 18 senior nurses, 43 staff nurses, 11 junior doctors, 3 physiotherapists, 3 medical students, 1 outreach sister, 2 acute critical care practitioners (ACCPs). This included 100% of ICU nurses and junior doctors. Feedback forms were completed after 57/81 (72%) of training sessions. Results as

follows: increase in confidence by one point or more on the Likert scale reported for both cricoid pressure (48/58, 83%) and the use of a bougie (49/58, 84%) (figure 1); improvement in the ability to assist with intubation reported by all participants- 56/58 (97%) strongly agreed, 2/58 (3%) agreed; similar training in the future was requested by all participants- 47/58 (81%) strongly agreed, 11/58 (19%) agreed.
CONCLUSIONS Our 'Bath tea trolley' training programme provided effective, practical and non-threatening multidisciplinary airway training in the workplace. Training was provided to 100% of our ICU staff - during their usual shifts and for minimal cost. It was quick and easy to set up, flexible and fun! This training method could be transferable and reproducible in other ICUs.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0894

INTRODUCTION. Oesophagectomy is a major oncological surgical procedure, associated with significant morbidity and mortality. Tracheostomy insertion is sometimes necessary to enable liberation from mechanical ventilation. This can be performed either at the end of the operation (electively), or post-operatively (delayed). Currently, the decision to insert a tracheostomy in our institution is based on clinician judgement. Prior studies have shown patients requiring a tracheostomy had longer lengths of stay, more days ventilated and more critical care unit complications.[1]
OBJECTIVES. Our aim was to determine which pre and intraoperative factors are associated with the need for tracheostomy in our institution. We also aimed to compare the outcomes in patients who did require a tracheostomy.
METHODS. We conducted a retrospective observational analysis of patients undergoing oesophagogastrectomies at the Royal Marsden over a 5-year period from September 2010 to December 2015.

RESULTS. A total of 157 patients underwent oesophagectomy. Of those 98 did not require tracheostomies, 36 had an elective tracheostomy and 23 a delayed tracheostomy. Patients who had an elective tracheostomy when compared to the no tracheostomy group had higher BMIs (Relative risk ratio (RRR) (95% CI) 1.12 (1.03-1.21) p< 0.01), were more likely to be ex or current smokers (RRR 10.8 (2.42-48.17) p< 0.01) and RRR 20.0 (3.42-116.8) p< 0.01 respectively), had higher ASA scores (ASA 1/2 versus 3/4 RRR 6.64 (2.86-15.40) p< 0.001), were more likely to have had a 3 stage procedure (RRR 15.63 (1.76-138.9) p< 0.05) had a lower anaeorobic threshold (RRR 0.78 (0.64-0.96) p =< 0.05) and VO_2 max (RRR 0.86 (0.75-0.97) p< 0.05), and had longer surgery (RRR 1.01 (1.01 - 1.02) p< 0.001). Patients who required a delayed tracheostomy had higher BMIs (RRR 1.15 (1.05-1.27) p< 0.01) and longer duration of surgery (RRR 1.01 (1.00 - 1.01) p< 0.05) than those who did not require a tracheostomy.

Patients who did not require a tracheostomy had a median ICU stay of 6 days (interquartile range [IQR] 5-8). Patients who had an elective tracheostomy had a median stay of 10 days (IQR 8-14) and those with delayed tracheostomy of 19 days (IQR 14-27); p< 0.001. This trend was mirrored by VAP rates, hours of ventilation and length of hospital stay (p< 0.05). No significant difference was seen in mortality rates.

CONCLUSIONS. This study shows patients undergoing an elective tracheostomy in our institution were more likely to have higher BMIs, to have smoked, to have had longer and more complex surgery and had a lower anaerobic threshold and VO_2 max. The need for a delayed tracheostomy was associated with higher BMIs and longer duration of surgery. Prospective randomised studies are required to further analyse the benefits of elective versus delayed tracheostomy for oesophagectomy.

Endotracheal tubes with polyurethane cuffs and subglotic aspiration port - what's the evidence?

R. Knafelj[1], P. Radsel[1], M. Fister[1], M. Noc[1], I. Lopatic[2], T. Flerin Poropat[2]
[1]University Medical Center Ljubljana, MICU, Ljubljana, Slovenia;
[2]University Medical Center Ljubljana, Radiology, Ljubljana, Slovenia
Correspondence: R. Knafelj

INTRODUCTION. Oral care plays important part of ventilatory associated pneumonia (VAP) prevention bundle. Tt is performed multiple times (>3 times) a day in all intubated/tracheotomized patients and requires endotracheal tube (ET) repositioning within oral cavity. Longitudinal and lateral ET movements are present during oral care which pose risk for micro aspiration.

OBJECTIVES. To determine whether polyurethane cuffed endotracheal tube with subglotic port (sCET) and intermittent subglotic aspiration reduces aspiration compared to polyurethane cuffed endotracheal tube without subglotic port (CET) and manual aspiration.

METHODS. 20 porcine necks purchased at local butcher were intubated with sCET (Halyard Microcuff, n=10) or with CET (Parker ThinCuff, n=10) cuffs were inflated to 25 cm H2O. 5 mL of iodine based contrast media was instilled in trachea over cuffs mimicking oral secretions. Porcine necks were positioned in 30 degree elevated position simulating patient in ICU environment. During 24h aspiration with aspiration catheter (CET) or designated port (sCET) was performed every 8h and and tube manipulaion simulating oral care was performed. After first (1h) and forth (24h) endotracheal tube manipulation, CT was performed and 3D reconstruction were obtained. Images were analyzed by radiologist who was blinded for tube types or designs (1). Leakage was scored as none (no contrast pass), minimal (contrast only coating/visible in cuff micro-folds), moderate (traces of contrast passing the cuff), substantial (contrast clearly visible distal to cuff in trachea).

RESULTS. After first ET manipulation no contrast was visible passing the cuff in all of the sCETs (Figure 1 A) and minimal contrast passing was visible in 3 CETs (Figure 1 C). After 24h no contrast pass was demonstrated in 2 and minimal pass in 8 sCETs (Figure 1 B). Minimal contrast pass was demonstrated in 1 CETs and moderate in 9 CETs (Figure 1 D).

CONCLUSIONS. Polyurethane cuffed sCETs provide superior seal and potentially ensure better prevention from microaspiration compared to polyurethane CETs. Further clinical studies are warranted.

The bedhead EndoTracheal tube airway information (BETTA-In) project

E. Davies, A. Sills, B. Covas, D. Atkinson
Manchester Royal Infirmary, Department of Critical Care, Manchester, United Kingdom
Correspondence: E. Davies

INTRODUCTION. Airway emergencies contribute to significant morbidity and mortality on the intensive care unit (ICU), as explored by the 4th National Audit Project of The Royal College of Anaesthetists (NAP_4). There was an apparent failure to identify ICU patients who had high-risk airways.[1] Bedhead signs have been introduced to provide easy access to airway information. They provide a reference point for assessment and have the potential to save time in emergencies. Tracheostomy and laryngectomy signs have had widespread success in the United Kingdom due to the National Tracheostomy Safety Project.[2] Signs detailing other airway variances or devices have been introduced. NAP_4 recommended that "patients at risk of airway events should be identified and clearly identifiable to those caring for them".[1] The Greater Manchester Critical Care & Major Trauma Services Network also recommends that signs record any intubation difficulties.[3]

OBJECTIVES. The aim of this project was to improve compliance with use of a bedhead endotracheal tube (ETT) sign on our ICU.

METHODS. A standard was set: 100% patients with an ETT in situ on ICU should have a bedhead airway information sign. A quality improvement project was carried out at Manchester Royal Infirmary from 2017 to 2018. In each study period, all intubated patients on ICU were identified at the start of a day shift for 5 consecutive days. The presence or lack of an airway sign was noted. Percentage compliance was calculated. Interventions were made between study periods. Following presentation at the departmental audit meeting and feedback throughout the project, the sign was redesigned by the authors. (Figure 1)

RESULTS. Baseline compliance was 8%. Following interventions, this was increased and maintained despite changeover of staff and stopping intervention. The project has yet to meet the standard. (Figure 2)

CONCLUSIONS. The identification of patients at risk of adverse airway events and subsequent display of information are crucial in preventing harm on the ICU. This project identified a need to improve compliance with bedhead airway information signs for intubated patients. Interventions improved compliance. The project is ongoing but a cultural change has already been shown. The authors would support the use of this sign's design on other ICUs.

Surgical tracheostomy performed by a dedicated ENT surgeon in a Tunisian medical intensive care unit: early and late complications in an outcome study

W. Zarrougui[1], R. Ben Dabebiss[1], G. Sboui[1], R. Atig[1], O. Beji[1], R. Mani[2], H. Hmouda[1]
[1]Sahloul University Hospital, Medical Intensive Care Unit, Sousse, Tunisia; [2]Sahloul University Hospital, Maxillo-Facial Surgery Department, Sousse, Tunisia
Correspondence: W. Zarrougui

INTRODUCTION. Surgical tracheostomy (ST) and percutaneous dilatational tracheostomy are commonly performed in most Tunisian intensive care units by the intensivist. Both techniques are usually safe, but early and late lifethreatening complications have been described with both strategies. The availability of an experienced and dedicated ENT surgeon may reduce early and late complications, in addition to close follow-up until removal of the tracheostomy canula, and tracheoscopy.

OBJECTIVES. To assess early and late complications of tracheostomy, in addition to long term outcome of ST performed by a dedicated ENT surgeon in the operating room on patients admitted to the medical intensive care unit (MICU) in a Tunisian university hospital.

METHODS. A retrospective study was performed in the MICU between January 2011 and February 2018.Were included all patients who required tracheostomy for prolonged ventilator support, airway protection, pulmonary toilette, or facilitation of weaning from the ventilator.

All tracheostomies were performed by a dedicated ENT surgeon in the operating room, using the standard technique, and follow up was ensured by the same ENT surgeon during ICU stay, and after discharge for patients who required home ventilation or airway management.

The study collected clinical features at admission, reason for admission, severity of illness, ICU course, and acute management procedures. Duration of tracheal intubation, oxygenation parameters, per and post interventional complications were recorded.

RESULTS. A total of 33 patients were included: 20 male (61%) and 13 female (39%), with a mean age of 54.2 ±18.1 years (range15 to 79 years). Mean Charlson index was 2.6±2 and mean SAPSII at admission was 46.5±12.5. Twenty nine patients (87.8%) received invasive mechanical ventilation as a first line ventilator support, 18 (56.4%) required vasopressors. All the patients had ST. The indication for tracheostomy was weaning difficulty in 16 patients (48.5%) and prolonged intubation in 13 patients (39.4 %). The mean time from tracheal intubation to tracheostomy was 14.9±10.4days.There were no serious perioperative complications. There was no death related to tracheostomy. Postoperative minor complications occurred in only 4 patients (12.1%). They included secondary wound hemorrhage in 2 cases, and air leak attributed to tracheomalacia in the 2 others. Tracheostomy tube was removed in only 1 patient during ICU stay. Twenty patients (60.6%) were discharged alive, among them 12 patients required home ventilation.The mortality rate at one year was 36.3% and 3 patients (15.7%) were successfully decannulated.

CONCLUSION. The rate of early and late complications was extremely low when tracheostomy was performed by a dedicated ENT surgeon. These findings will aid in the development of protocols and pathways for airway management in critically ill patients to maximize cost-effective, high-quality care and ensure acceptable risk/benefit ratio of the procedure.

Tracheostomy in a Tunisian medical ICU: practices and outcomes

H. Zorgati[1], A. Azouzi[1], M.A. Boujelbèn[1], D. Ben Braiek[1], N. Fraj[1], S. Kortli[1], A. Khedher[1], I. Ben Saida[1], K. Meddeb[1], M. Boussarsar[1,2]
[1]Farhat Hached University Hospital, Medical Intensive Care Unit, Sousse, Tunisia; [2]Ibn Al Jazzar Faculty of Medicine, Research Laboratory N° LR12SP09 Heart Failure, Sousse, Tunisia
Correspondence: M. Boussarsar

INTRODUCTION. Tracheostomy in the intensive care has many advantages when prolonged ventilation is required. It reduces sedation needs, promotes oral and pharyngeal hygiene, improves patient comfort, offers tracheal stability, decreases incidence of ventilator acquired pneumonia. However, as any procedure, it is not free from risks and complications can be observed.

OBJECTIVES. To describe state of tracheostomy practice and outcomes in a Tunisian medical ICU.

METHODS. A retrospective descriptive study was carried out in a 9-beds medical ICU at teaching hospital of Farhat Hached Sousse Tunisia, from January 2015 to December 2017.

In this survey were compiled the underlying diseases, diagnostic at admission, SAPSII, indication,timing and technique of tracheostomy, length of stay and the various complications (early and late). Outcomes were assessed by in-hospital mortality rate and at the first year and potential decannulation.

RESULTS. 717 patients were admitted in the ICU within the study period, 522 were mechanically ventilated. Tracheostomy was performed in 76(14.5%) patients among them 42.1% were COPD GOLD D. Median age was 63.5[53.2-73.7]years, 53(69.7%) male and SAPSII at 33±12. Bedside surgical technique was used in 99.1%. Most tracheostomies were performed during the second week, 37(48.7%), with mean delay at 11.46.8 days, 11(14.5%) in the first, 16(21.1%) in the third and 7(9.2%) in the fourth week. The median length of stay was 26[19-36]days. Overall, 19 complications were reported including 2 cardio-respiratory arrests, 2 pneumothoraces, 4 local infections, 7 problems were related to cannula (displacement, 3 and decannulation, 2). 13(17%) patients were decannulated during their hospitalization and 7(9.2%) after ICU discharge. 24(51.1%) patients were released with a home mechanical ventilator. 12(25.5%) patients had full autonomy. 14(18.4%) patients were lost to follow up. 29(38.2%) patients died during their hospitalization. The mortality rate after discharge was 66.7% among them 51.5% died in the first year.

CONCLUSIONS. The present study demonstrated a frequent use of tracheostomy in severe COPD patients but with a relatively late delay and rather poor outcomes.

Percutaneous tracheostomy can be safely performed without bronchoscopic guidance

S. Appavu

University of Illinois College of Medicine, Surgery, Rockford IL, United States

INTRODUCTION. Published articles increasingly recommend bronchoscopic guidance (BG) for percutaneous tracheostomy (PT) in the critically ill. However, BG is not without clinical, technical and logistical problems including hypercarbia and respiratory acidosis. In most patients, PT can be performed without BG both at the bedside (BS) and in the operating room (OR).

OBJECTIVE(S). To confirm the feasibility and safety of PT without BG both at BS and in the OR.

METHODS. We retrospectively reviewed PTs performed between January 1, 2015 and December 31, 2017 by a single experienced critical care surgeon. When PT was the only procedure, it was done at BS; when another procedure such as a feeding access was needed, then it was done in the OR. Chiaglia single pass dilator kits and Bivona silastic tracheostomy tubes were used in all procedures. An experienced anesthesiologist managed the sedation and the airway. Briefly, the procedure itself consisted of 4 essential steps: 1. Needle puncture of trachea and guidewire passage, 2. Advancement of a short tracheal dilator, 3. Single pass of "Blue Rhino" dilator and 4. Passage of the tracheostomy tube. Data collection included demographics, primary diagnosis, physical location of the procedure and duration, complications and final outcome.

RESULTS. We had 46 patients; 22 males and 24 females aged 21 to 88 years; 13 of the 46 (28%) had had an acute neurologic event such as intracranial hemorrhage or stroke. The remaining patients had acute respiratory failure from various causes including pneumonia,

ARDS, acute pancreatitis and sepsis. Fourteen PTs were done at BS and 32 in the OR. The mean procedure duration from incision to insertion of the tracheostomy tube and confirming with EtCO2 was 6 minutes. There were 3 complications (6.7%): 2 pneumothoraces, both from a longer tube entering the right main stem bronchus in patient with severe kypho-scoliosis or very short stature. They were immediately identified and treated with chest tube. One patient had mediastinal emphysema due to the dilator slipping out of the trachea and entering the superior mediastinum; it did not require specific therapy. There was no procedure related death. Thirty-five were discharged to chronic ventilator care facility, four went home and five went on hospice or comfort care due to worsening primary critical illness. One patient died of sudden cardiac arrest from an unrelated cause 14 days later. Another 4-week pregnant suicide victim with brain death was taken off life support after planned Caesarian section at 25 weeks.

CONCLUSIONS. PT can be performed at BS or in the OR without mortality, with acceptable complication rate.

The use of high flow nasal cannula oxygen outside the intensive care unit

S. Zemach, M. Shitrit, P. Levin

Shaare Zedek Medical Center, Jerusalem, Israel

Correspondence: P. Levin

INTRODUCTION. The use of High Flow Nasal Cannula Oxygenation (HFNCO) therapy for non-invasive respiratory support in the ICU is evidence based and routine. Due to ease of application and clinical success, non-evidence based use of HFNCO has spread to non-ICU wards. ICU physicians may be consulted regarding the advisability of therapy in the non-ICU environment.

OBJECTIVES. To describe the use and outcomes of HFNCO outside the ICU.

Methods - An observational study of the use of HFNCO as prescribed by non-ICU physicians in non-ICU areas for patients with respiratory failure who had failed prior non-invasive oxygenation support. Primary outcome measures included changes in patients´ respiratory distress (measured using a visual analog scale (VAS)), and changes in pulse, blood pressure, respiratory rate and blood oxygen saturation before and 30 minutes after initiation of HFNCO treatment. Secondary outcomes included early (< 72hours after starting therapy) and late (>=72 hours) mortality, and a composite measure of mortality, ICU admission and intubation.

RESULTS. Data were collected on 111 patients over 20 months. Overall, 90/111 patients (81%) reported decreased respiratory distress (VAS score before vs after HFNCO therapy 7.3±2.1 vs 4.7±2.1, P< 0.001). Pulse (97.4±22.5 vs 93.2±19.6 beats per minute, p=0.002) and respiratory rate (31±10 vs 26±7 breaths per minute, p=0.001) also decreased while saturation increased (84±12% vs 94±56%, p< 0.001) with HFNCO therapy.

Secondary outcomes: Of the 111 subjects treated with HFNC, 55 (50%) died, 24/111 (22%) within 72 hours of beginning HFNC, and 31/111 (28%) later. However, 41/111 (33%) patients had a DNR order (of whom 38/41, 93% died). Amongst the 70 patients without a DNR order, overall mortality was 18/70 (26%) [early mortality < 72 hours 9/70 (13%), late mortality 12/70 (17%)]. Overall 35/70 (50%) patients without a DNR order met the composite outcome measure for successful treatment (no ICU admission, no intubation and survival to hospital discharge).

On multivariate analysis increased severity of respiratory distress (pre-HFNCO VAS score OR 1.75 95%CI 1.35-2.28, p< 0.001) and a past medical history of respiratory disease (OR 3.52 95%CI 1.27-9.72,

p=0.01) were significant predictors of improvement in respiratory distress with HFNCO.

CONCLUSIONS. HFNCO treatment outside the ICU was associated with improved VAS scores and physiological parameters. HFNCO was used in many patients who had a DNR order, suggesting that it's use may have been palliative. Early mortality (directly associated with HFNCO therapy) in non-DNR patients was considerable (13%) and warrants caution in the widespread application of this therapy outside the ICU.

INTRODUCTION. Overall, the use of noninvasive positive pressure ventilation (NPPV) for acute respiratory failure (ARF) in critically ill patients is associated with improved clinical outcomes as compared with invasive mechanical ventilation. However, multiple studies have indicated that patients failing NPPV have worse outcomes compared with patients with successful NPPV treatment, and limited data is available on timing associated with NPPV failure and outcomes. The aim of this study is to evaluate the risk of mortality according to the timing between start and failure of NPPV in ARF patients.

METHODS. An international, observational, multicenter non interventional study was carried out. We included consecutive adult critically ill patients admitted in the intensive care unit (ICU) due to ARF and subjected to any attempt of NPPV as first ventilatory support between Abril 1st 2016 to May 31st 2016. NPPV failure was defined as the need for intubation after a trial of NPPV. Primary outcome was ICU mortality. Statistical analysis: The risk of mortality was evaluated by a propensity score analysis, and patients were classified as: successful NPPV attempt (as reference category); early failure as NPPV failure during the first 24 hours; late failure as NPPV failure after 24 hours from the initiation of NPPV. Adjusted odds ratios (OR) and 95% confidence interval (CI) were assessed.

RESULTS. Overall, a total of 1,228 patients were included and NPPV failure was observed in 374 (30.7%) patients. Early failure occurred in 182/374(48.7%) patients, and late failure occurred in 192/374 (51.3%) patients. After performing propensity score analysis, late NPPV failure was associated significantly with higher ICU mortality compared with early NPPV failure (Odds Ratio (OR) 2.4, 95% CI 1.4 to 4.2, p=0.002). Regardless the reason to start NPPV, the risk of ICU mortality

remained significantly higher compared with successful NPPV (see table). The risks were higher when failure occurred after 24 h from the initiation of NPPV.

CONCLUSIONS. Timing of failure of NPPV and delayed intubation longer than 24 hours is associated with higher ICU mortality, independently of the reason of ARF.

Table 1 (abstract 0901). Risk of ICU mortality in patients failing NPPV, adjusted by IPTW analysis. Successful NPPV is used as variable of reference

	Early failure NPPV (N=182)	Early failure NPPV (N=182)	Late failure NPPV (N=192)	Late failure NPPV (N=192)

Non-invasive ventilation for very old patients: 5-year experience from a tertiary care center

M. Esteves Brandão[1], S. Xavier Pires[2], A.P. Dias[3], N. Barros[3], F. Esteves[3]
[1]Centro Hospitalar de Trás-os-Montes e Alto Douro, Respiratory Medicine, Lordelo, Vila Real, Portugal; [2]Hospital da Senhora da Oliveira, Guimarães EPE, Internal Medicine, Guimarães, Portugal; [3]Centro Hospitalar de Trás-os-Montes e Alto Douro, Intensive Care Medicine, Vila Real, Portugal
Correspondence: M. Esteves Brandão
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0902

INTRODUCTION. Due to ageing of the general population, the proportion of very old patients admitted to hospital and to intensive care is rapidly growing.Whereas non-invasive ventilation (NIV) is an attractive technique for the management of acute respiratory failure (ARF) in very old persons, specific data for this population are limited[1].

OBJECTIVES. To identify conditions in which NIV is applied to very old patients in the intensive care unit (ICU) and to assess whether its efficacy is similar to younger patients.

METHODS. Retrospective cohort of all patients admitted to the ICU of a tertiary hospital during a 5-year period and managed using NIV.-Demographic characteristics, context of NIV, severity of illness, duration of mechanical ventilation, intubation rate, ICU length-of-stay (ICU-LOS), hospital length-of-stay (hospital-LOS), ICU and hospital mortality rates were compared for very old (age≥80 years) and younger patients.Logistic regression was performed to identify predictors of NIV failure (defined as need for endotracheal intubation or death) in the very old population.

RESULTS. During the study period, 810 adult patients received NIV as first-line therapy for treatment of ARF, of which 162 (20.2%) were older than 80 years of age.The most frequent cause of ARF in very old group was pneumonia (19.8%), followed by post-operative respiratory failure (18.5%).Exacerbation of COPD and cardiogenic pulmonary oedema were less frequent admitting diagnosis (13% and 8% of patients, respectively). Forty nine very old patients (30.2%) received NIV in the context of a do-not-intubate order.At ICU admission, compared with younger patients, very old patients were more severely ill as expressed by higher APACHE II, SAPS II and SAPS 3 scores (p< 0.001).NIV failure rates did not differ between the two groups (51.2% vs 54.5%).In multivariate analysis, only SAPS II score independently predicted NIV failure in the very old patient population

(p=0.01,OR 1.076,95% CI 1.02-1.14). Very old patients had a significantly higher ICU (23.5% vs 13.9%,p=0.003) and hospital mortality rates (35.8% vs 21.1%,p=0.001) and a lower intubation rate (38.3% vs 48.8%,p=0.018) than younger patients.However, ICU and hospital mortality rates were similar in the two groups when NIV was applied for exacerbation of COPD.

CONCLUSIONS. Very old patients represented 20% of all patients managed with NIV in our ICU. NIV failure rates were similar between very old and younger patients.SAPS II score at admission was an independent predictor of NIV failure in the very old population.Very old patients showed increased in-ICU mortality when compared to the younger group. Importantly, in-ICU and hospital survival rates of very old were comparable to the younger group when NIV was applied in a "gold" clinical indication like COPD exacerbation.

Cost-minimization analysis of Non-invasive and Invasive mechanical ventilation for de novo acute hypoxemic respiratory failure in an Eastern European setting

V. Ilieva[1], T. Mihalova[2], Y. Yamakova[1], R. Petkov[2], B. Velev[2]
[1]Medical University Sofia, Anesthesiology and Intensive Care, Sofia, Bulgaria; [2]Medical University Sofia, Pulmonology, Sofia, Bulgaria
Correspondence: V. Ilieva
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0903

INTRODUCTION. Non-invasive ventilation (NIV) is now a standard of care worldwide for hypercapnic acute respiratory failure (ARF) but the results regarding hypoxemic ARF are inconclusive. In the official ERS/ATS clinical practice guidelines[1] the task force does not make any recommendation on the use of NIV for de novo hypoxemic ARF. On the basis of uncertainty about the superiority of Invasive mechanical ventilation (IMV) over NIV in this setting we made a cost-minimization analysis comparing both methods in a single National Center for Pulmonary Diseases in Bulgaria.
OBJECTIVES. The main objective of our study is to estimate the direct medical costs generated by a patient on IMV and NIV during their ICU stay. Other objectives are to identify which aspect of the treatment is most expensive.
METHODS. A total of 36 patients, separated in two groups - NIV (n=18) and IMV (n=18), with de novo hypoxemic ARF were included in our study. We calculated the direct medical costs and compared them. Costs for human resources, capital equipment, and overheads were not included. All calculations were made in Euro based on the price list for 2018 used in University Hospital of Pulmonary Diseases, Sofia, Bulgaria. Statistical processing was done with the programming package R.
RESULTS. On admission the PaO_2/FiO_2 (135.02 ± 32.44 vs. 127.5 ± 23.73, p=0.07), respiratory rate (31.44 ± 6.11 vs. 29.55 ± 3.9, p=0.92) and SAPS II score (37.9 ± 18.47 vs. 30.9 ± 10.34, p=0.06) were comparable in both groups.
We observed a statistically significant difference in the overall costs per patient for pharmacy (NIV=10410.45 ± 1346.96, IMV=29015.61 ± 2788.88, p=0.01), consumables (NIV=45.26 ± 5.86, IMV=72.94 ± 7.01, p=0.05) and diagnostic tools (NIV=6514.05 ± 475.98, IMV=16417 ± 1160.58, p=0.019). When all costs were summed the difference became even bigger (NIV=17304.45 ± 861.91, IMV=47400.9 ± 1874.10, p< 0.001).
We also computed the costs per patient per day and there was a significant difference in the costs for pharmacy (NIV=45.26 ± 5.86, IMV=72.94 ± 7.01, p=0.05) and consumables (NIV=1.65 ± 0.12, IMV=4.95 ± 0.34, p=0.003) but not in the diagnostic tools (NIV=28.32 ± 2.07, IMV=41.27 ± 2.91, p=0.09). Summed together the costs per patient per day were worth NIV=75.24 ± 3.75, IMV=119.16 ± 4.71, p=0.03.
The large standard deviations observed in some of the calculations are due to some big price differences in Bulgaria.

CONCLUSIONS. In the setting of de novo hypoxemic ARF NIV reduces significantly the overall costs of treatment in comparison to IMV. The decreased costs in NIV are not associated with severity of disease according to the respiratory quotient and SAPS II score.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0904

INTRODUCTION. Acute respiratory failure (ARF) due to pneumonia represents a serious clinical problem, with high mortality rate and frequent ICU admissions. Oxygenation modalities (OM) such as Continuous Positive Airway Pressure (C-PAP) and High-Flow Oxygen through Nasal Cannula (HFO) could be useful in those cases, preventing endotracheal intubation (ETI) and reducing mortality[1,2]. No study has ever compared helmet C-PAP and HFO in adult patients with hypoxemic ARF.
OBJECTIVES. We compared HFO and helmet C-PAP in patients with moderate hypoxemic ARF sustained by pneumonia.
METHODS. We performed a retrospective analysis, reviewing all patients with pneumonia and moderate hypoxemic ARF, admitted to our Intermediate Care Unit (IMCU) from June 2016 to December 2017 (18 months). The inclusion criteria were age ≥18 years old, pneumonia (community acquired or hospital acquired) with moderate hypoxemic ARF (PaO2/FiO2 100-200 mmHg) at admission, oxygenated by HFO or helmet C-PAP (stand-alone system) for 2 consecutive days at least. Exclusion criteria were history of chronic obstructive pulmonary disorder (COPD) or other chronic respiratory disorders; lung cancer; acute cardiogenic edema; severe neutropenia; circulatory failure. We analyzed two groups (C-PAP and HFO) matched for age, SAPS2 score, SOFA score and PaO2/FiO2 ratio before OM. We also collected demographic characteristics, comorbidities and we investigated rates of ETI, IMCU mortality and mortality at 90 days.
RESULTS. We review 38 patients: 20 in HFO group and 18 in CPAP group. Demographic characteristics are shown in Table 1. The two groups were well matched (PaO2/FiO2 ratio before OM p = 0.7; SAPS 2 score p = 0,3; SOFA score p = 0,3; age = 0.07; see Table 2). We found no significant difference in ETI rate [HFO 2/20 (10%), CPAP 3/18 (17%)], IMCU mortality [HFO 2/20 (10%); CPAP 3/18 (17%)] and mortality at 90 days [HFO 3/18 (17%); CPAP 2/15(13%)] between the two groups (see Figures). ARDS patients was mainly treated by helmet CPAP (13/17) so that we corrected this confounding factor and we found no significant difference in ETI rate (p = 0.94) and IMCU mortality (p = 0.94) between the two groups.
CONCLUSIONS. In patients with moderate hypoxemic respiratory failure due to pneumonia, treatment with helmet C-PAP or HFO did not result in significantly different ETI and mortality rates.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0905

INTRODUCTION. Acute respiratory distress syndrome (ARDS) is a life-threatening form of respiratory failure that accounts for 10% of intensive care admissions[1].The role of non-invasive ventilation (NIV) in treatment of ARDS is still controversial,mostly due to the concern about the association between NIV failure,delayed intubation and consequently increased mortality.
OBJECTIVES. To describe the current practice and efficacy of NIV use in ARDS patients admitted to an intensive care unit (ICU) of a tertiary hospital.
METHODS. Retrospective analysis of all patients with ARDS admitted to our ICU between 2010 and 2015 and primarily managed with NIV.Patient's demographics, cause of ARDS,severity of illness,duration of mechanical ventilation,intubation rate,ICU length-of-stay (ICU-LOS),hospital length-of-stay (hospital-LOS),and mortality rate were recorded. Logistic regression was performed to identify predictors of NIV failure (defined as need for endotracheal intubation or death).
RESULTS. During the study period,NIV was used in 332 patients with ARDS:36.1% mild,43.1% moderate and 20.8% severe,according to Berlin definition.The mean age of study population was 64 ± 15 years and 207 (62.3%) were male.Pneumonia (43.7%) followed by post-operative respiratory failure (19%) were the most common causes of ARDS.Sepsis was present in up to 90% of patients at ARDS onset.Baseline mean PaO2/FiO2 ratio was 179 ± 107 mmHg and mean APACHE II was 21 ± 8.NIV was successful in 31% of patients, while 63.9% required endotracheal intubation.Prone positioning was used in 32 patients (9.6%).In-ICU and hospital mortality rates were 14.5% and 19.9%,respectively.Similar survival rates were observed between patients who improved with NIV and those patients who required invasive mechanical ventilation (80.5%vs75.7%). Patients with mild-to-moderate ARDS were less likely to fail NIV (66.2%vs79.7%;p=0.03) and showed significantly lower in-ICU (11.4%vs26.1%;p=0.04) and hospital mortality (17.4%vs30.4%;p=0.049) when compared to severe ARDS patients. Baseline APACHE II (p< 0.001;OR 0.89,95%CI 0.83-0.95), SAPS II (p< 0.001;OR 1.08,95%CI 1.04-1.12) and SOFA scores (p< 0.001;OR 1.22,95%CI 1.08-1.37),lactate elevation at 24h of ICU admission (p=0.045; OR 1.5, 95% CI 1-2.2) and nosocomial infection (p< 0.001;OR 3.3, 95%CI 1.7-6.2) were independent predictors of NIV failure.
CONCLUSIONS. In our cohort, the use of NIV helped in avoiding intubation in about 31% of patients with ARDS.Outcomes were significantly better in mild-to-moderate ARDS. Severe systemic illness as reflected by higher disease severity scores (APACHE II, SAPS II and SOFA) and nosocomial infection appear to have an important role on NIV failure. The use of NIV did not delayed endotracheal intubation in those who failed to respond, as demonstrated in a survival rate comparable to the NIV success group.

Ethical framework of the integration of palliative care in intensive care: results from a qualitative study with professionals

S.M. Pereira[1,2], C.M. Teixeira[3,4,5], P. Hernández-Marrero[1,2], A.S. Carvalho[1,2]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0906

INTRODUCTION. The integration of palliative care (PC) in intensive care (IC) can be framed ethically as it fosters the integration of PC ethical core principles (i.e., autonomy, beneficence, non-maleficence, justice, dignity, integrity, vulnerability, solidarity) in IC. Although several initiatives have been described worldwide on the organizational integration of PC in IC, very little is framed using an ethical perspective or approach.

OBJECTIVES. To ethically frame and understand the integration of PC in IC considering healthcare professionals' perspectives.

METHODS. Qualitative exploratory study, using in-depth interviews. Participants were healthcare professionals (physicians, nurses, psychologists, physiotherapists, social workers) working in Portuguese PC and IC units. These professionals were gathered using a purposive sampling procedure complemented with snowball sampling until reaching theoretical saturation. A total of 22 professionals (11 physicians, 9 nurses, and 3 other professionals) from various cities were interviewed.

RESULTS. In the participants' speech, the integration of PC in IC was considered to be a way of improving end of life care and decision-making processes. Once life-supportive measures were either withheld or withdrawn, professionals working in IC considered to implement a palliative care approach already. According to the professionals working in PC, an earlier and better integration of PC in IC was needed to prevent invasive interventions, disproportionate care and admissions in IC units. From an ethical perspective, these findings can be framed using the ethical principles of beneficence, non-maleficence, justice and dignity. Professionals working in PC also considered that the integration of PC in IC could promote patient autonomy, by allowing patients to be cared for and die in their place of choice. It was also recognised, by both professionals working in PC and IC, that patients in IC are particularly vulnerable. The integration of PC in IC could therefore protect them from any further harm and futile interventions. While professionals working in PC considered that the integration of PC and IC should be promoted via a mixed-organizational model, professionals from IC units mentioned that an educational model, empowering them with PC knowledge and competences, would suffice.

CONCLUSIONS. This is the first empirical study addressing the integration of PC in IC in Portugal. It adds to the already existing evidence by embracing and developing an ethical framework. Professionals working in IC and PC seem to have different perspectives on how the integration model should be. Findings show the potential for a successful integration, which is aligned with core ethical principles. More research is needed to implement and study the impact of an effective, sustainable and ethically sound integration model.

Correspondence: P.K. Routray
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0907

INTRODUCTION. India being a developing nation with limited financial resources amongst majority of the population, lack of insurance and limited critical care resources in government hospitals, most of sick patients were taken to corporate hospitals. Corporate Hospitals cater to majority of the sick patients, but a large subset after few days take their patient out of corporate hospitals due to mounting cost. But rarely these patients were followed up. It is a try from our side to understand the epidemiology of Discharge against Medical advice and their long term follow up of 3 months.

OBJECTIVES. To study whether the subset of patients who were discharged against medical advice succumbed to illness as soon as they were withdrawn from aggressive care as assumed or they have variability in their morbidity and mortality.

METHODS. Retrospective data of patients who were discharged against medical advice were collected from OCTOBER 2016 to DECEMBER 2017 in our hospital.

INCLUSION CRITERIA - Patients who were admitted in Medical ICU with in the period of OCTOBER 2016 to DECEMBER 2017 but were taken away from our hospital due to various reasons. All these patients were contacted through phone and after due permission they were asked a questionnaire with specific yes or no answer. Questionnaire was first tested bilingually both in English and Oriya (local language) and with volunteers.

EXCLUSION CRITERIA - All patients with cardiac arrest with CPR and who died within hospital premises while shifting were excluded.

RESULTS. Total 1170 patients were admitted. Out of which 115(9.8%) patients were discharged against medical advice and we could contact 105(8.9%) patients over phone.

85(80%)went for financial reasons

10 (9.5%)went away due to end of life care

10(9.5%) went away due to dissatisfaction over treatment.

77(73%) went with an ET tube in situ

74 (70%)went home

31 (29.5%) went to another hospital

Amongst all 59(56%)died within 6 hours of discharge and 22(20%)died within 24 hrs of discharge while 12(11%) died within 72 hrs of discharge. 5 patients survive for a 7 days and finally succumbed. But another 7(6.6%)patients survived for more than 90 days and out of which 5(4,7%) remained bed ridden 2(1.9%)patients attained their full functional recovery are on continuous follow up.

CONCLUSIONS. There has been a lot of debate regarding medical miscalculation regarding extubation and de-escalation in a tertiary care medical ICU and interestingly our majority of decisions were guided from guidelines from European or American studies. This study showed that 12 patients(11.4%) patients survived inspite of being taken home and drastic de-escalation from ventilator as well as other life supports.

This needs to be validated in large studies to find out whether we are overdoing the guidelines to keep ourself safe or a subset of patients should be given a trial of aggressive de-escalation before sending them home as discharged against medical advice.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0908

INTRODUCTION. Turkey´s elderly population has increased by 17 percent in the last five years. There are few palliative care and nursing home in Turkey. It is not legal to take end-of-life decision in Turkey, according to Turkish criminal law. Thus, there is a high ratio of terminal stage patients in ICUs in Turkey. The major faith tradition in Turkey is Islam.

OBJECTIVES. This study was performed to determine the views and perceptions of Turkish ICU physicians about end-of-life decisions.

METHODS. The Kocaeli University Ethical Committee and Review Board approved the study. An online survey was distributed through Survey Monkey,an online survey response collecting software. The survey was targeted toward ICU physicians practicing in Turkey. The survey consisted of 29 questions designed to assess demographics, training, religion, ICU facilities, bed capacity and ICU experience. In addition, the views of ICU physicians about end-of-life desicions (withdrawing, witholding or limiting life sustaining therapy) and the factors that may affect these decisions were determined. Statistical analyses were performed using SPSS version 20.0 (SPSS Inc, Chicago, Illinois).

RESULTS. A total of 607 physicians completed the online survey. While 92.2% of the ICU physicians expressed that it is necessary to make changes to allow do-not- resuscitate (DNR)orders in Turkish criminal law, 81.1 % of them stated that it is necessary to make changes to allow do-not-intubate (DNI) orders in Turkish criminal law. DNR and DNI acceptances were not changed by the physicians' age, sex, religious beliefs and ICU experience (p>0.05). 67.0 % of ICU physicians expressed that they would choose to forgo CPR and intubation /mechanical ventilation if they were dying of a terminal illness. While 81.3 % of the ICU physicians expressed that at least some of the life support treatment should be withhold in terminally ill patients, 8.7 % of them expressed that no any new treatment should be start in terminally ill patients. Similarly, 76.7 % of the ICU physicians expressed that at least some of life support treatment should be withdrawn in terminally ill patients and 21.8 % of them expressed that all of the life support treatment, except sedative and analgesic drugs, should be withdrawn.

CONCLUSIONS. It is necessary to make changes to allow end of life desicions in Turkish criminal law.

Correspondence: H.-T. Chang
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0909

INTRODUCTION. Evidence suggested the association of early palliative care for the terminal illness with lower medical cost, but few studies have examined the effectiveness of implementing early family meeting (EFM) for discussion about the decision to withdraw (DTW) life-sustaining treatments from end-of-life patients reduce medical costs in the intensive care unit (ICU) setting.

OBJECTIVES. To investigate the relationships of EFM, defined as a palliative family conference held within seven days after ICU admission, and DTW during ICU stay with health-care costs and relevant outcomes.

METHODS. We retrospectively analyzed the medical and administrative data of patients who died at the medical ICU of a medical center from 2012 to 2016. The documentation of family meeting was confirmed by the meeting record in the medical records and the relevant claim code the administrative data of the patients. DTW was documented by the meeting records. We first compared the patients with and without the DTW life-sustaining treatments regarding their costs, ICU stays, and outcomes. We then performed a propensity-score matching to compare the medical costs between the cases with and without (designated as controls) DTW and EFM.

RESULTS. A total of 579 patients, accounting for 16% of the medical ICU admissions, were included. Patients with DTW life-sustaining treatments had longer ICU stays than those without (12.9±7.1 days vs. 8.4±9.6 days, p < 0.001), and were more likely to have a ´do-not-resuscitate´ order (97.3% vs. 80.4%), more likely to have family meetings (89% vs. 16.2%, p < 0.001). The patients with DTW also had lower health-care costs (New Taiwan Dollars [NTD] 231,542±130,057 vs. 273,942 ± 301,293, p=0.038). Multivariate regression analysis showed that longer ICU stay (OR: 1.076, 95%CI: 1.045-1.108, p < 0.001), do-not-resuscitate status (OR: 6.08, 95%CI 1.365-26.88, p = 0.017), blood transfusion (OR: 4.407, 95%CI 2.339-8.305, p < 0.001), and early family meeting (OR: 3.425, 95%CI 1.873-6.262, p < 0.001) were associated with DTW. Comparison between cases and controls after propensity-score matching showed that the cost reduction associated with DTW was significant (NTD 109,545, 95%CI 28,903-190,187, p < 0.001), and EFM in the patients with DTW further reduced the cost (NTD 96,119, 95%CI 42,912-149,325, p=0.008).

CONCLUSIONS. An early family meeting followed by a decision to withdraw life-sustaining treatments significantly lowered costs during end-of-life management in the ICU. The results confirm the value of early palliative care, including family meetings to agree upon end-of-life management.

Prevalence, risk factors and clinical characteristics of burnout in critical care units from Colombia

S.M. Navarro Estrada, J.G. Franco, F.J. Molina Saldarriaga, J.D. Velásquez Tirado, C.A. Agudelo Vélez, M. Larios Gómez
Universidad Pontificia Bolivariana, Medellin, Colombia
Correspondence: S.M. Navarro Estrada
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0910

INTRODUCTION. According to Maslach, the definition of burnout involves 3 fields: emotional exhaustion, depersonalization and lack of personal fulfillment[1]. Most studies in intensive care have found that the prevalence of the disorder is around 25% (range 6% to 47%)[2].

OBJECTIVES. To describe the prevalence, risk factors and characteristics of professional exhaustion in professionals and technicians of intensive care units in Colombia

METHODS. A cross-sectional analytical observational study was conducted. The Spanish survey version of professors Gil-Monte and Peiró was used[3]. We interviewed professionals (doctors, nurses and other technicians) working in intensive care in Colombia, affiliated to the Colombian Association of Critical Care Medicine and Intensive Care (AMCI). We used both the dichotomous score (epidemiological

aspects and comparisons between groups) and continuous score (factorial analysis of the construct in the sample). We report risk analysis (bivariate and multivariate logistic) and factorial for depletion defined according to the *Maslach Burnout Inventory* (MBI)

RESULTS. 211 respondents were included. Of these, 62 (29.4%) have professional exhaustion. Being young (OR 0.93, 95% CI 0.899-0.979), having between 6 and 10 years of experience (OR 2.82, 95% CI: 1.283-6.216), being in charge of more than 10 patients per day (OR 3.31, 95% CI: 1.580-6.918), the perception of hostility of patients or companions (OR 2.96, 95% CI: 1.488-6.006) and the perception of having an anxious or depressive disorder (OR 2.87, 95% CI: 1.345-6.104) were related in a direct way with exhaustion in the multivariate analysis. Having some hobby was a protective factor against burnout (OR 0.44, 95% CI 0.209-0.923

CONCLUSIONS. The prevalence of burnout in intensive care in Colombia is high. The disorder is characterized by affective alterations and personal satisfaction in those who suffer it. It is necessary to implement detection strategies and interventions on psychological factors and the institutional setup since the early years of professional practice

Intensive care unit (ICU) nurses' death perception, end of life stress and end of life nursing attitudes

K. Sera, N. Mi jin, L. Soon Heang
Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of
Correspondence: K. Sera
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0911

INTRODUCTION. This study aimed to survey the death perception according to the general characteristics of ICU nurses and to analyze the problems of the current ICU related to end of life stress and end of life nursing.

METHODS. A descriptive research study design was used to confirm the contents of death perception, end of life stress and end of life attitude of nurses in ICU. Data were collected from a total of 16 general hospitals and 975 nurses in the intensive care unit were randomly selected to answer structured questionnaires. Data were analyzed using descriptive statistics, t-test, ANOVA, correlation analysis, and multiple regression analysis.

RESULTS. The death perception of ICU nurses was measured as 4.38 points. The attitude of end of life nursing was as follows: The higher age, marital status, proportion of faith in life, satisfaction, frequency of death and endurance education and longer duration of ICU work, The better recognition of death and attitude of end of life nursing. The average duration of nursing stress was 3.90. With the higher age, the smaller number of patients in charge, the more need for healing programs related to death or dying, the less demand for dying, and the lower of satisfaction for enduring nursing, the end-of line nursing stress was high.

CONCLUSION. The results of this study suggest that continuing research is necessary to develop guidelines for attitudes toward end of life nursing, education for end of life, and effects of practical application after the development of a nursing care bundle.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0912

INTRODUCTION. Life expectancy is strikingly increasing during the last decades. We are more and more faced with the difficult task of deciding a patient´s needs to be admitted to Intensive Care Units (ICU) and implementation of invasive techniques must be weighed.

OBJECTIVES. To compare elderly ($\geq$ 75 yr), and younger (r< 75yr) ICU patients in relation to ICU underlying diseases, treatment intensity, as well as ICU and in-hospital mortality.

METHODS. Observational retrospective study with a prospectively collected database carried out in a medical-surgical 30-bed ICU without coronary admissions. All patients admitted from January 2013 to December 2018 were included. We analysed demographic characteristics, severity of the illness at admission measured by Acute Physiology and Chronic Health Evaluation II (APACHE II) scale, invasive treatment, origin, reason for admission, length of stay and mortality in the ICU and hospital.

Qualitative variables are presented as the absolute numbers, whereas frequency and quantitative variables are presented as median (25th percentile to 75th percentile). Analysis was performed using chi-square or exact Fisher test for qualitative variables and Student t test or Mann-Whitney U test for quantitative variables when appropriate. P values of less than 0.05 were regarded as statistically significant.

RESULTS. 6,598 patients were analysed, 5,136 (75.84%) were < 75yr and 1,462 (22.16%) were $\geq$ 75 yr. The results are shown in the tables below.

CONCLUSIONS. In our series, elderly patients present more serious illness at the admission and more comorbidity, mainly DM, COPD and CKD. A higher mortality is found among the elderly patients during their ICU and hospital stay. Elderly patients receive less invasive treatments probably due to the limitation of therapeutic efforts.

Ethography in intensive care unit: the *'Emergent ICU Body'* and two models of care

I. Anastasiou[1,2]
[1]University of Durham, Medical Anthropology, Durham, United Kingdom; [2]Southampton University Hospital, Biomedical Research Centre (BRC), Southampton, United Kingdom

INTRODUCTION. The present study examines how caring and technology are interrelated in the Intensive Care Unit (ICU) setting. It is a qualitative study focused on the phenomenology of "lived experience" of the healthcare personnel intended to be an ethnography that "evokes", rather than "represents" the discursive practises generated in relation to the ICU technologies. In this setting the organic, the technical, and the cultural domains interrelate composing a reality not of individuals, objects, and subjects being autonomous things-in-themselves, but as **"things-in-phenomena"**.OBJECTIVES To explore how the patient, as "person-with-a-body", is perceived in the context of the Intensive Care Unit. To identify issues which indicate de-personification of the patients and/or objectification of the patients' body.
METHODS.
Research setting: Two public hospital ICUs in Greece
In-depth Interviews: 15 participants. The Modified Ethnographic Decision Modelling (EDM) **Fig.1** Combining the Ethnographic Research Cycle and Linear Hypothesis-Testing Plan.
Phenomenology: The theoretical background for data generation and analysis.
Grounded Theory: To construct a theory"grounded" on data **Fig.2** The techno-cultural domains' interactions that generated the data. ANALYSIS A core category was constructed embodying a phenomenon apparent in the interrelationships of all categories, *the functional intercoupling of patient-carer-technology.* The ill-person remains a *subject* for the caregivers mostly defined by the **synthetic -sub**, meaning under my control, my vigilance, and my acts. The ICU devices change the ill-person's physiology and anatomy (opening of non-pre-existed holes, eliminating the normal digestive system) creating **a transformed body,** also **a suspended personhood.** There is also the making of **subjected carers** as the fieldwork has revealed. In critical care, machines, persons, knowledge, tools even spaces are all entangled in "hybrid assemblages" both producing and produced by culture. I call this functional ICU amalgamation, the **Emergent ICU Body (EIB)** emerging through the inseparability of its three parts.The prevalent model of care in the two Greek ICUs is the **Authoritative Model of Care.** The technology is the *bridge*, between the caregiver and the patient. However, there is a different perspective to approach the same ICU "phenomena". I call it **Altruistic Model**, a kind of **Prosthetic Model** of critical *care*. K. Barad's quantum physics-based concept of *intra-acting parts of a phenomenon* renders the possibility for the phenomenological *EIB* to exist, embodying the agency of the patient regardless his/her de-personification.The altruistic *EIB* follows the "paradigm of relation" rather than the "paradigm of control".
CONCLUSIONS. The *Emergent ICU Body* efficiently arises in full functionality and *vitality*, whenever the Altruistic Model of Care is practiced. Whenever the Authoritative Model of Care is being chosen, the *EIB* will always be fragmented and inefficiently functioning.

Fig. 1 (abstract 0913). See text for description.

Fig. 2 (abstract 0913). See text for description.

Training increased the number of participants familiar with the national donation law (89.4%*vs99.3%,p< 0.001) and who considered it appropriate to incorporate donation into the end-of life care plan(92.2%*vs97.9% p< 0.001), making more of them favourable to ICU admission (89.4%*vs 95.2% p< 0.001) and to the use of the same resources as for any other critically ill patient(90.1%*vs 93.1% p=0.068) in those managed as possible donors once treatment has been deemed futile.

Education increased the knowledge of DCD legal regulation (70.9%*vs96.3% p< 0.001) and of the difference between controlled and uncontrolled DCD (62.2%*vs99.5%;p< 0.001). It also increased the positive attitude towards it(87%*vs95.9% p< 0.001), with more of them prone to ask about donation after LLST decision ((89.6%*vs98.3 p< 0.001) and to initiate pharmacologic(92.5%*vs97.9%) and invasive measures(91.2%*vs96.6%) to preserve the organs for donation before declaration of death, provided relatives have consented to DCD after LLST (p< 0.001).

Training improved perception of both DBD and DCD reflected by an increase in the number of positive adjectives (maximum of 5) selected by participants to describe such programs (4.7±0.6*vs 4.8±0.5 p< 0.001) and (3.4±1.5*vs3.8±1.3 p< 0.001) respectively.

CONCLUSIONS. Although medical staff showed high knowledge and positive attitude about end-of-life care and organ donation, the training program showed that is still room for improvement to eliminate misperceptions and improve attitude.

OBJECTIVES. To asses the impact of on-line training on perception and attitude of physicians on end-of-life care and the donation process.
METHODS. From 2015-2017 a national on-line training program on LLST, DBD and DCD was delivered to 857doctors from162 hospitals in Spain. Participants working in critical care settings(n=698) were asked to complete a survey on their perceptions and attitudes before* and after the educational intervention. Mcnemar´s test was used to compare paired nominal data. Significance p< 0.05, SPSSv21©.
RESULTS. 77.1% (n=538;133 hospitals) of the participants completed both surveys (36.8±8.5 years old,67.5% female). 67.1% were specialists and 32.9% were trainees of intensive care(86.2%) and anaesthesiology(13.8%). 65.8% had < 10 years of experience.
After the course, an increasing number of participants agreed on that LLST is a common practice (75.2%*vs87% p< 0.001) and that nursing staff should be more involved in the decision process(57.2%*vs 71.1% p< 0.001) . Training also increased the number of those who believed that the responsibility of the family should consist in understanding a medical decision (62.5%*vs91.9% p< 0.001).
Post-course more participants rated "withdrawal" and "withholding" as leagaly and ethically similar actions within LLST(70.7%*vs87.9%, p< 0,001). Training led to an increasing group of participants considering appropriate the use of pre-emptive sedation in all patients undergoing LLST (71.6%*vs 79.5% p< 0.001).

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0915

INTRODUCTION. Brain death is defined as the complete and irreversible cessation of the functionsof all intracranial neurological structures. The use of the transcranial doppler is based on its capacity for the detection of cerebral circulatory arrest, through the use of ultrasonography. In Spain, complementary tests are widely used in clinical practice and highly recommended since they allow to improve the diagnostic certainty in even shortening the stipulated observation periods.
OBJECTIVES. The main objective of this study was to establish how the use of the transcranial doppler could have influenced the optimization of the diagnostic times of brain death, if it was useful or, on the contrary, if it meant a delay in the diagnosis.
METHODS. It is an observational, descriptive cross-sectional study of patients with criteria for brain death. The study period covers 2012 to 2017 and was carried out in a polyvalent Intensive Care Unit with 24 beds at a third level University Hospital with Neurosurgery and accredited for the organ and tissue extraction by the Spanish National Transplant Organization. The sample was made up of patients in a brain death situation in our hospital during the study period.We studied demographic data, diagnostic methods used and time necessary to perform the diagnosis of brain death. The statistical package SPSS version 19 was used for the analysis. The quantitative variables were compared by Student´s T test and the qualitative variables by the X2 / Fisher´s test.
RESULTS. During the 7 years of study, 127 patients presented criteria for brain death. The mean age was 58,2 years, with a 67,7% of males. A 34,6% were foreign patients. The confirmatory test for the diagnosis of brain death was in 110 patients (86.12%) the transcranial doppler; in 9 patients a second clinical test of brain death; in 7 patients the EEG and in one patient the angio-CT. 84,3%

of patients were diagnosed of brain death within 6 hours.When the test used to confirm brain death was the transcranial doppler, the mean time to establish the diagnosis was significantly lower (0,5 (0,5 ; 2,0)) compared to the mean time when another diagnostic method was used (9,0 (6,0 ; 24,0)); p < 0.001. Table 1 show the results of the diagnostic methods and times needed for the confirmation of brain death.

CONCLUSIONS. In our environment the transcranial doppler was the most used diagnostic method and the one that allows faster diagnosis in all the circumstances studied.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0916

INTRODUCTION. Donor shortage together with the increase in organ demands have led to the development of different strategies aimed at raising organ retrieval rates. Amongst these strategies, the evaluation of expanded criteria donors has aroused as an alternative.

OBJECTIVES. To assess the viability of livers harvested from very elderly donors (≥80 years), and to study the evolution of both the graft and the recipient during a minimum follow-up period of six months.

METHODS. Retrospective study (January 2011 - December 2017), including very elderly liver donors, which were offered by the National Transplant Organization to the Transplant Coordination Team of Puerta de Hierro Majadahonda University Hospital. We compared livers discarded exclusively because of donor's age to those who were implanted. The following variables were studied: age, sex, body mass index, cardiovascular risk factors, toxic habits, comorbidities, natraemia, use of vasoactive drugs, development of diabetes *insipidus*, use of antibiotics (prophylactic or therapeutic) and length of ICU stay. We also conducted a six-month minimum follow-up of recipients, assessing graft and patient survival.

RESULTS. During the period studied a total of 96 livers were offered (Figure 1). Of the 73 (76%) livers rejected, in 41 (42.7%) the reason stated for rejection was age exclusively. Twenty-three (23.9%) livers ≥ 80 years of age were implanted, of which two needed retransplantation. There were no statistically significant differences between livers rejected and implanted in the variables detailed above, except for the number of comorbidities, which were lower in the rejected group. During the follow-up period five deaths were registered.

CONCLUSIONS. In our series, liver rejection due exclusively to age was frequent.

Recipients of livers that came from very elderly donors had an evolution that is similar to what has been previously described for younger livers.

Very elderly patients should be evaluated carefully as liver donors before discarding them based exclusively on age criteria.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0917

INTRODUCTION. During the last years, the number of kidneys retrieved from controlled circulatory death donors (cDCD) has significantly increased. In order to improve kidney graft function a major concern exists regarding the minimization of both warm and cold ischemia times.

OBJECTIVES. To describe the evolution of kidney recipients with renal grafts retrieved from cDCD and optimized with normothermic regional perfusion with an extracorporeal membrane oxigenator (NRP) in the Autonomous Community of Madrid (CAM) and to analyze the incidence of delay in graft function (DGF) in comparison with those obtained through in situ (cold) preservation.

MATERIAL AND METHODS. Descriptive and retrospective study (April 2017-December 2017) that includes cDCD managed with NRP. The variables analyzed were sex and age of donors and recipients and the number of organs retrieved and implanted. Warm ischemia time (WIT) was defined as the time from systolic blood pressure < 60 mmHg to the beginning of the NRP and cold ischemia time (CIT) as the period between the start of the preservation infusion to organ implantation. The duration of the NRP together with creatinine variations during NRP were recorded. The incidence of DGF, defined as the need for dialysis within seven days after transplantation, was also studied. A historical cohort (2012-2017) of kidney grafts obtained by in situ preservation at the same tertiary hospital was used in the comparative analysis. Recipients prognosis was collected one month after transplantation.

RESULTS. During the period studied, 15 cDCD were identified [ten males (66.6%)] with a mean age of 57.2 ± 8.9 years. A total of 26 kidney grafts were retrieved and finally 19 were implanted (73%). The seven rejections experienced were due to: atheromatosis (2),

infection (2), atrophy (1), unfavorable biopsy (1) and alteration of the renal artery (1). The recipients were mostly male [14 (73.6%)] with an average age of 54.6 ± 12.2 years. WIT, CIT and NRP duration were: 14 min, 11 hours and 77.3 min respectively. During NRP there was a mean increase of creatinine of 0.05 ± 0.4 mg/dl. Four patients (21%) managed with NRP presented with a DFG, which represents a lower rate than what we found for the *in situ* preservation group (48.2%). There were no complications associated with the transplant. The monthly survival rate was 94.7% (18). The only death was due to causes unrelated to kidney transplantation.

CONCLUSIONS. NRP for cDCD is a reality in the CAM.

The first experience with NRP for c-DCD offers good results a lower incidence of DGF when compared with *in situ* preservation.

Importance of intensive care units (ICUS) in organ and tissue donation. 20-year experience in the Mexican Social Security Institute (IMSS) in León, Mexico

E.M. Olivares-Durán

IMSS. UMAE Specialty Hospital N°1, National Medical Center of El Bajío, Hospital Donation Coordination, León, Mexico

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0918

INTRODUCTION. There are few publications on the relevant participation of ICUs in the productivity of organ and tissue donation for transplantation purposes in Mexico [1, 2].

OBJECTIVES. To report 20-year productivity of the Adult ICU (AICU) of the High Specialty Medical Unit (UMAE, for its acronym in Spanish) No. 1 and the Pediatric ICU (PICU) of the UMAE No. 48, of the National Medical Center of El Bajío, IMSS, in the city of León, Mexico, as medical services of organ and tissue donation for transplantation purposes.

METHODS. Deceased organ donation in the city of León, Mexico, began in July 1997 in both the Adult ICU and the Pediatric ICU of the National Medical Center of El Bajío, IMSS. This study reports two decades of organ donation activity in these ICUs, from then to December 2017.

RESULTS. 150 donations were achieved at the National Medical Center of El Bajío, IMSS, in the city of León, during the study period. In 7 cases (4.67%), patients were not hospitalized in any ICU. The other 143 donations, made by ICUs' patients (95.33% of the total), were analyzed, out of which 130 patients (90.91%) were from the AICU and 13 patients (9.09%) from the PICU. The mean age of donor-patients from the AICU was 35.51 ± 9.79 years old and from the PICU was 10.85 ± 2.43 years old. 75 (52.45%) patients were male and 68 (47.55%) were female. The most frequent blood groups were O Rh + (n = 89, 62.24%) and A Rh + (n = 39, 27.27%).

135 cases (94.41%) were patients with confirmed brain death and 8 (5.59%) were donors after cardiac death. The causes of brain death were: 66 cases (48.89%) due to a cerebrovascular disease (intracranial hemorrhage or ischemic stroke), 53 (39.26%) due to a traumatic brain injury, 13 due to a primary brain tumors (9.63%) and 3 due to cerebral abscess (2.22%). From these 143 donations, there were obtained a total of 224 kidneys, 230 corneas, 15 livers, 10 hearts, 1 pancreas, and in 9 cases bone was donated; summing a total of 489 organs and/or tissues.

CONCLUSIONS. During the last 20 years, at the National Medical Center of El Bajío, IMSS, in the city of León, Mexico, a large majority (95.33%) of the deceased organ and tissue donations were achieved from patients hospitalized in their ICUs. Therefore, at this Medical Center, ICUs are fundamental medical services for organ donation and transplantation.

Predisposing factors of failed apnea test during brain death determination in potential organ donor

J.J. Kim, E.Y. Kim

Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Division of Trauma and Surgical Critical Care, Department of General Surgery, Seoul, Korea, Republic of

Correspondence: J.J. Kim

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0919

INTRODUCTION. Apnea test is an essential component in the clinical determination of brain death, but it may incur a significant risk of complications such as hypotension, hypoxia and even cardiac arrest. We analyzed the risk factors associated with failed apnea test during brain death assessment in order to predict and avoid these adverse events.

OBJECTIVES AND METHODS. Medical records of apnea tests performed for brain-dead donor between January 2009 and January 2016 in our institution, were reviewed retrospectively. Age, gender, etiology of brain death, use of catecholamine and results of arterial bleed gas analysis (ABGA), systolic/diastolic blood pressure (SBP/DBP), mean arterial pressure (MAP) and central venous pressure (CVP) prior to apnea test initiation were collected as variables. A-a gradient and P_{aO_2}/F_{iO_2} were calculated for more precise assessment of the respiratory system. In total, 267 cases were divided into a group which was completed apnea test and the other which was failed the test.

RESULTS. 13 cases failed the apnea test and the majority of reasons were severe hypotension (SBP < 60mmHg). In terms of hemodynamic state, SBP was significantly higher in the completed test group than the failed group (126.5 ± 23.9 vs. 103 ± 15.2, respectively; $p = 0.001$). In ABGA, the completed test group showed significantly higher P_{aO_2}/F_{iO_2} (313.6 ± 229.8 vs. 141.5 ± 131.0, respectively; $p = 0.008$) and lower A-a gradient (278.2 ± 209.5 vs. 506.1 ± 173.1, respectively; $p = 0.000$). In multivariable analysis, low SBP ($p = 0.040$) and high A-a gradient ($p = 0.002$) were independent risk factors associated with failed apnea test.

CONCLUSIONS. Although the unexpected adverse events during apnea test for brain death determination do not occur frequently, they could be fatal. If a brain-dead patient shows low SBP and high A-a gradient, clinicians should pay more attentions and preparations prior to apnea test.

INTRODUCTION. Differences in EOLP were previously reported in Europe in the Ethicus I study [1].

OBJECTIVES. This study evaluated differences in EOLP after 15 years in European ICUs that also participated in the Ethicus I study.

METHODS. All previous Ethicus I centers were invited to participate in the Ethicus II study. Consecutive admitted ICU patients who died or had treatment limitations during a 6 month period from 1.9.2015 to 30.9.2016 were prospectively studied. Previous EOLP and region definitions were used [1]. EOLP in the different regions of the Ethicus I study [1] were compared to the same ICUs in the Ethicus II study.

RESULTS. 22 of the original 37 ICUs participated again in this study. Limitations of life-sustaining therapies occurred in 1601/1785 (90.0%) patients and 1274/1458 (87.4%) of dying patients in Ethicus II and 1918/2807 (68.3%) and 1812/2701 (67.1%) of dying patients in Ethicus I. Figure 1 shows the differences in EOLP by region. Table 1 demonstrates that limitations were taken sooner in Ethicus II but ICU lengths of stay and time to death after limitations were similar.

CONCLUSIONS. In Europe in 15 years, EOLP has changed and includes more and earlier treatment limitations without changing time to death. There was less CPR (especially in the South) with more withholding and withdrawing therapies. Shortening of the dying process (SDP) remained uncommon.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0921

OBJECTIVE. To analyze our experience after the establishment of a mobile team created to support donors after controlled cardiac death (DCD) with normothermic regional perfusion (NRP) using and extracorporeal membrane oxygenator (ECMO) in those hospitals across the Autonomous Community of Madrid (CAM) that do not have access to one.

METHODS. Descriptive study (April 2017 - April 2018). In July 2016 a program to assist DCD with NRP was stablished. A total of two NRP teams were created in the CAM, one from Hospital Universitario Clínico San Carlos and one from Hospital Universitario Puerta de Hierro Majadahonda. Each of these teams included an intensivist, a surgeon with vascular experience and a perfusionist together with an ECMO machine. Teams were activated by the National Organ Transplantation network who decided when NRP would be applied according to donor characteristics and organs to be retrieved.

RESULTS. During the period studied there were 224 effective donors in the CAM, 54 of them (24.1%) in a DCD situation. Out of these 54, NRP was used in 33 cases with the NRP team intervening in 23 occasions in seven different hospitals. This meant that the NRP team was present in 42,6% of all the DCDs and in 70% of the DCD assisted with NRP in the CAM.

Mean DCD donor age was 56,3 ± 11,5 years. Fourteen males (60,9%). Reason for ICU admission: acute ischemic stroke (13;56,5%), cardiac arrest (9;39,1%) and amyotrophic lateral sclerosis (1;4,3%). Mean UCI stay until withdrawal of life support was 10,6 ± 7,7 days.

The NRP teams retrieved a total of 11 livers, 42 kidneys and 3 lungs and 9 (81,8%), 33 (78,6%) and 2(67%) of each group were effectively implanted.

CONCLUSIONS. NRP teams in the CAM are a reality nowadays and have been present in almost half of all the DCDs since the beginning of the program.

A long-term analysis of the recipients is needed in order to assess the real impact of the program in graft function.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0922

INTRODUCTION. Donostia University Hospital is a third-level hospital without solid organ transplantation programme, neither cardiac surgery unit nor extracorporeal membrane oxygenation (ECMO) assistance programme. In 2015, we started two programmes in donation after circulatory death (DCD): both controlled (cDCD) and uncontrolled (uDCD). During these 3 years, we've reached an average of 88 donors pmp.

OBJECTIVES. Analysis of the characteristics of cDCD donors in a three years period.

METHODS. Prospective observational study. Center: Donostia University Hospital, reference center for 700.000 inhabitants. Period of study: March 2015 - April 2018. Sample: patients with terminal illness and poor prognosis, where medical team decides the withdrawal of life-sustaining therapy (WLST) based upon futility of further care. Variables: sex, age, cause of WLST, place of extubation, total number of hospital admission days, functional warm ischemia time (f-WIT) and total warm ischemia time (WIT), preservation time, number of grafts removed and transplanted. Technique: normothermic regional perfusion (nRP), with specific authorization by the patient's legal representatives. This includes ante mortem heparinization and cannulation of vessels (under appropriate sedoanalgesia), percutaneously. Both procedures were fully completed at the Intensive care unit (ICU).

RESULTS. Total number of donors: 58. 32.8% were female (19), 67.2% male (39). Mean age 69 years old [35-78]. Cause of WLST: 39.7% anoxic encephalopathy, 29.3% brain hemorrhage, 8.6% traumatic brain injury, 5.2% amyotrophic lateral sclerosis, 6.9% acute ischemic brain injury and 5.1% other causes. Mean days of hospital admission 10 [1-41]. 13.8% (8) of elective intubation for cDCD. 15.5% (9) admission at the ICU exclusively for donation centered care. 75.8% of extubation took place at the ICU, 24.1% at the operating theater. WIT 13.7′ [7′-26′], f-WIT 11.5′ [6′-20′], nRP time 117′ [13-235]. Transplanted organs: first pancreas transplant in Spain. 8 lungs, 39 livers (67.2%), 112 kidneys removed and 74 transplanted (66%). 7(12.1%) liver refusals for elevated liver enzymes during ECMO. 13.8% contraindications for liver donation.

52 cornea donors. 21 tissue donors: bone and tendons, average of 16 samples per donor [11-20].

CONCLUSIONS.
Starting a cDCD programme, in our region, represents 27.6 donors pmp. 28.8% of the total donors.

cDCD can be performed in a Hospital without a solid organ transplantation programme.

cDCD programmes with previous family interview and donation centered ICU-care, offer the possibility of fulfilling the patient's right for organ donation, for those patients with terminal illness but without brain death.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0923

INTRODUCTION. Severe traumatic brain injury (TBI) is one of the leading causes of death in intensive care units (ICUs). Hypotension is known to be associated with increased mortality in TBI patients. A systolic blood pressure (SBP) of < 90 mmHg is the threshold for hypotension in consensus TBI treatment guidelines; however, some evidence suggests hypotension should be defined at higher levels for these patients.

OBJECTIVES. To determine the influence of hypotension on mortality in severe TBI patients requiring ICU admission using different thresholds of SBP on arrival at the emergency department (ED).

METHODS. We performed a retrospective cohort study of all patients with severe TBI (Abbreviated Injury Scale Head score $\geq$ 3) admitted to the ICU at the Queen Elizabeth II Health Care Centre (Halifax, Canada) over a 12-year period (2002-2013). Patients were grouped by SBP on ED arrival (< 90 mmHg, < 100 mmHg, < 110 mmHg). Logistic regression was used to control for the effect of age, gender, Injury Severity Score (ISS), mechanism of injury, isolated TBI, and trauma team activation (TTA) on mortality in ICU patients.

RESULTS. A total of 1233 patients sustained a severe TBI and were admitted to the ICU during the study period. The mean age was 43.4 ± 23.9 years and most patients were male (919/1233; 74.5%). The most common mechanism of injury was motor vehicle collision (491/1233; 41.2%) followed by falls (427/1233; 35.8%). Mean length of stay in the ICU was 6.1 ± 6.4 days, and the overall mortality rate was 22.7%. SBP on arrival was available for 1182 patients. The < 90 mmHg group (54/1182; 4.6%) had a mean ISS of 20.6 ± 7.8 and a mortality of 40.7% (22/54). For the < 100 mmHg group (110/1182; 9.3%), mean ISS was 19.3 ± 7.9 and mortality was 34.5% (38/110). In the < 110 mmHg group (198/1182; 16.8%), mean ISS was 17.9 ± 8.0 and mortality was 28.8% (57/198). After adjusting for confounders, the association between hypotension and mortality was 2.22 (95% CI 1.19-4.16) using a < 90 mmHg cutoff, 1.79 (95% CI 1.12-2.86) using a < 100 mmHg cutoff, and 1.50 (95% CI 1.02-2.21) using a < 110 mmHg cutoff.

CONCLUSIONS. After adjustment for known confounders, the odds ratios for SBP < 90, < 100, and < 110 mm Hg remained significantly associated with mortality. Our results demonstrate that while the risk of mortality is double in patients with a SBP < 90 mmHg, this risk is only marginally reduced at a higher SBP threshold of 110 mm Hg.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0924

INTRODUCTION. Despite the fact that Whole-Body CT (WBCT) is an increasing practice in many centers for severely injured patients, high rates of negative scans have been described specially in medium risk patients, so controversy exists about its indications.

GKCT (Granze Kroper CT) score [1] and Manchester Trauma Imaging Protocol (MTIP)[2], are two decision tools developed in order to determine the need for WBCT in trauma patients. They are both based on mechanism of injury, physiological parameters and demographic data.

In our institution, patients requiring partial trauma team activation (PTTA) are assessed by two ICU physicians in the emergency room and radiological exams are indicated according to clinical suspicion.

OBJECTIVES. This study aims to determine the rate of negative WBCT between patients requiring PTTA and to evaluate whether any of these scales is a suitable tool to reduce unnecessary CT scans.

METHODS. We performed a retrospective observational study during a 56 month period. All patients >16 years old who required PTTA because of a blunt injury were recruited. Patients in whom PTTA was produced > 30 minutes after arrival, were excluded.

We recorded data from pre-hospital care, mechanism of injury, physical exam and radiological exams (indication and results). We classified CT findings as no injury, no significant/significant injury or ICU admission need. We calculated GKCT and MTIP scores and retrospectively considered indicated a WBCT if a punctuation higher than 0 or 3 was respectively obtained. For each scale, we determined OR for significant injury or need for ICU admission and false negative rate (proportion of patients without indication of WBCT which were admitted to ICU).

RESULTS. During the period of the study, we enrolled 1384 patients, 141 of which were admitted to ICU. 1032 (74%) patients were male. The median age was 37 y.o. (IQR 27-47). 656 patients underwent WBCT. In 227 CT exams (35%), insignificant injuries were reported whereas in 156 (24%) significant injuries were found.

OR for significant injury and for ICU admission are respectively 0.9 (95% CI 0.54-1.39) and 1.9 (95% CI 1.01-3.60) for GKCT and 2.902 (95% CI 1.75-4.79) and 3.649 (95% CI 1.95-6.71) for MTIP. False negative rate was 3.8% for GKCT and 4.37% for MTIP.

CONCLUSIONS. A proportion of unnecessary exams could be avoided by using GKCT or MTIP. A positive MTIP score is associated with a high probability of significant injuries and ICU admission requirement. However, false negative rate is lower for GKCT, thus, it is a suitable tool to avoid unnecessary WBCT.

Is the shock index a good predictor of mortality in trauma patients?

L. Pariente Juste, M. Koo Gomez, A. Vergara Serpa, I. Macía Tejada, A. Bonet Burguera, I. Otero Quintana, C. Prat Llimargas

Hospital Universitario de Bellvitge, Anesthesiology, Reanimation and Pain Clinic, Barcelona, Spain

Correspondence: L. Pariente Juste

INTRODUCTION. Trauma is the third leading cause of death in patients under the age of 45. An early treatment and adequate admission triage are directly related to outcomes in patients. Different tools for fast determination of critical clinical conditions that correlate with outcomes in this kind of patients have been developed, such as the Glasgow Coma Score (GCS) and the Injury Severity Score (ISS). The Shock Index (SI) is the ratio between heart rate and systolic blood pressure, and it is a useful indicator to identify shock and correlate with mortality.

OBJECTIVES. The objective of this study was to compare the SI and the ISS as predictors of early mortality, hospital length of stay (HLS) and critical care length of stay (CLS).

METHODS. It is a retrospective, observational study, with a cohort of 184 patients who arrived as a trauma code and required critical care hospitalization at Bellvitge University Hospital, a level 1 trauma center, between 2013 and 2016. The SI was calculated from the first prehospital values. A logistic regression was used to compare SI and ISS, and to relate it with mortality, CLS and HLS. A p-value ≤ 0.05 was considered significant.

RESULTS. Out of the 184 patients, 150 were male (81.5%), with a median age of 43.5 years old (31-59). The mean ISS was 29 (22-36). There were 61 patients (33%) with GCS ≤8.

In relation to mortality, the SI adjusted Odds Ratio was 0.5 (CI 0.12 -1.66; p = 0.302), the ISS Odds Ratio was 1.07 (CI 0.12 -1.66; p = 0.302) and the GCS Odds Ratio 10.67 (CI 2.91 - 53.33; p=0.001). For CLS and HLS, the adjusted SI Odds Ratio were 1.59 (CI 1.02-2.64: p=0.64) and 1.62 (CI 1.00-2.83) respectively.

CONCLUSIONS. In this model, there is no correlation between SI and early mortality, HLS or CLS. These results probably correlate to this specific group of critical trauma patients studied. Moreover, this study was performed retrospectively and is prone to bias incurred by missing data. GCS and ISS are more reliable predictors of mortality, considering the SI a valuable addition to triage criteria to active trauma team responses.

Correspondence: S. Søvik

INTRODUCTION. Acute kidney injury (AKI) is a common complication after severe trauma and is associated with increased intensive care unit (ICU) length of stay, increased patient morbidity, mortality, and costs. In single centre studies, severity of trauma, initial degree of shock, use of nephrotoxic agents and various pre-trauma patient characteristics have been linked to AKI incidence and outcome.

OBJECTIVES. To perform a systematic review and meta-analysis of studies of AKI occurring in trauma patients admitted to the ICU. The review was registered in PROSPERO on May 12 2017 (CRD42017060420).

METHODS. We searched papers and guidelines published Jan 1, 2004 - Jan 23, 2018 in PubMed, Cochrane Database of Systematic Reviews, UpToDate and NICE (National Institute for Health and Care Excellence), using MeSH and text words including acute kidney injury, multiple trauma, nervous system trauma, wounds and injuries, penetrating wounds, accidents, trauma, traumatic, polytrauma, and multiple injuries, alone or in combination. Ongoing reviews were

identified in the PROSPERO database. The search was limited to studies diagnosing AKI with RIFLE, AKIN or KDIGO criteria. Screening of studies for eligibility according to pre-defined inclusion criteria and data extraction on a pre-defined data extraction form was performed in duplicate by two independent collaborators. Study quality was evaluated on the Newcastle - Ottawa quality assessment scale by two independent collaborators. AKI severity was categorised as mild (RIFLE Risk, AKIN Stage 1, KDIGO Stage 1), moderate (RIFLE Injury, AKIN Stage 2, KDIGO Stage 2), or severe (RIFLE Failure or worse, AKIN Stage 3, KDIGO Stage 3). Several methods of data synthesis for estimation of risk will be used.

RESULTS. Altogether 22 studies comprising 23479 patients (77% male) were included. 16 studies were from general, mixed trauma populations, 4 from neurotrauma, and 2 military. All studies were observational. Study quality was variable. Only 8/22 studies used full, unmodified AKI criteria, the remaining did not include urine output. In 11/22 studies, exclusion of patients with chronic kidney disease was insufficient. Data on renal replacement therapy was reported in 18/22 studies. Subgroup analysis of risk factors was limited by variable and missing reporting.

Overall, 18% of patients developed AKI; 9.7% mild, 5.4% moderate, and 2.7% severe. Unadjusted, pooled mortality in trauma patients with AKI was 24% (17% in mild, 24% in moderate, and 49% in severe AKI), vs. 6.6% in non-AKI patients.

CONCLUSIONS. A review of studies on AKI occurring in patients admitted to the ICU after severe trauma revealed significant morbidity and mortality associated with AKI. Lack of consistency in reporting reduced available data for risk estimation.

Infection-related ventilator-associated complications in patients with acute brain injury

A.R. Corrêa[1], F. Bruzzi de Carvalho[2], T.V. Chaves[1], F.M. Assunção[1], V.A. Nobre[3]
[1]Universidade Federal de Minas Gerais - UFMG, Escola de Enfermagem, Belo Horizonte, Brazil; [2]Hospital João XXIII, Centro de Terapia Intensiva Adulto, Belo Horizonte, Brazil; [3]Hospital das Clínicas da UFMG, Núcleo de Investigação em Medicina Intensiva - NIIMI, Belo Horizonte, Brazil

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0927

INTRODUCTION. Acute brain injury victims are considered to be at high risk for ventilator-associated pneumonia (VAP). Recently, Infection-related Ventilator-Associated Complication (IVAC), Possible VAP and Probable VAP criteria were proposed to simplify surveillance of infectious complications of mechanical ventilation.

OBJECTIVES. The primary objective of this study was to describe factors and outcomes associated with the first episode of IVAC in patients with an acute brain injury receiving invasive mechanical ventilation (MV).

METHODS. A retrospective cohort of patients admitted to a trauma Intensive Care Unit (ICU) was studied. Acute brain injury was defined as a Glasgow Coma Scale (GCS) score ≤12 due to medical or traumatic reasons. The first VAP episode in 14 days in the ICU was described as IVAC, Possible VAP and Probable VAP, adapted from the CDC guidelines for Ventilator-Associated Events. Neurological outcome was censored at hospital discharge using the Glasgow Outcome Score scale, with values 1, 2 and 3 as unfavorable and 4 and 5 as favorable. A p value < 0.05 was considered statistically significant.

RESULTS. During the 8-month study period, 907 patients were admitted and 236 were included in the study. Males were 80.8%, 97.9% were trauma victims and the hospital mortality rate was 31,6%. On average, IVAC was noted at 6.34 (2.95) days and treatment lasted for 7.03 (9.14) days. IVAC criteria was met in 48.3% of patients, whereas Possible VAP and Probable VAP was observed in 45.3% and 22,9% respectively. *Staphyloccocus aureus* (24,3%) and *Acinetobacter sp.* (20.7%) were the most frequent isolated pathogens. In day 6 of MV, PaO2/FiO2, Leucocyte count, C-reactive protein, peak temperature and purulent secretions were different in IVAC and non-IVAC patients. IVAC was associated with a longer ICU (18.0 vs.15.6 days,

p=0.008) and hospital (63.9 vs. 44.3 days, p=0.010) length of stay (LOS), and with less 28-MV-free days (12.4 vs. 15.9, p< 0.001), without a mortality difference. In multivariate analysis, thoracic trauma (OR 3.3 CI95% 1.53; 7.1 p= 0.013) and the presence of an intracranial catheter (OR 1.88 CI95% 1.08; 3.26 p= 0.025) were associated with IVAC occurence, with similar associations for Possible and Probable VAP. A later tracheostomy (OR 1.18 CI95% 1.05; 1.32 p= 0.004) and 28-MV-free days (OR 1.15 CI95% 1.07; 1.24 p= < 0.001) were associated with a favorable neurological outcome.

CONCLUSIONS. IVAC occurs frequently and is associated with longer ICU and hospital LOS, reduced 28-MV-free days, but not to hospital mortality or neurological outcomes in patients with acute brain injury. Patients with thoracic trauma and intracranial catheters were at a higher risk of IVAC. In this series, Possible or Probable VAP criteria was not superior to IVAC to discriminate for risk factors or clinical outcomes.

Correspondence: B.M. Tomazini
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0928

INTRODUCTION. Pneumonia occurs in up to 47% of critically ill trauma patients with pulmonary contusions[1]. Despite usual care, there is a lack of evidence in how to prevent nosocomial pneumonia in this population.

OBJECTIVES. To compare a conservative antibiotic therapy strategy on the incidence of microbiologically documented nosocomial pneumonia in critically ill patients with pulmonary contusion.

METHODS. A retrospective cohort of adult patients admitted to a surgical ICU of a tertiary university hospital between 2012-2016. Antibiotic therapy group was defined by any antibiotic use for more than 48h starting on hospital admission, while the conservative group was defined by antibiotic use no greater than 48h. The most common reasons for antibiotic prescription were: open fractures or cerebrospinal fluid leakage. Antibiotics for pulmonary contusion were not prescribed routinely. The primary outcome was microbiologically documented nosocomial pneumonia in the first 14 days after hospital admission. A logistic regression model, including variables with a p-value < 0.2 in the univariate regression and other clinically relevant variables, was used to estimate the association of risk factors and primary outcome.

RESULTS. From 2040 ICU admissions, 177 patients with chest trauma and diagnosis of pulmonary contusion on CT scan were included. Patients characteristics and outcomes are shown in table 1. Antibiotic therapy group had lower Glasgow coma scale (GCS), higher rates of mechanical ventilation, Simplified Acute Physiology Score 3 (SAPS 3), Sequential Organ Failure Assessment score (SOFA), and Injury Severity Score (ISS) at ICU admission than the conservative group. There was no difference between groups in the incidence of microbiologically documented nosocomial pneumonia at day 14 and ICU mortality.

The univariate and multivariate analysis are shown in table 2. In the analysis, the only risk factor associated with the incidence of nosocomial pneumonia was mechanical ventilation at ICU admission, while antibiotic therapy and other variables showed relation to the outcome. In patients with microbiological isolates at time of diagnosis, the previous use of an effective antibiotic against the bacteria did not decrease ICU length of stay or ICU mortality (OR 1.2; 95% CI 0.22-6.33; p=0.83).

DISCUSSION. Our results show that antibiotic therapy does not decrease the incidence of microbiologically documented nosocomial pneumonia within 14 days of admission. Therefore, a conservative strategy seems to be safe and can reduce antibiotic use.

The retrospective nature of the data, imbalance between groups, and the fact antibiotic therapy could decrease microbiological confirmation of nosocomial pneumonia has to be considered when interpreting the results. However, given the lack of literature on this topic and the high incidence of pneumonia in patients with pulmonary contusion, our results must guide future research on this topic.

A new trauma-burn care system should be established near future

Q. Zhang

Burn Center of Rui Jin Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0929

INTRODUCTION. The severe burn patients treated in the Emergency Burn Care Center of Shanghai, the largest Commerce city have not reduced with quick development of the city.

OBJECTIVES. A retrospective study of the characteristic and tendency for the patients with a total area of more than 30% TSBA in Burn Center of Shanghai Ruijin Hospital, admit from 2005 to 2016, was performed for development of future mode of burn center.

METHODS. This study retrospectively analyzed adult burn patients who had a total burn area greater than 30% TSBA and older than 18 years old treated in burn center from January 1, 2005 to December 31, 2016. The age, gender, area of burns, The injured place, the time from injury to hospital, hospital transfer, inhalation injury, the outcome of treatment and ICU duration.

RESULTS. A total of 895 patients with severe burns were included in this study. The average age of patients was 41.23 ± 13.43 yrs old with a mean burn area of $56.83 \pm 21.97\%$ TSBA. The average age of patients significantly increased from 38 years in 2005 to 45 years in 2016 (F = 3.45, P = 0.00). The proportion of female patients older than 60 years old increased significantly, and the incidence of female patients showed an upward trend (X2 = 15.64, P = 0.00) Flame was the main cause of severe burn, accounting for 77.7%, but the proportion showed a decreasing trend (X2 = 9.99, P = 0.02). Severe burns patients were mainly injured in the workplace 65.5%, followed by 23.8% of domestic burns. The incidence of severe burns in the household is on the rise, with severe burns in the work place declining (X2 = 25.60, P = 0.00). The proportion of female patients in the family burn group was significantly higher than that of the female in the workplace. Mortality in patients with severe burn ICU increased gradually (X2 = 8.52, P = 0.04). The burn area with 50% risk of death was 96.83% TSBA with a 95% confidence interval (91.28-104.30). Age is the main reason for the treatment outcome.

CONCLUSIONS. The results suggest that with Shanghai´s transition from an industrial city to a service and business center, there was no reduction in severe burns at the burn center, and the incidence of female patients increased and the incidence of family burns increased. The age of severely burned patients was on an upward trend and the mortality showed an upward trend in patients with ICU prolonged survival, increased age is an important reason affecting the outcome of patients. The present study suggest that the work of burn center in Shanghai needs to be transformed rapidly and an effective industrial and household prevention system is urgent. A rescue / transshipment system that effectively connects local and burn centers should be set up to improve the efficiency of local treatment and transport. There is an urgent need to establish an effective rehabilitation system to alleviate the burden on the family and society and allow more patients to return to society and occupation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0930

INTRODUCTION. Critical Burn patients care requires a highly specialized healthcare service(1). A global of 238.000deaths due to fire-related burns, with a mortality in Europe around 21.400patients and a lost one disability-adjusted life year around 500.000 are reported(2). A European review(3) reported between 4-22% of patients presenting with burns at the emergency department, were admitted to the intensive care unit(ICU).

OBJECTIVES. To describe the clinical characteristics of adults admitted to the burn intensive care unit(BICU) at Vall d'Hebrón University Hospital a reference center from Catalonia, Balneares and Andorra; between February 2009 and January 2017, and assess differences between survivors and nonsurvivors.

METHODS. Retrospective monocentric cohort study of adult with major burn injury; defined as total body surface area(TBSA) burned over 15% or inhalation injury. Demographic data, comorbidities, mechanism of burn, inhalation injury, vasopressor support requirement, length of mechanical ventilation(MV-LOS) and length of stay(LOS) in BICU were collected from hospital medical records.

RESULTS. 276 patients were admitted, 206(74.6%) were male. Median age was 46ys (IQR25-75:32.2-62). Principal cause of admission was burned by flame in 154(55.8%). Median TBSA was

22%(IQR25-75:16-35). 79 patients(28.6%) had inhalation injury. BICU-LOS median was 1days(IQR25-75:1-20) and MV-LOS median was 15days(IQR25-75:5-28). ABSI score was 6 median(IQR25-75:4-8), Median Bauxscore 75(IQR25-75:55.2-98) and Median Revised Baux score 77.5(IQR25-75:60-101). 51 patients(18.5%) were dead. When comparing survivors and non survivors; no differences in gender, or mechanism of injury were observed. Regarding comorbidities; non survivors had significantly higher proportions of diabetes, liver disease, psychiatric and heart disease. A higher proportion of patients in the non survivor group presented septic shock 16(31%) versus 8(3%), p=< 0,001, necessity of mechanical ventilation 38(74%) versus 89(39%), p=< 0.001, inhalation injury 28(55%) versus 51(22%), p=< 0.001, requirement of renal replacement therapy 12(23%) versus 12(5%), p= < 0.001 and ventilator associated pneumonia 22(44%) versus 37(16%), p= < 0.001.

CONCLUSIONS. Patients admitted to this BICU during the study period were predominantly middle age men burned by flame with a TBSA between 15.2 and 35.7%TBSA. High mortality rate is observed globally especially in those with a TBSA over 35.7% of TBSA.

INTRODUCTION. It is known that trauma injury triggers the initiation of inflammatory reaction as a direct immune response. An effect of local injury is the formation of drainage fluid.

OBJECTIVES. The aim of the study is to investigate the local and systemic inflammatory activity in multitrauma patients.

METHODS. Fourteen multitrauma patients admitted to the emergency department of a general hospital, in Athens Greece. Demographic and clinical data were recorded. Drainage fluid and blood samples collected the 1st, 4th and 7th day of hospitalization. Tumor necrosis factor (TNF)-a and interleukins (IL-) -6,-8,-10 determined in serum and pleural fluid by Enzyme-Linked Immunoabsorbent Assay (ELISA).

RESULTS. On admission, IL-6 and IL-10 were significantly higher in pleural effusion, compared to circulating levels, but TNF-a had no significant differences.

Subsequently, during the time course, the local release of TNF-a and IL-6 was invariable, while the anti-inflammatory IL-10 showed a reduced profile.

In parallel, systemic IL-6 was gradually decreased, TNF-a showed a significant increase on the 7th day and IL-10 was fluctuating during the week.

Comparing the time course of cytokines release, local IL-6 and IL-10 levels remained elevated than systemic release, while systemic TNF-a was significantly elevated the 7th day than local.

CONCLUSIONS. At the onset of trauma injury, within the 1st week, systemic and local inflammatory reaction showed different profiles. The early strong local inflammatory response is counterbalanced by an immediate and sustained anti-inflammatory induction, expressed by IL-10, while the mild systemic reaction, showed a second hit, expressed by TNF-a, within the week.

INTRODUCTION. Glial fibrillary acidic protein (GFAP), phosphorylated neurofilament heavy subunit (pNF-H), and heart-fatty acidic binding protein (H-FABP) are current remarkable serum biomarkers for outcome of traumatic brain injury (TBI), although neuron specific enolase (NSE) and S100B protein are traditional biomarkers in this field. However, there is not enough data that these biomarkers could predict positive head computed tomography (CT) findings of mild to moderate TBI cases in emergency department (ED).
OBJECTIVES. To assess the usefulness of these and traditional biomarkers to predict positive CT findings of TBI cases in ED.
METHODS. Serum biomarkers (GFAP, pNF-H, H-FABP, NSE, and S100B) were measured in mild to moderate TBI on admission, and all cases were performed head CT. These biomarkers were compared by receiver operating curve (ROC) analysis.
RESULTS. 57 cases of TBI cases were analyzed. Median age was 70 y.o., 39% males, and median GCS was 15. Median serum GFAP, pNF-H, H-FABP, NSE, and S100B were 0.11 ng/mL, 53.9 pg/mL, 5.2 ng/mL, 12.6 ng/mL, and 7.2 pg/mL, respectively. 12 cases (21%) had positive head CT findings. ROC analysis showed that area under the curve (AUC) of GFAP, pNF-H, H-FABP, NSE, and S100B were 0.845, 0.569, 0.518, 0.744, and 0.753, respectively.
CONCLUSIONS. Serum GFAP showed the superiority from other serum biomarkers to predict positive head CT findings of mild to moderate TBI cases in ED, based on ROC analysis.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0934

INTRODUCTION. Posttraumatic meningitis is one of severe complications and results in increased mortality and longer hospital stay among trauma patients. Factors such as cerebrospinal fluid (CSF) fistula and skull base fracture are associated with posttraumatic meningitis. On the other hand, advanced age, external ventricular drainage, and repeat operations are associated with postcraniotomy meningitis. However, it remains unclear whether procedures such emergency craterization and re-operation would be associated with posttraumatic meningitis.
OBJECTIVE. The aim of this study is to assess factors associated with posttraumatic meningitis with a nation-wide hospital-based trauma registry in Japan.
METHODS. This study was a retrospective observational study and the study period was 12 years between January 2004 and December 2015. We included trauma patients registered in Japanese Trauma Data Bank whose head AIS score was >=3 in this study. Multivariable logistic regression analysis was used to assess potential factors associated with posttraumatic meningitis such as CSF fistula, emergency craterization at emergency department and reoperation within 48 hours after first operation.
RESULTS. Among 60,390 patients with severe head injury, 284 (0.5%) patients had posttraumatic meningitis. Factors associated with posttraumatic meningitis were emergency craterization at emergency department (adjusted odds ratio [OR] 2.219 [95% confidence interval {CI}; 1.444-3.411]), craniotomy in operation room (adjusted OR 4.553 [95% CI; 3.038-6.821]), craterization in operation room (adjusted OR 2.231 [95% CI; 1.433-3.473]), external decompression surgery (adjusted OR 2.142 [95% CI; 1.521-3.017]), external ventricular drainage (adjusted OR 1.869 [95%CI; 1.175-2.972]), re-craniotomy within 48 hours after first operation (adjusted OR 3.145 [95%CI; 2.109-4.691]), re-craterizaion within 48 hours after first operation (adjusted OR 4.190 [95%CI; 2.174-8.076]), CSF fistula (adjusted OR 3.334 [95% CI; 2.211-5.028]), and skull base fracture (adjusted OR 1.696 [95% CI; 1.213-2.372]).
CONCLUSIONS. In this population, emergency craterization at emergency department and external decompression surgery were associated with posttraumatic meningitis among trauma patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0935

INTRODUCTION. Multi organ failure (MOF) is a serious clinical condition in major trauma patients that influence outcomes, complications and economic costs in intensive care unit (ICU). Several studies demonstrate the role of infiammatory citokynes in the physiopathological mechanisms leading to MOF in trauma. Inflammatory response is common in the most of severe injured patients. Early hemofiltration, even without renal failure can help to remove citokynes.

Aim: The aim of our study is to inteviage the feasibility of early hemofiltration in trauma patients affected by MOF due to inflammatory response.

METHODS.
We performing a Systematic review using the following keyword search: "Wounds and Injuries" OR "trauma*" OR "injury" OR "accident" OR "crash" AND "Renal Dialysis" OR "hemofiltr*" OR "renal replacement therapy" OR "biofiltration" OR "ultrafiltr*" OR "blood purif*" OR "diafiltration" OR "hemodiafiltr*" AND "humans"

We retrospectively analyzed patients admitted to the Intensive Care Unit of the "Ospedale Bufalini-Cesena" from January 2015 to December 2017with Injury Seeverity Score (ISS) >16 and hemofiltration started in the first 48 from ICU admission.

A great vein was incannulated, such as giugular or femoral, with a specific catheter for hemofiltration. The severity of trauma was evaluated with ISS. The hemofiltration was realized with polyphenylene membrane filter, low-flux technique and twelve hours of duration. The sequencial organ failure assesement (SOFA) score was used to evaluate the apperence of organ failures in the next 48 hours after stopped hemofiltration.

RESULTS. We found 3783 studies with the search strategy above described but no one was selected as relevant by the research.
In our experience Twenty-five patients in level I trauma center were analyzed retrospectively from January 2015 to December 2017
Median ISS was 32, Inter quartile range (IQR) 20; median SOFA 11 (IQR 4.25). Overall mortality was 24%.
No significative correlation (Spearman's Rho Test) was found between ISS and SOFA score (Rho 0.157)
Median ISS of died patients was 39.5 (IQR 21) vs 29 (14.25) of discharged from hospital group (p 0.378); Median SOFA of died patients was 14 (IQR 2) vs 11 (4) of discharged from hospital group (p 0.073).

CONCLUSIONS. Although the discussion about the usefulness of hemofiltration for removal cytokine from blood is still in progress, our experience in this case series suggest that these techniques of blood purification could be feasible. We hope that large trial will be performed to improve our understanding of this issue.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0936

INTRODUCTION. Few has been researched about differences and the prognosis clinical between isolated severe TBI and severe TBI associated with multiple trauma. A priori, the clinical conditions are different, due to the different pathophysiology of TBI in the context of multisystem trauma.

Objetives: The objectives are 1º / To know the clinical characteristics and mortality of the isolated severe TBI and TBI associated with multiple trauma. 2º / Determine mortality and associated risk factors in isolated severe TBI.

Method: Retrospective cohort study using local data collected for the national registry of traumatic patients (Project RETRAUCI) from 02/2013 to12/2016. A comparative study of patients with severe TBI in two groups, according to the presence of isolated severe TBI or severe TBI with multiple trauma was conducted. Given that the objective is to evaluate mortality, severe TBI is defined, all TBI with GCS score $< = 8$, without other injuries or with non-serious injuries (AIS < 3) in any anatomical region. We defined severe TBI associated with polytrauma, TBI with GCS score $< = 8$, with severe injury in some other anatomical region (AIS$> = 3$). Through a logistic regression analysis, predictive factors of mortality are identified. Statistical analysis with STATA software 13.0.

Results: 54 patients with severe TBI were included in the study, 40 had isolated TBI and 14 TBI associated with multiple trauma. Overall hospital mortality of severe TBI was 29.63% (16 patients). There were no significant differences in mortality between isolated TBI and TBI with multiple trauma (30% vs 28.57%, p: 0.92). There were significant differences in the mechanism of injury, ISS, high base déficit DB and at admission transfusion requirements in the first 6 hours, the latter two being less frequent in isolated TBI.

In the logistic regression analysis of the variables analyzed in the group of isolated severe TBI, only the low GCS score (OR: 0.53, CI: 0.31 to 0.90) and age (OR: 1.05, CI: 1.01 to 1.10) were the factors associated with an increased mortality risk, with an AUC ROC: 0.8571.

Conclusions: Factors related to the severity of the injury (ISS and DB) and higher transfusion requirements were the main differences between isolated severe TBI and that associated with multiple trauma. However, there were no significant differences in mortality.

Thoracic blunt aortic injury (TBAI) in polytrauma: how to define clinical priorities?

C. Valentina[1], S. Ranieri[1], P. Cavallo[2], C. Coniglio[2], G. Gordini[2]
[1]Policlinico Sant'Orsola-Malpighi, University of Bologna, Department of Medical and Surgical Sciences, Anesthesiology and Intensive Care Unit, Bologna, Italy; [2]Trauma Center "Maggiore" Hospital, AUSL Bologna, Anesthesia, Intensive Care and EMS Department, Bologna, Italy
Correspondence: C. Valentina
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0937

INTRODUCTION. TBAI is a rare but significant cause of impending death following deceleration trauma. TBAI rarely occurs as isolated injury, therefore the decision on the priority of surgical treatment can be very challenging.

OBJECTIVES. To review the epidemiology and treatment of TBAI, comparing perioperative variables and timing of aortic repair in case of multiple injuries.

METHODS. In this retrospective observational study we considered all consecutive patients who presented at our Trauma center from

2010 to 2017, clinical and procedural variables were collected. Diagnosis and grading of TBAI were derived from CT-scan imaging.

RESULTS. 15 cases of TBAI were identified, with a predominance of males (86,6%) and mean age of 54 years. The most frequent mechanism of injury was motor vehicle collision (80%). Age, sex distribution, and ISS values were comparable to literature [1]. All patients had multiple associated injuries mostly in chest, abdomen and extremity, with a mean ISS of 35. The ISS was significantly higher in patients with more severe TBAI. 12 patients underwent aortic repair and the mean time from trauma to aortic intervention was 6,5 hours.

9 patients with Grade III (pseudoaneurysm) and IV (active extravasation) had an immediate intervention. 2 patients with Grade IV TBAI had a delayed repair because of other sources of impending bleeding. One patient underwent to perihepatic packing and bladder repair, the other to legs fractures stabilization. In these patients time from trauma to the aortic repair was 8 and 10 hours, reasonably comparable with the average times of the immediate repair group.

A delayed repair was also provided for one patient with intramural hematoma and no signs of impending aortic rupture, controlling heart rate and blood pressure while awaiting repair. A conservative management was provided for 2 patients with type I injuries (intimal tear). 10 were treated with endovascular repair (TEVAR) and 2 with open repair (OR), no mortality or paraplegia described. The mean ICU stay was 24,4 days, death occurred in 2 patients. There were no procedure or device related complications.

CONCLUSION. Considering the high risk of rupture within the first 24 hours, the actual recommendations suggest a prompt repair, unless patients have more immediately life-threatening injuries that require intervention (damage control approach) or if the patient is a poor operative candidate [2]. In our series, the clinical management was consistent with this approach. Although tailored treatment is obviously necessary in complicated setting as polytraumatic patients, damage control resuscitation management approach and TEVAR repair instead of OR have been crucial points to guide our clinical management with favorable outcomes.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0938

INTRODUCTION. Trauma still remains the first cause of death and invalidity among young people representing about 9% of total deaths in the word.

It's generally recognised that a rapid treatment of multi-injured patients by a team of specialists with well-established protocols can significantly affect mortality and morbidity with concomitant optimization of medical resources. Despite this,organization of trauma centres may be difficult because of economical, organizational and educational problems; standard of care in Italian trauma centres is not well known.

OBJECTIVES. Italian Sanitary System is organised in regional districts; the aim of this survey is to describe standard of care in Lombardia, a 23 Km^2 area with ten million inhabitants and a median of trauma per year around 4000. A Trauma System was set up in 2012 dividing hospitals in 3 categories:

High Speciality Trauma Centre: covering all injuries definitive care (6 CTS)

Zone Trauma Centre with neurosurgery: covering definitive care of major injuries excluding high specialities (13 CTZ nsgy)

Zone Trauma Centre without neurosurgery (10 CTZ)

Patients are centralised according to vital signs´ stability and suspicion of brain trauma.

METHODS. Between October 2017-January 2018 an online questionnaire was submitted to ED managers of trauma centres, investigating trauma team organization in daily practice such as education, hospital protocols, accordance to international guidelines.

RESULTS. Data are summarized in Table 1.

A total of 26 centres (89%) replied to questionnaire.

Whole CTS validated a trauma protocol including a trauma team composed in all but one case by non-dedicated physicians.

While a checklist for major trauma identification is present in all CTS, trauma team activation is not always automatic after checklist filling.

When established, Massive Transfusion Protocol (MTP) is activated mainly according to ATLS shock classes definition or to medical discretion (shock index and BE in 6% of interviewed).

Extra hospital utilization of tranexamic acid seems to be quite low: 35% of interviewed defines its use as common in prehospital care.

Concerning education, a local trauma registry is present in 23% of hospitals and only 30% of centres organizes periodical morbidity & mortality conferences and in situ simulations courses.

CONCLUSIONS. Surveys' evaluation of clinical practice, particularly in countries like Italy where Trauma System is still developing, allows a better knowledge of the state of the art and helps to improve organization. In less than 5 years a lot of work has been done in order to enhance trauma care in Lombardia but several aspects can still be ameliorated especially in non-High Speciality Trauma Centres, in education and trauma team working.

The relation between neutrophil subsets mobilized after trauma and the occurrence of infectious complications

L. Hesselink[1], R. Spijkerman[1], L.P.H. Leenen[1], L. Koenderman[2], F. Hietbrink[1]
[1]UMC Utrecht, Trauma Surgery, Utrecht, Netherlands; [2]UMC Utrecht, Department of Respiratory Medicine, Laboratory of Translational Immunology, Utrecht, Netherlands
Correspondence: L. Hesselink
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0939

INTRODUCTION. After severe trauma, patients are prone to develop infectious complications. The consequential immune response correlates with trauma severity and, thereby, the risk for these complications. Neutrophils are the first immune cells to respond to both tissue damage as well as infection. Different neutrophil subsets can be distinguished after trauma and during systemic inflammation, such as sepsis and after the administration of lipopolysaccharide (LPS). Based on morphology and receptor expression immature banded cells (CD16dim/CD62Lbright), mature segmented cells (CD16bright/CD62Lbright) and immunosuppressive hypersegmented cells (CD16bright/CD62Ldim) can be distinguished. In the last decade much information is gained concerning the role these cells might play in the pathophysiology of infectious complications.

OBJECTIVES. The aim of this study was to review literature and experimental data with emphasis on the recent findings in the last 10 years on neutrophil subset kinetics and function after trauma in relation with the development of infectious complications.

METHODS. A literature search was performed on neutrophil subsets. Studies were included on neutrophil subsets after trauma, neutrophil subsets in relation to infectious complications, and functionality of neutrophil subsets. Both clinical and experimental studies were included. Unpublished data on neutrophil subsets after trauma from our laboratory completed this study.

RESULTS. Directly after trauma, overwhelming inflammation leads to a release of large amounts of banded (immature) neutrophils into the circulation, with reported percentages up to 70% of total neutrophil count. During the following days a shift in neutrophil phenotype is observed towards the mature phenotype. From day 5 on, immunosuppressive neutrophils able to inhibit T-cells, are observed in the blood. After administration of LPS, these immunosuppressive neutrophils are characterized by diminished bacterial killing capacity compared to the other subtypes. It is unknown if systemic inflammation after LPS administration is comparable to the situation after trauma. However, severe infectious complications mainly occur after 5 days post trauma, which might indicate a similar process.

CONCLUSIONS. Distinct neutrophil subtypes with different functional characteristics are observed on specific time points after trauma. It is tempting to speculate that there is a relation between the appearance of immunosuppressive neutrophils in the blood and the occurrence of infectious complications after trauma.

Effect of Fluid resuscitation in first 3 hours and fluid balance on the mortality in pediatric septic shock

E. Ha, S. Park
Asan Medical Center, Pediatric Department, Seoul, Korea, Republic of
Correspondence: E. Ha
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0941

INTRODUCTION. Septic shock is life-threatening emergencies. Fluid resuscitation plays a fundamental role in the treatment of septic shock. The surviving sepsis guidelines recommend early aggressive fluid resuscitation. Although rapid fluid administration may offer benefit, studies on the timing of resuscitation are lacking, and especially more in pediatric patients.

OBJECTIVES. We tried to assess the amount of fluid administered in hours within 24 hours following the onset of septic shock. So we aimed to determine whether how much fluid was administered and how quickly it was administered after septic shock onset time is associated with the outcome of the patients, and to find out the optimal strategy for septic shock resuscitation.

METHODS. This is a retrospective cohort study of consecutive pediatric patients with septic shock who received fluid resuscitation admitted to Pediatric Intensive Care Unit between January 2012 and August 2017. Data were collected from reviewing the electronic medical records. We assessed the total amount of fluid administered and output within 24 hours from the onset of septic shock.

RESULTS. Of 155 patients with septic shock screened, 133 had detailed fluid data. Mean age was 9.0 ± 7.1 years, mean Pediatric Risk of Mortality (PRISM) III score was 14.1, and the 28-day mortality rate was 24.8 %. Hemato-oncology patients had majority of total patients (n=55;42.1%). Within 24 hours, an average 109.0 ml of fluid per body weight was administered, and 20.5 % of total fluid within 24 hours was administered within first 3 hour. Survivors received significant higher median amount of fluid within first 3 hours than nonsurvivors (22.7 cc/kg vs 18.8 cc/kg,p=0.048), but there was no difference in the amount of fluid after first 3 hours between these two groups. The proportion of fluid received within first 3 hours given to total amount administered over 24 hour period showed the significant difference between survivors and nonsurvivors(21.5% vs 17.3%,p=0.039). After 6 hours from onset of septic shock, the greater the amount of fluid administered, the higher the mortality rate tended to be.

CONCLUSIONS. Our results showed that the higher proportion of total fluid received within first 3 hours was associated with decreased 28-day mortality in pediatric patients with septic shock. The earlier fluid resuscitation within first 3 hours is thought to be a very important factor in the strategy for septic shock patients. And we think that further evaluation may be necessary to make these things more common.

The positive impact that a nurse led vascular access team can have on central line-associated complications

H. Baker[1], V. Shawyer[2], C. Coutice[2], J. Nixon[2], S. Hill[2], S. Bellamy[2]
[1]Royal Devon and Exeter Hospital, Intensive Care Unit, Exeter, United Kingdom; [2]Royal Devon and Exeter Hospital, Exeter, United Kingdom
Correspondence: H. Baker
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0942

INTRODUCTION. Peripherally inserted central venous catheters have become an increasingly common method of venous access in the ICU patient (Wilson et al, 2012).

The development of a nurse lead Vascular Access Team (VAT) within an acute care hospital has reduced catheter related blood stream infections (CRBSI) and minimized the incidence of venous thromboembolism (VTE). The VAT placed peripherally inserted central catheters (PICCS) as an alternative to short term central venous catheters, which have a low incidence of CLABSI. An initial rise in CLABSI correlated with the increase in number of patients

requiring parental nutrition. Consequently an education programme was implemented trust wide to reduce the CLABSI.

OBJECTIVES. Review 10 years of nurse led PICC line placement in relation to ICU patients to establish safety and efficacy of PICC in this population.

METHODS. A retrospective single centre study in general ICU in the UK. We included patients aged between 18 and 99 years, requiring a PICC during a period between January 2008 and January 2018. Our primary endpoints were CRBSI up to 30 days after catheter placement, UEVTE or misplacement. We defined CLABSI based on the Centre for Disease Control and Prevention's National Healthcare Safety Networks (NHSN) 2015 surveillance definitions. Secondary endpoints were numbers of line related days, indications for placement, number of attempts.

All PICCS were inserted by the VAT at the patient's bedside, using ultrasound and full sterile precautions in adherence to EPIC 2 guidelines. Infection rates were calculated per 1000 line days, from the introduction of the Vascular access service 8 months prior to the implementation of the educational programme and then for 12 months after. The educational programme involved

- Ward based teaching
- Junior Doctors training
- Monthly central line workshops
- Patient education

RESULTS. There were no insertion related bacteraemia during the surveillance period. The increase in line infections correlated with the increase in patients prescribed PN. There were 3 VTE in 2015 this correlated in greater surveillance. Through the surveillance of all the lines inserted by the VAT the specific educational needs of the staff and patients were identified and targeted.

CONCLUSION. A structured educational programme that includes doctors, nurses and patients has a direct impact on the reduction of central line associated bloodstream infections and VTE. This positive impact can be sustained through ongoing education and surveillance of line infections and VTE.

Efficacy and safety of early high-dose rehabilitation in ICU patients

M. Bychinin, S. Andreychenko, T. Sukonnikov, T. Klypa
Federal Research and Clinical Center, FMBA of Russia, Moscow, Russian Federation
Correspondence: M. Bychinin
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0943

IINTRODUCTION. Survivors of critical care illness frequently experience poor physical outcomes, including persistent impairments in muscle strength, exercise capacity and physical function. Rehabilitation including active and passive in-bed cycling ergometry, tilt table and neuromuscular electric stimulation are promising techniques for patient mobilization, although it is still unclear optimal time and dose of rehabilitation interventions [1].

OBJECTIVES. To access impact of early high-dose rehabilitation with relevant technology in general ICU-patients.

METHODS. Patients were assigned to either early mobilization (intervention) or to standard care (control). Early high-dose mobilization commenced ≤ 2 days of admission and completed 1 hour 5 days per week and included functional activities, sitting, in-bed cycling ergometry and tilt table. An intensive care unit Mobility team initiated the protocol within 48 hours. Each day participants

were examined and were excluded from eligibility for a giving session on that day if they were cardiovascular or respiratory instability. Our primary outcome was a favorable outcome on the modified Rankin Scale and ICU-mobility Scale at day of ICU discharge. Secondary outcomes were number of serious adverse events (failing to the floor, cardiac arrest, dangerous arrhythmia during exercise, oxygen saturation less than 80%, unplanned extubation, or loss any invasively inserted line), ICU and hospital length, mortality. We used the Mann-Whitney U test for continues variables.

RESULTS. 17 adult ICU-patients admitted in general ICU were enrolled in the study, 7 patients in the intervention group and 10 patients in control group.

CONCLUSIONS. We found that delivery of early high-dose mobilization in patients of general ICU was safe and associated with non-significant difference in tendency of better mobility scale score and less ventilator-free days.

Hemisphericcerebral oximetry (r_cSO_2) readings in status epilepticus in a pediatric emergency department: relationship to seizure complexity, anticonvulsant therapy and possible prediction trends

T. Abramo[1], H. Hargrave[1], Z.L. Harris[2], T. McCarty[1], N. Hobart-Porter[1], C. Velasco Gonzalez[1]
[1]UAMS/ACHRI, Pediatrics, Little Rock, United States; [2]Lurie Children's Hospital Northwestern School of Medicine, Pediatrics, Chocago, United States

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0944

Pediatric seizures can cause neuronal injury and pharmaco-resistant.For every first-line anticonvulsant minute delay (> 5minutes), a 10% greater risk for longer seizures >60 minutes, diminishing anticonvulsant efficacy, increase status epilepticus (SE) incidence and duration.A seizure 's cerebral physiology assessment tool, which current ED lacks, would enhance critical decision-making. Pediatric hemispheric $r_cSO_2$reading reflects cerebral physiology; r_cSO_2< 60%, >80% equates to abnormal cerebral physiology, neurological insult, and pathology.In EEG - $r_cSO_2$seizures, altered $r_cSO_2$correlated to seizures. PED non-epileptic generalized seizure patients, $r_cSO_2$readings were either < 60% or >80% and returned to pre-seizure $r_cSO_2$readings.Comparison of hemispheric generalized SE r_cSO_2 readings < 60 to >80% in relationship to seizure severity and anticonvulsant interventions is lacking.

OBJECTIVE. Correlational analysis of $r_cSO_2 < 60\%$ or $>80\%$ readings to seizure complexity and anticonvulsant administration in a pediatric emergency department (PED).

METHODS. Observational study comparing SE r_cSO_2 readings to seizure complexity and anticonvulsants in PED non-traumatic, neurologically normal, first-time seizure patients.

RESULTS. TABLE 1.

There were more $< 60\%$ than $>80\%$ seizure r_cSO_2 readings (p< 0.001), seizure r_cSO_2 readings: $r_cSO_2 < 60\%$, had a longer EMS (p=0.0002)/PED (p=0.001) seizure duration, required more EMS (p=0.001) and PED (p=0.0009) anticonvulsants compared to $r_cSO_2 > 80\%$. Overall PED comparison: $r_cSO_2 < 60\%$ had longer seizures (p=0.0002) and required more anticonvulsants (p=0.003). Patients < 2 years old had more $< 60\%$ r_cSO_2 readings (p=0.0005) versus >2 yrs. For >2 yrs, had more seizure r_cSO_2 readings $>80\%$ (p=0.003). However, age had no correlation with anticonvulsants (p=0.08) or EMS seizure duration (p=0.19). Seizure r_cSO_2 readings $< 60\%$ [left 48.3% (37.8-58.2, p=0.0007), right 42.6% (35.7-55.3, p=0.0005)], and EMS seizure duration >23 minutes (p=0.005) required more anticonvulsants while age no significance (p=0.17). Correlation of seizure rcSO2 readings during seizure´s nonresponsive anticonvulsant, < 60%, >80% rcSO2 readings were consistent with delta change of < 5% (p< 0.0001). Seizure r_cSO_2 reading $r_cSO_2 > 80\%$ changed earlier than $r_cSO_2 < 60\%$(p=0.001) and both changed earlier than EMR seizure cessation time (p=0.001).

CONCLUSION. In PED SE seizures, EMS seizure duration >23 minutes and seizure r_cSO_2 readings $< 60\%$ correlated with greater seizure complexity by longer seizure duration and more anticonvulsants compared to $r_cSO_2 > 80\%$. Comparing seizure cessation times, seizure $r_cSO_2 > 80\%$ changed earlier than $r_cSO_2 < 60\%$ while both r_cSO_2 readings changed earlier then clinical seizure cessation. Seizure neuroresuscitation should strive for rapid cerebral physiology and therapeutic assessment which hemispheric r_cSO_2 functionality has shown and should be an integral component for initial pediatric seizure assessment.

Table 1 (abstract 0944). See text for description

Evaluation of cerebral circulation in children with congenital heart disease—comparison of those with and without systemic oxygenated disturbance

M. Yamamoto, T. Mori, Y. Morimoto
Hokkaido University Hospital, Anesthesiology, Sapporo, Japan
Correspondence: M. Yamamoto
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0945

INTRODUCTION. Cerebral disorders after cardiac surgery are still a serious problem in children with congenital heart disease (CHD). Several studies have reported that the patterns of cerebral circulation are different according to the type of CHD in the fetus[1]. However, there seem to be few studies after birth.

OBJECTIVES. In this study we evaluated the cerebral blood flow velocity (CBFV), cerebrovascular resistance and cerebral oxygen saturation (rSO_2) in children with CHD scheduled for cardiac surgery and compared these items for those with and without systemic oxygenated disturbance.

METHODS. After obtaining institutional review board approval (016-0505), we performed an observational prospective study of children under 15 years old scheduled for cardiac surgery. After induction of anesthesia, CBFV of the middle cerebral artery (systolic, Vs; mean, Vm; diastolic, Vd) was measured by transcranial Doppler sonography, EZ-Dop (DWL, Germany) and the pulsatility index (PI: [Vs-Vd]/Vm) was calculated as an index of cerebrovascular resistance. The rSO_2 was measured using an INVOS-5100B (Somanetics, Troy, MI). Simultaneously, mean systemic arterial blood pressure (mBP) was recorded and blood gas analysis was performed. Then the patients were divided into 2 groups according to whether PaO_2/FiO_2 (P/F) ratio was over 300 or not. These items were compared between the groups by using the unpaired t-test and P < 0.05 was considered significantly different.

RESULTS. Fifty-one patients (age in months: 13.1 ± 20 [mean ± SD]; mean body weight [kg] 6.8 ± 4.6) were evaluated. There were 37 children with systemic oxygenated disturbance (P/F ratio < 300) (group D: hypoplastic left heart syndrome, pulmonary atresia, etc.) and 14 children without the disturbance (group N: ASD, VSD, etc.). The PI in D was significantly higher than that in N (1.61 ± 0.46 [D] vs. 1.27 ± 0.13 [N]; P=0.01) and there was a tendency for Vm (cm/s) in D to be lower (46.0 ± 20.7 [D] vs. 56.2 ± 27.3 [N]; P=0.2). The rSO_2 (%) in D was significantly lower (64 ± 15 [D] vs. 74 ± 15 [N]; P=0.03). There was no significant difference in mBP (mmHg)(46 ± 9 [D] vs. 52 ± 12 [N]; P=0.1) and the hematocrit (%) in D was significantly higher (41.5 ± 7.2 [D] vs. 35.0 ± 7.5 [N]; P=0.01).

CONCLUSIONS. Unexpectedly, cerebrovascular resistance was higher in the children with CHD who had systemic oxygenated disturbance. This may be related to high blood viscosity due to high hematocrit in these patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0946

INTRODUCTION. Serious bacterial infection (SBI) is a major cause of morbidity and mortality in children. Distinguishing SBI from self-limiting viral infections is very important task in emergency department (ED)[1], especially among the febrile children who show fever without source (FWS).

OBJECTIVES. The aim of this study was to evaluate whether parents' statements on clinical manifestations are reliable for diagnosis of SBI among the children with FWS.

METHODS. This study was conducted using prospectively acquired cohort data of all the febrile children ('fever registry') in a tertiary pediatric emergency department. The subjects of the study were the children under 5 years of age with FWS from August 2016 to August 2017. The SBIs were defined as cases of positive blood culture, meningitis, urinary tract infection (UTI), and pneumonia on chest X-ray. The parents' statements were categorized into 3 or 4 grades according to the severity of four clinical manifestations (activity, feeding, urination, and duration of fever). The linear-by-linear association test was used to examine linear association between the severity of clinical manifestations and SBI. Receiver operating characteristics curves and the area under the curves (AUC) were obtained to evaluate the predictive performance.

RESULTS. Among the 587 children included in the study, 25 (4.3%) were diagnosed with SBI including 6 pneumonias, 17 UTIs, 0 meningitis, and 2 bacteremias. There was no linear association between the severity of the clinical manifestations and SBIs, duration of fever (p=0.299), activity (p=0.781), feeding (p=0.161), urination (p=0.834). The AUC for duration of fever was 0.54 (95% CI 0.41-0.67), 0.52 for activity (95% CI 0.40-0.64), 0.42 for feeding (95% CI 0.32-0.53), 0.51 for urination (95% CI 0.39-0.62).

CONCLUSIONS. The clinical manifestations, even considering the severity, shows little predictive performance for diagnosis of SBIs among FWS children. For optimal evaluation of FWS children, more comprehensive approach, including laboratory and imaging tests, are needed.

Clinical profile, intensive care needs and predictors of outcome in children with drowning: adeveloping country perspective

M. Samprathi, A. Agarwal, M. Jayashree, A. Bansal, A. Baranwal, K. Nallasamy, S.K. Angurana
Postgraduate Institute of Medical Education and Research, Pediatrics, Chandigarh, India
Correspondence: M. Samprathi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0947

INTRODUCTION. Unintentional injuries are the sixth leading cause of death in children less than 5 years of age and the leading cause of unintentional injury is drowning. Data on children with drowning in developing countries are scarce. Such data would help in effective management, prognostication and prevention of drowning.

OBJECTIVES. This study was undertaken to know the epidemiology, intensive care needs and predictors of outcome of children with drowning.

METHODS. This retrospective study, done at a tertiary care referral hospital in North India, included children younger than 12 years admitted with drowning from January 2009 to August 2017. Data collected from case records or electronic medical records comprised of demographic details, circumstances and management on site, clinical profile, PICU needs and outcome. Multivariate analysis was used to identify predictors of unfavorable outcome.

RESULTS. Twenty seven children were included, 14 were boys. Median age was 18 months (IQR-12, 30). Event was witnessed in 11 (40.7%). Site of drowning was in or around the house in more than half (n=15, 55.5%) and outdoors in 11 (40.7%). Most children (70.3%)

had drowned in fresh water. Ponds outside houses (n=10) and buckets of water in bathroom (n=9) were commonest sites. When first found, 23 (85.2%) were unconscious, 15 (55.5%) were apneic and 17 (62.9%) were blue. Duration of submersion was known in 20 (74.1%), median being 4 minutes (IQR- 3,9). On site resuscitation was attempted by untrained bystanders in thirteen (48.1%). Most common center where health care was first sought was government hospital (48.1%). Median time lapse between the event and reaching first health care center was 30 minutes (IQR- 22, 60) and reaching our center was 240 minutes (IQR- 94, 360). Six children (22.2%) presented in cardiac arrest, requiring cardiopulmonary resuscitation (CPR), 13 (48.1%) were hypoxic (saturation < 92% on room air) and half (51.8%) had encephalopathy (GCS $\leq$ 13). Ten children (37%) had seizures, 8 (29.6%) had shock, 10 had (37%) raised intracranial pressure (ICP). Hypo/hypernatremia was uncommon (18.5%). Ten were transferred to PICU; indications were raised ICP (n=6), ventilation (n=5) and hemodynamic monitoring (n=4).

One child died, 4 survived with sequalae; rest (22=81.5%) were neurologically normal at discharge (normal cognition, no motor deficits). Predictors of unfavorable outcome (death or survival with sequalae) on univariable analysis were hypoxia, GCS< 8, hypotension, requirement of CPR at admission, raised ICP, shock and mechanical ventilation but none of these could predict outcome on multivariate analysis.

CONCLUSIONS. Inadequate resuscitation on site, delayed and ineffective referral, physiological destabilization or requirement of CPR at admission and raised ICP contribute to unfavourable outcome in children with drowning in developing countries.

0948

Diaphragm pacing in complex pediatric respiratory care can have a significant role in treating respiratory failure from spinal cord injury to multiple other diseases including spinal muscle atrophy, pompe's and acute flaccid myelitis

R. Onders[1], M. Elmo[2], C. Kaplan[2]
[1]University Hospitals Cleveland Medical Center, Surgery, Cleveland, United States; [2]University Hospitals Cleveland Medical Center, Cleveland, United States
Correspondence: R. Onders
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0948

BACKGROUND. Chronic invasive mechanical ventilation (MV) in children increases medical complexity of care and adds to familial depression, anxiety and health care dollars. Diaphragm Pacing (DP) uses laparoscopically placed electrodes into the diaphragm muscle to deliver electrical stimulation to phrenic nerve motor points.

OBJECTIVE. Report largest consecutive series of DP in the pediatric population.

METHODS. Prospective, nonrandomized, interventional experience under IRB approval. Pediatric patients underwent laparoscopic implantation of four intra-muscular electrodes. Patients were discharged home where conditioning ensued to wean from the ventilator.

RESULTS. From 2009 to 2017, 23 patients between 2 years to 17.5 years (average 9) had surgical evaluations of their diaphragms with 20 patients being implanted. Three patients had completely denervated diaphragms and were not implanted. Other previous abdominal operations include 18 gastrostomy tubes, 3 VP shunts and one baclofen pump. There were no peri-operative complications. Time spent on MV prior to DP was 9 days to 92 months (33 months average). There were 80 cumulative pacing years (up to 8 years). No long term infections have been reported and no patient has required electrode removal or surgical revision. Three subsequently had scoliosis surgery. 50% achieved full time pacing with no mechanical ventilation. 4 pace during daytime over 12 hours a day and 5 pace 4-6 hours a day and still weaning. Two patients eventually were not pacing (1-brittle bone disease; 1 chronic skin reaction). Two patient had full recovery of volitional breathing and had the electrodes removed. Parents report an ability to perform more "normal" activities such as taking the child who uses the pacer to the beach. In addition, they report significant greater ease in caring for the pacer

compared to the ventilator. Social functions such as church and school are simpler without the noise of the ventilator and the excess tubing from the ventilator.

CONCLUSION. DP is easily implanted in children, has no deleterious effects and can decrease or replace MV. DP is the preferred breathing method by patients and their families, even when compared to non-invasive ventilation. Similar to adults, early implantation decreases wean time and identification of denervated diaphragms can save untoward effects from physiologically impossible ventilator weaning. For pediatric populations with intact phrenic motor neurons DP can be an option in a wide group of patients.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0949

INTRODUCTION. Chickenpox is a common infection in childhood, caused by varicella zoster virus (VZV). Although generally considered as an innocent infection, the disease course can be complicated and even fatal, both in previously healthy as in immunocompromised children. Few data regarding critical illness and mortality associated with VZV-infections in children are available.

OBJECTIVES. By describing our ten-year experience, we aim to improve the knowledge about PICU-admissions, complications, sequelae and mortality associated with VZV-infections.

METHODS. We analysed retrospectively all admissions on our Pediatric Intensive Care Unit (PICU) involving patients with primary or secondary diagnosis of VZV-infection, using the hospital database of our PICU. All patients aged 1 month to 15 years and admitted from Jan 1st 2005 till Dec 31st 2014 were included.

RESULTS. 50 patients aged 4 months to 12 years were included. Mean PICU-length of stay was 7.3 days.18/50 patients had relevant comorbidity, of which most were immunocompromised. Diagnosis on admission were most frequently bacterial surinfection of soft tissues, septic shock, respiratory failure and epilepsia. 15/50 patients required invasive mechanical ventilation, 13/50 vasoactive mediaction, 2/50 ECMO. Mortality rate was 4/50, of these 2 children were previously healthy, the other two had serious comorbidity and were institutionalised in the same service. Blood stream infections with *Streptococcus pyogenes* (7), *Staphylococcus Aureus* (1) and *Escherichia coli* (1) were demonstrated. A significant part of our patients patients suffered long-term sequelae (under which neurologic sequelae, venous thrombosis and peripheral limb amputation).

CONCLUSIONS. Our data demonstrate the serious course of many VZV-infections in a Pediatric Intensive Care Unit. Also in previously healthy children, serious complications, occurrence of sequelae and significant mortality rates are noted.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0950

INTRODUCTION. Augmented renal clearance (ARC) is an increase in kidney function, resulting in the enhanced elimination of circulating solute including renally cleared drugs. This concept has been increasingly recognized in critically ill adults, whereas in the pediatric intensive care setting, research remains scarce.

OBJECTIVES. The primary objective of this study was to investigate the incidence of ARC in critically ill children. Secondary objectives included a risk factor analysis for the development of ARC and a comparison of methods for detection of ARC.

METHODS. Single center, prospective, observational study at the pediatric and cardiac intensive care unit of the Ghent University Hospital, Belgium.

Glomerular filtration rate (GFR) was measured by means of a daily 24-hours creatinine clearance (24h Cl_{Cr}) and estimated used the modified Schwartz formula, for a maximum of four consecutive days. ARC was defined as a GFR exceeding normal values for age plus two standard deviations. Logistic regression analysis was used to identify risk factors for ARC.

RESULTS. Data were collected from 105 patients (median age 1.4 years, IQR 2.5). Overall, 59% of patients expressed ARC and the proportion of ARC patients decreased during consecutive days. ARC patients had a median Cl_{Cr} of 144.5 ml/min/1.73m^2 (IQR 47.1). Male gender and antibiotic treatment were independently associated with the occurrence of ARC. Patients after cardiac surgery were less likely to develop ARC. The modified Schwartz formula was less accurate for ARC detection in individual patients.

CONCLUSIONS. A large proportion of critically ill children develops ARC during their stay at the intensive care unit. As ARC may lead to subtherapeutic treatment of renally eliminated drugs, early detection of patients at risk is important.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0951

INTRODUCTION. The treatment of critically-ill children in pediatric intensive care units (PICUs) is associated with better outcomes, such as lower mortality rates; thus, we hypothesized that the incidence of healthcare-associated infections would also be lower in PICUs.

Acinetobacter baumannii is an important nosocomial pathogen associated with mortality among critically-ill patients. We compared the incidence of A. baumannii infection among pediatric patients treated only in PICUs with those treated in adult ICUs or multiple ICUs.

OBJECTIVES AND METHODS. We retrospectively reviewed the medical and laboratory records of 1041 critically-ill patients of the Department of Pediatrics aged under 18 years who were admitted to the ICUs of a tertiary referral hospital between May 2009 and June 2017. We investigated all kinds of specimens obtained after 48 hours of ICU admission to identify culture results positive for A.baumannii during ICU admission.

RESULTS. A total of 643 ICU admissions were included in this study, of whom 377 were treated only in the PICU (PICU group), and 266 were treated in the adult ICUs (AICU group). There were no significant differences between the PICU and AICU groups in length of ICU stay.

The PICU group had a higher prevalence of respiratory disease (54.1% vs. 33.1%) and neuro-muscluar disorder (40.3% vs. 25.2%), while the AICU group had a higher prevalence of hemato-oncological diseases (21.2% vs. 46.2%) and cardiovascular diseases (16.7% vs 36.8%).

A. baumannii was isolated 13 times in the PICU group (3.4%) and 19 times in the AICU group (7.1%); thus, the incidence densities of positive culture results for A. baumannii were 1.77 and 5.79 per 1000 ICU-days, respectively. After multivariate analysis, PICU group had lower hazard ratio of positive culture results for A. baumannii compared with AICU group (adjusted hazard ratio: 0.453, 95% CI: 0.210-0.980).

CONCLUSIONS. Critically-ill children treated only at PICUs had a lower incidence of A. baumannii infection.

Complications associated with central venous catheter in neonates: what is the problem?

N.M. Lee

Chung-Ang University Hospital, Pediatrics, Seoul, Korea, Republic of
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0952

INTRODUCTION. Central venous catheters (CVC) were frequently used for partial or total parenteral nutrition (TPN) in neonatal intensive care unit (NICU). However, it can be associated with various complications, such as infection, obstruction, thrombosis, pleural or pericardial effusion and cardiac tamponade. Among these, cardiac tamponade is a very rare complication but fatal that can lead to death.

OBJECTIVES. We evaluated the CVC associated complication and related risk factors.

METHODS. We conducted a retrospective study by utilizing medical records of neonates admitted in the NICU of Chung-Ang University Hospital from January 2012 to December 2017. Among these, nine neonates were diagnosed with CVC associated complications according to effusion analysis. The following parameters were recorded and analyzed: gestational age, birth weight, gender, central line type, insertion site, tip site, fluid rate and TPN osmolarity. Examination of pericardial, pleural effusion and ascites were performed and their results were analyzed. The diagnosis of CVC associated complication was based on high level of glucose and triglyceride in effusion.

RESULTS. Nine neonates were diagnosed with CVC associated complications. All cases (six pericardial effusions, two pleural effusions and one ascites) had drainage or aspiration of fluid, and the fluid analysis was consistent with total parenteral nutrition (elevated glucose and triglycerides). The mean volume of fluid drained 21.6 ml (range: 7.5-46ml). The mean glucose and triglycerides level of fluid drained were 1634 mg/dl (range 362-3550mg/dl) and 638 mg/dl (range 167-1734mg/dl). We used

neutriline in eight neonates and umbilical catheter in one neonate. Central line tip were located at T1-6 level. The mean TPN fluid rate and TPN glucose was 8.2cc/hr (range 4.4-13.1cc/hr) and 7.2 % (range 5-12 %). Among nine neonates, only one neonate was expired.

CONCLUSIONS. Among CVC associated complications, cardiac tamponade is very fatal. If cardiac arrest occurs in neonates with central lines, we should suspect cardiac tamponade by CVC associate complication and perform the echocardiography. These neonates can be successfully resuscitated with urgent echocardiography and prompt pericardiocentesis.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0953

INTRODUCTION. An augmented renal clearance (ARC) has been described in some critical patient groups.

OBJECTIVES. The aim was to assess the relationship between ARC and poor outcome.

METHODS. This is a prospective study in a surgical and medical intensive care unit (ICU). From July 2017 to March 2018, patients who stayed between 48 and 72 hours in the ICU were included. We exclude individuals referred from another hospital. Creatinine clearance was calculated from a 24-hours urine collection. Poor outcome was defined as a composite of death and long hospital stay, defined as the 75th percentile (>19 days). The logistic regression model was used to identify if ARC was independently associated with poor outcome.

RESULTS. Sixty patients were included in the study. Three patients died and sixteen (26%) presented the composite end point. In multivariate analysis, the development of ARC at third day at ICU predicts poor outcome (p=0.04, OR: 1.02 95% CI: 1.0005-1.04) (AUC ROC: 0.76, 95%CI 0.63-0.86).

CONCLUSIONS. A relationship between ARC and poor outcome was established, however a large sample size is needed to confirm our results.

A 20 year review of outcomes for critical care patients aged over 90 years

C. Mearns, T. Samuels

Surrey and Sussex Healthcare NHS Trust, Dept of Critical Care, Redhill, United Kingdom

Correspondence: C. Mearns

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0954

INTRODUCTION. In 2010 the UK had a population of three million people aged more than 80 years[1]. This is projected to double by 2030. The Department of Health estimates that the average cost of providing hospital and community health services for a person aged over 85 years is around three times greater than that for 65-74 year olds. This study aimed to assess whether the increasing age of the general population is reflected in that of our critical care patients, and to review ICU mortality against age.

METHODS. The Ward Watcher database for Surrey and Sussex Healthcare NHS Trust critical care was interrogated for the period

1994 to 2014. Data were reviewed for patients aged over 90 years regarding primary organ system failure, initial APACHE II score and mortality.

RESULTS. Total admissions and admissions in elderly patients have increased over time (Figure 1). During the 20 year period, 126 patients aged over 90 years accounting for 1.4% of the total (80 female, 46 male). Patients were admitted following emergency abdominal surgery (53%), orthopaedic surgery (11%), respiratory failure (15%), and cardiovascular failure (including sepsis) (12%).

Where the APACHE II score was greater than 25 the mortality rate was 71.4%. The ICU mortality of patients was 24.6% with a total hospital mortality of 40.4%. Mortality was lower in females vs males (18% vs 34.7%).

CONCLUSIONS. Elderly patients are increasingly being admitted to critical care, particularly following surgical intervention. Patient selection may influence comparative mortality between age groups but given the higher mortality rates for older patients, further work regarding identification of factors that may assist in quantifying risk would be useful.

High central venous pressure and cumulative fluid balance is associated with mortalitay in ICU

B. Lubis[1,2], P. Amelia[3,4], A.H. Nasution[1,2], T. Hamdi[1,2]
[1]University of North Sumatera, Anesthesiology, Medan, Indonesia; [2]Adam Malik Hospital, Anesthesiology, Medan, Indonesia; [3]University of North Sumatera, Faculty of Medicine, Medan, Indonesia; [4]Adam Malik Hospital, Medan, Indonesia
Correspondence: A.H. Nasution

INTRODUCTION. Central venous pressure (CVP) was often used in Intensive Care Unit (ICU). Extreme values of CVP may be considered the downstream pressure of venous return rather than a measure of preload. Several studies have linked CVP with the incidence of renal failure that has been found to be associated with mortality. Mortality in ICU is related to excess fluid, In this study the we wanted to know whether there was a correlation of CVP > 8 cmH_2O with mortality and positive fluid in ICU patients.

OBJECTIVES. The main purpose of our study is to asses for an association between high central venous pressure (CVP) and cumulative fluid balance with mortality in Intensive Care Unit (ICU).

METHODS. A cross-sectional study was conducted from from January to December 2017 in ICU Adam Malik Hospital Medan. Patients with

age over 18 years admitted to our ICU were included. The demographic data, CVP value, and cumulative fluid balance were compaired between survivors and nonsurvivors.

RESULTS. During the study period, 100 patients were admitted; 52% were male with mean age 48.5 ± 16.5 years old. The overall mortality of 100 patients was 38%. There was an association between high central venous pressure with mortality in ICU (p=0.004). But there was no association between cumulative fluid balance and mortality in ICU (p=0.109).

CONCLUSIONS. High central venous pressure was associated with mortality in ICU patients, and it could be a simple predictor in addition to APACHE II score. But there was no association between cumulative fluid balance and mortality in ICU patients. Further study is needed to explore the accuracy of central venous pressure to reduce the mortality in ICU patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0956

INTRODUCTION. In mechanically ventilated (MV) COPD patients, the minute ventilation should be titrated rather to pH than $pCO2$; but there is still a huge gap between recommendations and daily practice.

OBJECTIVES. To assess the impact of airway pressures on mortality among MV AE/COPD patients.

METHODS. Medical records were abstracted for all mechanically ventilated consecutive patients who were admitted for AE/COPD from November, 2015 to February, 2018 in the MICU of Farhat Hached teaching hospital, Sousse, Tunisia. Data regarding demographics, clinical variables, airway pressures (upon admission and at day 4 of hospitalization), high pressure ratio (HPR = number of days spent with high pressures: Peak ≥40 and/or plateau ≥30 and/or driving pressure ≥15 and/or auto-PEEP ≥6 cmH2O, divided by length of stay) and outcomes were recorded. Univariate and multivariate regression analyses were performed to identify factors independently associated to mortality. ROC curves were used to check for the discriminative properties of the significant associated factors.

RESULTS. Among 304 mechanically ventilated patients collected within the study period, 105(34.5%) were admitted for AE/COPD. Their main characteristics were : mean age, 67 ± 11 years ; male sex, 91(86.7%) ; COPD GOLD D, 86(81.9%) ; mMRC ≥ 2, 96(91.2%) ; mean SAPS II, 34.3 ± 11.2 ; ; pH, $7.29\pm0,1$; pCO2, 63.5 ± 22 mmHg ; P/F ratio, 192 ± 84 mmHg ; median mechanical ventilation duration, 8[4-18.5] days ; tracheostomy, 27(25.7%) ; median length of stay, 13[6-21] days, mortality, 59(56.2%).

Mean airway pressures were respectively for peak, plateau, driving and auto-PEEP as following : upon admission: 36.2 ± 8.5, 20.6 ± 5, 13.4 ± 5.3, 7.2 ± 4.4 cmH2O ; and at day 4 : 35.8 ± 10,21.1 ± 6, 13.9 ± 4.7, 6.5 ± 4.4 cmH2O . The median number of days with high pressure and the median HPR were respectively 3[1-9] days and 0.35[0.13-0.9].

Univariate analysis showed respectively for deaths and survivals the following significant factors : peak at day 4 (38.2 ± 10.8 vs 32.7 ± 7.9 cmH2O, p=0.003), plateau at day 4 (23.3 ± 6.7 vs 18.4 ± 3.9 cmH2O, p < 10^{-3}) and driving at day 4 (14.9 ± 5.2 vs 12.6 ± 3.6 cmH2O, p=0.012) and HPR (0.75[014-1] vs 0.22[0.11-0.36], p< 10-3) to be associated to mortality.

Multivariate logistic regression identified plateau at day 4 (OR, 1.15 ; 95%CI, [1.003-1.333] ; p=0.043) and HPR (OR, 11.3 ; 95%CI, [2.6-51.1] ; p=0.001) as the only independent risk factors for mortality. The ROC-AUCs were : plateau at day 4, 0.73 ; HPR, 0.75.

CONCLUSIONS. In mechanically ventilated AE/COPD patients, an increasing plateau pressure and/or a persistent elevated airway pressures are independently associated to mortality. This could be explained by the addition of an elastic component to the already resistive mechanics.

0957
Exercise capacity and muscle strength differences in working aged patients with normal or impaired physical functioning after critical illness at three months after the hospital discharge

M. Niittyvuopio, J. Liisanantti, J. Pikkupeura, S. Sälkiö, T. Ala-Kokko
Oulu University Hospital, Department of Anesthesiology and Intensive Care, Oulu, Finland
Correspondence: M. Niittyvuopio
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0957

INTRODUCTION. A significant portion of the patients recovering from prolonged critical illness suffer from Intensive Care Unit Acquired Weakness (ICUAW) [1]. Some of the typical manifestations of ICUAW are reduced exercise capacity and muscle strength [2].

OBJECTIVES. In this study we wanted to find out the prevalence of impaired physical functioning (PF) and differences in exercise capacity and muscle strength in working aged patients, with an ICU length of stay (LOS) for more than four days, who were stratified to either impaired or normal physical functioning according to RAND-36 health related quality of life (HRQoL) questionnaire´s physical functioning (PF) dimension.

METHODS. The study was conducted in our post-ICU follow-up clinic. All the patients aged between 18 and 65 living in our hospital district area with LOS for more than four days and who met the invitation criteria were invited. The follow-up clinics invitation protocol excludes the patients with severe psychiatric comorbidities, alcohol and substance abuse issues, communicating and co-operation deficits and cardiac surgery patients. At the follow-up clinic the exercise capacity was measured by a six minutes walking distance test (6MWD) and the muscle strength was measured by a hand-grip test. The patients also filled the RAND-36 HRQoL questionnaire and were divided into two groups: Either normal or impaired physical functioning according to RAND-36´s PF dimension. PF was defined as impaired if the scores were less than 2SD of the age and sex matched general population mean.

RESULTS. Between years 2004-2012 There were 468 eligible patients who were invited to the follow-up clinic and 351 (76%) attended for the survey control. The data could be calculated on 332 patients. The median age was 50 (38-57) and 63% of the patients were male. The median APACHEII and SAPSII scores on admission were 18 (13-23) and 38 (28-49) and the median LOS was 7 (4.8-11.8) days.

The PF was defined impaired in 131 patients (39.5%). The patients with impaired PF achieved significantly reduced results in 6MWD (393 m vs. 500 m, p< 0.001) and in the hand grip test (left hand: 28 kg vs. 32 kg, p=0.004 and right hand 29 kg vs. 34 kg, p=0.001). There was no significant difference in PF outcome between genders, APACHEII or SAPSII scores or LOS.

CONCLUSIONS. The patients with impaired RAND-36´s PF dimensions scores had significantly reduced exercise capacity and muscle strength.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0958

INTRODUCTION. Invasive mechanical ventilation (IMV) in COPD patients is frequently associated with difficulty of weaning considering that over 50% of the first weaning attempts are unsuccessful. This prolonged weaning process and the extended IMV are predictive of poor outcome and various complications. Newtonian equation of motion clearly illustrates the respective restrictive airway pressures to predict difficult weaning process.
OBJECTIVES. To identify the discriminative properties of respective airway pressures to predict difficult weaning process.
METHODS. Medical records were abstracted for all mechanically ventilated (MV) consecutive patients who were admitted for AE/COPD from November, 2015 to February, 2018 in the MICU of Farhat Hached teaching hospital, Sousse, Tunisia. Data regarding demographics, clinical variables, airway pressures (upon admission and at day 4 of hospitalization), high pressure ratio (HPR = number of days spent with high pressures: Peak $\geq$40 and/or plateau $\geq$30 and/or driving pressure $\geq$15 and/or auto-PEEP $\geq$6 cmH2O, divided by length of stay) and outcomes were recorded. Poor outcomes were defined as: a ventilator-free days at day 28 (VFDs) = 0, a duration of IMV $\geq$ 14 days and a composite outcome: death or length of stay (LOS) $\geq$ 14 days. Univariate and multivariate regression analyses were performed to identify factors independently associated to difficulty of weaning. ROC curves were used to check for the discriminative properties of the significant associated factors.
RESULTS. Among 304 MV collected patients, 105(34.5%) were admitted for AE/COPD. Their main characteristics were : mean age, 67±11 years ; male sex, 91(86.7%) ; COPD GOLD D, 86(81.9%) ; mMRC $\geq$2, 96(91.2%) ; SAPS II, 34.3±11.2 ; pH, 7.29±0,1 ; pCO2, 63.5±22 mmHg ; P/F ratio, 192±84 mmHg ; median IMV duration, 8[4-18.5] days ; tracheostomy, 27(25.7%); median VFDs, 0[0-3] days ; median LOS , 13[6-21] days, mortality, 59(56.2%).
Mean airway pressures were respectively for peak, plateau, driving and auto-PEEP upon admission: 36.2±8.5, 20.6±5, 13.4±5.3, 7.2±4.4 cmH2O; and at day 4 : 35.8±10,21.1±6, 13.9±4.7, 6.5±4.4 cmH2O. The median number of days with high pressure and the median HPR were respectively 3[1-9] days and 0.35[0.13-0.9].
Univariate analysis then multivariate logistic regression showed that plateau pressure at day 4 (OR, 1.69 ; 95%CI, [1.15-2.49] ; p=0.008), auto-PEEP at day 4 (OR, 65.3 ; 95%CI, [2.25-1893] ; p=0.005) and HPR (OR, 1.57 ; 95%CI, [1.15-2.17] ; p=0.005) were related to a poor

composite outcome with the ROC-AUCs estimated respectively at : 0.83, 0.72 and 0.76. An elevated HPR (OR, 17 ; 95%CI, [3.76-76.6] ; p$\leq$10^{-3}) was related to zero VFDs with a ROC-AUC of 0.757. Furthermore, a number of days with high pressures $\geq$ 3 days was associated to a prolonged duration of IMV : (OR, 6.32 ; 95%CI, [1.89-21] ; p=0.003) ; ROC-AUC=0.69.
CONCLUSIONS. High airway pressures in MV COPD patients could impede weaning and increase length of stay.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0959

INTRODUCTION. A parameter that is often discussed and compared between different ICUs is the Standardised Mortality Ratio (SMR). Although a complex measure, difficult to interpret, it is used as a quality indicator of the care given in the ICU and hence is of great importance for hospitals, managers and politicians who use it as a benchmarking tool[1,2]. In 2013, the ICU in South Stockholm General Hospital (Södersjukhuset) had a higher SMR than the average in the whole of Sweden. A project was initiated consisting of a retrospective register study identifying areas of improvement and a subsequent quality improvement project.
OBJECTIVES. Register study: To describe survivors and non-survivors after intensive care regarding differences in gender, SAPS-score and limitations-of-care (LOC).Quality improvement project:To increase the proportion of patients where a decision about treatment strategy including a decision about LOC is made during the first 24 hours after admission and thereafter daily during the whole ICU stay.
METHODS. The project took place at the ICU in Södersjukhuset.The Swedish Intensive Care Registry (SIR) was used for outcome data.
The register study population consisted of all non-survivors (patients who had died within 30 days from ICU admission) and a control group of survivors, which consisted of the 12 first admitted patients every calendar month who survived 30 days after admission (144 patients) during 2013. The study was approved by the regional ethical review board in Stockholm.
The improvement project started in June 2014 and a multidisciplinary improvement team was formed. The interventions focused on measures to facilitate that treatment strategy and decisions about LOC were discussed and documented daily.
RESULTS. Register study: A total of 773 patients were admitted to the ICU during 2013. Of those, 135 (17%) died within 30 days from ICU admission, the majority of those (89;66%) died after the ICU stay. The non-survivors were significantly older (mean 75 yrs vs 61 yrs, p< 0.00) and had higher SAPS 3 (69 vs 51, p< 0.00) than the survivors. The documentation of treatment strategy was poor and only 3% of the survivors and 17% of the non-survivors had a documented decision within the first 24 h after admission.
Improvement project: The proportion of patients where a decision about treatment strategy including a position about LOC is made during the first 24 hours after admission has greatly increased, see Figure 1.
CONCLUSIONS. It is possible to make improvements in such a complex area as treatment strategy for patients in the ICU. The initial register study gave us a lot of new knowledge about our patients and highlighted the key issues for improvement.

INTRODUCTION. Prolonged ICU stay is associated with high mortality, morbidity, and costs. Understanding the predictors of prolonged ICU stay may help care providers to plan for preventive interventions and lead to an efficient consumption of hospital recourses especially with the high demand of ICU admission.
OBJECTIVES. To identify characteristics and associated factors to prolonged ICU stay.
METHODS. It is a retrospective study performed in the ICU of Farhat Hached teaching hospital of Sousse between January 2017 and December 2017 and including all hospitalized patients for more than 48 hours. Underlying condition, severity, diagnostic at admission, invasive interventions, electrolytes disorders, medication used, complications and adverse events were collected by reviewing the medical patients' charts. Prolonged ICU stay was defined as stay in the ICU for ≥15 days. Variables found to be statistically significant in univariate analysis were included into a multivariate regression model to identify factors independently associated to prolonged ICU stay.
RESULTS. During the review period, 260 patients were included. Patients' characteristics were : mean age, 56.82 ±18.45 ; female, 94(36.2 %) ; mean SAPSII, 31.27±11.65 ; mean Apache II, 13.26±6.5 ; Respiratory disorder on admission, 165(63.5%) ; invasive mechanical ventilation (IMV), 155(59.6%) and vasopressors use, 110 (42.3%).
The median length of ICU stay was 7[5-14]days. Sixty patients (23.1%) have required a prolonged ICU stay (≥15 days). The overall mortality was 28.5%.
Univariate analysis identified several factors associated to prolonged ICU stay respectively in prolonged ICU stay and controls: The use of mechanical ventilation (88.5% vs 60.9%, p=0.000), the use of vasopressors (62.5% vs 46%, p=0.043) and adverse events (56.7% vs 28%, p=0.000).
In multivariate analysis, two predictors were independently associated with prolonged ICU stay : the use of IMV (OR, 3.5 ; 95%CI, [1.4- 8.9] ; p=0.008) and adverse events (OR, 2.8 ; 95%CI, [1.4- 5.6] ; p=0.003).
CONCLUSIONS. The frequency of a prolonged ICU stay reveals relatively high in our study. Invasive mechanical ventilation and adverse events were the only independent predictors of prolonged ICU stay.

Long-term outcomes in tracheoventilated patients

R. Di Benedetto, S. Orlando, E. Antonucci
Intermediate Care Unit - Guglielmo da Saliceto Hospital, Piacenza, Italy
Correspondence: R. Di Benedetto
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0961

INTRODUCTION. Tracheoventilated patients represent a high-risk population. During intensive care unit (ICU) stay, those patients usually show frequent infections and need of prolonged invasive mechanical ventilation (IMV) and hospitalization[1]. Although many studies have examined short-term outcomes after tracheostomy, long-term outcomes in tracheoventilated patients have been poorly investigated in the literature.
OBJECTIVES. We hypothesized that tracheoventilated patients show poor long-term outcomes such as high rates of mortality, hospital re-admission and condition of frailty at discharge.
METHODS. We reviewed all patients admitted in our intermediate care unit (IMCU) after tracheostomy and still needy of IMV (from June 2014 to June 2017, 36 months). The inclusion criteria were age ≥18 y.o., need of IMV at IMCU admission, tracheostomy performed during the previous ICU stay. We collected demographic characteristics, timing of tracheostomy and type of discharge (e.g. home; long-term care facilities). We identified three primary long-term outcomes: 1) mortality rate (during IMCU stay; at 28-day, 6-months and 1-year); 2) hospital readmissions in the first year (ICU and/or IMCU readmissions; number of readmissions; total day of hospitalization), 3) conditions of frailty at hospital discharge (presence of devices, pressure ulcers and rate of bedridden patients). We also evaluated the rate of decannulation at 1-year.
RESULTS. 91 patients respected the inclusion criteria. Demographic characteristics are shown in the Table 1. The majority of patients was admitted in ICU for respiratory/cardiovascular problems (73/91, 80%) whereas neurological patients were 18/91 (20%). 8/66 patients (12 %) were discharged at home, 58/66 (88 %) at long-term care facilities. Patient showed high-mortality rates: IMCU mortality (27,5%), mortality at 28-days (40,7 %), mortality at 6-months (53,8%), mortality at 1-year (58,2%, see Figure 1). 33/57 patients (58 %) were re-admitted in the hospital during the first year. In particular, 10/33 patients (30,3 %) were re-admitted in ICU and 6/33 (18,2 %) in IMCU. Patients had a mean of a single re-hospitalization (min. 0, max. 6) for a mean hospital stay of 19 days (min. 1, max. 107). Table 2 shows the condition of frailty at hospital discharge. 29/91 patients (32 %) were decannulated during IMCU stay whereas further 12 patients were decannulated at 1-year (41/91, 45%).
CONCLUSIONS. Long-term outcomes in tracheoventilated patients currently remain poor. Our preliminary study showed high rates of mortality and frailty in this cohort of patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0962

INTRODUCTION. Our institution serves as the tertiary centre for neurosurgery, maxillofacial and neurology. The West of Scotland is considered one of the poorer areas in the United Kingdom. The SIMD-2012(1) (SIMD) takes into account employment, income, health, education/skills/training, geographic access to services, crime and housing. In practical terms it is found by looking up the patient's postcode (zip code) in a database. Previous publications have noted an effect of deprivation on health care(2-3).
OBJECTIVES. To assess the socioeconomic status of our ICU admissions overall and examine if lower socioeconomic groups had a lesser outcome.
METHODS. Using the electronic recording system (Wardwatcher), data was collected prospectively for all admissions to the unit. We examined the 2724 neurosurgical admissions from 1st January 2008 to 31st December 2017. 2605 of those had a postcode recorded. Outcome at end of ICU admission was analysed along with SIMD quintiles using R and Excel. Ethical and information governance permission was granted.
RESULTS.
Figure 1, SIMD quintile and outcome (absolute numbers)
Figure 2, SIMD quintile and outcome (% of each SIMD quintile)
CONCLUSIONS. The population of the West of Scotland is dominated by poorer socioeconomic groups. The data collected showed that there is little difference in patient´s outcome based on their SIMD. We intend to look in detail at SIMD and it's impact on our patient population.

INTRODUCTION. Improving survival-to-discharge rates from an admission to an intensive care unit (ICU) has led to increased interest in the long-term sequelae of an episode of critical illness (1). Morbidity and mortality rates are increased following discharge from an ICU, but the causes for this have not been fully elucidated (2-4). No current research exists on the incidence of cancer diagnosis after an episode of critical illness.

OBJECTIVES. This study aimed to investigate whether an admission to an ICU was associated with an increased incidence of cancer in the 5 years following hospital discharge.

METHODS. This was a retrospective observational study, investigating ICU admissions in the West of Scotland from January 2000 to December 2008. Four linked databases were used to identify adult patients, surviving at least 30 days following hospital discharge, who had subsequently received a diagnosis of cancer. A standardised incidence ratio (SIR) for the most common cancers in each sex was calculated, and compared to the observed incidence in the study population.

RESULTS. 27674 patients were identified as suitable for inclusion. In the 5 years following an admission to an ICU, the observed incidence of a new diagnosis of cancer was significantly increased compared to the population SIR. The majority of this effect was noted in an increased observed incidence of lung cancer in both sexes. Observed incidences of breast and prostate cancers were lower than expected.

CONCLUSIONS. In the West of Scotland between 2000 and 2008, patients surviving an episode of critical illness had a significantly increased incidence of diagnosis of cancer in the 5-year follow-up period. The increase was particularly marked in incidence of lung cancer. This is noted as a correlation, and this study was not designed to assign causality for this finding. Possible explanations related to critical illness may include shared lifestyle risk factors, levels of deprivation, pathophysiological processes such as inflammation and immunosuppression, and the long-term consequences of organ support therapies. Further research is required to investigate these.

INTRODUCTION. Frailty is a syndrome characterized by loss of physiologic and cognitive reserves leading to increase susceptibility to adverse events and a higher risk of death[1]. Frail patients have an increased risk of hospital and long-term mortality[2,3], and more difficulties recovering the homeostatic stability. Frailty allows to identify more vulnerable patients, who are more susceptible to complications and death, provide a realistic prognosis and empower the patient and their carers to anticipate solutions in post-discharge[1,2].

OBJECTIVES. Analyse the incidence of frailty syndrome in ICU patients and its association with mortality, at ICU discharge and at 6 and 12 months after ICU discharge, length of mechanical ventilation and ICU stay. Secondarily, to analyse which scale better correlates with those outcomes.

METHODS. A prospective, observational study, included 63 patients aged ≥65 years hospitalized for ≥24h, during a 6-month study period. Frailty was determined using the frailty phenotype (FP), the clinical frailty score (CFS), the Katz Index of Independence in Activities of Daily Living (IADL) and Charlson Comorbidity Index (CCI). Patients were separated as follows: FP score ≥3 and CFS≥5[3]. Other collected variables included body mass index (BMI), type of admission (medical, surgery, trauma), SAPS II, SOFA, days of mechanical ventilation (MV), ICU mortality, 6 and 12 months mortality.

RESULTS. Frailty was observed in 29% and 21% of patients based on an FP score≥3 and a CFS≥5, respectively. At admission to the ICU there was a statistically significative difference in SAPSII for frail (M=66.39; ±18.34) and nonfrail (M=54.49; ±22.83), (p=0.04). There were no significant differences between frail and nonfrail patients concerning BMI, type of admission, SOFA, MV and ICU, 6 and 12 months mortality. We found a positive strong correlation between the CFS and the IADL [r=0.78, p=0.00]; and a weak correlation between CCI and FP [r =0.42, p=0.001], and between CCI and CFS [r =0.44, p =0.00].

CONCLUSIONS. We were not able to find a scale that could efficiently predict the risk of death at the ICU/hospital or at 6/12 months in frailty patients. Instead, and as other authors proclaimed[1,2], frailty may be useful to predict the need of future care and institutionalization. Additionally, we found that that IADL and CFS, both functional measures, may provide similar information.

Correspondence: M. Boussarsar
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0966

Introduction
Many studies investigated ICU mortality but data on medical critically ill patients who experience early deterioration and death are rare and of particular concern.

Objective
To identify the independent factors associated with ICU death occurring within the first 48 hours of admission.

Methods
This was a 5-year (2011-2015) retrospective study conducted in a Tunisian medical ICU. Were included all consecutive patients who experienced early and late deaths defined as occurring within or after 48 hours following ICU admission, respectively. Were assessed patients' characteristics, comorbidities (Charlson index), basal functional status (Barthel index BI), diagnostic discrepancies, ICU admission delay, severity, admission time, reference. Multivariate logistic regression analysis was performed to identify independent factors associated with early deaths.

Results
Among the 1474 admitted patients, 542(36.7%) deaths occurred, in whom 227(41.8%) early deaths. General population characteristics were: median age 62[46-73]; sex ratio 1.6/1; COPD 131(24.2%); heart failure 137(25.3%); hypertension 187(34.5%); diabetes, 136(25.1%) ; hematological disease, 27(5%) ; median Modified Early warning Score (MEWS), 5[4-7] ; BI, 75[70-80] ; Charlson index, [2-5] ; acute respiratory failure (ARF), 316(58.3%) ; shock, 115(21.2%) ; neurological

distress, 123(22.7%); vasopressors use, 197(36.3%) ; mechanical ventilation, 358(66%) ; median SAPSII, 41[30-54] ; SOFA, 7[5-9]. Early death group had a median ICU stay at 17[8-27] hours.

Univariate then multivariable logistic regression analyses identified the following factors as independent predictors of early death : BI, (OR=1.05, 95%CI, [1.03-1,07]; p=0.0001), hematological disease (OR=2.9, 95%CI, [1.1-7.7], p=0.027), SAPS II, (OR=1.04, 95%CI, [1.02-1,08], p=0.0001) and vasopressors use at admission, (OR=2.47, 95%CI, [1.59-3.81]; p=0.0001).

Conclusions

This study shows that early deaths in medical ICU admission are common. Severity at admission, poor baseline functional status, use of vasopressors and hematological disease were identified as independent predictors of early ICU death.

Table 1 (abstract 0967). Frailty Score versus adverse events

Clinical Frailty Score	Number of patients	ICU deaths	Hospital deaths	Mean LOS	Mean Age
1	6	0 (0%)	0 (0%)	0.85	48

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0967

INTRODUCTION. As we deal with an increasingly ageing population, it is important to consider the concept of frailty. Frailty is a syndrome characterised by a loss of physical and cognitive reserve. With increasing frailty the risk of adverse outcome rises significantly. It is therefore crucial consider frailty when assessing patients for ICU admission and initiating invasive treatment. Numerous tools exist to allow quantification of frailty.

OBJECTIVES. The Clinical Frailty Scale is a validated tool, which grades frailty on a 9-point qualitative scale. It can be applied rapidly, making it compatible with the ICU environment. In this study we aim to measure the burden of frailty in our ICU and question whether it should be routinely measured for all ICU admissions.

METHODS. The SICSAG Wardwatcher database was utilised to identify all ICU admissions over a six-month period. Case notes were requested for retrospective analysis. Using admission documentation and nursing records we determined the level of frailty using the Clinical Frailty Scale (CFS). We recorded ICU mortality, length of stay, hospital mortality, level of organ failure, APACHE score and co-morbidities to determine if there was an association between frailty and adverse

RESULTS. There were 101 admissions over a six-month period, of these 57 case notes were successfully obtained and analysed. Patient age ranged from 22 to 83. There were eight elective patients who all survived. Of these eight, five were ranked CFS 3 and three were ranked CFS 4.

As outlined by the table above, our data signals that with increasing frailty, both ICU and hospital mortality increases. There were no ICU admissions with a CFS rank of 7, 8 or 9.

CONCLUSIONS. The results above are interesting and suggest that frailty on admission to ICU does influence outcome. With increasingly frailty there is an increased mortality, prolonged length of stay and increased risk of multi-organ failure independent on initial APACHE score. Although average age increases throughout our frailty groups, this does not seem enough to independently explain these results. In the future frailty scoring may influence ICU admission but more work is needed. We argue that to allow further assessment of the burden of frailty in ICU and its effect on outcome we should collect frailty data nationally using the clinical frailty scale.

Correspondence: M. Boussarsar

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0968

INTRODUCTION. Therapeutic plasma-exchange (TPE) represents the treatment of choice in many immune diseases. It is used in critically ill patients for various indications, either as a first-line therapeutic intervention or as an adjunct to conventional therapies. Data on TPE in the ICU setting are scarce.

OBJECTIVES. To describe the local experience of TPE according to frequency, indications, any procedural or patient adverse events and outcomes.

METHODS. All adult patients treated by plasma exchange in a 9-bed medical ICU of Farhat Hached teaching hospital between March 2009 and March 31, 2018 were included. Data were collected from identified patient medical records. Demographic variables, the indication for TPE, the TPE procedure characteristics, ICU mortality, duration of ICU stay and adverse events were analyzed.

RESULTS. During the study period, 2707 patients were admitted to the ICU. Sixteen (0.6%) patients underwent 66 plasma exchange procedures. Patients' characteristics were : median age, 32.5[26.5-56.5] ; male, 7(43.8%) ; mean SAPSII at admission, 28.44±13.7 ; invasive mechanical ventilation, 6(37.5 %) and vasopressors use, 4(25%). The median length of ICU stay was 7.5[6-12.7]days. The overall mortality rate was 18.8%.

Indications of TPE were: Thrombotic Thrombocytopenic Purpura (TPP), (n=4) ; neurological disorders: Guillain-Barre syndrome, (n=1) ; myasthenia gravis, (n=3), ADEM, (n=1) and autoimmune diseases: anti-glomerular basement membrane (anti-GBM) disease, (n=3) ; cryoglobulinemia, (n=1), lupus (n=1) and catastrophic antiphospholipid syndrome (n= 1).

The median number of procedures performed per patient was 4[3.25-5]. The mean exchange volume per procedure was 1796.13 ±247.4ml. The mean duration of procedures was 118.14±31.9min.

Almost all procedures (93.7%) were performed via a central venous catheter. All of TPE procedures were performed with citrate anticoagulation. Fresh frozen plasma was used for 15 patients as the sole replacement fluid. Adverse events were observed in 5 procedures including severe hypotension for 2 patients, two experienced mild urticaria, three patients had mild chills and one patient developed a cardiac arrest.

CONCLUSIONS. In this study, TPE use is rather uncommon. TTP was the most common indication. Some adverse events had occurred but most of them were not life-threatening.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0969

INTRODUCTION. Pneumonia is a common presenting disease process to critical care and is associated with multiorgan dysfunction (1). It has a high mortality and is associated with chronic illness.

OBJECTIVES. We aimed to quantify and characterise the burden of pneumonia in the intensive care unit of a large teaching hospital in the West of Scotland.

METHODS. We conducted a retrospective observational cohort study of all admissions to 18 bedded tertiary ICU of the Queen Elizabeth University Hospital in Glasgow from 1/5/15 to 28/2/18. We used the WardWatcher system to collate diagnostic, demographic, physiological severity and outcome data and separate the patients into pneumonia and non-pneumonia and also subtypes of pneumonia.

RESULTS. There were 2022 admissions during the study period. 377 (18.6%) had a diagnosis of pneumonia. Results are presented in Table 1. Patients with pneumonia were more likely to have severe respiratory disease, had higher APACHE-II scores and predicted mortality, were ventilated for longer, stayed in intensive care for longer and were more likely to die. Subgroup analysis revealed that survivors of pneumonia were younger, with a lower incidence of severe respiratory disease and immunosuppression and were less likely to have early signs of organ failure. Further subgroup analysis suggested that patients with aspiration pneumonia were younger than those with bacterial, fungal or other pneumonias and had a shorter length of stay and lower mortality.

CONCLUSIONS. We confirmed that pneumonia is a common presenting condition to our ICU and carries a significant mortality and severity of illness. This study allows us to identify factors in patients with pneumonia associated with mortality and allows us to help give more accurate prognostic information to patients and their relatives.

INTRODUCTION. A Red blood cell transfusion (RBCT) aims to restore an adequate oxygen supply. RBCTs are not without risks and therefore, unnecessary transfusions should be avoided[1]. No objective and reliable methods are available to determine an individual's need for a RBCT [2, 3]. Mitochondria are the ultimate target for oxygen supply; therefore mitochondrial oxygen tension monitoring seems an evident choice. In animal experiments a correlation between cutaneous mitochondrial oxygen tension (mitoPO$_2$) and the critical hematocrit has been demonstrated [4]. With the development of the COMET measurement system [5] cutaneous mitoPO$_2$ measurements became clinically feasible in patients receiving a RBCT.

OBJECTIVES. To measure the response of cutaneous mitoPO$_2$ during a RBCT or fluid challenge in a low-risk patient population of chronic anemia patients.

METHODS. In- and outpatients with chronic anemia, who receive a RBCT on a regular basis, were included in a single center two arm randomized IRB-approved study at the Erasmus Medical Center Rotterdam. Group 1 first got a RBCT followed by a 500 ml NaCl fluid challenge (FC) and group 2 visa versa (FC->RBCT). The COMET monitor (Photonics Healthcare BV, Utrecht, The Netherlands) uses the protoporphyrin IX-Triplet State Lifetime Technique (PpIX-TSLT) to measure mitoPO$_2$ [6]. A 5-aminolevulinic acid (ALA) patch was applied the day before RBCT to induce mitochondrial PpIX.

MitoPO$_2$ was measured every min, the first 5 measurements were taken as baseline. After ¾ till the end of the intervention, e.a RBCT or FC, the highest value was taken as the result.

RESULTS. 12 patients were measured twice and 9 once, one was re-measured and one was deleted due to insufficient signal quality (31 measurements). There was a mixed response and three groups could be distinguished during the RBCT. The mitoPO$_2$ increased, stayed equal or decreased after the RBCT sequence. A threshold of 10% change was used to categorize the effect of RBCT on the mitoPO$_2$ seen in Figure 1. No difference in Hb was observed, 7.95 ±0.92 g/dL vs 8.01±0.68 g/dL. For all the RBCT given the mitoPO$_2$ decreased in 65% of the cases, increased in 23%, and remained the same in 13%.

CONCLUSION. The COMET monitor could detect the effect of a RBCT on mitoPO$_2$ and showed a decrease during RBCT in 65% of the cases. If the mitoPO$_2$ started high it was likely mitoPO$_2$ would decrease. If the baseline mitoPO$_2$ was low it was likely that the mitoPO$_2$ would rise. These clinical results demonstrate that mitoPO$_2$ could potentially be of value in understanding which patients need a RBCT based on their individual mitochondrial PO$_2$ level.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**0971

INTRODUCTION. Over 80% of ICU patients are anaemic by the end of their first week[1]. Anaemia is associated with increased cardiovascular morbidity and ICU length of stay (LOS). Although the aetiology of ICU anaemia is multifactorial, iatrogenic blood sampling contributes significantly to this burden. We aimed to assess the relationship between our iatrogenic blood letting practices, ICU LOS and blood transfusion requirements.

METHODS. Data from 102 patients were collected during the 8 week period. We excluding patients admitted with major bleeding and short length of stay (less than 3 days). Prospective attempts to accurately record the volume sampled for each patient was inaccurate so we used a retrospective survey of ICU staff to estimate volume sampled. This was combined with Electronic Patient Records to ascertain the exact number of arterial blood gases sampled, laboratory samples and blood transfusions required.

RESULTS. Our survey concluded that a median volume of 4ml of blood (IQR 3-5ml) was discarded at each sampling episode. As shown in figure 1 below: at 7 days, a median volume of 260ml (IQR 184-289ml) of blood was taken, of which 143ml (IQR 71-179ml) was discarded from the IV line dead-space. At 14 days, a median volume of 511ml (IQR 358-569ml) of blood was taken, of which 298ml (IQR 149-373ml) was discarded. At 21 days, a median volume of 745ml (IQR 518-832ml) of blood was taken, of which 424ml (IQR 212-530ml) was discarded. At 28 days, a median volume of 975ml (IQR 677-1091ml) of blood was taken, of which 524ml (IQR 262-656ml) was discarded. At 28 days, mean total volume of packed red blood cells (PRBC) transfused per patient was 533 ml.

CONCLUSIONS. Our data suggests that there is a linear relationship between ICU LOS and ICU anaemia. The LOS on ICU contributes significantly to ICU anaemia, as shown in figure 1. By day 13 our patients had lost the equivalent of one unit of whole blood (450ml), and we had discarded almost the equivalent of one unit of PRBCs (300ml). At 28 days, the volume of blood discarded (524ml) was almost identical to the mean volume transfused per patient (533ml). This data supports evidence that strategies to reduce iatrogenic blood letting such as the use of non-discard IV sampling lines, paediatric blood sampling tubes and the timely removal of invasive lines could reduce the burden of ICU anaemia and cut transfusion requirements. We have implemented changes to our blood sampling practice and will be re-auditing these in the future.

INTRODUCTION. In the Kyrgyz Republic, postpartum haemorrhage is still the leading cause of maternal mortality and is 15.8 cases per 100,000 live births (data from the confidential enquiry of maternal deaths (CEMD), 2014-2015). One of the missed opportunities is inadequate infusion-transfusion therapy during blood loss replacement.

OBJECTIVES. To study the effectiveness and safety of colloids (hydroxyethyl starch 6%) in the treatment of hypovolemia in postpartum haemorrhages.

METHODS. The study included 62 cases of massive bleeding after vaginal delivery (blood loss more than 30% of the circulating blood volume). The average age of the patients was 33.4 ± 2 years. Infusion-transfusion therapy was carried out simultaneously with hemostasis. Its composition varied according to the National Clinical Protocol, depending on the magnitude of blood loss. With massive blood loss, along with crystalloids, fresh frozen plasma and erythrocyte mass were used, and after bleeding control HES derivatives were added. All patients underwent complete clinical and diagnostic examination, in addition, an analysis of the clinical course of the postpartum period was carried out up to 6 months

RESULTS. Against the backdrop of infusion-transfusion therapy based on the use of hydroxyethyl starch (with strict adherence to the

conditions of the drug usage) and a significant limitation of indications for blood transfusion, no case anuria and hourly urine output below 40ml / h were noted. The proposed infusion-transfusion therapy of massive postpartum hemorrhage allowed to prevent the development of severe hemorrhagic shock. So, despite the presence of massive blood loss, only 2 (3.2%) cases were complicated with hemorrhagic shock of severe degree (stage III). In all the remaining 60 (96.8%) cases despite the volume of blood loss was more than 30% of the circulating blood volume, development of hemorrhagic shock reached only moderate degree (stage II). Also, 1,5 times reduction of blood transfusion was observed in comparison with cases of similar bleeding occurred before the introduction of the National Clinical Protocol. The duration of hospitalization in the postpartum period was 5 ± 2 days.

CONCLUSIONS. The use of colloids in the infusion-transfusion therapy for blood loss replacement during massive obstetric hemorrhages, in most cases, allowed to avoid a number of severe complications of hemorrhagic shock. Further study on role of colloids (HES) in the treatment of hypovolemia due to obstetric bleeding is needed.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0973

INTRODUCTION. Anemia is a common problem in the intensive care unit (ICU). Red blood cell transfusion (RBCT) can increase oxygen availability to the tissues and help correct the mismatch between oxygen delivery and oxygen consumption in this setting. However, studies evaluating the effects of RBCT on tissue oxygenation have provided conflicting results, with some showing improvement and others not.

OBJECTIVES. To systematically review the effects of blood transfusion on hemodynamics and oxygen variables.

METHODS. We performed a systematic review of all prospective, retrospective, observational and interventional studies that included ICU patients who had RBCT without active bleeding. The PubMed database was searched for relevant studies from inception until the end of March 2017. We excluded animal studies and all studies where cardiac output was maintained constant before and after transfusion. We also excluded studies that did not have sufficient data to enable calculation of the change in hemoglobin concentration and at least one of the following variables after RBCT: cardiac index/ cardiac output, mixed venous oxygen saturation/ central venous oxygen saturation ($S\bar{v}O_2/ScvO_2$), oxygen delivery (DO_2), oxygen consumption (VO_2) and oxygen extraction ratio (O_2ER). We also collected heart rate (HR) and blood lactate levels before and after RBCT. Studies were considered according to the patient population included: sepsis, acute respiratory failure, cardiac surgery, non-cardiac surgery, trauma, neurologic and mixed. A meta-analysis and a meta-regression analysis were performed for each hemodynamic and oxygenation variable to explore whether any baseline pre-transfusion variable could predict an increase in VO_2 after blood transfusion. All analyses were conducted using Comprehensive Meta-analysis Software V2˚. The statistical significance alpha level was 0.05.

RESULTS. Of 2441 eligible studies, 37 met the inclusion criteria: sepsis (n=17), acute respiratory failure (n=4), cardiac surgery (n=5), non-cardiac surgery (n=3), neurologic (n=1), trauma (n=1) or mixed (n=6). Cardiac index did not change after RBCT (k=19; diff means= -0.03; 95%CI, -0.10 to 0.04; p=0.444), HR decreased (k=19; diff means= -1.09; 95%CI, -1.86 to -0.32; p=0.005), $S\bar{v}O_2/ScvO_2$ increased (k=29; diff means= 2.90; 95%CI, 2.16 to 3.63; p< 0.001), O_2ER decreased (k=22; diff means= -3.35; 95%CI, -4.55 to -2.16; p< 0.001),

DO_2 increased (k=22; diff means= 90.56; 95% CI, 68.59 to 112.53; p< 0.001) and VO_2 increased (k=22; diff means= 2.87; 95%CI, 0.35 to 5.38; p=0.025). Blood lactate concentration was the only variable that predicted an increase in VO_2 after transfusion: for every 1 mEq/L increase in blood lactate, VO_2 increased by 6.2 mL/min/m^2 (p=0.006).

CONCLUSIONS. We observed variable effects of RBCT on systemic hemodynamics in heterogeneous cohorts of critically ill patients. Elevated lactate level before RBCT is the only predictor of an increase in VO_2 after transfusion.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0974

INTRODUCTION. Although lifesaving, blood transfusion is associated with morbidity and mortality. This association is especially observed in the critically ill, which may be a result of ongoing inflammation (1). Extracellular vesicles (EV) from red blood cells (RBC), which are present in high concentrations in RBC units, have been related to adverse effects of blood transfusion (2-4). Thereby, knowledge of their clearance is important to design safer blood products.

OBJECTIVES. To investigate clearance mechanisms of RBC-derived EVs in human endotoxemic recipients by measuring the presence of known RBC membrane markers that are associated with phagocytosis.

METHODS. Six healthy male volunteers were injected with Escherichia coli lipopolysaccharide. After two hours, an autologous RBC unit was transfused 35 days after donation. Samples were collected from the RBC unit and blood was collected from the volunteers before and after transfusion. RBC-derived EVs were labeled with (anti) glycophorin A, combined with (anti) CD44, CD47, CD55, CD59, or CD147, or lactadherin, a protein that binds to exposed phosphatidylserine (PS). Labeled EVs were analyzed on an Apogee A50 Micro flow cytometer.

RESULTS. Before transfusion, the RBC unit contained 3.1×10^{10} EVs/ mL (IQR 1.3- 5.3 x 10^{10}). 7.8% of these RBC-derived EVs exposed PS, whereas all other membrane markers were below the detection limit (Figure 1). In the blood sample collected before transfusion, 22% of the circulating RBC-derived EVs exposed PS and 9.1% were positive for CD59. The levels of EVs positive for CD44, CD47, CD55, and CD147 were low. After transfusion, the concentration of RBC-derived EVs increased 2.4-fold in two hours and decreased towards baseline levels thereafter. The number of EVs positive for PS increased slightly (p = 0.028), whereas the level of EVs positive for other membrane markers remained constant (Figure 2).

CONCLUSION. Besides a minor fraction of PS-exposing EVs, RBC-derived EVs produced during storage do not expose detectable levels of RBC membrane markers that are associated with phagocytosis. Taken together, our results suggest that other yet unknown mechanisms are involved in clearance of RBC-derived EVs after transfusion.

INTRODUCTION. Thromboelastography (TEG) is a global test of coagulation which analyzes the whole coagulation process. TEG is popular in trauma, liver transplant, and cardiac surgeries, but studies in sepsis are limited (1).
OBJECTIVES. To estimate transfusion savings prior to invasive techniques in septic patients when guiding transfusion by TEG in comparison with transfusion guided by the Spanish ICU transfusion recommendations based on conventional coagulation tests.
METHODS. Not blinded randomized observational study. Inclusion criteria: septic patients admitted in the ICU (apr-dec 2017). Exclusion criteria: absence of informed consent. Randomization: **TEG group** (prophylactic transfusion guided by TEG) or **control group** (prophylactic transfusion guided by conventional coagulation tests) prior to an invasive technique. We analysed clinical variables (var), coagulation and need of transfusion. Analysis: description of quantitative var in means or medians (CI95%) according to Shapiro test and qualitative var in proportions. Bivariate analysis of qualitative var with Chi-squared test and quantitative var with Mann-Whitney U test. Significance p< 0.05.

RESULTS: n=43. Males were 67% (CI95%:51-81), age 62.4y (CI95%:58.4-66.5), APACHE II 28.1 (CI95%:24.7-31.5), SOFA 8.3 (CI95%:7.2-9.4), ICU length of stay (LOS) 9 days (CI95%:7-18), ICU mortality 17.5% (CI95%:83-33%), and in-hospital mortality 25% (CI95%:14-41%). 55% of the patients were randomized in control group and 45% in TEG group. Incorrect transfusion was found in 21.7% of the patients in the control group and in 6.9% patients in TEG group (p=0.04). No haemorrhagic complications were found in any group. Fresh frozen plasma (FFP) transfusion in control group was 437mL (CI95%:280-550) vs 286mL (CI95%:284-290) in TEG group (p=0.4) and platelet transfusion in control group was 550mL (CI95%:447-625) vs 265mL (CI95%:256-275) in TEG group (p=0.08).
TEG results were: normal (43%), hypercoagulable (HyperC) (43%), hypocoagulable (HypoC) (14%). 45.5% of patients with INR≥1.3 had a normal TEG, 45.5% hyperC TEG and 9% hypoC TEG. 75% of the patients with APTTr≥1.3 had normal TEG, and 25% hypoC TEG. 60% of patients with high fibrinogen levels and no one with normal fibrinogen had an hyperC TEG (p=0.03); all patients with high platelet count and 10% of patients with low platelet count had an hyperC TEG (p=0.01).
CONCLUSIONS. TEG previous to realization of invasive techniques in septic patients optimizes transfusion. INR and APTTr in septic patients do not relate with patients coagulation capacity.
TEG prior to invasive techniques in septic patients can save transfusion. TEG better reflects the coagulation state in septic patients than the conventional coagulation tests (INR and APTTr).

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0976

INTRODUCTION. Coagulation is a major concern during ECLS and disseminated intravascular coagulation has been described as a complication [1,2]. We have observed that thrombocytopenia and hypofibrinogenemia are usual manifestations of ECLS-related coagulopathy (ECLS-RC).
OBJECTIVES. Describe a case series of ECLS-RC that was managed by circuit exchange.
METHODS. Retrospective analysis of patients from our ECLS cohort between March 2012 and November 2016 who developed ECLS-RC (defined as persistent thrombocytopenia and/or hypofibrinogenemia) and were managed with circuit exchange. We excluded circuit exchange for other reasons. The decision of circuit exchange was made on clinical grounds.
RESULTS. From a total of 44 ECLS runs we found 6 patients with circuit exchange due to ECLS-RC. Epidemiological data as median [interquartile range] were: age 65 years [48-70], circuit run 13 days [11-16], APACHE II 34 points [20-34], SOFA 9 points [7-9]. The etiologies were: Influenza AH1N1 (n=2), acute interstitial pneumonia (n=1), respiratory syncytial virus (n=1), ARDS (n=1) and pneumonia (n=1).
We found in these patients a significant decrease of fibrinogen levels (Fig 1A) and platelet counts (Fig 1B) with recovery after circuit exchange. A significant reduction of transfusion needs was also noted after circuit exchange (Fig 1B). Four patients had mucosal bleeding associated to ECLS-RC, while the other two patients had not clinical expression of ECLS-RC.
CONCLUSIONS. These data suggest that in ECLS-RC circuit exchange is associated with recovery of fibrinogen and platelets levels as well as a reduction in transfusion needs. Circuit exchange may be considered as part of the treatment of ECLS-RC if ECLS removal is not

possible. We propose that in ECLS-RC the circuit behaves like a diseased organ that self-perpetuates coagulopathy. Given the retrospective nature of the study and the small number of cases, prospective studies are warranted to confirm this hypothesis.

Major bleeding, can we identify some useful predictor of mortality?

E.A. Ines, C.R. Pablo, M.F. Mónica, G.V. Rita, F.M. David
University Hospital of A Coruña, Intensive Care, A Coruña, Spain
Correspondence: E.A. Ines
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0977

INTRODUCTION. Major bleeding (MB) is a situation with high mortality. Protocols are needed, a multidisciplinary action and to know the characteristics of the population. Our objective is to describe the population in a tertiary hospital.
OBJECTIVES. It is difficult to define those factors that play a role in the incidence of MB, but it is a priority to try to identify those that influence the mortality. Our objective is to find some eterminant factor in mortality.
METHODS. Retrospective study of 303 episodes of MB (transfusion> 5concentrated red blood cells (CH) in 4 hours or> 10CH in 24 hours) occurred in 298 patients who they required entry into the critical units during the 2009-2015 period. A descriptive analysis of the variables of interest was carried out, which may be related to themortality: age, sex, origin of bleeding, SOFA on the day of the episode, coagulation parameters, type of intervention (surgical, radiological and / or medical), support and hospital stay. The statistical package SPSS 19 was used for the analysis.
RESULTS. 303 episodes of MB were identified. 73.6% were male, the mean age was 61.2 (SD15.2) years and Charlson Index 4.5 (DE3.0). The score mean on the SOFA scale the day of the episode was 13.3 (SD4.8). The origin was cardiovascular in 58.40%, digestive in 33% and other causes 8.60%. The overall mortality was 47.9%. At univariate analysis we found an association significant with the mortality of: age (63.1 vs.59.4, p = 0.036), PH (7.21 vs 7.0, p = 0.023), APTT (1.7 vs.1.6; p = 0.02), noradrenaline (NA) dose (1.0 vs. 0.4; p < 0.01) and hospital stay (32.9 vs. 46.7, p < 0.01). In the multivariate analysis, he identified age (OR 4.4), NA dose (OR 15.7) and hospital stay (OR 7.9) as independent predictors of mortality.
CONCLUSIONS. The MB in our series presents a mortality acceptable. Patients with older age, as well as doses higher NA partners are associated independently with mortality.Hospital stay can be a factorconfusing to be influenced by gravit.

Washing of red blood cells prior to transfusion decreases trapping of donor cells in organs in a pneumosepsis rat model

L. van Manen[1,2], R. van Bruggen[2], N.P. Juffermans[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0979

INTRODUCTION. Red blood cell (RBC) transfusions are often given to septic patients, but are associated with organ injury in the critically ill (1). The mechanisms are unknown, but adherence of donor RBCs to an activated endothelium could play a role (2,3). We hypothesized that washing of RBCs before transfusion may reduce trapping of donor cells in organs and thereby reduce organ injury (4).
OBJECTIVES. To investigate the effect of washing of a RBC transfusion product on donor RBC clearance and trapping of RBCs in organs in rats with pneumosepsis.
METHODS. Sprague-Dawley rats were inoculated intratracheally with 10^7 colony forming units of S. pneumonia or vehicle as a control. After 20 hours they received a 2-weeks old, washed or non-washed biotinylated RBC (bioRBC) transfusion from syngeneic rats or saline (N=8 per group). Blood samples were taken directly after transfusion and 24 hours later. After 44 hours, the rats were sacrificed. The circulation of the rats was flushed with saline and organs were removed. Homogenized parts of the organs and blood were stained with streptavidin to detect the bioRBC by flow cytometry. The organs were histologically scored by a pathologist on a scale of 0-24.
RESULTS. All infected animals had severe pneumonia, as evidenced by bacterial outgrowth in the lungs. Mortality rate was 7,5%. Directly after transfusion, 18.9% (IQR 17.0-21.0%) of the circulating RBC were bioRBC. The median 24-hour post transfusion recovery of the bioRBC was 49.2% (IQR 47.2-53.5%). Neither Infection nor washing had an effect on post transfusion recovery (p=0.66) (Figure 1). A transfusion with a washed product reduced the percentage of donor RBCs in the liver and kidney compared to a non-washed transfusion. In contrast, washing increased the percentage of donor RBC in the spleen compared to non-washed products (p< 0.05) (Figure 2). Transfusion did not further augment the amount of lung injury induced by pneumonia, but washing decreased the amount of lung injury, (histology score 5.5 (IQR 4-7)vs 10 (IQR 8-13) in un-washed controls) . There were no differences in liver or kidney injury between groups.
**CONCLUSIONS.** Infection does not increase the clearance or trapping of donor RBC. In infected rats, a washed RBC product decreases trapping of RBC in liver and kidney and increases clearance of the RBC by the spleen.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0982

INTRODUCTION. Blood transfusion in severe trauma is a cure tool that must occur. And, it is well known that packed red blood cell (pRBC) transfusion may increase the risk of infection in trauma patients. But, there is no uniform guideline on the impact of transfusion volume and time to start transfusion.

OBJECTIVES. Recognition of transfusion effects in trauma patients is essential. Especially, although severe trauma patients have many hypovolemic shock in the early stages, but septic shock accompanied by infection is predominant over time.We studied the relation between timing of pRBC transfusion and incidence of infection after trauma.

METHODS. From January 2016 to December 2017, we studied 469 patients who were admitted to single regional trauma center of Southwest area of Korea. Outcome assessment included nosocomial infection (bacteremia and pneumonia) rates between 2 groups: the early transfusion group (< 4hours of admission) and the control group (4-24hours of admission). We used multivariable logistic regression to estimate the relative odds of bacteremia and pneumonia associated with the timing of pRBC transfusion.

RESULTS. A total of 58 (62.4%) of 93 patients developed bacteremia, and 53 patients (57%) who developed pneumonia received pRBC transfusion. Transfusion was associated with the increased rate of nosocomial infection, compared with non-transfusion patients (p< 0.05). Patients receiving RBC within 4hours had an increased odd of developing bacteremia (odd ratio, 1.9; p < 0.001) and pneumonia (odd ratio 1. 5; p< 0.001).

CONCLUSIONS. Transfusion of red blood cells increases the risk of developing pneumonia and bacteremia. Avoiding the unnecessary use of packed red blood cell transfusions in emergency room may decrease the occurrence of nosocomial infection.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0983

INTRODUCTION. Atrial fibrillation is the most common arrhythmia in ICU patients with an incidence of between 4.5-15%.[1] Patients that develop AF in ICU have increased ICU stay, increased hospital length of stay and increased mortality.[1] International guidance recommends the use of CHADSVASc and HASBLED scoring to determine patients that will benefit from anticoagulation and at risk of bleeding.[2] These scores are not validated in ICU and whether patients with AF benefit from anticoagulation in ICU is unclear.

OBJECTIVES.
Describe anticoagulation strategies used in ICU in patients with AF
Determine the thromboembolic (TE) and bleeding risks of ICU patients with AF
Determine outcome associated with AF, anticoagulation and bleeding in ICU with AF

METHODS. Patients admitted to ICU between Jan-Dec 2017 that developed AF during their admission were enrolled in the study. Data was extracted retrospectively from daily ICU observation sheets, electronic patient records system and electronic patient investigation systems. Demographic data and co-morbidities were recorded. Data regarding anticoagulation at first and subsequent episodes of AF was recorded. TE and bleeding events were recorded for all patients that developed AF. CHADSVASc and HASBLED scores were calculated for each patient and correlated with TE and bleeding events.

RESULTS. The overall incidence of AF was 6.2%. The incidence of new onset AF (NoAF) was 2.6%. Only 21.6% of patients developing AF received therapeutic anticoagulation within 48 hours of AF onset. No patients with NoAF received anticoagulation. 2 patients with pre-existing AF received anticoagulation but after more than one episode of AF. The most commonly used anticoagulant was low molecular weight heparin followed by unfractioned heparin. 92% of patients had a CHADSVASc high enough for anticoagulation to be recommended. 53% of patients had a HASBLED score that indicated moderate/high risk of bleeding. There was no association between CHADSVASc and TE events. HASBLED score correlated with bleeding events but did not reach significance.

CONCLUSIONS. Patients with pre-existing AF are more often anticoagulated compared to NoAF. The majority of ICU patients with AF meet guideline recommendation for anticoagulation. There is no statistical significance between CHADSVASc and TE events in ICU patients. Patients with high HASBLED scores tended to suffer more bleeding events. Patients appear to suffer more bleeding events in ICU compared to TE events. Current guidelines may not be suitable for critically unwell patients in ICU.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0984

INTRODUCTION. Massive Hemorrhage (MH) is a quite widespread entity in emergency department, validation of Massive Hemorrhage Protocols (MHP) has been associated with reduced mortality and morbidity but till now there is not a univocal definition of MH. Historically, recognition of MH has been overlapped with massive transfusion (MT), usually defined by retrospective data (e.g. more than ten units in 24 h or more than a half of circulating mass in 24 h) not helpful in real management of ongoing bleeding patient. Several scores have been proposed to predict MT needs but the higher the specificity, the lesser the applicability during emergency because of the complex calculations required.

In 2015 we drafted an institutional MHP (including standardized transfusion packs) to standardize MH recognition and treatment (Fig 1). Our staff was trained with dedicated courses.

OBJECTIVES. To evaluate the adequacy of our institutional protocol in identification of massive hemorrhage patients and consequent MT treatment.

METHODS. We analyzed data between June 2016-March 2017 (1 y after MHP creation). MT appropriateness was retrospectively evaluated considering Hb levels (after hemorrhage resolution and at 24 hours), in accordance with MHP transfusion targets. We also evaluated correct protocol activation in accordance with hemodynamic status criteria (Fig. 1).

RESULTS. 35 cases of MHP activation were reviewed, 20 of which following trauma. Activation of MHP was appropriate in 24 patients (68%) and in all trauma patients. The following results are referred to the appropriate cases. The continuous double-check (Clinicians and Transfusion Medicine experts), allowed that 24 h Hb did not exceed 10 gr/dl in 98% cases. Beside the amount of packed RBCs (mean 6.2, min 2, max 14), all patients were severely hemorrhagic and seriously ill, as assessed by mortality (37.5%) and mean ISS score for trauma patients(38). Finally, our pre-settled ratio between hemocomponents was ensured in all 24 appropriate cases.

CONCLUSIONS. Definition and activation of MHP in our center resulted in a good level of appropriateness of both recognition of MH and transfusion, maintaining the correct ratio and avoiding overtransfusion. Our results confirm that a retrospective definition of MH by the number of transfusions may underrate its real incidence, because an early, aggressive and balanced transfusion diminish the amount of haemocomponents.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0985

INTRODUCTION AND OBJECTIVES. This work aimed at showing that the reliability of the distensibility index of the inferior vena cava diameter (ΔIVC) for predicting preload responsiveness is low in case of low tidal volume (Vt) (6 mL/kg of predicted body weight). We also tested whether the changes in ΔIVC and in pulse pressure variation (PPV) induced by a "Vt challenge", consisting in increasing Vt from 6 to 8 mL/kg could reliably predict preload responsiveness detected by a passive leg raising (PLR) test.
METHODS. In 30 critically ill patients with acute circulatory failure ventilated with Vt at 6 mL/kg, we measured cardiac output (PiCCO2) before and during a PLR test. Each patient, ventilated in the assist control mode, was sufficiently sedated and well adapted to the ventilator. Preload responsiveness was defined by a PLR-induced increase in cardiac index ≥10%. We measured ΔIVC and PPV at baseline, at Vt=6 mL/kg, during a 1-minute increase in Vt at 8 mL/kg (Vt

challenge) and 1 minute after starting PLR, which was performed at Vt=6 mL/kg.
RESULTS. The PLR test performed at Vt=6mL/kg was positive in 15 patients ("preload responders"). At Vt=6 mL/kg, ΔIVC was similar in responders and non-responders (8±2% and 7±2%, respectively, p=0.1) and did not allow the detection of preload responsiveness (area under the receiver operating characteristic curve (AUROC)=0.67 ±0.10, p=0.1). It was also the case for PPV (12±4% in responders, 9 ±5% in non-responders, respectively, p=0.1), with an AUROC=0.69 ±0.10 (p=0.07). At Vt=8mL/kg, ΔIVC was higher in responders than in non-responders (15.4±2.8% and 5.6±3.1%, respectively, p=0.0004) and detected preload responsiveness (AUROC=0.93±0.04, p=0.001, threshold=10.7%). It was also the case for PPV (16±3% in responders, 9 ±5% in non-responders, respectively, p=0.001), with an AUROC=0.89 ±0.07 (p=0.001, threshold=12%). The Vt challenge-induced changes in ΔIVC detected preload responsiveness reliably (AUROC=0.98±0.02, p=0.001, threshold=2.5% increase in absolute value). It was also the case for the Vt challenge-induced changes in PPV (AUROC=0.98±0.01, p=0.001, threshold=1% increase in absolute value). The PLR-induced changes in ΔIVC did not detect preload responsiveness (AUROC=0.57 ±0.11, p=0.52), but the PLR-induced changes in PPV did (AUROC=0.97 ±0.03, p=0.001, threshold=3% decrease in absolute value).
CONCLUSIONS. ΔIVC is not reliable for predicting preload responsiveness in patients ventilated with Vt=6 mL/kg. A reliable detection of preload responsiveness was achieved by increases in ΔIVC as well as in PPV induced by a Vt challenge (transient increase in Vt from 6 to 8 mL/kg). Detection of preload responsiveness was also possible through the decrease in PPV induced by PLR, but not through the PLR-induced changes in ΔIVC.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0986

INTRODUCTION. Optimizing the circulatory condition of our patients is a daily challenge for the intensivist. Fluid is one of the therapeutics, through the increase of venous return and then cardiac output. Several tools may assess that, such as transthoracic echocardiogram (TTE), which allows the visualisation and the study of the respiratory variability from the inferior vena cava (IVC). However, the IVC visualisation is difficult in some situations (obesity, gut surgery, emphysema). Alternatively, the IVC is easily seen by a transhepatic way in her retrohepatic section (also called mid axillary).
OBJECTIVES. We hypothesised that the shape of the IVC and her variation taken by a transhepatic way could be predictive of fluid responsiveness.
METHODS. We performed fluid challenge in patients under mechanical ventilation. VT was set at 6ml/Kg and peep between 5 and 10 mmH2O. The need for fluid therapy was decided by the intensivist in charge. We performed a echocardiogram and took two measures of the transhepatic ICV (THICV) : major axis and minor axis. An elastometry index (EI) was determined as the ratio of minor axis to minor axis. The fluid challenge was 250ml of isotonic saline. We performed a new TTE and took the same ultrasound slice. We considered a 15% increase of the cardiac index (IC) as a success of the filling. Exclusion criteria were patients with A right cardiac insufficiency, an arrhythmia and/or a HTAP. The statistical analysis was performed using R software.
**RESULTS.** Between January 2017 and september 2017, 50 patients were included. The average age is 61 years (24-81), IGS2 of 50 (20-84), Ejectionnal Fraction of 48 % (35-75) and the S wave tricuspid is 14 (9-21). The main causes of the filling were an oliguria (31 %), a low blood pressure (25 %), a low cardiac output (30 %), a hyperlactatémia (11 %). A positive correlation between EI

(teleinspiratory phase) and the increase of the IC was detected, as well as the shape variation of the THVCI (DeltaEI) and the classic respiratory variations of the VCI (p< 0.05) Results are summarized in table 1. Classic variation of IVC by the subcostal way could only be obtain for 33 patients (no visualisation or bad alignment). The other variables are not predictive (BP, E/e´, E/A,CVP). The data are summarized in the figure 1. ROC curves has been established (table 1 and figure 1).

CONCLUSIONS. Shape of the THICV and there variations is a potential tool to assess fluid responsiveness. The main limit of the method is the necessity of being very perpendicular at the risk of falsifying the EI. A teleinspiratory ovoïd vena cava (EI : 0.85) is very sensitive and its variation very specific. We hypothesized that the combination of shape and his variation reflects the potential to elevate the mean mean filling pressure in order to increase venous return at the same capacitance.

Table 1 (abstract 0986). See text for description.

SIGNIFICANT PARAMETERS			
	R	IC	p
Variation IVC	0.64	0.38-0.377	0.04
Teleinspiratory EI (EI)	0.34	0.067-0.56	0.016
Respiratory variation of EI	0.35	0.007-0.57	0.015
ROC CURVES			
	AUC (IC95)	Se/Sp	Treshold
Variation IVC	0.72 (0.67-0.91)	86/75	14%
Teleinspiratory EI	0.75(0.60-0.86)	88-73	0.87
Respiratory variation of EI	0.76(0.61-0.86)	76-87	0.12

External validation of the Smith & Madigan formula to quantify the final end-diastolic volume of the left ventricle

G.P. Santana Hernandez[1], E. Monares Zepeda[1], J. Cruz Lopez[1], J.c. Cuesta Torres[1], F. Flores Puente[2], R. Cebrian Garcia[1], R. Lozano Zúñiga[1]
[1]Hospital San Angel Inn Universidad, Critical Medicine, Mexico City, Mexico; [2]Hospital 20 de Noviembre, Cardiology, Mexico City, Mexico
Correspondence: G.P. Santana Hernandez

INTRODUCTION. The final left ventricular end-diastolic volume (VDFVI) is an indicator of left ventricular preload; no invasive monitoring currently available outside the echocardiogram adequately estimates the VDFVI. Echocardiography, however, is technically difficult and operator dependent, requires experience, trained personnel and equipment to perform this measurement, it is not available 24 hours in intensive care units. The inotropism formula developed by Smith & Madigan (SMII) is carried out through USCOM monitoring in a semi-automatic way, it has been validated as an adequate surrogate of inotropism, prognostic marker and guide in resuscitation of septic shock. In another study, the Smith & Madigan working group demonstrated an adequate correlation between this formula and the VDFVI.

OBJECTIVES. Validate the VDFVI obtained by Smith and Madigan and the one obtained in patients with septic shock.

METHODS. In 56 patients diagnosed with septic shock, the following formulas were measured using USCOM ultrasound from the stroke volume (SV), mean arterial presion (MAP), presion mean gradient (Gp), body weigth index (IBW) and flow time (FT).

$$SMII = (SV \times (MAP - CVP + Gp))/(7.5 \times IBW \times FT)$$
$$VDFVI = SV \times 2.7/SMII.$$

The VDFVI obtained by the SMII formula was estimated and compared with that obtained using the conventional echocardiography technique, Bland & Altman, correlation coefficient R, Linn coefficient and percentage of error were performed in order to determine the concordance between both measurements.

RESULTS. 56 measurements were made in 56 patients. We compared VDFVI results, measured by echocardiography and Smith & Madigan formula, using the Bland & Altmann method (figure 1), we obtained an $R2 = 0.92$, a Linn coefficient of 0.92 with an LC95% higher 32.45, LC95% Lower - 39.45 and an error rate of 32%.

CONCLUSIONS. Smith formula & Madigan could be useful for the calculation of VDFVI. Although the percentage of error is greater than 20%, we must determine if this measurement is useful for making clinical decisions.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0988

INTRODUCTION. Pulse pressure variation (PPV) and stroke volume variation (SVV) are some of the best validated dynamic fluid responsiveness predictors. Still, respiratory limitations such as low tidal volume (TV) (< 8 ml/kg)[1], low heart-rate-to-respiratory-rate (HR/RR) ratio (< 3.6)[2], and low respiratory system compliance (Crs) (< 30 ml/cmH_2O)[3] have been identified, limiting applicability in the ICU[4]. Since the widespread use of lung-protective ventilation, these limitations are often combined in the same patient and firm conclusions about the role of one specific limitation are difficult to draw. Regarding the low TV limitation, some studies have identified a proportional relation between TV and PPV. Hence, PPV at low TVs may predict PPV at higher TVs, indicating that low TV might not be a limitation itself and indexing PPV or SVV to TV or driving pressure has been suggested.
OBJECTIVES. The study aim was to investigate PPV's and SVV's predictive ability when omitting data not fulfilling the HR/RR ratio and Crs validity criteria. We also assessed the impact of indexing PPV or SVV to TV or driving pressure on the predictive performance of these variables.
METHODS. MEDLINE was searched for relevant prospective studies published within the present decade. Authors were asked for sharing respiratory and hemodynamic data. Fluid responsiveness was defined as a fluid challenge induced increase in cardiac index (CI) or stroke volume (SV) (study specific) by 15% or more. Either PPV or SVV was analyzed. PPV was analyzed if PPV and SVV were both available. The area under the receiver operating characteristic curve (AUC) was determined for all patients and for sub-cohorts with omitted datasets where the HR/RR ratio or Crs limitations were violated. PPV and SVV were also indexed to VT and driving pressure and were similarly assessed.
RESULTS. 11 authors shared data, comprising in total 567 datasets; 256 (45%) were fluid responsive. TV was (mean ± sd) 7.1 ± 1.2 ml/kg, Crs was 36 ± 16 ml/cmH2O, HR/RR ratio was 5.1 ± 1.6. Low TV, low Crs, and low HR/RR ratio were found in 454, 197, and 97 subjects, respectively. PPV was available and used from 10 studies, SVV was available from seven studies and used from one study. The resulting variable is referred to as "dynamic variable" when AUCs are presented in table 1.

CONCLUSIONS. Omitting data based on the HR/RR ratio and lung compliance limitations and subsequently indexing dynamic variables to TV or driving pressure did not lead to satisfactory accuracy to predict fluid responsiveness. Only when all respiratory limitations were respected did PPV or SVV provide acceptable prediction, confirming their importance in the interpretation of functional hemodynamics.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0989

INTRODUCTION. Traditional resuscitative targets such as cardiac output, blood pressure and lactate are either up- or downstream of respiring tissue, but do not interrogate the tissues themselves. There is no measure of sufficiency, and the treatment goal is usually directed at normal resting values expected in health. Mitochondrial monitoring allows a direct assessment of the adequacy of oxygen delivery to support respiration.
Nicotinamide dinucleotide hydride (NADH) is the reduced moiety of NAD and the principal electron carrier from the Krebs' cycle to the electron transport chain (ETC). Under conditions of mitochondrial hypoxia, NADH levels rise. NADH is fluorescent under excitation by ultraviolet light whereas its oxidised counterpart (NAD^+) is not. This autofluorescence provides a natural window through which mitochondrial oxygen supply sufficiency can be interrogated in real time. Combining NADH and tissue haemoglobin saturation (StO_2) monitoring in one device allows direct assessment of the relationship between tissue oxygenation and oxygen sufficiency.
OBJECTIVES. To observe changes recorded by the combined probe during progressive fatal haemorrhage in an anesthetised rat model.
METHODS. A bespoke combined fibreoptic NADH and tissue oxygen saturation probe was implanted into the vastus lateralis thigh muscle of instrumented, anaesthetised Wistar rats. Tissue oxygen tension was recorded in the contralateral thigh (Oxylite, Oxford Optronix, Abingdon, UK). Ten percent of initial estimated blood volume (EBV, 66 ml/kg) was withdrawn via an indwelling carotid line every 15 minutes until cardio-respiratory arrest. At this point, the withdrawn blood volume was returned, and the animals observed for 20
minutes then euthanised. NADH fluorescence, tissue saturation, tissue PO_2 and arterial blood pressure were recorded continuously and arterial blood gas analysis sampling performed at intervals.

RESULTS. Initial tissue saturation varied from 50-70%, with an NADH fluorescence index of 0.15-0.22 units. Animals suffered cardiac arrest between 40-60% loss of EBV. Peri-arrest StO_2 was universally near zero, with NADH fluorescence rising to between 0.34 and 0.42 units. Animals responding to resuscitation renormalized NADH to baseline, whereas non-survivors continued to increment.

CONCLUSIONS. Monitoring both tissue oxygen saturation and NADH fluorescence is useful in delineating tolerated limits in haemorrhagic shock states. StO_2 < 10% and sustained NADH rises >0.35 units portend cardiovascular collapse. This form of combined monitoring may have utility in deeply shocked patients.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0990

INTRODUCTION. Respiratory failure is a life-threatening condition characterized by impaired gas exchange and increased work of breathing (WOB), resulting in a decrease in motor activity. The serine/threonine kinase mammalian target of rapamycin (mTOR) is a key regulator of protein synthesis, cell proliferation and energy metabolism. Respiratory overload affects the diaphragm muscle, but its impact on physical inactivity and signaling pathways associated with protein synthesis in skeletal musculature, such as mTOR, are less known.

OBJECTIVES. To evaluate the effect of resistive overload on the expression and activation of the mTOR pathway in the diaphragm and soleus muscle and locomotion behavior.

METHODS. Twenty-two Sprague-Dawley rats were randomized to Tracheal Banding (TB) or Sham (SH) groups. After the procedure, subjects were extubated, and they were observed for 7 days. Motor activity was assessed on days 1 and 6 with 6 min - Open field test (OFT). At the end of the observation period, subjects were euthanized, and diaphragm and soleus muscle were extracted. mTOR expression (mTOR/total protein) and activity (p-mTOR^{ser2448}/mTOR) was measured by western blot. Variables expressed as mean and SEM.

RESULTS. All animals survived initial surgery. After surgery, animals allocated to TB group had stridor and tachypnea and SH had no respiratory distress. On the clinical follow up, TB group had a mortality of 41.7% and SH 0% (p< 0.01). There was a significant weight loss in both groups, being more pronounced in TB group.

On OFT there were no differences on day 1, but at day 6 distance traveled pf BT was 46% lower than SH. The expression and activity of mTOR in diaphragm was higher in BT compared to SH (figure1). On soleus muscle activity of mTOR was lower in BT group compared to SH (figure2).
CONCLUSIONS. In subjects with increased resistive WOB we found a suppression a mechanical load-induced growth via kinase-dependent pathway in soleus muscle associated to a decrease of locomotor behavior. Opposite effects were found in diaphragm muscle. The role of this molecular signaling pathway may help to identify the benefit of interventions to reduce disuse-induced muscle wasting.

METHODS. Experimental ARDS was performed by saline lavage on 16 piglets. A recruitment maneuver (sustained inflation to 40 cmH2O for 30 seconds) was then performed followed by mechanical ventilation with tidal volume 6 ml/kg body weight. PEEP was initially set to 20 cmH2O then decreased by 2 cmH2O-steps down to 2 cmH2O. Piglets were then randomized into 3 PEEP groups based on best dynostatic compliance during PEEP trial, best end-expiratory lung volume during PEEP trial, or a PEEP-FiO2 table. Finally, 7 levels of VT ranging from 4 to 20 ml/kg were applied at optimal PEEP . Transpulmonary pressure measurements and computed tomography were performed at end-expiration and end-inspiration in the following conditions: at baseline after ARDS onset, during the PEEP trial, 1 hour after setting optimal PEEP, and during the variable VT trial.

RESULTS. PL_{ABS} ranged from -6 to 23 cmH2O at end-expiration and 5 to 58 cmH2O at end-inspiration. PL_{EL} ranged from 1 to 23 cmH2O at end-expiration and 5 to 65 cmH2O at end-inspiration. PL_{ABS} and PL_{EL} were significantly correlated (r=0.80, p< 0.001). Bias between PL_{EL} and PL_{ABS} amounted to 4 cmH2O (limits of agreement ranging from -2 to 11 cm H2O).

Non-inflated compartment significantly increased in deciles of end-expiratory PL_{ABS} below 4.8 cmH2O (Figure 1), and in deciles of end-expiratory PL_{EL} below 11.8 cmH2O. Table 1 provides the diagnostic performance of end-expiratory PL_{ABS} and PL_{EL} to detect a non-inflated compartment below 5% and 10% of total lung volume, respectively.

Overinflated compartment significantly increased in deciles of end-inspiratory PL_{ABS} above 25.8 cmH2O and in deciles of PL_{EL} above 30.7 cmH2O. ROC curve identified an end-inspiratory PL_{ABS} above 19.6 cmH2O and an end-inspiratory PL_{EL} above 24.6 cmH2O as best thresholds to identify an overinflated compartment greater than 2% of the total lung volume (table 1). There was no significant difference between area under ROC curve (AUC) assessed with both techniques.
CONCLUSIONS. Both measurement techniques of transpulmonary pressure have similar diagnostic performance to identify near complete alveolar recruitment at end-expiration and hyperinflation at end-inspiration. Near complete alveolar recruitment may be achieved with PL_{ABS} greater than 5 cmH2O and PL_{EL} greater than 10 cmH2O.

INTRODUCTION. Using esophageal pressure to compute transpulmonary pressure is an appealing technique to individualize PEEP setting in ARDS. Transpulmonary pressure can be computed 1. as the difference between airway pressure and esophageal pressure (absolute measurement PL_{ABS}); 2. as the product of airway pressure by the ratio of lung elastance to respiratory system elastance (elastance-derived measurement PL_{EL}).
OBJECTIVES. The aim of the study was to evaluate the relationships between both measurements of transpulmonary pressures and computed tomography-derived measurements in an experimental model of ARDS.

Table 1 (abstract 0991). See text for description.

	Classification	Sensitivity [95% CI]	Specificity [95% CI]	Threshold [95% CI]	AUC
PL_{ABS}	Non-inflated cpt. > 5% of lung volume	87% [81%-92%]	87% [80%-93%]	5.2	0.94 [0.91-0.97]
PL_{EL}	Non-inflated cpt. > 5% of lung volume	94 % [89%-97%]	79% [71%-86%]	10.3	0.93 [0.90-0.96]
PL_{ABS}	Non-inflated cpt. > 10% of lung volume	86% [78%-92%]	86% [80%-91%]	3.8	0.92 [0.89-0.96]
PL_{EL}	Non-inflated cpt. > 10% of lung volume	85% [77%-91%]	85% [79%-90%]	7.6	0.92 [0.89-0.95]
PL_{ABS}	Over-inflated cpt. > 2% of lung volume	0.91 [0.59-1]	0.81 [0.76-0.86]	19.6	0.91 [0.85-0.98]
PL_{EL}	Over-inflated cpt. > 2% of lung volume	0.91 [0.59-1]	0.79 [0.73-0.83]	24.6	0.91 [0.83-0.98]

Fig. 1 (abstract 0991). See text for description.

were randomized into 3 PEEP strategies (5 animals each): PEP set using a PEEP-FiO2 table, PEEP set 2 cm H2O above PEEP of maximal dynostatic compliance, and PEEP set 2 cm H2O above PEEP of maximal end-expiratory lung volume. Tidal volume was further adjusted to keep plateau pressure below 30 cm H2O. A last set of measurements was performed after 1 h PEEP application (T2).

RESULTS. Measurement are reported in the table below. Groups were not different before randomization, except for a significantly lower amount of tidal recruitment on CT in the PEEP-FiO2 group. Set PEEP after randomization was significantly lower in the PEEP-FiO2 group, intermediate in the maximal compliance group, and significantly higher in the maximal EELV group. Tidal hyperinflation was not different between groups. Change in tidal recruitment from T1 was significantly lower in the maximal EELV group.

CONCLUSIONS. Setting PEEP using a PEEP-FiO2 table or dynamic compliance was not associated with detectable differences in respiratory mechanics, EELV or computed tomography after one hour of application. Minimization of tidal recruitment requires a very high PEEP level even in an easily recruitable experimental model of ARDS.

INTRODUCTION. Individualization of PEEP setting based on bedside measurements of lung characteristics during ARDS is an appealing strategy to minimize ventilator-induced lung injury. Cyclical recruitment-derecruitment related to tidal volume is one of the mechanisms involved in the deleterious effect of mechanical ventilation. We hypothesize that PEEP setting aiming at maximizing dynamic compliance or end-expiratory lung volume (EELV) would reduce tidal recruitment in experimental ARDS.

OBJECTIVES. To compare the effect on tidal recruitment of PEEP strategies based on individual respiratory mechanics measurement and a PEEP-FiO2 table.

METHODS. Experimental ARDS was performed by saline lavage on 15 piglets under mechanical ventilation. A recruitment maneuver (40 cm H2O for 30 seconds) was then performed followed by mechanical ventilation with tidal volume 6 ml/kg body weight. PEEP was initially set to 20 cmH2O then decreased to 2 cmH2O by 2 cmH2O-steps lasting 2 minutes each. Immediately after lung injury (T1), and at each PEEP step, the following measurements were performed: airway and dynostatic pressures, airflow, esophageal pressure, EELV using the nitrogen washin-washout technique, blood gas, and whole lung CT scan during end-expiratory and end-inspiratory pauses. Following a second recruitment maneuver, piglets

INTRODUCTION. Critically-ill patients in acute respiratory failure require appropriate PEEP levels to keep sufficient gas exchange. Measuring transpulmonary pressure (P_L), transpulmonary gradient (ΔP_L), esophageal pressure, end-expiratory lung volume (EELV), pulmonary compliance (Cstat) and intraabdominal pressure (IAP) is helpful to determine ventilator settings. We analyzed these parameters in swines with intraabdominal hypertension and saline lavage induced acute lung injury.

OBJECTIVES. To compare the effect of different PEEP levels in lung mechanics, gas exchange, cardiocirculatory parameters at induced clinical picture.

METHODS. Swines received general anesthesia, were tracheotomized and supplied with an esophageal balloon, intraabdominal balloon to induce intraabdominal hypertension, central venous and PiCCO® lines and bladder catheter. After inducing lung injury by surfactant washout and nonprotective ventilation, animals were randomised into 3 groups (Group A=PEEP 5 cmH_2O, B=10 or C=15) and ventilated in pressure controlled/volume guaranteed mode with a tidal volume of 8ml/kg bodyweight for 6 hours. 10 mmHg IAP was generated and maintained in all groups after inducing lung injury at hour 0. EELV, Cstat, esophageal pressures, P_L, ΔP_L, IAP and circulatory parameters were measured at baseline, hour 0 and every 2 hours until hour 6.

RESULTS. 18 swine (N=18) were included in the study. There were no significant differences between groups at the baseline except higher chest wall elastance in group C (p=0,012). EELV, Cstat, Horowitz index decreased, ΔP_L and driving pressures increased after inducing lung injury in all groups. In group A there was an increase in ΔP_L (16.2±2.4 vs. 21.5±4.3, p=0,003) and driving pressure (22.3±2.4 vs. 27.7±3.9, p=0,003), decrease of Cstat (22.2±3.3 vs. 18.2±3.1, p< 0,001) and stable EELV/kg (15.1±3.2 vs. 14.2±5.5, p=0,35) compared hours 0 and 6. EELV increased at PEEP 10 (11.6±4.2 vs. 13.5±6, p=0,04). Elevated values of EELV (12.6±1.9 vs. 19.3±5.2, p=0,017), Cstat (18.7 ±4 vs. 24.2±4.5, p= 0,02) and lower driving pressure were seen at PEEP 15. Horowitz Index increased in group A 1.5±0.3 (p=0,01), B 2.0 ±0.4 (p=0,01) and C 5±3.4 (p=0,002) times respectively. The heart index decreased at PEEP 10 (4.4±0.7 vs. 4±0.4, p=0,02) and PEEP 15 (5.2±0.9 vs. 3.7±0.2, p=0,009). Comparing all groups ΔP_L decreased with increasing PEEP: 21.5±4.3 (A), 18.2±4.5 (B), 14.3±2.2 (C) respectively (p=0,03). Higher ΔP_L values were associated with lower Cstat and EELV at hour 0 (R= 0.75, p< 0,001) and 6 (R=0.7, p=0,001) respectively.

CONCLUSIONS. Higher PEEP can improve lung mechanics and gas exchange in moderate abdominal hypertension with acute lung injury in a swine model.

Metabolic activity in atelectactic regions differs among mechanisms of lung injury

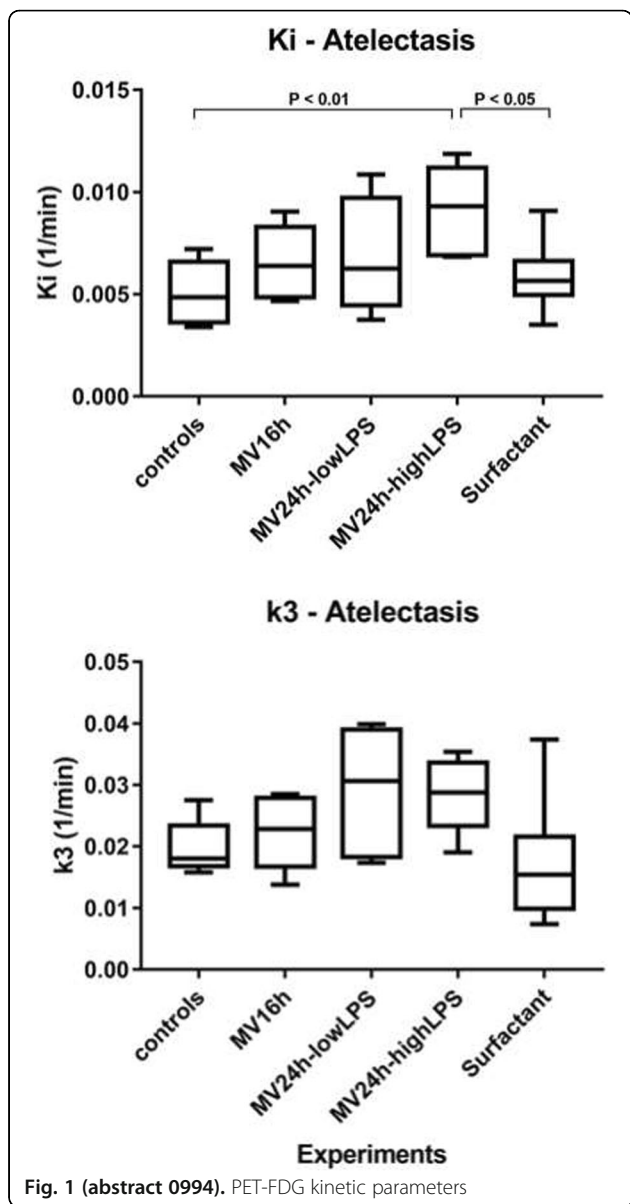
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0994

INTRODUCTION. Atelectasis is frequently present during acute lung injury resulting in hypoxemia and a risk for infection. Yet, imaging studies of atelectasis have been mostly restricted to the identification of lung densities either on chest X-ray or Computed Tomography (CT) images. Positron Emission Tomography (PET) imaging with 2-deoxy-2-[(18)F] fluoro-D-glucose (FDG) allows for the quantification of tissue metabolism predominantly related to neutrophilic inflammation.

OBJECTIVES. To use PET-FDG techniques to investigate the in vivo metabolism of atelectatic regions in distinct types of acute lung injury.


METHODS. Supine sheep (n=23, 20.6 ± 3.6 kg) were anesthetized, intubated, and mechanically ventilated. Four conditions were studied: 1) 16 hours mechanical ventilation (MV16h, n=6); 2) 24hours MV with low dose continuous intravenous Lipopolysaccharide (MV24h-lowLPS, 2.5 ng/kg/min, n=5); 3) 24hours MV with high dose continuous intravenous LPS (MV24h-highLPS, 10.0 ng/kg/min, n=6); and 4) 6hours MV with surfactant depletion by lung lavages (Surfactant, n=6). Animals with atelectasis at baseline in Groups MV16h, MV24h-lowLPS, and MV24h-highLPS served as controls (n=8). Ventilation settings were: Group MV16h: tidal volume (V_T)=6-8 mL/kg, positive end-expiratory pressure (PEEP)=0 cmH_2O, and inspired oxygen fraction (F_IO_2)=0.3; Groups MV24h-lowLPS and MV24h-highLPS: based on ARDSNet low PEEP protocol, i.e., V_T=6-8 mL/kg, PEEP=5 cmH_2O, and F_IO_2=0.3; and Group Surfactant: V_T=10 mL/kg, PEEP=10 cmH_2O, and F_IO_2=0.6. PET-FDG was used to compute FDG net uptake rate (Ki) and FDG phosphorylation rate (k3) in atelectatic regions. These were derived from CT (= gas content < 10%).

RESULTS. Ki was significantly higher in the atelectatic regions of group MV24h-highLPS, approximately two-fold, than in groups controls and Surfactant (Figure). However, k3 didn't show a distinction between groups. Moreover, group MV16h had similar Ki to group MV24h-lowLPS, which was ventilated even 8 hours longer. Meanwhile, Ki were similar in groups controls and Surfactant.

CONCLUSIONS. Although all atelectatic regions look similar in CT scan, FDG uptake levels are distinct depending on experimental conditions. This study reveals that LPS affects tissue metabolic activity concentration-dependently. High dose LPS resulted in the highest FDG uptake rate in atelectatic regions, suggestive of increased neutrophilic inflammation. This implies that "lung rest" (permissive atelectasis) does not guarantee the presence of unaltered metabolic activity and inflammation even during protective ventilation.

Fig. 1 (abstract 0994). PET-FDG kinetic parameters

INTRODUCTION. CAL02 is a novel antimicrobial liposomal agent that acts as a toxin-trap by mimicking microdomains targeted by bacterial virulence factors. CAL02 is active against pore-forming toxins, enzymes and appendages involved in the progress and severity of infections including those caused by drug-resistant pathogens. Preclinical data showed synergistic effects with antibiotics and ability to cure mice from deadly infections caused by Gram+ and Gram- pathogens. We present herein results from the first-in-man trial in intensive-care-unit (ICU) patients with severe community-acquired pneumococcal pneumonia (CAPP).

METHODS. CAL02-001 is a randomized, multicenter, double-blind, placebo-controlled trial carried out in adult patients admitted to the ICU due to severe CAPP defined by mechanical ventilation or vasopressors or 3 minor criteria. Two dosing regimens of CAL02, Low Dose (4 mg/kg) and High Dose (16 mg/kg), were compared to a Placebo, in addition to standard-of-care antibiotic therapy. CAL02 was administered QD on 2 consecutive days, starting within 12h of the onset of CAPP severity and within 24h of IV antibiotics. The primary objective was safety. Efficacy and pharmacodynamic (PD) parameters were also assessed.

RESULTS. A total of 19 patients were randomized to the Placebo (n=5), CAL02 High Dose (n=11) and Low Dose (n=3) arms. One patient from the High Dose arm was deleted before unblinding due to a major eligibility criteria violation. At baseline, 56% of patients were in septic shock, the average APACHE II was 21.3 and SOFA 7.4. Baseline characteristics were homogeneous across arms, although the CAL02 High and Low Dose arms proved slightly more severe than the Placebo arm, with an APACHE II of 22.1 and 25.3 vs 17.4, respectively. The 3 Low Dose patients were all intubated and in septic shock. CAL02 demonstrated to be safe and well tolerated. No differences in the incidence and profile of adverse events were observed between the 3 arms.

A 50% decrease in the SOFA score was already achieved after 5 days in the CAL02 arms. The APACHE II score and PD biomarkers (CRP, PCT, IL-6) also decreased more rapidly with CAL02. Duration of ICU stay was significantly reduced, from 12 days in the Placebo arm to 5 days in CAL02 High Dose arm (p< 0.05).

CONCLUSIONS. This is the first clinical trial assessing CAL02, a first-in-class broad-spectrum anti-toxin agent. Safety primary endpoints were met. Despite being more severe than those in the Placebo arm, CAL02-treated patients showed a more rapid clinical improvement. Efficacy trends were consistent across different clinical and biological parameters with both a faster resolution in organ dysfunction and a faster decrease in PD biomarkers. These observations are in line with the mechanism of action of CAL02, which aims at protecting against toxin-mediated organ damages and inflammation. These promising efficacy superiority signals need to be confirmed in a larger Phase 2 trial.

INTRODUCTION. Sepsis is the major cause of infection-associated mortality and remains among the leading causes of death in intensive care units (ICUs) worldwide.

OBJECTIVES. To evaluate the efficacy and safety of antimicrobial combination therapy (defined as at least two antimicrobials of different mechanistic class) in patients with sepsis.

METHODS.

Data Sources: Randomized controlled trials from PubMed, EMBASE, CENTRAL, Scopus (inception to February 2017), reference lists of relevant articles, grey literature.

Selection criteria: Two reviewers independently identified randomized controlled trials comparing antimicrobial monotherapy with combination therapy in critically ill patients with sepsis or septic shock.

Data collection: Two reviewers independently extracted trial-level data including patient characteristics, interventions, outcomes, and funding source. Risk of bias of included studies was assessed using the Cochrane Risk of Bias tool.

RESULTS. The literature search identified 2725 citations, of which 36 were deemed to be potentially relevant. Ten publications met the inclusion criteria and were included in the meta-analysis. All the included trials had high risk of bias (no blinding). Combination therapy showed no significant difference in mortality compared to monotherapy (RR 1.04, CI 95% 0.89 to 1.20, I^2 0%; 9 trials; 2206 participants). None of the subgroup analyses or secondary outcomes showed significant differences between groups. Drug reported adverse events were significantly higher in the combination therapy arm (RR 0.75, CI 95% 0.60 to 0.93, I^2 15%; 7 trials; 1609 participants).

CONCLUSIONS. Combination therapy may not have a benefit over monotherapy in septic patients. At this time the available evidence doesn't support or recommend combination therapy for the treatment of sepsis or septic shock. As we were unable to discriminate based on severity of illness, a meta-regression adjusting by risk of death is needed to indicate whether patients may benefit from combination therapy. Large randomized controlled trials looking at patient-related outcomes are required to further explore the benefits and harms of this intervention.

INTRODUCTION. In the last years, the use of albumin to resuscitate septic patients became highly controversial. We conducted an RCT to compare the effects of a 4% albumin solution on crystalloid solution on survival as compared to crystalloid solution alone during the early phase of resuscitation in septic patients.

OBJECTIVES. The aim of his study was to investigate the effects of the administration of albumin and crystalloids, as compared with crystalloids alone, in a population of cancer patients with sepsis.

METHODS. We performed a single centre, randomized, double-blind, controlled-parallel trial between October 2014 to December 2016 at the Cancer Institute of the University of Sao Paulo, Brazil. Cancer

patients with severe sepsis or septic shock were randomly assigned to receive either bolus of 500 ml of 4% albumin in a crystalloid solution or crystalloid solution alone during the first 6 hours of fluid resuscitation. Primary outcome was defined as death from any cause at 7 days. Secondary outcomes were death from any cause at 28 days, the Sequence Organ Failure Assessment (SOFA), need for invasive mechanical ventilation, vasopressor therapy, renal replacement therapy, length of stay in the ICU and in the hospital.

RESULTS. A total of 360 patients were included. At 7 days, 46 of 180 patients (25.6%) in the albumin group and 40 of 180 patients (22.2%) in the crystalloid group died (absolute difference 3.3; 95% confidence interval [CI], -5.5 to 12.1; P=0.46). At 28 days, 96 of 180 patients (53.3%) in the albumin group and 83 of 180 patients (46.1%) in the crystalloid group had died (absolute difference 7.2; 95% confidence interval [CI], -3.3 to 17.3; P=0.17). No significant differences in secondary outcomes were observed between groups.

CONCLUSIONS: Adding albumin to early standard resuscitation with crystalloids, in cancer patients with sepsis had no effect on survival at 7 and 28 days (NCT01337934).

INTRODUCTION. Clinicians are re-examining the risks and benefits of a high volume intravenous (IV) fluid resuscitation strategy for severe sepsis and septic shock. The original early goal directed therapy (EGDT) and subsequent validation trials administered 90-160 ml/kg of IV fluid over 72 hours, and have shaped clinical practice/usual care. A restrictive IV fluid resuscitation strategy may produce similar or reduced morbidity and mortality outcomes compared to usual care.

OBJECTIVES. Compare 30- and 60-day mortality of a restrictive IV fluid resuscitation strategy that limits IV fluid administration to 60 ml/kg among septic patients for the first 72 hours of care vs. usual care.

METHODS. The Restrictive Intravenous Fluid Trial in Severe Sepsis and Septic Shock (RIFTS; clinicaltrials.gov: NCT03137446) was a randomized pilot trial that randomly assigned (1:1 ratio) sepsis/septic shock patients to a restrictive IV fluid strategy ($\leq$ 60ml/kg of resuscitative fluid for 72 hours) vs usual care. Participants met the Sepsis 2 International Consensus definition for severe sepsis or septic shock, did not require immediate surgery, have active fluid wasting, and were admitted to the medical ICU. Resuscitative fluids: crystalloid boluses or continuous infusions. Albumin, blood products and non-resuscitative fluids (IV fluids with antibiotics, electrolyte replacement, vasopressors, and other IV medications) were not restricted. The primary outcome was 30-day mortality and the secondary outcome was 60-day mortality.

Statistical analyses included all cases using an intention to treat analysis. Differences in baseline characteristics and outcomes were assessed using Fisher's exact test for categorical variables, t-tests for continuous normally distributed variables and a Wilcoxon test for continuous non-normal variables. We calculated 95% confidence intervals for medians and differences between group medians using the bias-corrected and accelerated bootstrap method.

RESULTS. Among the 113 participants, the restrictive IV fluid arm (n=56) received a mean of 15.7 ml/kg (1069 ml) less than the usual care group (n=57). There were no differences in 30- or 60-day mortality between the restrictive IV fluid strategy and usual care groups (19.6 vs. 22.8%, p=0.84 and 25 vs. 28.1% p=0.83 respectively).

CONCLUSIONS. In this pilot study, there was no difference in 30 or 60-day mortality for a restrictive fluid strategy vs. usual care, although it was not designed to test a non-inferiority outcome. Both the restrictive (45.4 ml/kg) and usual care (61.1 ml/kg) arms received significantly less IV fluid than the EGDT trials that administered 90-160 ml/kg of IV fluid over 72 hours and had similar or greater mortality rates. A larger multicenter trial further testing a restrictive IV fluid strategy with a greater difference in IV fluid between study arms is warranted.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):0999

INTRODUCTION. Sepsis and septic shock are severe inflammatory conditions associated to high morbidity and mortality. Extracorporeal blood purification represents an attractive therapy to modulate the inflammatory response by means of removing inflammatory mediators and/or bacterial toxins from the plasma that may improve outcome [1]. However, the role as adjunctive therapy in sepsis remains unclear [1-2].

OBJECTIVES. We performed an up-to-date meta-analysis of randomized trials to assess if extracorporeal blood purification reduces mortality in this setting.

METHODS. Online databases were searched up to April 1st, 2018 for randomized-controlled trials on the use of hemoperfusion, hemofiltration, and plasmapheresis as blood purification technique in comparison to conventional therapy in adults with sepsis or septic shock. We excluded trials employing hemofiltration for acute kidney injury. The primary outcome was mortality at longest follow-up available. We performed a random-effects meta-analysis using Cochrane methodology [3] and calculated relative risk (RR) with 95% confidence interval (CI).

RESULTS. Thirty-three trials with 2148 patients were included in the analysis. Blood purification was associated with lower mortality compared to conventional therapy (RR 0.73 [95%CI, 0.62, 0.85]; $p < 0.0001$). Hemoperfusion (RR 0.69 [95%CI, 0.56, 0.86]) and plasmapheresis (RR 0.63 [95%CI, 0.42, 0.96]) were associated with a significant lower mortality when analyzed separately while hemofiltration was not (RR 0.86 [95% CI, 0.68, 1.09]) (Figure 1). Hemoperfusion was associated with a lower mortality when polymyxin B was used (RR 0.63 [0.49, 0.82]; p 0.0005) but not when other hemoperfusion devices were used (RR 0.78 [0.55, 1.09]; p 0.14) (p_{groups} 0.35). Hemoperfusion trials conducted in Asia showed decreased mortality whereas pooled results from trials conducted in other continents were not significant ($p_{groups} < 0.0001$).

CONCLUSIONS. Blood purification is associated with a significant reduction in mortality in patients with sepsis and septic shock. However, the quality of evidence is low, since the results were mainly in influenced by polymyxin B hemoperfusion trials from Asia and most of the trials included were single-center with high risk of bias. Further large high-quality randomized controlled trials adequate powered for mortality are warranted to assess the potential beneficial effects of these techniques in septic patients.

INTRODUCTION. Catecholamines have been the mainstay of pharmacological treatment of cardiogenic shock (CS). Recently, use of epinephrine has been associated with detrimental outcomes.

OBJECTIVES. In the present study we aimed to evaluate the association between epinephrine use and short-term mortality in all-cause CS patients.

METHODS. We performed a meta-analysis on individual data with pre-specified inclusion criteria:
patients in non-surgical CS treated with inotropes and/or vasopressors and at least 15% of patients in the studies should have been treated with epinephrine administrated alone or in association with other inotropes/vasopressors. The primary outcome was 28 to 30 days, in-ICU or in-hospital mortality.

RESULTS. Fourteen published cohorts and two unpublished datasets were included. We studied 2,583 patients. Main patients characteristics are presented in Table 1. Across all cohorts of patients, the incidence of epinephrine use was 37% (17% to 77%) and short-term mortality rate was 49% (21% to 55%). The risk of death was higher in epinephrine-treated CS patients (OR [CI] = 2.9 [2.4-3.4]) compared to patients treated with other drug regimens. Adjusted mortality risk remained striking in epinephrine-treated patients (n=1,227) (OR = 4.7 [3.4 - 6.4]). After propensity-score matching, two sets of 338 matched patients were identified and epinephrine use remained associated with a strong detrimental impact on short-term mortality (OR = 4.2 [3.0 - 6.0]).

CONCLUSIONS. In this very large cohort, epinephrine use for haemodynamic management of CS patients is associated with almost three-fold increase in the risk of death.

Endocan and resolvin D1: two novel biomarkers for the management of acute heart failure?

M. Reina-Couto[1,2], J.P. Bessa[1], S. Paula[1], J. Afonso[1], R. Roncon-Albuquerque[1,2], J.A. Paiva[1,2], A. Albino-Teixeira[1], T. Sousa[1]

Correspondence: M. Reina-Couto

INTRODUCTION. Endothelial dysfunction contributes to the pathophysiology of heart failure (HF) and is associated with adverse outcomes in these patients (1). Endocan is an emerging biomarker of endothelial dysfunction (2) but remains scarcely explored in HF. Resolvin D1 (RvD1), a mediator of inflammation resolution, was shown to attenuate ventricular dysfunction after myocardial infarction (3) and endothelial disruption (4).

OBJECTIVES. To evaluate serum endocan and RvD1 in acute HF (AHF) and cardiogenic shock (CS) patients, their correlation with each other and association with C-reactive protein (CRP), B-type natriuretic peptide (BNP), high-sensitivity troponin I (hs-TnI), ejection fraction (EF) and APACHE II and SAPS II scores.

METHODS. Patients diagnosed with AHF (n=10) or cardiogenic shock (CS) (n=9) were included and blood samples were collected at admission and at days 3 to 5. Blood donors were used as controls (n=10). Endocan and RvD1 were measured with ELISA kits and CRP, BNP and hs-TnI with automated analyzers. Echocardiographic examination and calculation of APACHE II and SAPS II scores was performed in all patients.

RESULTS. On admission, endocan was increased in patients with AHF and significantly raised in CS when compared to controls (controls: 1.88±0.33; AHF: 5.17±0.95 ng/mL; CS: 20.0±3.84 ng/mL; controls vs AHF, p=0.0878; controls vs CS, p< 0.0001; AHF vs CS, p=0.0441). RvD1 on admission was significantly higher in AHF than in CS (AHF: 2.98±0.42 ng/mL vs CS: 1.39±0.24ng/mL, p=0.024) although there were no significant differences compared to controls (controls: 1.84±0.34 ng/mL). Within patients, we observed an inverse correlation between endocan and RvD1 (r=-0.434, p=0.0082) and a positive correlation between endocan and CRP (r=0.427, p=0.0094) but no correlation with cardiac markers. There were no significant differences between values on admission and on later time points. When patients were stratified according to EF, endocan significantly increased in line with the degree of EF impairment (p=0.017, preserved/mildly impaired vs severely impaired) whereas RvD1 decreased, although not significantly. We also observed that endocan increased across APACHE II tertiles and RvD1 decreased across SAPS II tertiles, although not significantly.

CONCLUSIONS. Endothelial dysfunction, assessed by endocan, is associated with inflammatory status in AHF and CS, being significantly higher in patients with marked impairment of EF and/or hemodynamics. Furthermore, RvD1 is inversely correlated with endocan. These results suggest that endocan and RvD1 may be useful biomarkers for risk stratification in AHF and important targets for drug development and improvement of AHF outcome.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1002

INTRODUCTION. The effects of positive end-expiratory pressure (PEEP) during acute respiratory distress syndrome (ARDS) on extravascular lung water (EVLW) measured by transpulmonary thermodilution (TPTD) have not yet been completely clarified. In theory, these effects might be of opposite direction. PEEP may impede the filtration of fluid from the pulmonary capillaries toward the interstitium. It might also increase EVLW by increasing the central venous pressure (CVP) and impeding the lymphatic pulmonary drainage. PEEP may also induce some artefacts in EVLW estimation with opposite effects. By squeezing some pulmonary vessels, it decreases the diffusion of the thermal indicator, inducing a decrease in EVLW. By recruiting some lung areas and relieving the hypoxic vasoconstriction in these regions, PEEP may extend the lung regions that are accessible to thermodilution, which might artifactually increase EVLW.

OBJECTIVES. To evaluate the effects of PEEP changes on EVLW determination in ARDS patients.

METHODS. In 30 ARDS patients who were mechanically ventilated, we measured EVLW (PiCCO2 device) at a PEEP level set to reach a plateau pressure (Pplat) of 30cmH_2O (PEEP$_{high-start}$) and at PEEP=5cmH_2O after 15' (PEEP$_{low-15'}$) and 45' (PEEP$_{low-45'}$). Then, we increased PEEP to the same previous level (PEEP$_{high-end}$) and performed TPTD. Inspiratory quasi-static pressure-volume curves were recorded to evaluate the PEEP-induced lung recruitment.

RESULTS. The PEEP reduction from PEEP$_{high-start}$ (14[13-15]cmH_2O) to PEEP$_{low-15'}$ decreased CVP from 14[12-16]mmHg to 10[8-13] (p< 0.0001), decreased the ratio of arterial oxygen tension over inspired oxygen fraction (PaO$_2$/FiO$_2$) from 152[123-177] to 120[108-168] (p=0.01), reduced the end-expiratory lung volume from 266[240-381]mL to 257[235-341]mL (p< 0.01), decreased respiratory system compliance from 34.1[31.3-37.6] to 30.8[27.7-35.9]mL/cmH_2O (p=0.04) and increased cardiac index from 2.96[2.24-3.26] to 3.04[2.50-3.61]mL/min/m^2 (p< 0.01). EVLW concomitantly decreased from 20[16-25] to 19[15-23]mL/m^2 (p< 0.0001). This reduction in EVLW was not different between patients classified as high and as low recruiters. There was no correlation between EVLW changes and the volume of lung recruited. Similarly, when PEEP was re-increased from PEEP$_{low-45'}$ to PEEP$_{high-end}$, we observed a significant increase in CVP, PaO$_2$/FiO$_2$ and a decrease in cardiac index. EVLW concomitantly increased (p< 0.001). Taking into account all the observed changes, there was a significant correlation between the changes in EVLW and in CVP (ρ=0.65; p< 0.0001) but no relation with any other haemodynamic or oxygenation variable was found.

CONCLUSIONS. The increase of PEEP levels determines a short-term increase in EVLW that is not linked to alveolar recruitment but which is correlated with the increase in CVP. This suggests that the impairment of the pulmonary lymphatic drainage, rather than the reversion of hypoxic vasoconstriction, is responsible for these effects.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1003

INTRODUCTION. Extracorporeal organ support is used with increasing frequency and a variety of devices. Many ICU-patients undergoing extracorporeal therapies suffer from multi-organ-failure. Therefore, *multi-organ support* is an intriguing concept. Recently the "advanced organ support" (ADVOS) device has been introduced. While the 1st generation (termed HepaWash) aimed at liver support, the second generation device has been developed for liver support, renal replacement, CO$_2$-elimination and modulation of the acid-base balance. To provide high efficiency, the device is equipped with two conventional dialyzers. This results in an increased volume of the extracorporeal circuit of about 500mL.

OBJECTIVES. A recent study demonstrated that connection to sustained low efficiency dialysis (SLED; extracorporeal volume about 250mL) did not result in relevant haemodynamic changes (1). We hypothesized that connection to the ADVOS-circuit might result in haemodynamic impairment due the increased 500mL volume of the extracorporeal circuit. Therefore, we analyzed the impact of connection to the ADVOS-device on parameters derived from TPTD and PCA in 25 treatments of six patients equipped with PiCCO monitoring.

METHODS. Transpulmonary thermodilution with the PiCCO-device (Pulsion; Germany) was performed immediately before and after connection (T1, T2) to the ADVOS-device and disconnection (T3; T4). The tubing was prefilled with 0.9% saline ("acute connection"). Connection, ADVOS-treatment and disconnection were performed with a blood flow of 100mL/min. Vassopressor dosages were kept stable.

RESULTS. 6 Patients (5m; 1f), 65±18 years, SOFA-score 11±3, aetiology: 3 cirrhosis, 1 alcoholic steatohepatitis, 2 sepsis; mechanical ventilation 24/25 (96%) treatments; vasopressors 20/25 (80%).

Connection to ADVOS did not result in significant changes in any of the following haemodynamic parameters at T2 compared to T1: MAP (77±9 vs. 81±8mmHg; p=0.054), SVRI (953±318 vs. 926±326; p=0.599), CVP (20.3±6.9 vs. 22.7±8.5 mmHg; p=0.060); GEDVI (888±250 vs. 912±243 mL/m^2; p=0.20), heart rate HR (102±12 vs. 102±12/min; vs. y; p=0.614), dPmax (1460±347 vs. 1483±381mmHg/s; p=0.840) and GEF (26.1±6.0 vs. 26.8±6.2%; p=0.134).

Only EVLWI (10.3±5.3 vs.11.0±5.4mL/kg; p=0.032), CI (5.17±1.53 vs. 5.49±1.30 L/min/m^2; p=0.022) and CPI (0.89±0.31 vs.1.00±0.30 W/m^2 ; p=0.005) decreased slightly, but with statistical significance.

Over 8h, ADVOS-therapy with a net filtration of 931±698mL did not result in significant changes in HR, MAP, CI, GEDVI, CVP, EVLWI, GEF and CPI after disconnection (T4) vs. before connection (T1). Only pulmonary vascular permeability index PVPI was significantly lower after ADVOS compared to before (1.33±0.54 vs. 1.53±0.70; p=0.82).

CONCLUSIONS. "Acute" connection to the ADVOS with pre-filled tubing did not result in haemodynamic impairment.

8h ADVOS therapy was haemodynamically safe and reduced PVPI.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1004

INTRODUCTION. Mean arterial pressure and vascular resistance are the most used variables to guide vasopressor therapy. However the effect of vasopressors could affect also pulsatile hemodynamics. The effect on pulsatile hemodynamics is relevant as it is related with the cardiac pump efficiency which could affect patient outcomes. In this study we present a new bedside index that could help to evaluate pulsatile hemodynamics and be helpful for vasopressor therapy monitoring.

OBJECTIVES. To evaluate the ability of the Pressure Pulsatility Index (PPI), the ratio between the pulse and mean arterial pressure, as a complementary tool to guide Norepinephrine (NE) therapy in septic shock patients.

METHODS. A prospective analysis of 47 patients at early stages of septic shock in which NE dose was modified as a result of a clinical decision. Arterial system was evaluated by means of carotid pressure (obtained by applanation tonometry, calibrated using radial invasive pressure) and aortic flow (obtained by an esophageal Doppler). We evaluated the continuous component of hemodynamics (vascular resistance) and also pulsatile component represented by compliance, reflection waves (reflection index) and the ventricular oscillatory power (represented as a percent of the total power, %VOP). Correlation between PPI and %VOP and difference between survivors and no survivors (30 days mortality) in the studied variables were also evaluated.

RESULTS. Comparing NE dose from lower to higher, a higher NE dose increased resistance (1137 ± 427 vs 1331 ± 527 dyn.s.cm^{-5}, $p < 0.001$), reflection index (0.21 ± 0.05 vs 0.23 ± 0.06, $p < 0.001$), %VOP (21.7 ± 6 vs $23.2\pm5.8\%$, $p < 0.001$), PPI (0.86 ± 0.32 vs 0.92 ± 0.35, $p < 0.001$) and decreased compliance ($1.68[1.48$ to $1.98]$ vs $1.32[1.12$ to $1.60]$ml/mmHg, $p < 0.001$). Changes in PPI and %VOP showed a good correlation ($r^2=0.57$, $p < 0.001$). The increase in %VOP (0.8 ± 2.23 vs $3.1\pm3\%$, $p=0.005$) as well as in PPI (3.2 ± 7.1 vs $15.4\pm8.9\%$, $p < 0.001$) resulting from a higher NE dose were bigger in non-survivors.

CONCLUSIONS. In septic shock patients, NE affected not only continuous but also pulsatile hemodynamics. The effect on pulsatile hemodynamics was higher in non-survivors patients. The PPI reliably tracked this effect appearing as promising tool for helping to guide vasopressor therapy.

INTRODUCTION. About 80% of patients resuscitated from cardiac arrest (CA) are comatose after return of spontaneous circulation (ROSC) because of anoxic-ischemic brain injury. Electroencephalography (EEG) is recommended after CA for neuroprognostication.

OBJECTIVES. The aim of this study was to evaluate the predictive value (PV) of EEG reactivity for neurological outcome after CA.

METHODS. All consecutive patients admitted in a Parisian intensive care unit between 2007 and 2016 still alive 48 hours after admission with at least one EEG performed during coma are included. A blinded certified neurophysiologist classified EEG according to American Clinical Neurophysiology Society (ACNS) nomenclatures: highly malignant, malignant, or benign pattern (reactive and absence of highly malignant or malignant pattern) and evaluated EEG reactivity as a reproductible waveform change in amplitude or frequency following standardized stimulation. We assessed the predictive values of EEG pattern, stratified on sedation, for neurologic outcome at ICU discharge using Cerebral Performance Category (CPC 3-4-5 assumed as poor outcome).

RESULTS. We included 428 patients mostly male (71%), with median age of 63 years, shockable rhythm in 49%. Median time to EEG assessment was 3(1-4) days. 113/428 (26%) patients had highly malignant patterns, 162/428 (38%) malignant patterns and 153/428 (36%) a benign EEG. A poor outcome was observed in 344 (80%) patients. Positive predictive value (PPV) of areactive EEG without highly malignant pattern to predict unfavorable outcome was 95.2%, up to 97.5% (IC95 91.3-99.7) when EEG was performed without sedation. By contrast, the PPV of benign EEG to predict favorable outcome was 49.7%, up to 66.2% (IC95% 54.3-76.8) when EEG was performed early at median time day 1 under sedation.

CONCLUSIONS. Post CA, absence of EEG reactivity was highly predictive of unfavorable outcome. Benign EEG was sparsely predictive of a favorable outcome. Assessment of reactivity seems to be influenced by sedation.

Smartphone video-assisted advanced life support for out-of-hospital cardiac arrest by emergency medical service teams under physician direction

D. Lee, S. Park
Seoul National University Bundang Hospital, Emergency Department, Seongnam, Korea, Republic of
Correspondence: D. Lee

INTRODUCTION. Direct medical control using video conferencing capabilities of smartphones has never been conducted in out-of-hospital cardiac arrest (OHCA) patients. This study was conducted to investigate the feasibility and treatment effectiveness of real-time smartphone video conferencing calls for the management of OHCA.

METHODS. This study was a pre-post intervention, prospective cohort study conducted from January 2013 through July 2015 in the City of Suwon, Gyeonggi Province, South Korea. The intervention was pre-hospital advanced life support (ALS) under a physician`s direction using a smartphone video call, and patients were compared pre- and post- the intervention implementation. Survival discharge rates and good neurologic outcomes were reviewed as primary outcomes.

RESULTS. In total, 942 cardiac arrests occurred over the 2-year period; 308 patients were excluded, leaving 634 patients for inclusion in our study. During the intervention period, there were 248/320 (77.5%) cases of smartphone video-assisted ALS. For patients in the pre- and post-intervention groups, the survival rate at discharge was 12.5% and 7.0%, respectively (adjusted odds ratio [AOR] 2.07, 95% confidence interval [CI] 1.11-3.86, P=0.002), and favorable neurological outcomes were ascertained in 6.9% and 1.9%, respectively (AOR 4.78, 95% CI 1.49-15.28, P=0.002). The smartphone voice and video quality were rated 8.5 and 8.2 out of 10, respectively, in physician evaluation, while the overall utility was rated 9.1.

CONCLUSIONS. Direct medical control between EMS personnel and physicians using a smartphone video is feasible for patients with OHCA. It was also shown to improve the survival rate and cerebral function recovery rate.

INTRODUCTION. Arterial hypotension in patients resuscitated from cardiac arrest is common and associated with increased mortality. The optimal blood pressure level during post-resuscitation care is unknown, and it is unclear whether supporting the circulation with vasoactive agents improves outcomes. [1]

OBJECTIVES. We performed a randomized pilot trial to evaluate the feasibility of targeting low-normal or high-normal mean arterial pressure (MAP) in comatose, mechanically ventilated patients after out-of-hospital cardiac arrest (OHCA) and the intervention's impact on the serum concentration of neuron-specific enolase (NSE) and on cerebral oxygenation measured by near-infrared spectroscopy (NIRS).

METHODS. In the Carbon dioxide, Oxygen and Mean arterial pressure After Cardiac Arrest and REsuscitation (COMACARE) trial, we used a 2^3 factorial design and randomly assigned patients after OHCA and resuscitation to low-normal or high-normal levels of arterial carbon dioxide tension, arterial oxygen tension and MAP. The results of the low-normal (65-75 mmHg) vs. high-normal (80-100 mmHg) MAP comparison are reported here.

The primary outcome was the serum concentration of NSE at 48 h after cardiac arrest. The main feasibility outcome was the difference in MAP between the groups during the first 36 h after ICU admission. Secondary outcomes included the results of continuous cerebral NIRS monitoring during the intervention.

RESULTS. Totally 123 patients were enrolled in the trial, and 120 patients were included in the final analysis. Despite a marked difference in MAP levels between the groups throughout the intervention (Figure 1), there was no significant difference in median NSE concentrations at 48 h after OHCA (for low-normal MAP, 21.2 µg/l [IQR, 15.2-34.9 µg/l], and for high-normal MAP, 22.0 µg/l [IQR, 13.6-30.9 µg/l], p = 0.392). The NIRS results were comparable in both groups (Figure 2).

CONCLUSIONS. Targeting a specific blood pressure level after resuscitation from OHCA is possible. However, the blood pressure level had no impact on the concentration of NSE at 48 h after OHCA. In addition, cerebral oxygenation, as measured by NIRS, was unaffected by the blood pressure level. These results suggest that autoregulation of the cerebral blood flow remains functional within a relatively broad MAP range during the post-resuscitation care.

Fig. 2 (abstract 1007). Median (IQR) regional cerebral oxygen saturation in the different intervention groups.

expressed by the length of catecholamine infusion. Number of vasopressors-free days, 6-hours repeated measures of blood pressure, daily fluid balance and mortality (ICU and day-28) have been evaluated as well.

RESULTS. 35 patients were included: 17 (median age 68.4, 59% male) in the HCO-CVVHD group and 18 (median age 66.3, 83% male) in the control group. Baseline characteristics did not differ between the two groups. Ventricular fibrillation was the first recorded rhythm in 23.5 and 44.4 % in the HCO-CVVHD and control group, respectively (p=0.289). Day-28 mortality rate was 64.7 and 72.2% in the HCO-CVVHD and control group, respectively (p=0.72). Probability of vasopressors discontinuation over time was similar in the two groups (Figure, p for logrank test=0.67). Number of catecholamine-free days was 25.1 [0, 26.5] and 24.5 [0, 26.2] in the HCO-CVVHD and control group, respectively (p=0.65). No difference was observed regarding the daily-dose of vasopressors and the 6-hours recorded systolic/mean/diastolic arterial pressure. No difference in terms of fluid balance was observed either.

CONCLUSIONS. In post-cardiac patients with acute circulatory failure, HCO-CVVHD did not reduced the duration of shock and had no effect on hemodynamic status.

BACKGROUND. After resuscitation of cardiac arrest (CA), an acute circulatory failure occurs in about 50% of cases, which shares many characteristics with septic shock. Most frequently, supportive treatments are unable to control this shock that may provoke multiple organ failure and death. We evaluated whether an early plasma removal of inflammatory mediators using high permeability hemodialysis (HCO-CVVHD) in addition to conventional treatments could improve hemodynamic status of this patients.

PATIENTS AND METHODS. We performed a randomized open-label trial. Successfully resuscitated comatose CA patients who had a post-resuscitation shock (defined as requirement of nor-epinephrine or epinephrine infusion > 1mg/h) were included. The experimental group received 2 separated sessions of HCO-CVVHD during the first 48 hours following ICU admission. The control group received continuous veno-venous hemofiltration (CVVH) if needed. Non-parametric tests were used to compare the two groups. The primary outcome was the duration of the shock

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1009

INTRODUCTION. Japan has one of largest proportions of geriatric patients in the world with >21% of the population aged 65 years or older, and is called a super-aging society. There have been no study of the survival and neurological outcome in elderly patients who have suffered out-of-hospital-cardiac-arrest (OHCA).

OBJECTIVES. We clarify the prognosis of Japanese elderly OHCA patients and investigate whether age is related to prognosis.

METHODS. We investigated elderly OHCA patients (≧65 years of age) who were registered in a nationwide Utstein-style Japanese database between 2005 and 2012. For descriptive purposes, the patients were grouped according to age (65-69, 70-79, 80-89, ≧90 years) and we compared the characteristics and prognosis (survival and favourable neurological status [cerebral performance category 1 or 2] at 1 month after cardiac arrest) between each group. Moreover, we investigated whether age is related to prognosis using multivariable logistic regression model.

RESULTS. A total of 655,352 patients were included in this study. Among them, 68,883 were in the age range from 65 to 69 years, 21,3583 were in the age range from 70 to 79, 26,724 were in the age range from 80 to 89 and 109,172 were in the age range over 90. With increasing age there were declines in survival and favourable neurological status at 1 month: 7.0%

and 3.7% in the 65-69 group, 4.9% and 2.3% in the 70-79 group, 3.4% and 1.3% in the 80-89 group and 2.3% and 0.8% in the over 90 group.

In the multivariable analysis, the odds of survival and favourable neurological status for every 10 years of age increase were 0.73 (0.71 - 0.74) and 0.65 (0.64 - 0. 67), respectively.

CONCLUSIONS. Increasing age among the elderly is associated with a lower 30-day survival and unfavourable neurological outcome after OHCA.

Advanced diagnosis of AKI

A combined biomarker of fibroblast growth factor 23, erythropoietin and klotho predicts the development of acute kidney injury and development of chronic kidney disease in critical care patients: results of a prospective cohort

L. Toro[1], N. Abarzua[1], C. Bascuñan[1], K. Arcos[1], C. Fuentealba[1], A.M. Tong[1], M.E. Pinto[1], C. Romero[1], L. Michea[1,2,3]

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1010

INTRODUCTION. Acute Kidney Injury (AKI) is frequent among septic patients admitted to the Intensive Care Unit (ICU), which is associated to higher mortality and risk of development of Chronic Kidney Disease (CKD). Observational studies have shown that plasma levels of Fibroblast Growth Factor 23 (FGF23) are increased in patients with AKI. Experimental data shows that FGF23 expression is modulated by Erythropoietin (EPO) and Klotho.

OBJECTIVE. To evaluate if a combined biomarker including FGF23, EPO and Klotho predicts the development of AKI and short/long-term morbimortality in ICU patients with sepsis.

METHODS. Prospective cohort of adult patients admitted to the ICU of Hospital Clínico Universidad de Chile (HCUCh), with diagnosis of severe sepsis/septic shock and normal renal function (eGFR > 60 mL/min/1.7m^2) before admission. Plasma levels of FGF23, EPO and Klotho were determined to calculate the value of the combined biomarker. Demographic, clinical and biochemical parameters were recorded. We evaluated short-term outcomes (requirements of vasoactive drugs, renal replacement therapy and 30-day mortality), long-term outcomes and development of CKD (6 and 12-month). Statistical analysis: Cox proportional test, Kaplan-Meier analysis and calculation of Hazard Ratios (HR). This study was approved by the Ethics Committee of HCUCh.

RESULTS. 698 patients with severe sepsis/septic shock were admitted to the ICU between 2013 and 2016. 594 were excluded due to absence of previous renal data or history of CKD. 104 patients were recruited. Age: 64,3 ± 8,4 years. Male: 61 (60%). Presence of AKI at admission: 35 (group 1). Development of AKI at 1-2 days: 34 (group 2). No AKI: 35 (group 3). In groups 1 and 2 FGF23 and EPO levels were significantly increased, as compared to group 3. In contrast, Klotho was significantly decreased in AKI patients compared to non-AKI patients. The combined biomarker increased in AKI patients (*P< 0.001 vs. group 3,* both groups). The magnitude of increase of the combined biomarker was proportional to the severity of AKI (KDIGO1=3x; KDIGO3=20x) and showed an appropriate accuracy, with an Area Under Curve of 0.91 [0.85-

0.96]. Defining a cut-off value of the combined biomarker =1.0 (A.U.), we found that values>1.0 associated with increased 30-day mortality (27% versus 7%, p=0.02; HR: 3.0), development of CKD (32% versus 8%, p=0.03; HR: 3.1; Fig 1) and 1-year mortality (43% versus 13%, p< 0.01; HR: 2.9; Fig 1).

CONCLUSIONS. The combined biomarker predicted the development of AKI in ICU patients with sepsis with high accuracy. The combined biomarker was an appropriate predictor of worse short and long-term outcomes, including mortality and development of CKD. This new biomarker should be evaluated in larger clinical trials, to study its applicability in AKI patients and post-AKI follow-up.

Downregulation of TIMP2 attenuates sepsis-induced acute kidney injury through NFκb pathway

Y.-M. Li[1], J. Zhang[1], L.-J. Su[1], K. John A.[2], Z.-Y. Peng[1,2]
[1]Zhongnan Hospital of Wuhan University, Wuhan, China; [2]University of Pittsburgh School of Medicine, Pittsburgh, United States

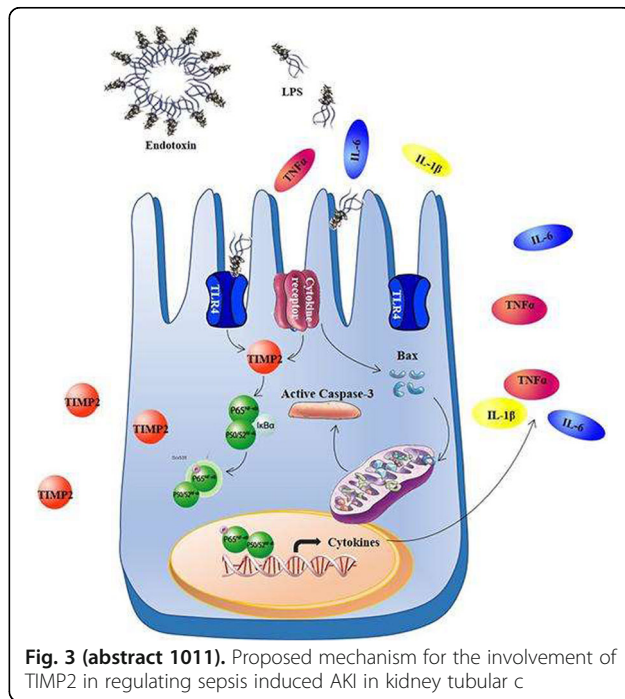
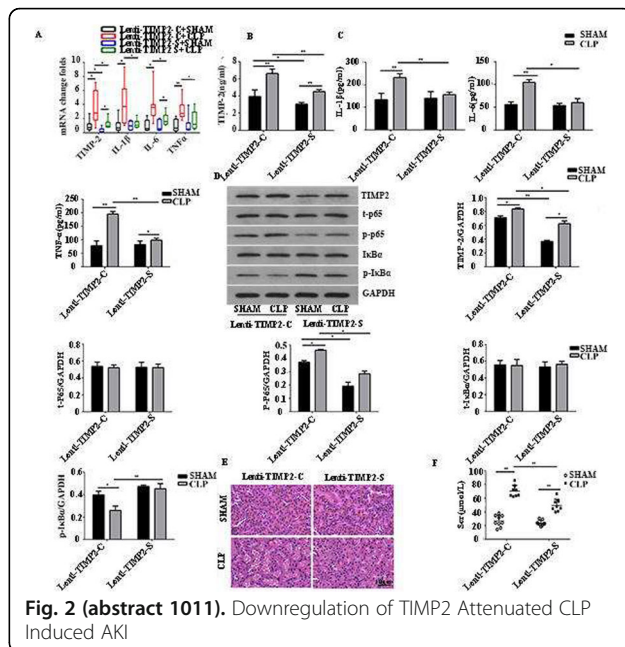
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1011

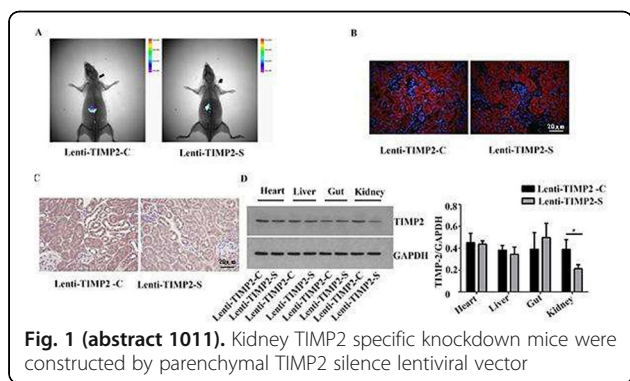
INTRODUCTION. Acute kidney injury (AKI) is a frequent complication of sepsis, and contributes to morbidity and mortality. Urinary tissue inhibitor of metalloproteinases-2 (TIMP2) has been recently

recognized as an early biomarker predicting AKI in critically ill patients. However, the biologic functions of TIMP2 remain largely unknown.

OBJECTIVES. In this study, we investigated the role of TIMP2 in mediating inflammation and tubular cell apoptosis in AKI.

METHODS. A murine model of sepsis-induced AKI was established by cecal ligation and puncture (CLP). Mice undergoing CLP and immortalized proximal tubular epithelial human HK-2 cells that were exposed to lipopolysaccharide (LPS) were treated with TIMP2 silence lentivirus expressing TIMP2 siRNA, Flow cytometry was used to test the apoptosis rate. Renal function was detected by serum creatinine. Statistical analysis was performed using Spearman rank correlation and paired two-tail t test.






RESULTS. In kidney tissue taken from mice exposed to cecal ligation and puncture (CLP) and in human kidney 2 (HK-2) cells exposed to LPS in culture, TIMP2 was significantly upregulated. The expression of TIMP2 in the kidney correlated with the severity of AKI in vivo. (Maximal figures number is 3; data not shown) In cultured HK-2 cell, LPS challenge markedly induced cytokine release and recombinant cytokines promoted TIMP2 expression and apoptosis. However, TIMP2 silence ameliorated LPS-induced cytokine release, apoptosis and cell injury. (data not shown) We further found that the effects of down regulation of TIMP2 on suppression of the inflammatory cytokine release was mediated by p-P65. Stable, kidney-specific TIMP2 knockdown mice were transduced by TIMP2 knockdown lentiviral vectors injection into kidney parenchyma.

Silencing of TIMP2 ameliorated CLP induced proinflammatory cytokines, kidney dysfunction measured by serum creatinine and histopathologic changes. Downregulation of TIMP2 exhibited renoprotective effects against endotoxin-induced AKI, which was associated with anti-inflammatory activity by inhibiting the NF-κB pathway.

CONCLUSIONS. In summary, we explored the possible roles of TIMP2 in septic AKI and found that TIMP2 does indeed promote kidney damage apparently by acting on NFκb. We hypothesize a feedback loop promoting apoptosis and leading to AKI. On the contrary, suppressing TIMP2 protects against kidney damage, reduces p-P65 activity, attenuates proinflammatory cytokines, improves cell viability and reduces apoptosis. Our results reveal a potential new therapeutic target for AKI in the setting of sepsis and possibly other conditions.

INTRODUCTION. The pathogenesis of septic acute kidney injury (AKI) may relate to metabolic changes rather than hypoperfusion[1]. In murine septic AKI, decreases in mitochondrial oxygen consumption parallel decreased GFR[2]. Mesenchymal-Stromal/Stem-cell (MSC) administration has been shown to reduce both incidence and severity of AKI in experimental models of sepsis, and may modulate transcriptional responses to mitigate bioenergy failure[3].

OBJECTIVES. To identify regulatory microRNAs (miRNAs) contributing to the therapeutic effect of MSCs in a murine model of septic AKI.

METHODS. Mice were randomized to either sham or caecum ligation and puncture surgery followed by either placebo or MSCs administration (N=4 per group). Total RNA from kidneys was extracted from these mice for profiling the renal response to sepsis (placebo) vs MSC treatment. Transcriptional and miRNA profiles were generated by hybridizing total RNA to the Illumina Mouse WG 6v2.0 or the miRCURY LNA[TM] microRNA arrays. In the R scripting environment, differentially expressed genes and miRNAs were identified via linear modelling. Putative regulatory relationships were identified based on Pearson and Elastic Net regression. Correlative relationships were discarded unless putative targets contained a predicted miRNA binding site. Gene ontology (GO) enrichment analysis was performed on both differentially expressed genes and the putative targets of differentially expressed miRNAs.

RESULTS. Mice that underwent CLP had elevated plasma creatinine and urea. Twenty-three miRNAs and 2021 probes or genes had significantly differential expression (false discovery rate < 0.05). GO analysis suggested that many of the differentially expressed genes related to mitochondrial function.

miRNA 484 had increased expression after CLP, and treatment with MSC restored an intermediate phenotype.

Regression revealed miRNA 484 to be a putative master-regulator, with 2428 genes having negatively correlated expression. Of these, 2 genes were amongst the 18 proven targets of miRNA 484; 491 genes contained a predicted binding site. GO analysis suggested that these 491 genes played a role in mitochondrial function.

CONCLUSIONS. miRNA 484 regulates mitochondrial fission and apoptosis[4]. miRNA 484-mediated mitochondrial regulation may play a significant role in the pathogenesis of AKI in a murine model of septic acute kidney injury.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1013

INTRODUCTION. Hemorrhage causes a depletion of systemic hemodynamics and oxygen delivery, and also triggers an inflammatory cascade. Despite treatment of macrocirculation with bleeding control, fluid resuscitation and blood transfusion, persistent microcirculatory dysfunction might remain and possibly contribute to acute kidney injury (AKI) following hemorrhagic shock.

OBJECTIVE. In this study, we examined whether or not there is macro- and microcirculatory coherence in kidney during haemorrhage and resuscitation. To this end we measured haemorrhage-induced microcirculatory alterations in both the kidney (CEUS) and sublingual tissue as a methodology that can easily be applied at the bed-side.

METHODS. 18 anaesthetised, mechanically ventilated female Yorkshire pigs were divided 2 groups as Hemorrhagic shock (HS) (40% blood loss) (n=12) and control (C) (n=6). In addition to hemodynamic parameters, CEUS and laser speckle perfusion imaging were used for determination of renal microcirculatory perfusion alterations in the exposed kidney and the SDF camera (Cytocam) for evaluation of sublingual microcirculation.

RESULTS. Despite normalized MAP after fluid resuscitation at T3, HR remained higher during resuscitation ($p < 0.05$ vs. C). At T3, CO was found significantly higher than the control ($p < 0,05$ vs. C) (Fig 1).

RBF and urine output were improved by fluid resuscitation at T3 ($p < 0,05$ vs. BL and Control) and perfusion. The intrarenal microcirculatory transit time (IRMTT) between a renal arterial and the renal microcirculation introduced by us (1) as a new CEUS parameter for measurement of intrarenal microcirculatory alterations showed a slowing down of microcirculatory perfusion during early resuscitation ($p < 0,05$ vs. C) (Fig 2).

At T3, other CEUS hemodynamic parameters FWHM (full-width half maximum) and PE (peak-enhancement) were also significantly reduced at end of resuscitation in HS group ($p < 0,05$ vs. C). Sublingual microcirculation analyzed automatically by our newly developed software followed this trend closely ($p < 0,05$; HS group T1 vs. T3) (Fig 3).

pH, base excess and lactate levels were not corrected after 1 hour fluid resuscitation ($p < 0,05$ vs. C).

CONCLUSION. Our results showed that correction of macrohemodynamics after hemorrhagic shock did not result in a parallel improvement in the microcirculation identifying the presence of a loss of hemodynamic coherence. Our study also identified that sublingual microcirculatory alterations were able to track similar alterations in the kidney microcirculation. Additionally, these findings support the microcirculatory basis for the development of AKI following resuscitation in haemorrhage.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1014

INTRODUCTION. Acute kidney injury (AKI) is common in pediatric patients who undergo surgery to correct congenital cardiac defects, and is associated with poor outcomes [1]. This study is a sub-analysis of a prospective blinded observational trial that assessed the clinical value of the Foresight near-infrared spectroscopy (NIRS) cerebral oximeter [2-3].

OBJECTIVES. The purpose of this analysis was to identify predictors of severe pediatric AKI (spAKI), stage 2 or 3 [4], after cardiac surgery, defined as a serum creatinine ≥ 2 times the baseline or urine output < 0.5 ml/kg/h for at least 12 hours or provision of dialysis. Secondly, we developed a prediction model for its occurrence during the first week of ICU stay.

METHODS. All patients from the NIRS study [2] without AKI on admission nor during the first 6 hours were included Admission data, laboratory results and ICU monitoring values were extracted from the electronic health record system (iMDsoft's MetaVision) and analyzed. Feature selection was performed with univariate testing and a stepwise logistic regression approach. Prediction models were then developed using different machine learning algorithms through 3-fold cross validation. The performance of the final model was reported with the area under the receiver-operator characteristic curve (AUROC), calibration curve, and Brier score.

RESULTS. From 177 patients of the NIRS study, 156 (88%) remained for the analysis. 55 patients (35%) developed spAKI during the first week. Median systolic arterial blood pressure and blood lactate levels resulted the only significant predictors of spAKI. Logistic regression was the most discriminative and well-calibrated model (figures 1, 2), with an AUROC of 0.74 and a Brier score of 0.17. A graphical representation of the model is shown in figure 3.

CONCLUSIONS. Although the pathophysiology of AKI is complex, a model including only systolic blood pressure and blood lactate levels was able to fairly predict AKI 6 hours in advance.

Fig. 2 (abstract 1014). Calibration curve

Fig. 3 (abstract 1014). Scatterplot of observed and predicted outcomes

stroke were significant AEs of the nervous system. Main AEs in the RR were respiratory depression, airway obstruction (3 developed hypoxic cardiac arrest). Airway obstruction & pulmonary aspiration were important AEs on the floor (2 had hypoxic cardiac arrest & death).

Most of the UIA patients stay in ICU 1-3 days with the result of immediate resuscitation & ICU care. Patient with septic shock had highest organ failure, ICU stay & mortality. Patient with hypoxic cardiac arrest & perioperative stroke had highest morbidity. Data from multivariate analysis showed predictor of 90 days mortality were age> 85yrs, ASA >III, emergency surgery, cardiac arrest, septic shock, multiorgan failure.

CONCLUSIONS. Unplanned ICU admission was found in 1/5 of ICU admission which ¼ of the AEs could be preventable. Causes analysis & carefully implement of prevention strategies should be done to reduce this UIA to improve perioperative quality care.

INTRODUCTION. Unplanned postoperative ICU admission (UIA) from the OR has been considered as a clinical indicator of perioperative quality care, safety of surgical patient & information for quality improvement (1,2).

OBJECTIVES. To study the incidence, detail of adverse events (AEs) that lead to UIA, preventability & outcome as resource utilization, organs failure & 90 days mortality.

METHODS. This prospective observational study was done in UIA from OR or within 24 hrs after major noncardiac surgery & admitting to the general SICU (14 beds) of the 3rd referral university hospital (2,400 beds, >33,000 ops/yr) from Jan 2016-Dec 2017. Study data: patient demographic data, co-morbidities, ASA physical status, type & duration of anesthesia, urgency of surgery, detail of AEs & outcome as resource utilization , organ failure while admitted in ICU & 90 days mortality.

RESULTS. There were 223 UIA or 34:10,000 operations. Age of 68.24 + 22.01 yrs, 54% & 30% were ASA III & > III respectively, 30% underwent emergency surgery, 68% of the AEs occur intraoperative, 48.4% were anesthesia related. The rest of the AEs associated with postoperative care as 18.8% & 13% were admitted from RR & within 24 hrs after operation respectively.3/4 of the intraoperative AEs were severe hemodynamic instability that 41%, 28% & 15% were from massive intraoperative bleeding, septic shock & combined neuraxial & general anesthesia respectively. The rest were from severe cardiac arrhythmias, massive PE (4 needed ECMO support, 1 had angiothrombolysis & 5 had surgical embolectomy), anaphylaxis (contrast media, high dose atracurium/cisatracurium, 4% gelatin), LAST & MH. One fifth of the AEs were airway & respiratory complications that 68% were from pulmonary aspiration (1/4 turned ARDS) which 40% were consensuses as preventable.The rest were from unexpected difficult intubation, laryngospasm & bronchospasm at the time of extubation & massive pneumothorax from invasive procedure. Delay recovery, perioperative

INTRODUCTION. We recently demonstrated that administration of balanced hydroxyethyl starch (HES) solution as part of intraoperative goal-directed fluid therapy (GDFT) was associated with better short-term outcomes than administration of a balanced crystalloid solution in patients having major abdominal surgery (1).

OBJECTIVES. In the present study, we performed a one-year follow-up of renal and disability outcomes in these patients.

METHODS. All patients enrolled in the earlier study were followed up one year after surgery for renal function and disability using the World Health Organization Disability Assessment Schedule 2.0 (WHODAS). The primary outcome measure was estimated glomerular filtration rate (eGFR). Secondary outcomes were serum creatinine (Scr) and WHODAS score. Groups were compared directly on a complete-case analysis basis, and modern imputation methods were then used in mixed-model regressions to assess the stability of the findings taking into account the missing data.

RESULTS. Of the 160 patients enrolled in the original study, follow-up data were obtained for renal function in 129 and for WHODAS score in 114. There were no statistically differences in Scr and eGFR (p>0.05) by pairwise testing or mixed-model regressions after imputation of missing data. However, the WHODAS score was significantly lower in the colloid than in the crystalloid group (2.7 [0-12] % vs. 7.6 [1.3- 18] %; p=0.0147).

CONCLUSIONS. In patients undergoing major open abdominal surgery, administration of a balanced HES solution as part of intraoperative GDFT did not affect long-term renal function compared to the use of a balanced crystalloid but was associated with less disability one year after surgery.

Evaluation of accuracy of noninvasive haemoglobin estimation by pulse-oximetry during major surgical haemorrhage

J. Divatia, S. Pradhan, P. Verma

Tata Memorial Hospital, Anaesthesiology, Critical Care and Pain, Mumbai, India

Correspondence: J. Divatia

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1017

INTRODUCTION. Non-invasive spectroscopic haemoglobin monitoring using pulse oximetry (SpHb) provides continuous, non-invasive haemoglobin (Hb) monitoring, and may be advantageous during major surgical haemorrhage.[1-4]

OBJECTIVES. To determine the reliability of SpHb monitoring in comparison with Hb estimated by the laboratory analyser (HbLab) in patients undergoing major cancer surgery with anticipated blood loss more than 30% of total estimated body volume (EBV).

METHODS. This prospective study was performed in 40 adult patients undergoing elective surgical procedures with expected blood loss > 30% EBV. The study was approved by the Institutional Ethics Committee and written, informed consent was obtained from all participants. SpHb was monitored using a Rainbow R-25a sensor connected to a Masimo Rainbow SET® Radical-7™ Pulse CO-Oximeter. Arterial blood samples were analysed for Hb levels with a laboratory haematology analyser (Siemens ADVIA 2120/2120i). Hb by both methods was compared at 4 time points: T1, after insertion of the arterial line and prior to surgery; T2, prior to transfusion of the first unit of packed red blood cells (PRBCs); T3, after transfusion of two units of PRBCs; and T4, after completion of surgery. Correlation, agreement and error grid analyses were performed with scatter plots, Bland-Altman plots[5] and Morey´s three-zone error grids.[6] To determine the reliability for the trend of Hb, at each time point (T1 to T4), the mean difference between SpHb and HbLab values was analysed using the paired 't' test.

RESULTS. 136 paired readings from 40 patients were analysed. Preoperative Hb was 11.96 ± 1.89g/dL. Median blood loss [interquartile range] was 2500 [1825-3400] ml and median volume of PRBCs transfused was 779 [474-1077] ml. Pearson correlation coefficient (r) for HbSpHb vs HbLab was 0.581. With reference to HbLab, the bias (precision) and Limits of agreement of SpHb were -0.3691 (1.71) and +2.98 to -3.72 g/dl. On error-grid analysis, while there were no measurements in the critical error Zone C, 44/136 (32%) of the values were in Zone B, which is the zone for potential error. Analysis of differences between mean Hb by the two methods at T1 to T4 showed that at T2, there was a statistically significant difference between mean SpHb and mean HbLab (-0.93 ± 1.69 g/dL, p=0.005)

CONCLUSIONS. The limits of agreement between SpHb and HbLab were wide. SpHb followed the trend of HbLab, but over-estimated the Hb, especially at T2, prior to transfusion of the first unit of PRBCs. One may thus make an erroneous decision to not transfuse the patient. Caution needs to be exercised when using the SpHb monitor as a sole method to guide intraoperative transfusion-related decisions.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1018

INTRODUCTION. Respiratory quotient (RQ) defined by the ratio of CO_2 production (VCO_2) and O_2 consumption (VO_2) was described as a non-invasive marker of anaerobic metabolism (1). The measurement of O_2 and CO_2 inspired and expired fractions (FiO_2, FeO_2, $FiCO_2$ and $FeCO_2$) is part of monitoring of the intubated-ventilated patient in the operating room. Thus, physician may have an indirect measure of the anaerobic metabolism based on the RQ.

OBJECTIVES. The main objective was to demonstrate the ability of indirect measurement of RQ to predict postoperative complications after major surgery. The second objective were to compare predictability of RQ, central venous oxygen saturation ($ScVO_2$), $gapCO_2$ ($PvCO_2$-$PaCO_2$) and arterial lactate.

METHODS. We conducted a multicentric and observational study. Patients operated of major surgery (abdominal, orthopedic, vascular) were included. We excluded cardiac, thoracic, laparoscopic surgery and acute or chronic respiratory insufficiency. Indirect RQ was performed by using average values of FiO_2, FeO_2, $FiCO_2$, $FeCO_2$ measured by anesthesia ventilator (Drager™ Perseus or Primus) at 4 times of the surgery (baseline hemodynamic optimization, 1 and 2 hours after surgical incision, skin closure). RQ was calculated by this formula $RQ= VCO_2/VO_2 = (FeCO_2-FiCO_2)/(FiO_2-FeO_2)$. All complications were recorded according to international guidelines until the 30th postoperative day (2). We also recorded the following parameters: blood pressure, cardiac output, arterial lactate, $GapCO_2$, $ScvO_2$ and O2 delivery (DO_2).

RESULTS. After ethics comittee agreement, 81 patients were included with a median age of 63 [55-71] years. 27(33%) patients had one post-operative complications and 8(10%) are dead. At skin closure, patients with complications had higher arterial lactate and RQ values. $ScVO_2$, $gapCO_2$ and total fluid administration did not differ between patients with/without complications.

In the overall population, indirect RQ was statistically correlated with arterial lactate(r=0,347, p=0,001) and inversely correlated to DO_2 (r=-0.206, p=0.031) and cardiac output(r=-0.238, p=0.028). RQ and arterial lactates predict complications with an area under the curve of 0.77($IC_{95\%}$:0.647 to 0.898, p=0.001) and 0.71(0.58 to 0.83, p=0.003). The best indirect RQ cut off was 0.93 (sensibility= 78% and specificity= 70%). $ScVO_2$ and gap CO_2 were not associate to post-operative complications.

CONCLUSIONS. Indirect measure of RQ could be considered as a non-invasive marker of anaerobic metabolism that was correlated to arterial lactate and predicted post-operative complications in high surgical risk patients.

INTRODUCTION. Caplacizumab, a bivalent Nanobody, targets the A1 domain of vWF, inhibiting the interaction between ultra-large vWF and platelets.

OBJECTIVES. We assessed the efficacy and safety of caplacizumab in patients with acquired thrombotic thrombocytopenic purpura (aTTP).
METHODS. Patients with an acute episode of aTTP who had received one plasma exchange (PE) treatment were randomized 1:1 to placebo or 10 mg caplacizumab, in addition to daily PE and corticosteroids. The study drug was given during the PE period and 30 days thereafter. If at the end of this period there was evidence of ongoing disease, such as suppressed ADAMTS13 activity, investigators were encouraged to extend the blinded treatment for a maximum of 4 weeks together with optimization of immunosuppression. All patients entered a 28-day treatment-free follow up period after the last dose of study drug.
RESULTS. 145 patients were randomized (73 placebo, 72 caplacizumab). Compared to placebo, caplacizumab-treated patients were >50% more likely to achieve a platelet count response (platelet count normalization rate 1.55, 95% CI 1.10 - 2.20, p< 0.01). During the study drug treatment period, treatment with caplacizumab resulted in a 74% reduction in TTP-related death, recurrence of TTP, or a major thromboembolic event (p< 0.0001). During the overall study period, patients administered caplacizumab had a 67% reduction in disease recurrence (p< 0.001). No caplacizumab-treated patients were refractory to therapy versus 3 on placebo (p=0.057).Treatment with caplacizumab was associated with a trend toward faster normalization of LDH, cardiac troponin I and serum creatinine. Treatment with caplacizumab resulted in a 38% reduction in the mean number of days of plasma exchange, and a 31% reduction in the mean length of hospitalization during the study drug treatment period. A third of the patients were admitted to the ICU. Treatment with caplacizumab resulted in a 65% reduction in the mean length of ICU stay (reduction of 6.3 days). The most common caplacizumab-related TEAEs were epistaxis, gingival bleeding, and bruising.
CONCLUSIONS. Treatment with caplacizumab reduced the time to platelet count response and resulted in a clinically meaningful reduction in aTTP-related death, recurrence of aTTP, or a major thromboembolic event during study drug treatment, as well as recurrences during the overall study period. Treatment with caplacizumab also resulted in meaningful reductions in healthcare resource utilization. The safety profile was favorable, with mucocutaneous bleeding the most frequently reported AE. Caplacizumab represents a novel adjuvant treatment option for patients with aTTP. (clinical-trials.gov: NCT02553317).

Prevalence and risk factors for ICU burnout syndrome among Thai intensivists and ICU nurses

P. Wacharasint[1], C. Laopakorn[1], P. Kunakorn[2]
[1]Phramongkutklao Hospital, Department of Medicine, Bangkok, Thailand; [2]Ramathibodi Hospital, Bangkok, Thailand
Correspondence: P. Wacharasint
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1020

INTRODUCTION. Burnout syndrome (BOS), a work-related constellation of symptoms and signs, which interfere individuals emotional stress, and associated with increasing job related disillusionment. While its prevalence was found highly in the intensive care unit (ICU) professionals and varied across the globe,[1] ICU-BOS among Thai intensivists and ICU nurses had never been explored.
OBJECTIVES. To study the prevalence of ICU-BOS among Thai intensivist and ICU nurse, and to identify the risk factors for ICU-BOS.
METHODS. We performed a multicenter, prospective, cross-sectional study in 17 hospitals in Thailand during September 2017 - February 2018. Demographic data and BOS-related data were collected from full-time ICU physicians and ICU nurses using electronic questionnaires. ICU-BOS was defined if participant exhibits at least 1 of 3 aspects (i.e. depersonalization, emotion exhaustion, and personal accomplishment) regarding to Maslach Burnout Inventory.[2,3] Primary outcome was prevalence of ICU-BOS among intensivists and ICU nurses, and secondary outcomes were risk factors for ICU-BOS.

RESULTS. Following total of 193 electronic survey sent, there were 171 participants (Thai intensivist; n=66 and Thai ICU nurses; n=105) responded by completing these questionnaires, and were included in this analysis. For intensivist, most of them were 34+4 years old and were male (53%), while most of ICU nurses were 33+8 years old and were female (93%). The prevalence of ICU-BOS of intensivists and ICU nurses were 65.2% and 62.6% respectively. Independent risk factors of ICU-BOS among Thai intensivists were 1) income < 20,000 THB/month, 2) thinking idea to quit their ICU job in last one year, and 3) need vacation >2 days/week (adjusted odds ratio (OR) of 31.5, 15.9, 7.4, and p-values of 0.04, 0.007, 0.035 respectively). Regarding to Thai ICU nurses, risk factors of ICU-BOS were 1) age >40 years old, 2) ICU experience >5 years, 3) patient's ICU length of stay >5 days, 4) thinking idea of too much ICU workload, and 5) thinking idea to quit their ICU job in last one year (adjusted OR of 15.7, 4.6, 10.0, 4.3, 5.3, and p-values of 0.009, 0.04, 0.004, 0.04, 0.007 respectively).

CONCLUSIONS. In this study, we found a high prevalence of ICU-BOS in Thai ICU professionals. Co-occuring risk factors for ICU-BOS among Thai intensivists and ICU nurses was thinking idea to quit their ICU job in last one year. Our findings support further interventions to reduce this high prevalence of ICU-BOS in Thai ICU professionals.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1021

INTRODUCTION. Lack of adherence to sepsis treatment bundles is associated with increased mortality. Organizational characteristics like different staffing patterns according to the period of day and the day of the week that patients are diagnosed can influence adherence to bundles and eventually outcomes. Very few studies evaluated the differences in adherence to sepsis bundles during nighttime and weekends, with contradictory results.

OBJECTIVES. To evaluate the effect of sepsis diagnosis at different periods of day (daytime versus nighttime) and weekends on adherence to sepsis treatment bundles and whether these differences may impact outcomes.

METHODS. We conducted an observational, multicenter and retrospective study including patients diagnosed with sepsis and septic shock between 2010 and 2017 in 10 hospitals in São Paulo, Brazil. Compliance with each recommendation of the 3-hour sepsis bundle was calculated according to the moment sepsis was diagnosed: day (07:00 AM to 6:59 PM) versus night (7:00 PM to 06:59 AM) and weekdays (Monday 7:00 AM to Friday 06:59 PM) versus weekends (Friday 7:00 PM to Monday 06:59 AM). Adherence to the entire 3-hour bundle was the primary outcome and subgroup analysis included compliance according to disease severity (sepsis/septic shock) and location of sepsis diagnosis (emergency room, ward or ICU). A multivariable analysis adjusted for age, sex, sepsis severity, location of sepsis diagnosis, type of infection and hospital was done to assess if diagnosis at nighttime and weekends was associated to bundle adherence.

RESULTS. We included 11,737 patients. Of these, 8,733 had sepsis and 3,004 had septic shock. SOFA score was 4 (2—7) and hospital mortality rate was 24.7%. Adherence to full 3-hour bundle was higher for cases identified at daytime versus nighttime especially for lactate collection and antibiotic administration (Table 1). There was no difference in the adherence according to the period of day and sepsis severity. The effect of period of day was maintained irrespective of location of sepsis diagnoses [emergency room odds ratio (CI) 1.60 (1.40-1.82), ward 1.18 (1.00-1.39) and ICU 1.33 (1.04-1.69), p=0.017]. In the multivariable analysis, adjusted odds-ratio (CI) for adherence to bundles for cases diagnosed at daytime versus nighttime (reference) was 1.35 (1.23-1.49), p< 0.001. There was no difference in compliance in weekends versus weekdays. The hospital mortality rate was not different for sepsis diagnosed at different periods of day and days of the week.

CONCLUSIONS. Adherence to sepsis bundles may be influenced by the moment of sepsis diagnosis. This effect was not related to sepsis severity and it was consistent in possible locations of sepsis diagnosis. Adherence was not affected by the day of the week. Despite the differences in the bundles compliance, nighttime and weekends diagnosis were not associated with altered mortality rates.

Table 1 (abstract 1021). Adherence to 3-hour sepsis guidelines according to period of day of sepsis diagnosis

Bundle Item	Total n=11737	Daytime n=7658 (65%)	Nighttime n=4079 (35%)	P value
Lactate collection	11170 (95.2%)	7321 (95.6%)	3849 (94.4%)	0.003
Blood cultures collection	10670 (90.9%)	6985 (91.2%)	3685 (90.4%)	0.122
Antibiotic Administration	10457 (89.1%)	6910 (90.2%)	3547 (87.0%)	<0.001
Entire 3-hour Bundle	9278 (79.1%)	6168 (80.6%)	3110 (76.3%)	<0.001
Fluid administration (n=4774 daytime) (n=2622 nighttime)	6951 (94.0%)	4502 (94.3%)	2449 (93.4%)	0.111

INTRODUCTION. Identification of latent safety threats (LSTs) i.e. errors in design, organisation, training or maintenance that may lead to medical errors, is crucial prior to transitioning to a new Intensive Care Unit (ICU) facility.[1] Simulation provides an opportunity for timely identification and remediation of LSTs and thus helps to improve patient safety.

OBJECTIVES. To identify LSTs using in-situ simulation sessions prior to moving into a new ICU.

METHODS. We conducted simulation scenarios over 6 weeks prior to moving into the new ICU. Healthcare providers (doctors, nurses, allied health personnel) participated in these scenarios .We included a 'virtual' ICU day to focus on testing the new model of care in the new environment. We conducted structured debriefings after each scenario. We developed 15 codes for 6 domains of LSTs by using an iterative process until consensus was reached. Using the Healthcare

Failure Modes and Effect Analysis (HFMEA) matrix developed by the National Centre for Patient Safety (VA NCPS)[2], we assigned a hazard score for each LST. LSTs were classified as catastrophic if they were likely to cause death or injury. The LST communication and action matrix was developed and agreed upon with the hospital management prior to commencement of the study.

RESULTS. A total of 24 simulation sessions were conducted with 61 participants. Ninety seven LSTs were identified, 36% of these were catastrophic and needed immediate remediation. Issues related to 'medication administration' and 'equipment' had the highest number of LSTs (34% and 19.6% respectively). Of the 35 catastrophic LSTs, 42% were related to 'medication administration' followed by issues related to 'models of care' (28.6%). Issues related to communication had the least number of LSTs (7.2%) and none were catastrophic (Table 1,Fig1)

CONCLUSION. In-situ simulation is a practical method for identifying LSTs prior to patient occupation of a new ICU. Patient safety can be enhanced by timely rectification of these LSTs. Our systematic approach to early LST detection using simulation is potentially adaptable and scalable to other new ICUs

Central line unit: a new activity outside of the ICU

M. López, E. Palleja Gutierrez, S. Vaquero Andreu, S. Gonzalez López, A. Campanario García, A. Loza Vázquez, P. Jiménez Vilches, A. Lesmes Serrano
Hospital Universitario Virgen de Valme, Sevilla, Spain
Correspondence: E. Palleja Gutierrez

OBJECTIVES. To describe the creation of a new Central Line Unit dependent on the Department of Intensive Care Medicine in our hospital.
METHODS. Observational study, analytical and prospective, completed in our university hospital of 500 beds with an intensive care unit of 14 beds that includes a department for central line cannulation. We report only the peripherally inserted central catheters (PICC). The PICC lines were inserted by personnel of the Department of Intensive Care Medicine, in the middle third of the arm through an aseptic technique and under echographic control. Data about PICC lines inserted between January, 2013 and December, 2016 were collected, including the demographic variables, types of patients, complications, results, follow-up in 3 months, its removal, and evaluation of the patients. A descriptive analysis was performed (SPSS), analyzing the qualitative variables in percentages and the quantitative variables in median values with standard deviation (SD).
RESULTS. 1,556 PICC lines were inserted in 1,327 patients. Age 59.97 ±15.37 years, 50.49% male. Outpatient procedure in 565 (42.58%), hospitalized patients in 762 (57.42%). From departments of Oncology (37.83%), Hematology (13.49%), Internal Medicine (10.78%), Intensive Care Medicine (5.5%). Underlying disease: solid tumors in 623 patients (46.95%) and hematologic malignancies in 188 patients (14.17%). Left arm 79% (Basilic vein 84.4%). Uses: Chemotherapy in 51.02%, Total parenteral nutrition in 21.63%. Average time of use 122.63±141.33 days (in 20% of patients, use for more than 6 months). Reason for removal: End of treatment in 55.92%, Exitus in 25.62%. Complications: Bacteremia in 50 (3. 76%)(0.28‰ days of catheter) , Deep vein thrombosis in 16 (9.52%). In 95.39% of cases no complications were observed during the insertion. Patient satisfaction during the follow-up in 3 months and in 6 months, 91.22% and 92.39%, respectively.
CONCLUSIONS. The cannulation of PICC lines in the Department of Intensive Care Medicine has demonstrated to diminish the rate of complications and to increase the safety of the patient, with a high rate of satisfaction.

Evaluation of rapid response team contact rate between day time and night time on surgical wards

M. Choi
Sungkyunkwan University College of Medicine, Surgery, Seoul, Korea, Republic of

INTRODUCTION. According to the previous study, there was diurnal variation in the patients-physician ratio and it was associated with the Rapid response Team (RRT) utilization . In real world, there is no surgical professional available for patients in general wards since they usually do their rounding early in the morning and spend most of the time in operating room. We hypothesized that this may attribute to no diurnal variation for use of RRT and its outcome in surgical patients.
METHODS. We conducted a retrospective observational study of 465 consecutive acutely deteriorating patients who were managed by RRT in surgical ward between March 2013 and July 2016. Patients treated between 08:00 to 17:59 were considered to receive day time care.

RESULTS. The half of RRT call was in the day time (08:00 ~ 17:59, 49.6%), however, the hourly rate of RRT call was higher during the day time (Figure 1). RRT call increased in the hours after routine surgeon's rounding (8:00~10:00), and decreased after they go to operating rooms. - it started to increase around noon when patients underwent surgery come back to wards, and peaked around 6pm when the physicians were finishing up the afternoon rounding. Patient characteristics and the reasons for RRT call were similar between the day and night. However, acute respiratory distress was higher during the night time (16.0% vs 23.9%, p=0.003). The in-hospital mortality (11.7% vs 16.2, p=0.157) and unexpected ICU admission rate (48.5% vs 49.6%, p=0.815) were not different between day and night. After adjusting potential confounding factors, night time RRT call was not associated with in-hospital mortality (RR 1.43, 95% CI 0.82-2.48, p=0.208).

CONCLUSIONS. The hourly rate of RRT call was higher during the day time. RRT call on day and night was not associated with unexpected ICU admission rate and in-hospital mortality.

Muscle weakness in ICU

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1025

INTRODUCTION. Intensive Care Unit (ICU) Acquired Weakness (ICUAW) is a common complication in the critically ill leading to muscle atrophy early during the disease course[1]. Myostatin is known as a major regulator in skeletal muscle growth and degradation. Until now myostatin dynamics in ICUAW are unknown.

OBJECTIVES. Our aim was to investigate whether ICUAW is associated with increased myostatin mRNA levels and serum concentration as well as its dynamic changes.

METHODS. We included 87 ICU patients and 91 healthy controls. The ICU patients were at high-risk for ICUAW through selection by a SOFA score ≥9. Informed consent for study participation was provided. Blood samples from ICU patients (day 4, 8 and 14) and once from controls, were investigated via ELISA for the measurement of myostatin serum concentrations. Open surgical muscle biopsies was performed within a subgroup of 58 ICU patients at day 5 and 15 and for 5 healthy references (controls) once during hip replacement to determine *MSTN* gene expression by rt-PCR. Values were normalized to healthy controls and expressed as fold change. Ethic vote (Charité EA 2/041/10).

RESULTS. Baseline characteristics of ICU patients and healthy controls did not differ significantly. MRC at first day of being adequately awake was available from 45 ICU patients scoring 3.0 IQR (2.0/3.7). First, at all time-points serum myostatin concentrations of ICU patients were massively decreased compared to health controls (p< 0.001). Second, lowest concentrations was found on day 4 with a significant increase to day 8 and 14 nevertheless still significantly lower than controls. Third, mRNA expression levels of *MSTN* were significantly lower in ICU patients compared to controls (p=0.016) resulting from a decrease tendency on day 5 and a significant decrease on day 15.

DISCUSSION. In opposite to our hypothesis we did not find increased myostatin levels in ICUAW patients. A massive decrease earliest investigated at day four makes an impact of myostatin on ICUAW implausible. If low levels represent a compensatory mechanism or just reduced production in skeletal muscle after very early muscle wasting is unknown.

CONCLUSIONS. For the first time, we show that myostatin levels are reduced in ICUAW patients with a slight recovery during ICU stay. The role of myostatin during ICUAW remains unclear and requires further investigation.

INTRODUCTION. Vitamin D deficiency has been associated with increased mortality in critically ill patients. Though blood 25-hydroxyvitamin D (25OHD) concentrations can be normalized within 48 hours with a large enteral dose, it may take a week or longer for the steroid hormone to exert its full range of pleiotropic effects.

OBJECTIVES. Post hoc analysis of the VITdAL-ICU trial, excluding study participants who died within 7 days of drug administration (placebo vs. 540,000 IU cholecalciferol).

METHODS. Chi-square and Fisher's exact tests were used to compare mortality rates between placebo and vitamin D treatment groups. Further, we explored predictors of mortality through logistic regression and multiple analyses, and included 25OHD and 1,25OHD response to treatment on day 3 among survivors and non-survivors, exploring the possible influencing factors.

RESULTS. Of the original 475 participants, 432 (91%) were alive after seven days. Survival was higher in the vitamin D arm at all time points, and achieved statistical significance at day 28 (p=0.03) and 6-months (p=0.04).
To explore the factors associated with mortality at 28 days, we calculated the odds ratio for vitamin D supplementation and for several covariates, and found a reduced mortality in the vitamin D arm.

In a bivariate logistic regression analysis, vitamin D still showed significant association with reduced mortality, even when adjusting the results for the same covariates (all p values < or = to 0.05), without showing interaction.

At enrollment 25OHD and 1,25OHD levels were not significantly different between survivors and non-survivors.

Both 25-hydroxyvitamin D and 1,25-dihydroxyvitamin D levels were significantly higher in survivors compared with non-survivors on day 3 in the vitamin D group.

Relevant influencing factors for a reduced 1,25-dihydroxyvitamin D level on day 3 (a reduced plasmatic increase after vitamin D administration), after centering the results for the baseline value, were (estimate; 95% Confidence Limit) body mass index increase (-1.8; -3,-0.6; p< 0.01), male gender (-19; -33,-5; p< 0.01), surgical admission (-24; -45,-4; p=0.02), presence of chronic kidney disease (-17; -30,-5; p< 0.01), and use of vasopressor on admission to the ICU (-20; -34,-6).

CONCLUSIONS. Excluding patients with an early death, high-dose vitamin D3 supplementation was associated with a significant reduction in mortality. Vitamin D treatment was associated with reduced mortality even when adjusting for confounding factors. In the treatment group, 25-hydroxyvitamin D and 1,25-dihydroxyvitamin D were higher on day 3 in survivors than in non-survivors, but the increase was less relevant in cases of increased BMI, surgical cases, and CKD, suggesting that these categories of patients may benefit from a higher dosage. The two ongoing large RCTs (VITDALIZE and VIOLET) will further elucidate the potential role of vitamin D supplementation in improving clinical outcomes in critical illness.

Table 1 (abstract 1026). Effect of vitamin D treatment on mortality outcomes when excluding the 110 deceased patients in the first 7 days

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1027

INTRODUCTION. Ultrasound measurements to determine body composition may become important in non- and critically ill patients for adaptation of medication dose, physical therapy and nutrition. Currently a standardized ultrasound protocol lacks.

OBJECTIVES. To test the intra- and interrater reliability of the USVALID ultrasound technique

METHODS. 2 measuring points on one randomly chosen upper arm and 3 measuring points on one randomly chosen thigh were landmarked with an erasable pen according to anatomical landmarks. On each measuring point a transversal and sagittal ultrasound scan was taken with minimal compression. Fat and muscle thickness was determined on each scan. For intrarater reliability each of the 5 examiners performed the ultrasound examination twice in 12 different patients. For interrater reliability all 10 possible examiner pairs performed the ultrasound examination twice in 60 other patients. The thicknesses of the transversal and sagittal ultrasound scans were averaged. Then the thicknesses of the measuring points for the thigh and those for the upper arm were averaged.

RESULTS. 2326 and 2374 measurements of fat and muscle thicknesses were recorded for intra- and interrater reliability respectively. 74 and 26 measurements were missing for intra- and interrater reliability respectively because of impossible ultrasound examination on distinct measuring points. Interrater and intrarater reliability was evaluated by Bland-Altman analysis. There was no statistically significant bias (Table 1,2, Figure 1). For intrarater reliability there was no difference in bias between examiners (P > 0.05, one-way Anova). For interrater reliability there was also no difference in bias between examiner pairs except for fat thickness of the thigh (P=0,047, one-way Anova).
CONCLUSIONS. The USVALID ultrasound technique is reliable. The bias lies within 0-3% of the mean value and ranges of agreement are comparable to other studies[1].

INTRODUCTION. Malnutrition is a clinically relevant condition in critically ill patients, because it causes immunological dysfunction, loss of lean mass and weakness of the respiratory muscles. Traditional tools for nutritional assessment are impractical in the Intensive Care Unit (ICU). The evaluation of lean mass can be a more reliable marker of malnutrition in this type of patients. Ultrasound (USG) is considered a practical and reliable tool for evaluating lean tissue in patients hospitalized in the ICU.

OBJECTIVE. To determine if accumulated caloric deficit (ACD) during the ICU stay contributes to the loss of lean mass in critically ill patients.

PATIENTS AND METHODS. A prospective study was conducted in critically ill adult patients admitted to the ICU who received artificial nutrition. Demographic and clinical variables were collected and the ACD and quadriceps muscle thickness (QMT) were measured on days 0, 3, 7, 10 and 14 of stay in the ICU. The correlation between ACD and delta of the QMT (DQMT) was evaluated by Pearson´s r. DQMT was compared between patients with critical caloric deficit (CCD) and non-critical caloric deficit (NCCD) by Student´s t test. A p value < 0.05 was considered statistically significant.

RESULTS. We analyzed 32 patients with a mean age of 48.5 years, 62.5% females, 75% received enteral nutrition and hospital mortality was 31.3%. Caloric deficit occurred in 90.6% of patients. The DQMT was 1.8 mm on day 3, 2.9 on day 7, 1.4 on day 10 and 1.3 on day 14 of ICU stay. The DQMT had a weak negative correlation with the ACD (r -0.026, p = 0.889). DQMT was 3.3 mm in patients with CCD and 2.4 mm in patients with NCCD (p = 0.582).

CONCLUSIONS. Caloric deficit is a phenomenon that occurs frequently in critically ill patients receiving artificial nutrition, especially by the enteral route. However, we found no correlation between the ACD and the QMT in these patients.

Prevalence of sarcopenia in a single institution adult intensive care unit and its clinical outcome

L.J. Tan, F.H. Jamaluddin, C.C. Ng, S.R. Ruslan, P.N. Sitaram, M.S. Hasan
University of Malaya Medical Centre, Anaesthesiology, Kuala Lumpur, Malaysia
Correspondence: F.H. Jamaluddin
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1029

INTRODUCTION. A cross-sectional study by Patricia et al showed that sarcopenia is highly prevalent among ICU patients and is not readily detected in patients using subjective global assessment.[1]

OBJECTIVE. To assess the prevalence of sarcopenia in an adult ICU and its clinical outcome - duration of ICU stay, duration of hospital stay, duration of invasive ventilation, risk of hospital mortality.

METHODOLOGY. This is a retrospective observational study done in the adult ICU of University Malaya Medical Centre, Kuala Lumpur, Malaysia. All patients admitted from January to December 2016 with CT abdomen prior to ICU admission were included. The skeletal muscle cross-sectional area (cm^2) from the CT image was manually measured at the caudal end of the third lumbar vertebra. The following formula were used for estimating skeletal muscle area(SMA) - for male (SMA = 126.9 X BSA - 66.2) and for female (SMA = 125.6 X BSA - 81.1). If the actual measured SMA was less than 80% of the estimated SMA, the patient was defined as sarcopenic.[2]

RESULTS. Out of 239 patients, 186(78%) were cases of sarcopenia. Male gender, surgical and older patients were associated with higher incidence of sarcopenia. Sarcopenic patients were noted to have higher SAPS score. There was more death among sarcopenic patients (34.4%) compared to non-sarcopenic patients (17%) (Table 1). However, there were no statistically significant differences in terms of length of hospital stay, length of ICU stay, and duration of invasive ventilation between the 2 groups (Table 2).

CONCLUSION. Prevalent of patients admitted to ICU with sarcopenia was high. In this study, sarcopenic patients were found to have higher risk of hospital death.

Correspondence: Å. Valsø

INTRODUCTION. Posttraumatic stress symptoms (PTSS) after treatment in intensive care units (ICU) are common. Follow-up consultations after ICU discharge have not been evaluated in patients regardless of their level of PTSS. No study has screened ICU patients for their individual PTSS level to identify those most in need for consultations. We hypothesized that patients with high level of PTSS would experience a decreased level of PTSS after targeted follow-up consultations.

OBJECTIVES. To evaluate the effect of early targeted nurse led follow-up consultations after ICU discharge to reduce PTSS in ICU patients with a high level of PTSS.

METHODS. In a randomized controlled trial, we aimed to consecutively include patients aged ≥18 years admitted for ≥ 24 hours to one of five ICUs in Norway from 2014 to 2016. Patients were screened for PTSS using Post Traumatic Stress Scale 10 (PTSS-10) after discharge from the ICU, and those with PTSS-10 score ≥ 25 (clinically relevant symptoms) were randomized into the intervention (IG) or the control (CG) group. Patients in IG participated in two or three individually adjusted follow-up consultations with a specially trained ICU nurse; the first at the ward early after discharge, and the second and third one and two months later at the ward or by phone call. A structured guide based on trauma focused cognitive behavioural therapy, combined with a narrative method, was used during the consulation. Patients filled in PTSS-10 early after ICU discharge at the ward (baseline), and 3, 6 and 12 months later. Possible differences between IG and CG after the consultations were analysed using a linear mixed model for repeated measures.

RESULTS. In total, 523 patients were screened, of whom 224 (43%) had a PTSS-10 score ≥ 25 (53% male) and were randomized into IG (n=111) or CG (n=112). Median age was 52 years (range 18 to 89), and mean PTSS-10 score was 37 (SD 10). Both groups showed statistically significantly lower PTSS-10 score over time (p< 0.01), but without significant differences between the groups (p=0.11). When assessing for gender differences regarding time trajectories, a different pattern was found for males and females, also stratified by groups (figure 1). Males in CG had significantly lower PTSS over time vs. IG (p=0.04), in contrast to women having a similar pattern for both groups.

CONCLUSION. A two month follow-up intervention did not show a significant effect on PTSS after one year in patients with high level of

PTSS, however, there was a significant drop in PTSS over time for all patients. Further research should pay attention to gender adjusted psychological treatment to discharged ICU patients.

Towards the acoustical characterisation of an intensive care unit

D. Dawson[1], R. Barham[2], M. Hamilton[1], B. Philips[3]
[1]St George's University Hospitals NHS Foundation Trust, General Intensive Care Unit, London, United Kingdom; [2]Acoustic Sensor Networks, Warninglid, United Kingdom; [3]St. George's University of London, London, United Kingdom
Correspondence: D. Dawson
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1031

INTRODUCTION. The intensive care unit (ICU) has long been considered a noisy environment, which impacts negatively on patient recovery[1], safe care and staff wellbeing. Noise is generated by the multiplicity of supportive equipment necessary for patient management and by the staff who provide or enable care. Staff conversation, equipment alarms and clinical treatment are cited as most disturbing[2].

OBJECTIVES. To identify the sources of sound and their relative contribution to the soundscape of an ICU.

METHODS. Fifty hours of observational data were recorded in a general ICU, using a datasheet designed and piloted for this purpose. Data was collected at four beds spaces for one month and provided equal representation across the bed spaces, hour of the day and day of the week. A priori, four categories of sound were identified communication, clinical tasks, housekeeping tasks and alarms and 55 individual sources of sound were reported under these categories. Concurrently, continuous sound pressure levels (SPL) were monitored at each bed space throughout the study period.

RESULTS. 16784 episodes of sound were identified during the 50hrs of data collection; the greatest number of episodes were reported in the communication category n=5699 (34%), with clinical tasks n=3282 (20%), housekeeping tasks n=3247 (19%) and alarms n=2939 (18%). The highest number of episodes for an individual source was nurse/nurse communication n=1595 (10%), followed by bin lids n=1004 (6%) and oxygen/nebulisers n=945 (6%).

Of the 55 sources recorded, the top 25 accounted for 86% of the episodes. The average L_{Aeq} across all four bed spaces during the study period was 65.1dB, with little variation between day (08.00-19.59hrs) 66.5dB and night (20.00-07.59hrs) 63.4dB, there was some reduction between 23.00-06.59.00hrs to 62.7dB and another modest reduction from 02.00-05.59hrs to 61.7dB. This correlated with a similar reduction in average episodes of sound from 175 during the day, 170 at night,163 from 23.00-06.59hrs and 160 from 02.00-05.59hrs.

CONCLUSIONS. Communication between staff, visitors and patients created the largest number of episodes of sound during the data collection with equipment alarms causing the least. Average SPL appear to be related to the number of episodes of sound. This data may provide a model for the degree of disturbance as a function of number and type of event and noise level. Many of the sources of sound are modifiable which could decrease noise disturbance in the ICU.

Learning from within: a quality improvement programme to identify and address key themes for successful critical care rehabilitation

S. Bean, R. Chapman, W. English
Royal Cornwall Hospital Trust, Critical Care Unit, Truro Cornwall, United Kingdom
Correspondence: S. Bean
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1032

INTRODUCTION. Each year around 110,000 people are admitted to critical care units in England and Wales and the majority survive to discharge home (1). Unfortunately many survivors face a protracted recovery period, with a high incidence of both physical and psychological problems.

OBJECTIVES. To describe the development and outcomes of a quality improvement programme using information gained by the critical care follow-up clinic team on the experiences of our patients and their relatives.

METHODS. Since April 2017 we have been obtaining structured feedback from patients and relatives attending our critical care follow-up clinic. This information has been used to identify important common themes of ways in which patient care can be improved. Addressing these themes has allowed our unit to collectively learn, develop and implement a number of fundamental positive changes, primarily concerning early rehabilitation and improved support and information for patients and relatives.

RESULTS. Main themes identified:
•Poor patient understanding of their illness and treatment.
•A high incidence of psychological morbidity. Amongst clinic attenders; 66% reported delusional memories, 20% reported persecutory delusions that had a significant impact on the quality

of their life, 15% had no recollection of their time on critical care and 25% had trauma screening scores suggestive of PTSD.
•Poor psychological preparation of patients for critical care discharge.
•Excessive noise levels in critical care.
•Poor access to psychological help after hospital discharge.

New service developments:
•Appointment of a rehabilitation link nurse specialist.
•Regular dissemination of patient and relative feedback to the critical care team, including high incidence of psychological morbidity.
•New agreed specialist referral pathways for patients requiring expert psychological input.
•Patient testimonials have been used to support a business case for regular clinical psychology input, to support a charity funding bid for noise monitoring equipment and to help embed the use of patient diaries into unit practice.
•Improved psychological preparation of long-term patients for critical care discharge. This has included visits to ward that they are due to be discharged to and steps to decrease reliance on staff help with activities of daily living.

CONCLUSIONS. Obtaining and using information sourced from patients and relatives at the critical care follow-up clinic has enabled the identification and subsequent introduction of many varied tools to help improve the care of our patients. Some have little or no additional cost associated with them. Some of the themes that we have identified will be common to other units.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1033

INTRODUCTION. Patients admitted to the Intensive Care Unit (ICU) are often subject to deleterious effects caused by long periods of immobilization. Early mobilization has stood out, for it helps the functional recovery, is able to reduce days in mechanical ventilation(MV) and ICU length of stay (LoS).
OBJECTIVES. To evaluate the prevalence of patients who underwent early mobilization, and its effects on mechanical ventilation and ICU length of stay.
METHODS. 255 patients of both sexes were enrolled, with a total of 941 physical therapy sessions. Patients were separated in two randomized groups: group 1 patients were submitted to physical therapy care within 12 hours of ICU admission; and group 2 underwent physical therapy care after 12 hours of ICU admission. Physical therapy protocol consisted of the aplication of four levels of mobilization: passive exercise (N1), active exercise (N2), orthostastism (N3) and deambulation (N4).Prevalence data were collected and the effects of early mobilization on the MV time and LoS were evaluated. Data were described in percentiles and average + standard deviation; in order to evaluate difference between groups, Student's t test was used. A p< 0,05 was considered to be statiscally significant.
RESULTS. 52,2% of patients were male, 58,4% were under mechanical ventilation and 39,9% were using vasoactive drugs. Main causes for ICU admission were abdominal surgery (19,2%), cardiac surgery (18%), and sepsis (16,5%). 62,3% of patients were moved from the bed; Concerning levels of mobilization, 48,6% were able to

perform active exercises and 13,2% to deambulate. There were no difference of SAPS-3 scores between groups; however, in the group that was mobilized earlier a reduction of both MV time (p< 0,05) and LoS (p< 0,05) was observed.
CONCLUSIONS. This study demonstrates that early mobilization, within a time-frame under 24 hours of admission, has helped to reduce the duration of mechanical ventilation and hospital length of stay, thus showing its potential to improve outcomes in the Intensive Care Unit.

Pre-extubation ultrasonographic measurement of intracricoid peritubal free space: a novel parameter to predict postextubation airway obstruction in children

A.K. Baranwal[1], M. Samprathi[1], J. Muralidharan[1], P.K. Gupta[2]
[1]PGIMER, Pediatrics, Chandigarh, India; [2]PGIMER, Biostatistics, Chandigarh, India
Correspondence: A.K. Baranwal
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1034

INTRODUCTION. Post-extubation airway obstruction (PEAO) is common in children, and prolongs stay in Paediatric Intensive Care Unit, increases morbidity and thus increases the overall cost of care.
OBJECTIVES. We hypothesised that Intracricoid Peritubal Free Space (IPFS) between inner circumference of cricoid and outer circumference of tracheal tube, as assessed by ultrasonography, may inversely correlate to cricoid oedema, and thus development of PEAO.
METHODS.
Design: Prospective observational study.
Setting and Participants: 15-bed Paediatric Intensive Care Unit at a tertiary care hospital in a lower middle income economy during Aug' 2016 to Dec' 2017. Ninety-three patients (3mo-12yrs) intubated for ≥48h and planned for extubation were included. Patients with pre-existent upper airway conditions, chronic respiratory diseases and poor airway reflexes were excluded.
Measurements: Cricoid was imaged just prior to planned extubation, and inner cricoid diameter was ascertained. Outer diameter of tracheal tube was deducted from inner cricoid diameter to obtain Intracricoid Peritubal Free Space-diameter (IPFS-diameter). Similarly, difference of cross-sectional area of inner cricoid and of outer tracheal tube circumference was calculated to obtain Intracricoid Peritubal Free Space-area (IPFS-area). Post-extubation airway obstruction was defined by Westley's Croup Score, ≥4.
RESULTS. 34%(32/93) patients developed PEAO, while 18%(17/93) needed re-intubation. Baseline disease characteristics were similar between patients with and without PEAO. IPFS-diameter (4.16 ±1.18mm *vs* 5.28±1.51mm) and IPFS-area ($56.72 \pm 24.25 mm^2$ *vs* $80.93 \pm 33.91 mm^2$) were significantly lower in patients with PEAO compared to those without. ROC Area under curve of IPFS-diameter and IPFS-area were 0.713 (95% CI, 0.608 -0.819) and 0.713 (95%CI, 0.606-0.819). Sensitivity and specificity at IPFS-diameter of 5.2mm were 84% and 50%; and at IPFS-area of $75mm^2$ were 88% and 50%.
CONCLUSIONS. It is feasible to perform airway ultrasound by clinicians to evaluate IPFS. It may help predict PEAO among

intubated children, and thus reduce the overall cost of care. However, a larger study is needed to confirm these initial findings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1035

INTRODUCTION. Little is known about mechanical ventilation (MV) discontinuation practices and outcomes in elderly (65-80 years) and very elderly (> 80 years) critically ill patients.

OBJECTIVES. We sought to characterize practices in end-of-life care and in weaning older critically ill adults from invasive MV and to describe the influence of selected discontinuation strategies on clinical outcomes.

METHODS. We included all newly admitted critically ill adults who were invasively ventilated for at least 24 hours in 142 intensive care units (ICUs) in 6 regions (Canada, United States, United Kingdom, Europe, India and Australia/New Zealand). We excluded patients transferred to participating ICUs without a clear time of intubation, with a tracheostomy at ICU admission, already on ventilator settings compatible with a spontaneous breathing trial (SBT) at ICU admission, and (iv) participating in studies with weaning protocols.

RESULTS. In 788 (586 elderly, 202 very elderly) patients undergoing MV discontinuation, we found that similar proportions of patients (22.5% and 23.8%, respectively) died before any attempt at discontinuation could be made. Compared to elderly patients, very elderly patients underwent direct extubation (19.1% vs. 19.3%), direct tracheostomy (6.8% vs. 5.0%), initial successful SBTs (79.5% vs. 78.1%) and initial failed SBTs (20.5% vs. 21.9%) with similar frequency. Compared to elderly patients, very elderly patients who underwent an initial tracheostomy experienced higher ICU and hospital mortality (15% vs. 50%, p=0.05; 23.5% vs. 71.4%, p=0.04) and significantly longer ICU stays (22.5 +/- 17.4 d vs. 43.8 +/- 28.9 d, p=0.02). Among elderly patients, those who failed (vs. passed) an initial SBT demonstrated a trend toward increased ICU mortality (21.0 % vs. 11.3%, p=0.07) and spent more time in the ICU (15.7 +/- 13.8 d vs. 10.9 +/- 10.6 d, p=0.008) with similar rates of readmission (4.8% vs. 4.2%; p=1.0), reintubation (14.5% vs. 14.3%, p=1.0), and hospital mortality (22.2% vs. 19.9%, p= 0.9). Similarly, among very elderly patients those who failed (vs. passed) an initial SBT had significantly higher ICU mortality (39.1% vs. 15.9%, p=0.03), trends toward higher hospital mortality (55.0% vs 30.8%, p=0.09) with similar rates of readmission (4.3% vs. 4.9%, p=1.0), reintubation (13.0% vs. 8.5%; p=0.8) and ICU lengths of stay. Regardless of the indication (weaning, prophylaxis,postextubation distress) noninvasive ventilation (NIV) was used nonsignificantly more often in the very elderly vs. elderly. We found large practice variation in the use of NIV and in the frequency with which various treatments were withheld and withdrawn across regions.

CONCLUSIONS. Our findings provide valuable information regarding outcomes associated with tracheostomy and initial SBT failure in elderly and very elderly critically patients.

Outcome comparison between alcoholic and non-alcoholic liver cirrhosis in intensive care

S. Hietanen[1,2], J. Herajärvi[1,2], A. Lehtonen[1,2], T. Ala-Kokko[1,2], J.H. Liisanantti[1,2]
[1]Oulu University Hospital, Division of Intensive Care Medicine, Department of Anesthesiology, Oulu, Finland; [2]Oulu University Medical Research Center, Research Group of Surgery, Anesthesiology and Intensive Care, Oulu, Finland
Correspondence: S. Hietanen
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1036

INTRODUCTION. Alcohol overconsumption is the leading cause of liver cirrhosis in western countries. According to the current studies the prognosis of alcoholic cirrhosis might be worse than the prognosis of liver cirrhosis caused by other etiologies (1-3). Only a few studies have focused on direct comparison between these patient groups.

OBJECTIVES. The aim was to compare the treatment profile and mortality between patients with alcoholic cirrhosis and patients with liver cirrhosis caused by other etiologies admitted to ICU.

METHODS. This retrospective cohort study included all patients with diagnosed liver cirrhosis and admitted to intensive care unit (ICU) in Oulu University Hospital in Finland between May 2015 and April 2017. Demographic data, the etiology of liver cirrhosis, and characteristics of treatment profile were obtained from electronic medical records and the ICU patient data management system. Patients were followed until the end of the year 2017 and the Finnish Population Register Center provided the data concerning mortality.

RESULTS. In a total of 100 ICU admissions with liver cirrhosis the etiology was alcohol in 78 cases (78.0%) and other etiologies in 22 cases (22.0%). The patients with alcoholic cirrhosis were younger and more frequently men. Median Sequential Organ Failure Assessment (SOFA) scores at admission were higher in patients with alcoholic cirrhosis resulting from lower Glasgow Coma Scale (GCS) points and higher bilirubin levels (Table 1). The most common cause of admission in total was gastrointestinal diagnoses, and the causes did not differ between groups. There was no difference between groups in the length of ICU stay, or in the need of organ support (Table 2). Overall ICU mortality was only 12.0% and there was no difference between groups. The long-term 180-day mortality was 42.0% and there was no difference between groups (Table 2, Figure 1).

CONCLUSIONS According to our data, the long-term survival of patients with liver cirrosis admitted to ICU is poor; nearly half of the patients are 180-day non-survivors. There are no significant differences in outcome between patients with diagnosed alcoholic or non-alcoholic liver cirrhosis.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1037

INTRODUCTION. End of life (EOL) care decision depends on consensus on goals of care between physicians and patients or their surrogates. EOL care decision usually results in death after withholding (WH) or withdrawing (WD) life sustaining treatment (LST). Important factors of good death concept should be addressed during goal of care discussions with patients or their surrogates.

OBJECTIVES. To evaluate public´s preference of LST and identify key factors on good death concept which are associated with attitudes toward aggressive treatment when meaningful recovery from critical illness is not possible.

METHODS. We recruited 798 participants (mean (SD) age: 59 (12.6) years; 165 (71%) males) from the community between December 2016 and September 2017 to complete a questionnaire on their attitudes of LST in critical illness (4 logical based questions, graph 1) and concept on good death (17 items)[1]. Their attitude towards LST was dichotomised into aggressive or non-aggressive treatment groups. Exploratory and confirmatory factor analysis were used to revise the model of good death questionnaire[1]. Logistic regression was used to identify predictors of preference for aggressive treatment. Inconsistent and invalid preference was defined as respondents who chose WH or WD LST but opted out of do not attempt resuscitation (DNAR).

RESULTS. We revised the original 3-factor model of good death concept to a better 4-factor (physical symptoms, psychological issues, social issues and self-control) model (CFI = .902, TLI = .878 and RMSEA = .065). Among 798 participants, 160 (20.0%) did not give a consistent response towards LST. Of the remaining 638 respondents, 113 (17.7%) of them preferred aggressive treatment even if the chance of meaningful recovery was minimal. Concerns about physical symptoms was the only factor which was associated with lower preference for aggressive treatment (OR: 0.44 95% CI:0.28-0.67).

CONCLUSIONS. Concerns about physical symptoms was strongly associated with preference for less aggressive treatment within a good death concept. Clinicians should emphasize information about physical discomfort related to LST to assist patients or their surrogates in making personal EOL care decisions when a meaningful recovery is unlikely.

Would you like to be admitted to the ICU? Intensivists' and the general public's preferences according to different outcomes

R. Fumis[1], G. De Paula Pinto Schettino[2], T. Domingos Corrêa[2]
[1]Hospital Sírio-Libanês, Intensive Care Unit, São Paulo, Brazil; [2]Hospital Israelita Albert Einstein, Intensive Care Unit, São Paulo, Brazil

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1038

INTRODUCTION. Discussions about invasiveness of care (advanced directives) and end-of-life issues have become frequent among intensivists and patients. Nevertheless, there are considerable divergences between the attitudes of intensivists and patients toward end-of-life care in the intensive care units (ICU) [1].
OBJECTIVE. Compare the preferences of intensivists with the general public's preferences about ICU admission of a hypothetical critically ill patient with six different outcomes.
METHODS. Intensivists and the general public (university graduate professionals outside the area of health) were invited to participate in this study. A survey was conducted with a hypothetical patient with six different clinical outcomes ranging from ICU discharge without any neurological sequelae or dependence for daily activities to death. The WHOQOL-BREF was applied to all participants. Comparisons were made between the answers given by intensivists regarding what they would choose for themselves and their patients and the preferences of the general public.
RESULTS. Between July 2013 and July 2016, 300 participants in 5 hospitals in São Paulo, Brazil were invited to participate in this study. Out of those, 257 (85.7%) answered the survey. Eighty-one intensivists responded what they would choose for their patients [median (IQR) age: 34 (31-41) years] , 82 intensivists responded what they would choose for themselves [median (IQR) age: 36 (31-40) years] and 94 participants from the general public [median (IQR) age: 40 (31-51) years] responded what they would choose for themselves. Quality of life did not differ among the groups. More than half of the participants from the general public do not wish to die in an ICU. In all scenarios, except when the outcome was severe disability or death, intensivists were more likely to propose ICU admission for their patients rather than for themselves (p< 0.01 for all). The general public was significantly less prone than intensivists to choose ICU admission in three out of six scenarios (p< 0.001 for all). Intensivists' opinion did not differ from the general public's in 50% of clinical scenarios. Intensivists were more likely to propose ICU admission for themselves rather than for the general public only when the best outcome clinical scenario is considered (p< 0.001).
CONCLUSIONS. Considerable divergences between intensivists' and patients' preferences toward end-of-life care exist. Advanced care planning and effective ongoing communication among intensivists, patients and relatives are essential to improve end-of-life decisions and the quality of care.

Ethical aspects of prognosis and the passage of time in intensive care. A qualitative triangulation

A.-H. Seidlein, A. Nowak, S. Salloch
University Medicine Greifswald / Institute for Ethics and History of Medicine, Greifswald, Germany
Correspondence: A.-H. Seidlein
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1039

INTRODUCTION. The decision-making environment in intensive care units (ICU) is strongly influenced by at least three important transformations on the individual and societal level that enhance complexity: Firstly, the patients' mean age and comorbidities have increased and they will continue to do so. Secondly, potentially life-prolonging treatment options are still on the rise. Finally, patients' right to self-determination is highly emphasized but the question how to respect their will in case of incompetence remains challenging in healthcare professionals' everyday practice.
OBJECTIVES. This qualitative study aims to explore patterns of decision-making concerning the continuation, withdrawal, and withholding of life-sustaining therapies (LST) in intensive care. The focus lies on different roles of the persons involved as well as influencing factors regarding the escalation and de-escalation of therapies and the modification of treatment goals.
METHODS. Data collection comprised four weeks of non-participant observation during day shifts on an ICU at an academic medical centre in northern Germany, followed by qualitative semi-structured interviews with five nurses and five physicians practicing at different ICUs in Germany. Qualitative content analysis according to Mayring was applied using MAXQDA software to analyse the interview transcripts and field notes.
RESULTS. Decision-making concerning LST is a dynamic process in which the intensity of treatment is influenced by multiple medical, social and psychological factors. Amongst other aspects, the prognosis for possible long-term outcomes is stressed by all parties involved as one of the most important criteria and major motivation to initiate, stop or forego certain treatments. At the same time, estimating the prognosis appears as one of the most difficult tasks to perform. The prediction of the patients' condition and the evaluation of his or her suspected preferences concerning possible outcomes tends to result in communicative challenges and conflicts between different professions as well as between professionals and relatives. Furthermore, it emerges that the passage of time has a fundamental influence on making a reliable forecast. This leads to an adjustment of prognosis during the patient's stay on the ward. Here, the ambivalence of the prognosis as a norm for decision-making in intensive care becomes apparent as decisions have to be made at a specific moment in time.
CONCLUSIONS. Estimating a patient's prognosis remains a difficult task which can lead to ethical uncertainties and conflicts. Explicitly considering the passage of time and the temporal dynamics of prognoses can help to avoid interprofessional tensions as well as conflicts with the patient's relatives.

Death verification - after 5 years, we still can't diagnose death

K. Archer[1], C. Groves[2], H. Mann[1], N. Arora[1]
[1]Birmingham Heartlands Hospital, Bordesley Green East, Birmingham, United Kingdom; [2]Good Hope Hospital, Rectory Road, Sutton Coldfield, United Kingdom

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1040

INTRODUCTION. Five years ago, we performed an audit looking at the process of death verification in comparison to the guidance published by the Academy of Medical Royal Colleges[1]. Our results

highlighted varied and sometimes inadequate practice amongst healthcare professionals. This lead to the introduction of a proforma for the verification of death in the intensive care units in our hospitals.

OBJECTIVES. Our objectives were to

i) see if practice has changed with regards to death verification,

ii) to see how many deaths were being verified using the proforma, and

iii) to see if the proforma made a difference to the quality of documentation.

METHODS. Using the same method of data collection as our previous audit, two investigators reviewed the death verification notes of patients who died between December 2017 - January 2018 across two hospitals within our NHS Trust.

RESULTS. The results of 100 patients were included in our audit. Whether the death verification had been performed using our proforma, as well as 28 other parameters, were recorded. Our results regarding the process of death verification without using our proforma were comparable to previous. There had been minor improvements with 83% of notes having the appropriate number of patient identifiers. There were 3 patients that did not have pulses palpated. 11 patients did not have heart sounds auscultated and in 8% there was no documentation of listening for breath sounds. 98% of patients had their pupils checked. Only 28% were tested for pain stimulus using supraorbital pressure, as per guidance. 7 entries did not have a printed name and 3 were illegible. 45% did not have a professional registration number documented.

18 of the 100 patients were verified using our proforma. Of these, 1 patient did not have the required patient identifiers on the document. 100% of patients had their pulses checked. Only 94% had their heart and breath sounds auscultated. All 18 of patients had their pupils checked. Only 89% were tested for painful stimuli using supra-orbital pressure. 100% were signed, dated and timed but 1 patient (6%) did not have the verifying professional's printed name or registration number stated.

CONCLUSIONS. The process of death verification remains varied and sometimes inadequate. Practice has not changed significantly from our audit 5 years ago. However, the proforma we created has helped healthcare professionals to carry out death verification in a more efficient and standardised way.

We are moving forward to take our proforma and make it a Trust-wide necessity for death verification.

Terminal extubation in critically ill patients

A. Estella, M. Recuerda, M. Gracia Romero, V. Perez Madueño, L. Perez Bello Fontaiña

Hospital SAS de Jerez, Intensive Care Unit, Jerez de la Frontera, Spain

Correspondence: A. Estella

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1041

INTRODUCTION. Limitation of Life support treatments (LLST) is part of end of life care. Terminal extubation is an unusual modality of LLST and it is scarcely documented in the literature.

OBJECTIVES. The aim of the study is to analyse the LLST practices of terminal extubations and to describe the clinical profile of this group of patients.

METHODS. Prospective observational study carried out in a medical-surgical ICU of 17 beds of a community hospital. Time of study was 12 months. We included intubated patients in whom terminal extubations were decided. The variables analyzed were: age, gender, diagnosis and conditions in which the LLST was decided. Statistical analysis was performed with SPSS v24 program. Quantitative variables are expressed in mean ± standard deviation and qualitative variables in percentage.

RESULTS. 1245 patients were admitted in ICU during the time of study, 142 patients died. Terminal extubations were performed in 12 patients, 7 women and 5 men. Mean age was 74 ± 5.1 years. Two-thirds were admitted from the Emergency Department. Charlson index resulted between 3 and 5 in 33.3% and was greater than 5 in 66.7%. 58.3% had a modified Rankin scale rating greater than 3. APACHE II score at admission was 19.6 ± 7.3. 75% needed vasoactive drugs and 25% renal replacement therapy. Diagnosis at admission was cardiac arrest in 33.3%, postoperative abdominal surgery 25%, head injury 16.7%, acute lung edema 16.7% and cerebrovascular disease 8.3%. 16.7% were organ donors. In all patients extubation was decided in the first week of ICU admission and mean time elapsed between extubation and dead was 15 ± 22 hours with a range [0-74]. 91.6% of the extubations were decided by a medical staff.

CONCLUSIONS. Decisions of terminal extubation are rare, are decided in the first days of admission and by the disciplinary team. Clinical profile was elderly patients with comorbidity, poor quality of life and high severity score at admission.

Life support limitation practices in an intensive care unit

L. Alegria, M. Vera, M. Amthauer, R. Castro

Pontificia Universidad Catolica de Chile, Intensive Medicine, Santiago, Chile

Correspondence: L. Alegria

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1042

INTRODUCTION. The life support treatment limitation is a meditative and consensual decision about withdrawing or withholding therapeutic measures when the course of the disease is irreversible or the treatment futile. In the intensive care setting, it is a common practice not executed without conflicts, often related to cultural, religious or social factors, including also some characteristics of the healthcare team (1)(2). This leads to a wide variability in the decision-making process and in the end of life care provided to patients, making it necessary to establish standards of care and to understand what the usual practice patterns are.

OBJECTIVES. The main purpose of this study is to observe and describe the life support treatment limitation practices and their general incidence in the Intensive Care Unit (ICU) of a teaching hospital.

METHODS. A prospective, observational study, carried out in the Intensive Care Unit at Hospital Clínico UC-CHRISTUS, between December 2016 and April 2018. Every deceased patient and every patient under any life support limitation measure was included.

RESULTS. A total of 104 patients were included, with a mean age of 65.5 years. The main reason for admission was a neurological cause (25%), followed by sepsis (24%). Of all patients included, 23% died without mediation of any life support treatment measure. In those patients in which any practice of life support treatment limitation was performed, 72.5% died in the ICU and 18.7% died after being transferred to another unit. The DNR order was the most frequent among life support limitation indications (58%), followed by the withdrawal of life supporting measures (51%).

CONCLUSIONS. In our ICU, most of the patients died after a decision of life support treatment limitation, existing a wide variability between those measures, which opens the discussion about the need of practices centered in the patient and the family during the end of life process.

Understanding & acceptance of the brain death concept among Cairo University Intensivists & Emergency Doctors. A survey study

M. El-Sayed[1], M. Nagy Mohamed[2], M. Mohamed Elgohary[2], M. Mahmoud Elkholy[2]
[1]Cairo University Hospitals, Cairo, Egypt; [2]Cairo University Hospitals, Anesthesia, Cairo, Egypt
Correspondence: M. El-Sayed
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1043

INTRODUCTION. Brain death (BD) is the cessation & irreversibility of all brain functions, including the brain stem.[1] Studies have shown substantial confusion &lack of understanding about BD among health professionals, even among those who accept BD as being legally dead.[2] Kasr Alainy, Cairo University hospital, a major tertiary care medical center in Egypt & the whole Middle East; has no clear guidelines for the actual diagnosis or acknowledgement of BD.To our best knowledge, there were no published formal surveys or questionnaires regarding this issue among medical personnel in Egypt. Available literature are rather narrative reviews or debates. [3,4]

OBJECTIVES. To assess understanding & acceptance of the conceptual basis of BD among intensivists & emergency doctors at Kasralainy, Cairo University hospital.

METHODS. A quantitative cross-sectional survey study in which a validated questionnaire was handed to I60 Physicians working in adult surgical, postoperative, neurosurgical & medical ICU´s as well as Emergency department of Cairo University hospital, with at least 1 year of experience in ICU. Questionnaire tool was partially based on a similar earlier study.[1] Other questions were approved by PTPODaT (Professional Training Program on Organ Donation & Transplantation) faculty. Information about specialty, academic degree, years since graduation, & years of expertise in ICU were collected. Questionnaire was designed to evaluate understanding & acceptance of the conceptual basis for BD rather than implementation of a diagnostic protocol.Questions were sequenced so that doctors initially define brain death, then interpret two clinical case scenarios, indicate their awareness of existing Egyptian laws& religious authorities´ statement & finally acceptance of BD concept & its future implementation as a diagnostic protocol.

RESULTS. 56 % (n=89) correctly defined BD, 11.25% (n=18) successfully interpreted the following 2 case scenarios & 8.75% (n =14) correctly defined BD & interpreted the following scenarios. There were no statistically significant difference between different specialties or academic degrees. 6% (n=9) were aware of the 2008 Egyptian consensus for BD diagnosis & 9.4% (n=15) knew that Egyptian religious authorities acknowledged BD as a medical decision. only 3.8% (n=6) received previous training about BD diagnosis.

CONCLUSIONS. Cairo University Hospital intensivists lack consistent knowledge & understanding of BD concept, they have concerns regarding the application of BD diagnosis protocol.

Table 2 (abstract 1043). Responses to the 1st three questions about BD definition & the 2 case scenarios among different academic degrees

	Residents	Assistant Lecturers	Lecturers	P Value
Define brain death [number(%within degree)]	31 (51%)	31 (53%)	27 (68%)	0.21
1st scenario Interpretation [number(%within degree)]	8 (13%)	11 (19%)	8 (20%)	0.59
2nd Scenario Interpretation [number(%within degree)]	41 (67%)	37 (62%)	32 (80%)	0.18
3 correct answers [number(%within degree)]	2 (3.3%)	5 (8.5%)	6 (15%)	0.12

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1044

INTRODUCTION. Brain death consists in an irreversible clinical condition with complete loss of brain stem and cerebral functions. Still is a complex term in ICU practitioners' routine.
Besides being short known to the overall population and medical students, it's been misunderstood quite often.
OBJECTIVES. This study's objective is to evaluate medical students, on 5th and 6th year of graduation, knowledge about brain death and organ donation.
METHODS. The study consists in the application of a multiple-choice test, containing 10 questions. Students were invited to participate. The test has been applied to medical students who were on 5th and 6th year of medical graduation.
RESULTS. One hundred and eight participants answered the test. Correct answers percentages for brain death were 30.55% on brain death definition, 76.85% on necessary neurological tests to diagnose brain death, 59.25% on time interval between exams, 73.14% on process of information to the family, 60.18% on complementary exams, 23.14% on legislation related question, 39.80% on physiology of brain death, 40.74% on clinical findings, 73.14 on medications that should be excluded during tests and exams. Correct answers for potential donors related questions were 87% on decision's responsibility, 78.70% on who can be the potential donor, 39.80% on potential donor maintenance.
CONCLUSIONS. In the study we observed important knowledge deficit among medical students over essential concepts for diagnosing and assessing brain death protocols, a very important theme on intensive care routine.

Improving patient care

1045

Reducing administrative burden: a core set of quality indicators for effective quality improvement and efficient accountability

M. Zegers, R.J. Verhage, J.G. Hoeven van der
Radboudumc, Intensive Care, Nijmegen, Netherlands
Correspondence: M. Zegers
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1045

INTRODUCTION. Healthcare professionals suffer from the amount of quality indicators they register. Their large number limits the time for implementing quality improvements. Moreover, healthcare professionals do not perceive all quality indicators as meaningful and useful for quality improvement.
OBJECTIVES. To select a core set of indicators for effective quality improvement and efficient accountability in the Intensive Care Unit (ICU).
METHODS. In 2017, we conducted a two-phase adapted Delphi study in four Dutch hospitals with 34 experts: 13 ICU physicians, 11 ICU nurses and 10 ICU survivors and relatives from the FCIC (Family and Patient Centered Intensive Care), the Dutch foundation for ICU survivors and relatives. We identified all quality parameters regarding the ICU (n=122). We asked participants to indicate the relevance of each quality parameter for quality improvement (round 1). Subsequently, the participants discussed the results of round 1 and determined the final core set of quality parameters in three focus group interviews (round 2).
RESULTS. The participants selected a core set of 16 parameters (see table 1). Four parameters were related to the organization of intensive care: safety culture, team climate (the ability of a team to

learn and improve), adherence to Crew Resource Management (principles related to teamwork and communication on the ICU) and results of the quality visitation of the professional organization of Dutch intensivists.
Four healthcare provider reported outcomes were selected: Standardized Mortality Ratio (SMR), ICU readmissions within 48 hours, incidence of decubitus and delirium, and parameter 'learning and improvement after serious incidents'.
Prominent aspects of the core set were experiences and short and long term outcomes reported by ICU survivors. Interestingly, also experiences and mental problems reported by relatives were part of the core set.
CONCLUSIONS. In conclusion, healthcare providers, ICU survivors and relatives selected a core set of 16 parameters for effective quality improvement and efficient accountability in the ICU. In 2018 and 2019, the effect of using only a core set of parameters on patient outcomes will be evaluated. Our hypothesis is that registering less quality indicators will leave more time for quality improvement and ultimately to better outcomes and experiences for patients and relatives. At the congress, we will show the first results of how we implemented the core set and de-implemented registrations in the clinical process.

Table 1 (abstract 1045). Core set of quality indicators for the ICU

	Organisation (structure and process)	Outcomes
Reported by Health care professional	Team climate Safety culture CRM-compliance Quality visitation	SMR/ ICU-mortality ICU-readmissions within 48 hours Incidence delirium and decubitus Learning and improvement after serious incidents
Reported by Patient and Relative	Experiences of ICU survivors and relative (interviews) Experiences relatives (questionnaire) Complaints	Quality of life of ICU survivors Quality of life of relatives Physical, mental and cognitive problems of ICU survivors Socio-economic impact Cost-effectiveness of ICU care

Association between burnout syndrome, emotional stress, suicidal thought and substance abuse in critical care professionals

A.Y. Rodríguez Santos[1,2], J. Franco Granillo[1], S.J. Aguirre Sánchez[1], G. Camarena Alejo[1], S. de la Cruz Balboa[3]
[1]American British Cowdray Medical Center I.A.P., Critical Care, Mexico, Mexico; [2]Universidad Nacional Autonoma de México, Critical Care, Mexico, Mexico; [3]American British Cowdray Medical Center I.A.P., Internship in critical care medicine, Mexico, Mexico
Correspondence: A.Y. Rodríguez Santos
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1046

INTRODUCTION. Burnout syndrome(BS) is a social disorder composed of exhaustion, depersonalization and low personal fulfillment, frequent in critical care staff. BS, depression and substance abuse has not been studied in mexican health workers.
OBJECTIVE. To characterize severe burnout syndrome scores(SBS), emotional stress(ES) and depression in Mexican health care workers and their association with demographic variables, working conditions and substance abuse.
**METHODS.** Multicentric cross-sectional study from Mexico conducted in health workers using the following validated questionnaires:

Maslach Burnout Inventory(MBI), perceived stress scale(PSS) and patient care questionnaire(PHQ-9) for depression. Substance abuse was defined as: AUDIT-c questionnaire≥8 points or self-reported marihuana or amphetamine abuse. We classified severe burnout(SBS) with two of the following: high emotional fatigue(EF), high depersonalization(DP) and low personal realization(PR); high stress: PSS≥27 points; major depression: PHQ-9≥10 points. Demographic variables were collected for all patients. We performed logistic regression analysis to calculate Odds Ratios(OR) using SSB as dependent variable and Pearson's r to establish correlations between MBI items and PSS.

RESULTS. We included 154 subjects, 50 residents from different areas(32.5%), 16 interns(10.4%), 53 nurses(34.4%), 20 medical doctors(13%), respiratory therapist 6(3.9%), physical therapy 9(5.8%). Severe burnout was present in 65 patients(42.2%). Patients with SSB vs lower scores were predominantly residents[(43.1 vs. 24.7%),0.016] had a higher proportion of substance abuse[(27.7 vs 10.1%),$p<0.005$], a higher proportion of chronic disease[(18.5 vs. 6.7%),p=0.025], worked the night shift or for over 24-hour period more often[(73.8 vs. 56.2%),p=0.003 and (60 vs. 36%),p=0.003, respectively] had a higher median number of assigned patients[(10 IQR: 4-15) vs. (6, IQR: 3-10),p=0.044] and higher mean weekly work hours[(82±34) vs. (69±31), p=0.014]. Mean PSS and PHQ-9 were higher in the SSB group[(29±7.1, vs. 20.8±7.8),$p<0.001$] and [(11.7±5) vs (5.9±5.1),$p<0.001$], respectively. Age, sex, body mass index and familiar status were similar between groups. Substance abuse and suicidal thoughts were strongly associated with SSB independently of age and sex[(OR=3.4, CI 95 % 1.3-8.4,p=0.008), (OR=4.1, CI 95% 1.6-10.5,p=0.002),respectively]. All items from the MBI correlated with the PSS (DP:r=0.542 $p<0.001$; EF:r=0.601, $p<0.001$;PR: r=-0.383,$p<0.001$).

CONCLUSIONS. SSB is associated with substance abuse and suicidal thoughts in Mexican health-staff independently of age and gender. The individual items of the MBI scale show correlation with PSS. MBI questionnaires could be a useful tool for the timely detection of high-risk behavior in health workers.

Using patient and staff experience to maximise empathy in acute care: the Patient Experience And Reflective Learning (PEARL) project

O. Brookes[1], C. Tarrant[2], C. Taylor[3], G. Packer[4], J. Bion[5], PEARL Collaboration
[1]University Hospitals Birmingham NHS Foundation Trust, Research & Development, Birmingham, United Kingdom; [2]University of Leicester, Social Science Applied to Healthcare Improvement Research (SAPPHIRE) Group, Leicester, United Kingdom; [3]University of Warwick, WMS - Population Evidence and Technologies, Coventry, United Kingdom; [4]University Hospitals Birmingham NHS Foundation Trust, Anaesthesia & Critical Care, Birmingham, United Kingdom; [5]University of Birmingham, University Department of Anaesthesia & Critical Care, Birmingham, United Kingdom
Correspondence: O. Brookes

INTRODUCTION. Empathic behaviours in healthcare transform patient experience, and staff who feel supported and valued provide better care. In critical illness patients and relatives are sensitised to staff behaviours, and a thoughtless word or gesture can transform grief into grievance. PEARL uses patient, relative and staff experiences to enhance the capacity of health care staff for self-awareness and empathy through reflective learning - personal insight development.

OBJECTIVES. To develop a reflective learning framework (RLF) for staff in acute medicine and critical care to improve patient, family and staff experience.

METHODS. Intensive Care Units (ICUs) and Acute Medical Units (AMUs) of three NHS Trusts have implemented two experience surveys: a continuous patient and relative survey; and an annual survey for staff. Survey data are supplemented by ethnographic interviews and observations in the workplace to evaluate barriers to and facilitators of reflective learning.

These data are presented to each Trust for discussion by facilitated local co-design groups representing patients, relatives, and multidisciplinary clinical and managerial staff from each AMU and ICU. The co-design groups will meet three times over six months to develop behavioural specifications for activities/interventions designed to maximise opportunities for reflection. Outputs will be collated and developed using expertise within the central project team. The conceptual theory and the design process utilise the COM-B framework (Capability, Opportunity, Motivation influencing Behaviour)[Michie 2011].

PRELIMINARY RESULTS. Performance-importance plots (fig 1) of patient and relative survey data show that communication strongly influences perceptions of quality in AMUs and ICUs, and these behaviours offer the greatest opportunity for improvement. Clinical care domain questions achieved higher 'best' ratings but had less influence on overall satisfaction. Median 'best' response rates were higher for ICUs (56%) than AMUs (31%), likely influenced by higher ICU staffing ratios, and possible 'contamination' of AMU data by inadvertent collation of emergency department, AMU and general medical ward experiences.

Ethnographic observations and staff survey identified multiple opportunities for learning from constructive as well as dysfunctional behaviours. Staff reported using informal approaches to reflection on their individual practice, but had few opportunities for reflection in-action or group reflection.

CONCLUSIONS. Non-technical skills, in particular communication, impact greatly on patient, relative and staff experience. The RLF must therefore include techniques which foster genuine emotional engagement from staff, group learning from best practice, resilience in coping with negative feedback, and the capacity to enact change.

Gaps between the expectations and perceptions of the patients and their families about the quality of healthcare service of a dedicated weaning unit for patients with prolonged mechanical ventilation: a study to investigate the needs and experience of the patients and their families

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1048

INTRODUCTION. Experience and satisfaction of the patients and their families might provide valuable insight for improving the quality of care of patients under mechanical ventilation (MV). However, less was known about the gaps between their experience and needs regarding the quality of healthcare service in the setting of prolonged MV.

OBJECTIVES. To investigate the gaps between the expectations and perceptions of the quality of healthcare service in the setting of prolonged MV.

METHODS. We conducted this prospective analysis in the Respiratory Care Center (RCC), a dedicated weaning unit for patients receiving prolonged MV, in a university-affiliated medical center from January to December 2017. Patients treated at the RCC and their visiting family members were provided with the information about this survey questionnaires before the patient left the RCC. The questionnaire was designed based on the SERVQUAL instrument by Parasuraman A et al. (See reference), which consisted of 22 questions in five dimensions, including Tangibles, Reliability, Responsiveness, Assurance, and Empathy. Two sections of the survey were included: expectation and perception, each containing 22 questions. We also collected background and care-related data of the patients, as well as background data of the respondents of the survey. We applied Important Performance Analysis (IPA) to identify priority items for improvement, and then analyzed the data and performed multivariate logistic regression analyses to understand the factors associated with the gaps between expectations and perceptions by the respondents.

RESULTS. During the 12-months study period, a total of 167 respondents consented to participate in the survey. Of the patients the respondents represented, 60.5% were male, with age averaged 71.5 years, 21.6% malignancy, 50.9% from medical intensive care units, and 68.3% already having tracheostomy upon admission to the RCC. Of the patients, the length of stay at the RCC averaged 19.4±10.8 days, and 70.7% were successfully liberated from MV upon discharge from RCC. IPA identified 4 question items of improvement priority. Multivariate logistic regression analyses showed that the male respondent, patient older than 75 years, tracheostomy, and needs for physical training or dialysis, were associated with an increased gap between perception and expectation for the priority items, especially for the question "employees of the RCC understand your specific needs."

CONCLUSIONS. Gaps exist between the perception and expectation in the quality of healthcare service in the setting of prolonged mechanical ventilation. We recommend that the healthcare systems apply similar approaches to understand the needs and their experiences to generate the improvement priorities for healthcare service quality.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1049

INTRODUCTION. Admission to an intensive care unit (ICU) is a stressful event for both the patients and their relatives. Some studies suggest that extending the time allowed to the families to visit their relatives admitted at the ICU is related to a reduction of patient´s anxiety and depressive symptoms and with an improvement in family satisfaction.

OBJECTIVES. To explore the degree of satisfaction of patients' relatives at ICU discharge as well as of the ICU workers, after the implementation of an extended-time ICU visit policy (from 11:30 to 20:30).

MATERIAL AND METHODS. Transversal, observational, prospective study in an ICU of a second level hospital. ICU patient´s relatives and ICU workers were surveyed using the instrument FS-ICU 34 to assess family satisfaction, as well as a specific satisfaction survey for ICU workers.

RESULTS. A total of 78 surveys were obtained, 40 from ICU patient's relatives and 38 ICU workers (7 Physicians, 22 Nurses and 9 nurse assistants). Most of the relatives surveyed were very satisfied with the extended-time visit schedule and with the care received and their participation in the decision-making process. The major concerns of the family members was focused on the process of transmitting information (coherence in the prognosis and hope provided on the recovery of their family), the environment of the ICU (excessive night lighting, scarcity of audio-visual resources to keep the patient stimulated) and environment of the ICU´s waiting room (location, absence of information point to relatives and notice of entry to the family visit). With regards to ICU workers, only 21.1% of the participants thought that the extended-time visit policy could result in patient´s instability whilst the 60.5% thought that it improves the mood

of the patient. The 57.8% thought it increases the physical and psychological burden of nursing but up to 60.6% considered that it does not interfere with the usual care of the critical patient. Virtually all responders agreed to increase the number of visits in end-of-life situations (95.7%) and up to 59.5% would be willing to maintain this policy of extended-time visits. Up to 92.5% of ICU workers agreed the need of a specific training to improve their communication skills with the patients' relatives.

CONCLUSIONS. After the introduction of extended-time ICU visit policy, the degree of satisfaction of the patients' relatives is elevated. However, several issues should be improved, such as the process of transmitting information as well as the environment of the ICU and waiting room. With regards to ICU professionals they think that the greatest impact of extended-time visits is the benefit to the patients rather than to the family or staff. In addition, they feel they need more training to improve the interaction with the patient´s relatives who stay in the ICU more than 8 hours a day. More than half of the professionals are in favour of maintaining the extended-time ICU visit policy.

1050

What information do ICU relatives want in the waiting room?

D. Zeinali, L. Hunter, K. McQueen, S. Singh, N. Robin
Countess of Chester Hospital, Anaesthesia & Critical Care, Chester, United Kingdom
Correspondence: D. Zeinali
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1050

INTRODUCTION. The relatives of ICU patients require adequate, accurate and timely information. Poor information causes stress and may lead to complaints and even litigation. An information package that can be viewed on screen in the ICU waiting room may be a practical solution to the delivery of generic information.
This would serve to compliment one to one doctor-family communication.
OBJECTIVES. To identify what information is considered important by relatives and ICU staff, in order to create a useful information programme to be displayed on a screen in the waiting area.
METHODS.
Phase 1: A working group was set up consisting of ICU doctors, nurses and hospital communications team to explore various ideas.
Phase 2: A qualitative unstructured interview with ICU relatives and with a variety of members of ICU staff was undertaken by a member of the working group (DZ).
Phase 3: The working group reviewed the results of the qualitative interviews and produced a questionnaire.
Phase 4: The structured questionnaires were circulated to ICU relatives and ICU staff both medical and nursing, in which respondents were asked to rate the importance of proposed information to be displayed using a scale of 1-5 with 1 being least important and 5 being most important.
They were also asked how best the information could be displayed (text, diagrams, videos etc) There was also a free text box.
RESULTS. Recurring themes from relatives included: fear experienced when seeing machines, equipment and monitors. Not understanding their function or significance. Wanting clarity about the relative seniority of doctors, nurses and other health care professionals. Frustration at having to wait without being given information and to see the patient.
Staff felt that information about the standard ICU day, procedures and interventions and information to help relatives understand why they may need to wait would be useful. In addition, information about research projects and common conditions such as delirium/confusion would be valuable.
Full questionnaires and results available on request from the first author.
70% favoured photos with labels, 50% text, 40% diagrams with labels and 30% videos with or without sound, as the mode of presenting information (more than one option was permitted).
CONCLUSIONS. Using a systematic 4 phase approach to determine the information required by ICU relatives in the waiting room, has

enabled us to embark upon the implementation phase (phase 5) confident that we will be producing an information screen which is fit for purpose. This will support relatives by providing appropriate and useful information as well as reducing stress, complaints and litigation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1051

INTRODUCTION. The admission of a family member to an intensive care unit (ICU) is an extraordinarily stressful experience for their relatives. Critical illness paired with an entirely new environment triggers significant stress, insomnia and anxiety.
OBJECTIVES. This study is the Run-in Phase of the ICU-Families project (ClinicalTrials.gov Identifier: NCT02931851) and examines the degree to which relatives of ICU-patients are affected by psychological symptoms over a 30-day period.
METHODS. This multi-centre study was performed in Austria and Switzerland. The Impact of Event questionnaire (IES) developed by Horowitz et al. was delivered to relatives upon admission of the patient to the ICU (0-2 days after admission, T0) and thirty days later (T30), using face-to-face and telephone interviews. Clinically relevant values on the IES score are >27 points, while values >35 can support a diagnosis of PTSD in the right context. Data collection took place between 2016 and 2017.
RESULTS. 42 relatives (12 male, 30 female) were included in the study, with an average age of 53 ± 15 years. Relatives were included in Graz (n=23), Vienna (n=10) and Bern (n=9).
At T0, a mean IES score of 31.4 ± 13.7 points was observed and at T30 the score decreased to 24.7 ± 10.6 points (p< 0.001, paired t-

test). IES-scores >27 were observed for 24 (57%) at T0 and for 15 (36%) at T30. IES-scores >35 were observed for 19 (45%) and 7 (17%) at T0 and T30, respectively.

On average, women scored higher than men at T0 (33.6 ± 14.4 vs 25.8 ± 10.2) and at T30 (25.0 ± 10.3 in women and 24.0 ± 11.6 in men). Those present at the event leading to ICU submission had significantly higher IES scores (T0 35.1 ± 9.2 vs 26.1 ± 15.6, p< 0.037, T30 28.6 ± 9.8 vs 20.6 ± 10.6, p< 0.017).

CONCLUSIONS. More than half of the relatives reported clinically relevant symptoms at T0 and T30. Women and those present at the event leading to ICU admission appear to at higher risk. The feasibility of effective support services in daily routine should be tested.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1052

INTRODUCTION. Many intensive care unit (ICU) survivors experience long-term physical, cognitive and mental problems, which are affected by patients' status before ICU admission. However, most long-term outcome studies do not take the pre-ICU status into account.
OBJECTIVE. To assess ICU patients' pre-ICU physical, cognitive and mental status.
METHODS. The prospective MONITOR-IC cohort study in 4 Dutch hospitals, started in July 2016. Patients aged ≥16 with ICU admission ≥12 hours are included and followed for 5 years. Patients with a life expectancy of < 48 hours or receiving palliative care are excluded. At ICU admission, patients (or their relatives), are asked to rate their pre-ICU status by filling in several questionnaires: Clinical Frailty Scale (CFS), Checklist Individual Strength (CIS-8), Cognitive Failure Questionnaire (CFQ-14), Hospital Anxiety and Depression Scale (HADS), and Short Form (SF-36). Clinical data are extracted from the electronic patient record.
RESULTS. We included 1,537 patients (69.4% inclusion rate) in 1.5 year. Common reasons for exclusion were refusal to participate (40%) and death before informed consent (17%). Median ICU stay was one day, with mainly elective surgery admissions (65%). Pre-ICU admission, 13% of the patients was frail, and almost 60% was tired (table 1). Low CFQ scores (20.2) indicate low levels of cognitive failure. A quarter of the patients reported depression and anxiety symptoms. The SF-36 physical and mental health component scores were lower compared to the age-matched Dutch population.
CONCLUSIONS. Pre-ICU admission, patients suffered from fatigue, depression and anxiety symptoms and had a lower physical and mental state than the normal population. These insights need to be taken

into account when assessing patients' long- term outcomes, and to identify adequate targets to prevent or mitigate long-term problems of critical illness.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1053

INTRODUCTION. Intensive care unit-acquired weakness (ICU-AW) is associated with weaning failure and unfavorable outcome in critically ill patients. Muscular ultrasound (MUS) is a non-invasive diagnostic tool that is able to display increased muscle echogenicity, which was linked to neuromuscular dysfunction.

OBJECTIVES. To evaluate the prognostic value of increased echogenicity detected by MUS to predict ICU-AW, weaning failure and long-term outcome in critically ill patients.

METHODS. Critically ill patients (SOFA-score ≥8 on three consecutive days after ICU admission) without preexisting neuromuscular diseases and age-matched healthy controls were included (ClinicalTrials.gov: NCT02706314). Longitudinal multimodal diagnostics at study days 3 and 10 including muscular research council-sum score (MRC-SS), electrophysiology, muscular ultrasound and serum analyte measurements were performed. ICU-AW was regarded as being present at an MRC-SS of < 48. Weaning failure was defined as a failed spontaneous breathing trial or the need for reintubation/tracheotomy. Ultrasound echogenicity of eight extremity muscles was assessed on the global muscle echogenicity score (GME) (1). The 3-months outcome was assessed on the modified Rankin scale (mRS) and the Barthel index (BI).

RESULTS. Thirty five critically ill patients (mean age 65.5±14.4 years) and five healthy controls (mean age 49.8±10.3 years) were analyzed. Patients' mean GME was significantly higher at both study days (day 3 GME 2.33±0.4; day 10 GME 2.29±0.4 vs. controls GME 1.07±0.1; each p< 0.001). ICU-AW was present in 17/32 patients. Three patients died before a diagnoses could be obtained. Patients with ICU-AW had higher mean GME values at day 10 (2.4±0.4) in comparison to patients without ICU-AW (mean GME 2.16±0.5). Muscular echogenicity decreased in patients without ICU-AW between day 3 (mean GME 2.35±0.5) and day 10 (mean GME 2.16±0.5), which was not observed in patients with ICU-AW (day 3 mean GME 2.36±0.3; day 10 mean GME 2.4±0.4). GME at day 10 correlated with the MRC-SS values (r=-0.433; p=0.024). Higher GME at day 10 was observed in patients with weaning failure (n=19; mean GME 2.39±0.4) compared to patients with successful weaning (n=15; mean GME 2.14±0.5; p=0.09). One patient died before weaning procedure. Mean GME at day 10 correlated with the 3-months outcome assessed on the mRs (r=0.490; p=0.028) and BI (r=-0.621; p=0.008).

CONCLUSIONS. Increased echogenicity detected by MUS is associated with critical illness and unfavorable 3-months outcome in critically ill patients. During the early phase of critical illness MUS might be helpful to predict ICU-AW and weaning failure.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1054

INTRODUCTION. For enteral nutrition (EN), ideally the nasoenteral tube (NET) should be placed to post-piloric area (PPA) for the patients especially who have risk of aspiration (1). The most common method of determining NET position is abdominal X-ray graphy (DXG). Due to delays in DXG imaging, imaging errors and situtation of NET not in PPA, EN is delayed for many hours and patients may be expose to more X-rays with repetitive shots. However, today we can determine passing NET to the PPA with ultrasonography (USG)(2).

OBJECTIVES. Our goal is to determine the success of the NET placement to PPA with USG and how much time is spent for placement.

METHODS. All patients who were older than 18 years age and needed to NET placement and admitted to Gazi University Hospital Medical ICU (MICU) between 01 October - 01 December 2017 were included in the study. With USG device (GE, S7 model), we visualized the NET at the proximal esophagus (11 MHz linear probe), in the esophagogastric junction and PPA(5 MHz convex probe). When NET was found in the stomach but not in the PPA, NET was moved back and forward or patient was taken to diffirent position or prokinetic agent was used for provide to pass NET to PPA. When the NET was placed in the PPA, we gave the 25 ml saline in through the feeding tube. We observed the echogenicity changes in PPA by using USG. After then we confirmed the NET position with DXG.

RESULTS. 21 patients were included in the study. The median age was 71 (54.5-79) years, 10 (47.6%) patients were male, and 13 (61.9%) patients were intubated. In 19 (90.5%) patients, USG guided NET insertion was successful and it was shown to pass into the PPA. Echogenicity changes in PPA following saline injection into the NET were detected in 17 patients by using USG. The NET position was confirmed with DXG. Complication was not observed during the study. The median time of NET insertion was 14 (9-22.5) minutes and median NET level was 74 (68-78) cm when placed to PPA. Placement time and NET level did not change with gender (p=0.314, p=0.468 for male and female patients) and intubation state (p=0.595, p=0.268 for intubated and not intubated patients).

CONCLUSIONS. USG guided NET placement can be safe in MICU patients. This method should be preferred because of the less radiation exposure and less time consumption.

INTRODUCTION. Extracorporeal membrane oxygenation (ECMO) is a therapeutic option in severe acute respiratory distress syndrome (ARDS). Despite its use for more than four decades, so far only one RCT suggests a reduction of mortality by ECMO. Strategies to improve the effectiveness of ECMO include optimized patient selection, less invasive techniques and combination of ECMO with ultra-protective ventilation. Pre-ECMO haemodynamics might help to better allocate patients to ECMO and to optimize the ECMO-set-up. Extracorporeal blood flow adjusted to the patients´ cardiac output (CO) is of high importance for effective extracorporeal oxygenation. This requires accurate measurement of CO before and during ECMO. However, there are concerns that pulmonary arterial and transpulmonary thermodilution (TPTD) might be confounded due to a

potential loss of indicator into the extracorporeal circuit, resulting in an overestimation of volumetric parameters. However, there is a lack of data on indicator dilution techniques during ECMO.

OBJECTIVES. Therefore, we compared TPTD-measurements before and during ECMO. We hypothesized that indicator injection using a *femoral* central venous catheter (CVC) close to the femoral ECMO drainage cannula might be more prone to indicator loss than using a *jugular* CVC.

METHODS. TPTD-derived parameters before and after initiation of the extracorporeal circuit were compared in a total of 14 ICU-patients with ECMO and TPTD-monitoring (PiCCO). 8 patients were equipped with a jugular, and 6 patients with a femoral CVC.

RESULTS. Cardiac index CI, global end-diastolic volume index (GEDVI) and extravascular lung water index (EVLWI) before ECMO as well as the ECMO flow (3.1 ± 1.3 vs. 3.3 ± 1.5 L/min, p=0.78) were comparable in patients with jugular and femoral CVC. After the onset of ECMO, CI did not increase compared to pre-ECMO values in the totality of patients (4.36 ± 2.12 vs. 4.49 ± 1.71 L/min/m^2; p=0.433).

By contrast, GEDVI (974 ± 384 vs. 791 ± 179 mL/m^2; p=0.041) and EVLWI (27.7 ± 11.1 vs. 21.3 ± 9.1mL/kg; p=0.001) were significantly higher during ECMO compared to before.

These changes in GEDVI (378 ± 247 vs. 36 ± 210; p=0.02) and EVLWI (10.5 ± 8.1 vs. 3.4 ± 2.4; p=0.051) were substantially more pronounced for *femoral* compared to *jugular* indicator injection. In multivariate analysis, for both GEDVI (p=0.004) and EVLWI (p=0.035) *femoral* indicator injection was independently associated with larger increases during ECMO compared to before.

By contrast, haemodynamic parameters not derived from TPTD such as systolic and diastolic arterial pressure, pulse pressure variation, dPmax and cardiac power index were not affected by the start of ECMO.

CONCLUSIONS. Our study demonstrates marked increases in GEDVI and EVLWI after the onset of ECMO which were more pronounced in case of *femoral* compared to *jugular* indicator injection. These findings are in line with the hypothesis of a loss of indicator into the ECMO-circuit.

Epidemiology of myocardial dysfunction in patients with hypoxemic respiratory failure and acute respiratory distress syndrome: an observational cohort study

T. Barnes, D.J. Niven, A. Soo, A. Ferland, P. Boucher, H.T. Stelfox, C.J. Doig, K. Parhar
University of Calgary, Department of Critical Care Medicine, Calgary, Canada
Correspondence: K. Parhar
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1056

INTRODUCTION. Acute respiratory distress syndrome (ARDS) is an inflammatory syndrome of the lungs characterized by hypoxemia, reduced lung compliance, and bilateral lung infiltrates. ARDS is associated with significant morbidity and mortality. Myocardial dysfunction, specifically acute cor pulmonale, has previously been associated with ARDS; however, limited data exists in Berlin definition ARDS patients undergoing lung protective ventilation.

OBJECTIVES.
Define the incidence and type of myocardial dysfunction in patients with hypoxemic respiratory failure and ARDS
Determine patient factors associated with the development of myocardial dysfunction in patients with ARDS
Determine if myocardial dysfunction in ARDS is associated with 28-day and 3-year outcomes

METHODS. A standardized screening program for ARDS, as a quality improvement initiative, was initiated at 4 adult ICUs within Calgary, Alberta, Canada over a 27-month period. All patients ventilated for $\geq$ 24 hours were prospectively and consecutively screened with an arterial blood gas on a standardized FiO_2 of 1.0. Chest X-Ray images were manually reviewed to determine if criteria for ARDS (Berlin definition) were met. Prospectively collected data through an electronic clinical-information system allowed assessment of patient demographics, details of ICU stay, mechanical ventilation practices,

including estimation of mechanical power and its determinants as well as 28-day and 3-year survival. Patients were included in this study if they had a transthoracic or transesophageal echocardiogram during their ICU stay. Patient demographics, details of ICU stay, as well as 28-day and 3-year outcomes were analysed by univariate and multivariable linear regression analysis.

RESULTS. Of 7944 patients, 986 patients (12.4%) had hypoxemic respiratory failure (PF < 300) on screening, and 731 patients (9.2%) met ARDS (Berlin definition) criteria. Of the 986 patients with hypoxemic respiratory failure, 505 had an echocardiogram during their ICU stay. The median age was 61 (IQR 50-71), with 36.3% of patients being female. Moderate or worse left ventricular (LV) systolic dysfunction was present in 103 patients (24%). Moderate or worse right ventricular (RV) systolic dysfunction was present in 129 patients (29.5%) and moderate or worse RV dilatation was present in 66 patients (34.9%). The presence of LV or RV systolic dysfunction did not influence survival. The presence of RV dilatation was associated with reduced hospital and 3-year mortality (p=0.018). Multivariable analysis of factors associated with RV dilatation included high body mass index and APACHE score.

CONCLUSIONS. In patients with ARDS, LV and RV systolic dysfunction as well as RV dilatation, were common in patients. The presence of RV dilatation was associated with reduced 28-day and 3-year mortality.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1057

INTRODUCTION. Lower respiratory tract infections (LRTI) in the intensive care unit (ICU) are mainly diagnosed by cultivation and direct microscopy, a method relatively time consuming, and often with a false negative response. When a LRTI occur neutrophils invade the site of infection resulting in local inflammation and lactate formation. Lactate is found in two stereoisomers: L-lactate and D-lactate. L-lactate is mainly produced by human cells. D-lactate, on the other hand, is usually produced by bacteria.

OBJECTIVE. The aim of this study was to assess neutrophils, L-lactate and D-lactate in sputum from intubated patients hospitalized at the ICU and explore their use as biomarkers for LRTI.

METHODS. Sputa from 43 intubated patients were obtained at time of intubation. Sputum was sent for cultivation, microscopy and PCR to verify eventual LRTI, and analysed for neutrophils, L-lactate and D-lactate. In this study we compared patients with microbiological verified LRTI or clinical/radiological suspicion of LRTI with a control group consisting of intubated patients without LRTI.

RESULTS. We found no difference between sputum neutrophil count from patients with verified LRTI (p = 0.5821) or suspected LRTI (p = 0.8497) relative to the control group, but we found a linear association between sputum neutrophil count and L- lactate (p = 0.0029). The concentration of L-lactate was increased in patients with verified LRTI (p=0.0501) and suspected LRTI (p = 0.0444) relative to the control group. Differentiating between viral LRTI and bacterial LRTI we found significant levels of L-lactate in connection with viral LRTI (p= 0.0062), but not for bacterial LRTI (p = 0.4822). We found no

increase in sputum D-lactate from patients with verified (p=0.3233) or suspected LRTI (p=0.4646) relative to the control group.

CONCLUSION. L-lactate was found to be a good indicator for LRTI at the time of intubation and was increased in patients with viral but not bacterial LRTI. A significant association was found between neutrophil count and L-lactate supporting the theory that neutrophils are the main producer of lactate in sputum. However, we were unable to demonstrate a clear association between neutrophils and LRTI in intubated patients. D-lactate was not a useful indicator for LRTI in intubated patients.

INTRODUCTION. Extracorporeal carbon dioxide removal (ECCO$_2$R) devices have been proposed as an adjunctive therapy in patients with acute exacerbations of chronic obstructive pulmonary disease (AECOPD) to avoid intubation or reduce the length of invasive ventilation. In acute respiratory distress syndrome (ARDS) patients it is used to allow ultra-protective ventilation (1-2).

OBJECTIVES. We investigated the benefits of ECCO$_2$R, complications encountered and mortality.

METHODS. We performed a single-center retrospective observational cohort analysis in a tertiary University Intensive Care Unit (ICU). Over a 34-month period, 59 patients were treated with arterio-venous (AV)-ECCO$_2$R for ARDS or AECOPD. We used a Novalung ® iLA Membrane Ventilator (Xenios, Heilbronn, Germany).

RESULTS. In total, 59 subjects were analyzed. In the ARDS group 35 patients were included, consisting of 16 male and 19 female patients with a mean age of 57 years (54-59) and a mean APACHE score of 25 (23-27). In the AECOPD group 24 patients were included, consisting of 12 male and 12 female patients with a mean age of 64 years (63-65) and a mean APACHE score of 24 (21-27). Mortality for patients treated with AV-ECCO$_2$R for ARDS or AECOPD was respectively 48.6% and 40.9%. In the ARDS group the mean duration of ventilation during ECCO$_2$R was 5.7 days (5.1-6.3), the mean length of ICU and hospital stay was 23.9 days (20.9-26.8) and 44.1 days (37.5-50.9) respectively. Mean arterial blood pH obtained at initiation of ECCO$_2$R treatment was 7.20 mmHg (7.04-7.36) and 7.40 mmHg (7.39-7.42) at termination of ECCO$_2$R therapy. Mean PaCO$_2$ value was 65.8 mmHg (63.3-68.4) at initiation of ECCO$_2$R therapy and 42.8 mmHg (40.9-44.7) at termination of the ECCO$_2$R treatment.

In the AECOPD group the mean duration of ventilation during ECCO$_2$R was 2.4 days (1.8-3.0), the mean length of ICU and hospital stay was 10.8 days (9.2-12.4) and 23.2 days (19.9-26.5) respectively. Mean arterial blood pH obtained at initiation of ECCO$_2$R treatment was 7.24 (7.22-7.26) and 7.42 (7.41-7.43) at termination of ECCO$_2$R

therapy. Mean PaCO$_2$ value was 80.3 mmHg (77.0-83.6) at initiation of ECCO$_2$R therapy and 56 mmHg (53.3-58.7) at termination of the ECCO$_2$R treatment. Complications due to AV-ECCO$_2$R had *no* significant impact on outcome in both groups.

CONCLUSIONS. ECCO$_2$R is a feasible, rapidly evolving technology and is an efficient treatment that allows lung protective ventilation. However, evidence for a mortality benefit with ECCO$_2$R is lacking and complications are frequent. Well-designed adequately powered randomized controlled trials (RCTs) are required to better elucidate risk-benefit balance.

Cardiac index (CI) derived from transpulmonary thermodilution (TPTD) with indicator injection into the pulmonary artery during ECMO: a comparison with indicator injection into the right atrium to derive CI from pulmonary arterial and transpulmonary thermodilution: the HEUREKA-II animal study

W. Huber, M. Konrad, S. Kammerzell, R. Schmid, A. Herner
Klinikum rechts der Isar; Technical University of Munich, Medizinische Klinik und Poliklinik II, Munich, Germany
Correspondence: W. Huber
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1059

INTRODUCTION. Adaption of the extracorporeal blood flow to the patient´s cardiac output improves the effectiveness of extracorporeal membrane oxygenation (ECMO). Pulmonary arterial (CI_PAC) and transpulmonary thermodilution (CI_TPTD) are considered as gold-standards to derive cardiac index (CI). However, there are concerns regarding both methods during ECMO due to a potential loss of indicator into the extracorporeal circuit in case of indicator injection into the right atrium. This might be overcome by injection of the indicator into the pulmonary artery for a modified transpulmonary thermodilution (CI_PATPTD).

OBJECTIVES. To compare bias and percentage error (PE) of CI_PAC_RA and CI_TPTD_RA vs. CI_TPTDPA.

METHODS. 8 pigs (49.4±4.2kg) with PAC, CVC (both via jugular vein) and a femoral arterial PiCCO catheter (Pulsion, Germany). Veno-venous ECMO with CARDIOHELP (Maquet/Getinge; Rastatt, Germany) via a femoral drainage and a jugular return cannula.

CI was measured before and during ECMO with increasing extracorporeal flow (0.5, 1.0, 2.0 and maximum flow of 3.5L/min). Each dataset consisted of three triplicate measurements (subgroup with CI_PAC_RA measurements of the HEUREKA-I study):

Conventional pulmonary arterial CI with indicator injection into the proximal injectate lumen of the PAC (CI_PAC_RA)

CI_PATPTD with indicator injection into the distal lumen of the PAC and detection of the thermodilution curve using TPTD (PiCCO)

TPTD with indicator injection into the RA (CVC) with PiCCO (CI_TPTD_RA).

Due the minimized risk of indicator loss CI_PATPTD was considered gold standard.

SPSS 24.

RESULTS. 34 datasets each including three different triplicate measurements of CI; mean ECMO-flow 1.56±1.15 (0 - 3.5) L/min.

CI_PAC_RA and CI_PATPTD significantly correlated (r=0.646; p< 0.001) and were comparable (2.94±0.56 vs. 3.07±0.67 L/min/m²; p=0.142) with an acceptable bias of 0.13±0.53 L/min/m². The PE was 34.7%. The bias (CI_PAC_RA - CI_PATPTD) significantly increased with

higher ECMO-flow (r=0.640; p< 0.001) and lower CI_PATPTD (r=-0.449; p=0.008). This was confirmed in multivariate analysis (r=0.823) for high ECMO-flow (p< 0.001; T=5.711) and low CI_PATPTD (p< 0.001; T=-5.752).

Bias (0.0023L/min/m^2) and PE (14.0%) regarding CI_PATPTD were lower for CI_TPTD_RA than for CI_PAC_RA.

The amount of deviation from the gold-standard CI_PATPTD was significantly higher for |(CI_PAC_RA - CI_PATPTD)| compared to |(CI_TPTD_RA - CI_PATPTD)|: 0.38±0.39 vs. 0.18±0.13 L/min/m^2; p=0.010. A bias of more than ±0.5L/min/m^2 regarding the gold-standard CI_PATPTD was significantly more frequent for CI_PAC_RA compared to CI_TPTD_RA (9 out of 34 vs. 0 out of 34; p=0.0021; Fisher´s exact test).

CONCLUSIONS.
TPTD to derive CI during ECMO seems to be more accurate and precise than pulmonary arterial thermodilution.
Increases in the bias of CI_PAC_RA with increasing ECMO flow support the hypothesis of an indicator loss.

Oxygen challenge test and prediction of decannulation from veno-venous extracorporeal membrane oxygenation

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1060

INTRODUCTION. Predicting weaning from veno-venous extracorporeal membrane oxygenation (VV ECMO) requires tests to ascertain whether the native lung function has recovered enough to support gas exchange necessary to satisfy metabolic demand. The 'oxygen challenge test' (OCT) consists of increasing the ventilator FiO_2 to 1.0 for 5-15 minutes and measuring the arterial PO_2 (PaO_2) and arterial oxygen saturation (SaO_2). SaO_2 of 100% and PaO_2> 30 kPa (positive OCT) are thresholds used to identify patients able to maintain oxygenation unassisted. There is little data to show if the OCT is a useful guide for weaning and decannulation.
OBJECTIVES. We tested the predictive accuracy of OCT as a diagnostic test in determining weaning and decannulation from VV ECMO.
METHODS. We report an observational cohort study of patients receiving VV-ECMO, from January to December 2016 who had daily OCT review prior to weaning from VV-ECMO. The study had institutional approval; informed consent was waived. Between-group comparisons were carried out with Welch t-test or Mann-Whitney U test, after ascertaining normality of data distribution. Diagnostic test evaluations (Sensitivity, Specificity, AUC and Youden J test) were performed using Receiver Operating Characteristics (ROC) curves. All analyses were performed using R project for Statistical Computing.
RESULTS. Seventy nine patients (40 males) underwent VV ECMO in 2016. Fifteen were excluded as died on ECMO. The median age, (interquartile range, IQR) was 44.5 years (37-51), with BMI 30 (24-33) Kg/m^{2}and median time on ECMO 14 days (5-14). Only 42.2% of patients with positive OCT were decannulated from ECMO < 48 hours following the first positive test. The median (IQR) time from positive OCT to decannulation was 3 days (1-5), range 0 (decannulated the same day as positive OCT) to 25. Although OCT had good prediction of decannulation (AUC 0.77, best cut-off value of 30 kPa), a positive OCT had low prediction of decannulation in the following 48 hours (AUC of ROC 0.62). Interestingly, patients decannulated < 48 hours of the first positive OCT had a lower mean tidal volume (310 vs 391 mL; p< 0.0001; or 4.5 vs 5.7 mL/Kg IBW); lower mean minute ventilation (5.2 vs 6.5 L/min; p=0.003), and higher f/VT

(89.9 vs 71.5 breaths/min/L; p= 0.046), but also a lower corrected minute ventilation (VEc) (6.0 vs 7.3 L/min; p= 0.0074). A lower VEc (a proxy of physiological dead space), may suggest a lower fraction of wasted ventilation, given that the two groups had similar mean ECMO sweep gas flow (4.1 vs 3.6 L/min; p= 0.06) and clinically - but not statistically - similar ECMO blood flow (3.8 vs 3.6 L/min; p= 0.002).
CONCLUSIONS. A positive OCT by itself has low prediction of ECMO decannulation in the next 48 hours. Additional physiological factors including physiological dead space and physician preference may affect the timing of decannulation. The contribution of the ECMO settings on the performance of the test needs further elucidation.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1061

INTRODUCTION. The loss of positive pressure in the airways during T-tube trials during weaning from mechanical ventilation, induces loss of aeration in the dependent regions of the lung. Electrical Impedance Tomography (EIT) has been evaluated to estimate changes in pulmonary air distribution and may be helpful during T-trials for early detection of weaning failure.[1]
OBJECTIVES. To evaluate the usefulness of electrical impedance tomography in predicting changes in lung aeration during a 2-hour T-tube spontaneous breathing trial (SBT) in patients with difficult weaning.
METHODS. Prospective, observational clinical study. Patients with criteria of difficult weaning (mechanical ventilation> 48 hours plus 1 of the following: shock, severe ARDS, heart disease / FC III-IV COPD, or previous failed SBT or extubation) were included. After patient inclusion, an EIT belt was placed around the patient's thorax and ventilation distribution data was measured at baseline (pressure support 5 cmH$_2$O and PEEP 5 cmH$_2$O) and at 30 and 120 min of the T-tube SBT. Clinical decision to extubate or not the patient was at the discretion of the attending physician independent of the data obtained by the test EIT.
RESULTS. Fourteen patients (aged 64±18 y.o) were evaluated. Five patients failed the SBT. When comparing data between baseline and 120 minutes, we observed an increase of the end-expiratory lung impedance in the successful group (470 ± 225 vs 1089 ± 947, P=0,06) while the unsuccessful group showed a decrease (430 ± 123 vs 349 ± 100 P=0.06)(Fig. 1). Regional ventilation delay index assessment showed a significant difference between ventral and dorsal regions (0.51 ± 0.13 vs 0.31 ± 0.13 respectively, P< 0.05) in baseline, condition that was reversed during the SBT (0.46 ± 0.18 ventral and 0.41 ± 0.3 dorsal P=0.7) (Fig. 2).
CONCLUSIONS. Electrical impedance tomography reveals a loss of aeration in dependent regions of the lung and a change in the ventilation pattern during T-tube SBT. This information may be useful in decision making during weaning in patients with difficult or prolonged weaning.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1062

INTRODUCTION. Adaptive ventilation modes reduce the clinical workload and total duration of mechanical ventilation [1] by automatically adjusting respiratory rate (RR) and tidal volume (V_T) continuously according to the individual patient's respiratory mechanics. Traditionally, the "optimal" ventilator settings to achieve the clinically desired minute ventilation (MV) are calculated using the Otis equation [2]. This equation provides RR and V_T to minimize the inspiratory work of breathing that is required for a given MV, assuming a sine wave pressure pattern during inspiration. However, it has been implied that closed loop ventilation modes based on this equation may not be ideal for lung-protective ventilation because they deliver relatively high V_T, especially in patients with more compliant lungs [3]. Therefore, an improved adaptive ventilation mode (AVM2) has been developed, which optimizes RR and V_T assuming a square-wave inspiration pressure with the aim of minimizing the inspiratory power delivered by the ventilator.

OBJECTIVES. To compare AVM2 to a traditional adaptive ventilation mode based on the Otis equation (AVM).

METHODS. We perform a randomized crossover study in 20 intubated and mechanically ventilated ICU patients (German Clinical Trials Register ID: DRKS00013540). Patients are ventilated with AVM and AVM2 for one hour each in a randomized order. Target MV is adapted, if necessary, according to measured end-tidal CO_2. After each phase, we collect data on delivered V, RR, ΔP (driving pressure, calculated as V_T divided by respiratory system compliance) and arterial blood gas samples.

RESULTS. To date, 14/20 patients were included (age 62±11 years, height 180±7 cm, PaO_2/FiO_2 269±98 mmHg, clinically selected PEEP 9.1±1.7 cmH_2O; all values mean±standard deviation). Delivered V_T was 8.7±0.7 ml / kg predicted body weight (PBW) with AVM and decreased to 7.4±1.0 ml / kg PBW with AVM2 (p < 0.05). ΔP decreased from 14.3±3.0 cmH_2O with AVM to 11.4±2.1 cmH_2O with AVM2 (p < 0.05). RR increased from 14±1.8/min with AVM to 16.5 ±2.1/min with AVM2 (p < 0.05). No significant differences in PaO_2/FiO_2, $PaCO_2$ and pH were observed.

CONCLUSIONS. Our preliminary results suggest that in comparison to closed-loop ventilation based on the Otis equation, ventilation with AVM2 may lead to lower V_T and ΔP, resulting in more "lung protective" ventilator settings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1063

INTRODUCTION. Recently, ventilators have been equipped with volumetric capnography (VC), facilitating the measurement of exhaled CO_2 as volume (VCO_2). Because CO_2 is an end product of metabolism, VCO_2 reflects the patient's metabolic state. Measuring the VCO_2 may clarify the inflammation status and provide clues for making clinical decisions. Several studies have compared the performance of VC between metabolic analyzers and VC-equipped ventilators(VC-V), but no study has compared values among VC-V. Therefore, we compared the VCO_2 measured by two VC-V connected to a respiratory model with adjustable CO_2 infused.

OBJECTIVES. To compare the accuracy of measuring exhaled VCO_2 between two VC-V.

METHODS. Two VC-V, a G5 (Hamilton Medical, Switzerland) and an Infinity 500 (Dragel, Germany) were compared. CO_2 was regulated by

a flow meter (F-05CO2; Yamato Industrial Co., Ltd, Japan) and infused into a test lung (Test lung; Mallinckrodt, Inc., USA). The test lung was connected to ventilators with two HMEs (Inter-ThermFilter/HME; Intersurgical, Ltd., UK) with a volume of 57 ml each, and a flow analyzer (CYTREX H4; IMT Medical, Switzerland). The ventilator was set to normal (Vt 500 ml Ti 1.2 sec RR15/min), restrictive (Vt 300 ml Ti1.0 s RR30/min) and obstructive (Vt 700 ml Ti 1.2 sec RR10/min) respiratory conditions with a PEEP of 3 or 5 cmH$_2$O. The infused CO$_2$ (actual VCO$_2$ [aVCO$_2$]) was increased in 50-ml increments from 100 to 300 ml/min for 2 minutes each, and the VCO$_2$ at the end of each phase (recorded VCO$_2$ [rVCO$_2$]) was recorded.

RESULTS. A regression analysis showed that the aVCO$_2$, and rVCO$_2$ had a strong correlation of r^2=0.99 under all respiratory conditions and with both ventilators. A Bland-Altman analysis showed a bias of 48 with the G5 and 47 ml/min with the Infinity under normal respiratory conditions, 11 with the G5 and 59 ml/min with the Infinity under restrictive respiratory conditions, and 41 with the G5 and 34 ml/min with the Infinity under obstructive respiratory conditions. The LOA (limits of agreement) values were 37-61 and 34-60 ml/min for the G5 and Infinity under normal respiratory conditions, 3-20 and 44-74 ml/min for the G5 and Infinity under restrictive respiratory conditions, and 33-49 and 26-41 ml/min for the G5 and Infinity under obstructive conditions, respectively. For restrictive respiratory conditions, the rVCO$_2$ of the Infinity showed a proportional difference. The error may need to be carefully considered when measuring the VCO$_2$ under restrictive respiratory conditions. Because we lack data on the VCO$_2$ in the field of intensive care, we cannot determine whether or not these bias and LOA are suitable, but we can say that the rVCO$_2$ is affected by respiratory conditions and ventilators.

CONCLUSIONS. The exhaled CO$_2$ volume by measured VC-V may be affected by the respiratory pattern and ventilator used.

INTRODUCTION. Esophageal pressure (Pes) evaluation is a critical step during monitoring of mechanical ventilation. Pes measurement can be affected both by inadequate filling volume (Fv) of esophageal balloon and by artifact exerted by esophageal wall. At this purpose, recently has been proposed esophageal balloon calibration (Ebc) in order to better evaluate the accuracy of Pes monitoring both in vitro and in clinical setting [1, 2].

OBJECTIVES. The study aim was to investigate feasibility of Ebc during robotic uro-gynecological surgeries with application of trendelemburg position (tp), pneumoperitoneum (pp), and positive end-expiratory pressure (Peep). Furthermore, during whole study period, were evaluated inspiratory (PesI) and expiratory (PesE) Pes and related swings at 3 different Fv of esophageal balloon: volume associated with the largest tidal increase of Pes (BV), BV with relative pressure values corrected to esophageal wall pressure (BVc), and volume suggested by the manufactures, 4ml (V4).

METHODS. A catheter with esophageal and gastric balloons was inserted nineteen elective patients undergoing volume controlled mechanical ventilation for robotic uro-gynecological surgery. PesI and PesE and related swings were recorded and computed at BV, BVc, and V4 over study period (T0: before start surgery; T1: pneumoperitoneum + trendelemburg position application; T2, T3, and T4: 20, 60, and 120 minutes from peep application; T5: end surgery). Furthermore, BV trend was post hoc analized at the same steps.

RESULTS. Ebc was successfully applied in all patients enrolled. Figure 1 shows BV trend over study steps. BV significantly increase from T0 to T2 (p< 0,05). PesE was depicted in figure 2. PesE measured at V4 was always significantly higher with respect to both BV and BVc (p < 0,05). PesI trend is depicted in figure 3. Both at BV and BVc were significantly smaller with respect to V4 (p < 0,05). Swing was not different between the 3 filling volumes. BV was higher at T2 and T3 than at T0 (p < 0,05). Finally, Pes tidal swing computed at V4 ml was smaller than both BV and BVc without significant differences.

CONCLUSION. Ebc is feasible in patients undergoing robotic uro-gynecological surgery. Finally, reliability of Pes measurement is improved by Ebc, confirming Mojoli findings also in operating room [2].

The predisposing factors of nutritional insufficiency for postoperative patients in surgical intensive care unit

J.J. Kim, E.Y. Kim
Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Division of Trauma and Surgical Critical Care, Department of General Surgery, Seoul, Korea, Republic of
Correspondence: J.J. Kim
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1065

INTRODUCTION. The enteral feeding has been strongly recommended to the critical ill patients because it could enhance the immunologic function which serves as the host defense mechanism against metabolic response to stress. We investigate the current nutritional status and estimate the adequacy of nutritional supply especially for the acutely ill patients who admitted to the surgical intensive care unit (SICU) after major operation. The predisposing factors associated with the poor nutritional status after operation are also analyzed in order to predict the adverse effect resulted from the nutritional insufficiency in postoperative period.
METHODS. From March to June 2016, the patients who stayed over 48 hours after major surgery at SICU in Seoul St. Mary's Hospital

were reviewed. The clinicopathologic characteristics and the nutritional parameters of patients were reviewed and the surgical outcomes were compared according to the status of nutritional support or the clinical department of patient.
RESULTS. A total of 85 patients (51 males and 34 females) were enrolled and the mean age was 60.2±14.4 years. Mean length of ICU stay was 4.1±4.3 days and the mortality was observed in 3 cases (3.5%). All patients were classified into two groups according to the nutritional status which was assessed by the ratio of total delivered calorie to total required calorie (D/R); group A (38 cases, D/R≥0.7) versus group B (47 cases, D/R< 0.7). The length of hospital stay and the proportion of colonic malignancies were significantly lower in group A than group B (13.5±7.1 days vs. 17.4±9.2 days and 32.4% vs. 78.6%, $p=0.037$ and $p=0.049$, respectively). Regarding the clinical departments, the number of patient in the colorectal department of general surgery was significantly lower in group A than group B (22.2% vs.77.8%, $p=0.049$). The proportion of incision at lower abdomen or the consultation to nutritional support team (NST) had significant differences between two groups (15.8% vs. 46.8% and 55.3% vs. 31.9%, $p=0.012$ and $p=0.046$, respectively). About laboratory results at admission, the level of albumin and BUN was significantly lower in group A (2.7±0.7 g/dl vs. 2.9±0.3 g/dl and 18.7±15.2 mg/dl vs. 35.4±25.2 mg/dl, $p=0.045$ and $p=0.003$, respectively) whereas the level of hematocrit was higher in group A than group B (35.0±5.1% vs. 32.7 ± 5.3%, $p=0.042$). In multivariate analysis, the incision at lower abdomen ($p=0.029$), the prolonged length of hospital stay ($p=0.035$), the absence of NST consultation ($p=0.041$) and the low level of hematocrit ($p=0.037$) were independent risk factors associated the poor nutritional status in the postoperative period.
CONCLUSIONS. We suppose that the clinicians should pay attentions if patients are in the department of general surgery, present low level of hematocrit, or absence of NST consultation which would be the predisposing factors of nutritional insufficiency resulted in the postoperative morbidities or the delay of recovery.

INTRODUCTION. Enteral nutrition (EN) in critically ill patients undergoing vasoactive support (VS) due to hemodynamic instability is controversial and challenging (1,2).
OBJECTIVES. To examine the feasibility and safety of EN in such patients.
METHODS. Prospective, observational, multicenter study (3). Inclusion criteria: adult patients admitted to 19 Intensive Care Units (ICU) in Spain, undergoing VS, as well as invasive mechanical ventilation (MV) for at least 48 hours after admission. Patients with refractory shock were excluded. Follow-up: 14 days. EN was delivered according to a protocol. Variables (Var.): descriptive, hemodynamic

status, efficacy and safety of EN. A descriptive analysis of the results was performed (means with 95% confidence intervals for continuous var., or frequencies for categorical var.).

RESULTS.

Main characteristics: 75 patients included, 64% men, 60 years old (57-64). 56% were medical patients. 72% developed early multiple organ dysfunction syndrome. MV days: 17 (14-20). ICU stay: 22 days (19-25). ICU mortality: 24%.

Hemodynamic status in the first 48 hours: lactate 3,6 mmol/L (2,9-4,3), noradrenaline dose 0,73 μg/kg/min (0,59-0,87), cardiac index 2,63 l/min/m2 (2,32-2,94), mean arterial pressure 67 mmHg (65-70).

Efficacy of EN: time from admission to the start of EN: 34,1 hours (29,3-38,8). 1148,3 Kcal (1053,9-1242,7) delivered by EN. Nutritional balance: - 400,2 Kcal (-505,3 to -295,2).

Safety of EN: EN-related complications were observed in 56 patients (78%), although no cases of mesenteric ischemia were recorded. The most common complications were constipation (36%) and high gastric residual volumes (36%). EN discontinuation was required in 30 patients (40%).

CONCLUSIONS.

Enteral nutrition, under proper medical supervision, can be feasible in these patients.

It is difficult to meet the nutrition requirements when this is the only feeding route.

NUTRIC core: validation of clinical nutritional score using SAPS II and c-reactive protein

T. Petrucci[1], D. Passos[1], G. Nobre de Jesus[1,2], S. Fernandes[1,2], J. Gouveia[1], A. Alvarez[1]
[1]Hospital de Santa Maria - Centro Hospitalar de Lisboa Norte, EPE, Serviço de Medicina Intensiva, Lisbon, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

INTRODUCTION. The NUTRIC score was developed to predict the risk of adverse events and denutrition in critically ill patients. Among other variables interleukin-6 (IL-6), a biomarker not available on usual critical practice, is used. This score was recently validated for the portuguese ICU population, without IL-6. As previously suggested, other inflammatory biomarkers could substitute Il-6 in this score to improve its accuracy, namely c-reactive protein (CRP). Moreover, APACHE II is used to calculate NUTRIC score, and validation for the use of SAPS II has never been tested.

OBJECTIVES. We aimed to address the effectiveness of the NUTRIC Score comparing the sensitivity and specificity of the score when replacing IL-6 for CRP and APACHE II for SAPS II, in a critically ill population in a university hospital ICU.

METHODS. We implemented a retrospective analysis of a cohort study from a tertiary university hospital general ICU. We defined a period of time for data collection of 2 months, calculated for inclusion of at least 70 patients. Data collected included variables of NUTRIC Score, CRP, procalcitonin, demographic data, ventilation, outcome. Previous authors defined a cut-off of CRP for inclusion on NUTRIC Score of 10 mg/dL, which was used in this study.

RESULTS. 74 patients were included, with an average age of 61 years and 37,8% female gender. Mortality was 27%, with a SAPS II of 47 (± 20,6), and a median lenght of stay of 7.9 days. Average CRP on survival population was 16.07 mg/d and on non-survival was 9.2 mg/

dL. We compared area under the curve (AUC) of several models (NUTRIC score using APACHE II vs NUTRIC score using SAPS II, with and without CRP). AUC for NUTRIC score using APACHE II without CRP was 0.83 and with CRP was 0.84. AUC for NUTRIC score using SAPS II without CRP was 0.77 and with CRP was 0.79. No statistical significance was found between the different scores to predict ICU mortality.

CONCLUSIONS. The use of NUTRIC Score, using APACHE II and IL-6 amongst other variables, has been validated for predicting mortality and patient denutrition at ICU admission. The use of SAPS II instead of APACHE II in this study did not alter significantly the NUTRIC Score predictive performance, and it may be licit to use it. Use of additional CRP on the NUTRIC Score did not change its predictive value, although the study may be underpowered for this effect.

Risk factors of enteral feeding intolerance in the intensive care setting in US and Europe: literature review

J. Puelles[1], K. Rennie[2], E. Terblanche[3], C. Almansa[4], G. Dukes[4], M. Binek[5]
[1]Takeda Development Centre Europe Ltd, London, United Kingdom; [2]OXON Epidemiology Ltd, London, United Kingdom; [3]Imperial College Healthcare NHS Trust, London, United Kingdom; [4]Takeda Development Center Americas, Inc., Cambridge, United States; [5]Takeda Pharmaceuticals International AG, Zurich, Switzerland
Correspondence: J. Puelles

INTRODUCTION. Enteral feeding intolerance (EFI) is a common complication in critically ill patients. Slow or altered gastric emptying and associated EFI is multifactorial in the critically ill patient and can lead to under delivery of enteral nutrition (EN) and malnutrition. It has also been associated with increased stay in intensive care, prolonged need for mechanical ventilation and higher mortality.[1,2] Therapy for EFI include prokinetics or changes to feeding regimen, such as interrupting or decreasing EN rates, post-pyloric EN feeding and administration of supplemental or total parenteral nutrition.[3]

OBJECTIVES. To assess risk factors associated with the development of EFI in patients in the critical care setting.

METHODS. Literature searches in MEDLINE®, Embase®, and Cochrane Library were conducted for primary studies in English (2007-2017), in adult intensive care patients receiving EN, to identify studies where EFI, and/or its associated symptoms were included. The search screened studies conducted in the US and Europe. Reviews and relevant primary studies were back-referenced to find any further relevant studies. Primary studies were evaluated for significant risk factors for EFI and grouped according to cause.

RESULTS. Overall, 94 studies were identified that included EFI for the qualitative synthesis, of these 28 full-text articles and 27 abstracts included assessment of risk factors and were included in this review. The literature review identified several risk factors which can be clustered under the following groupings; physiological condition and severity, physiological response, medication use, route of administration of medication, EN initiation (Figure 1). However, the assessment of risk factors was hindered by differences in the definition of EFI used between studies, small sample groups and heterogenous patient populations.

CONCLUSIONS. This study identified many important risk factors associated with the development of EFI. There is, however, a need for large population-based studies with consistent EFI definition to systematically assess multiple risk factors and cluster them in the clinical setting.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1069

INTRODUCTION. Diarrhea and vomiting are common complications in critical care 1). Approaches have been undertaken to make liquid enteral nutrition LEN solid and thereby decrease them 2), however, there was no study that semi-solid LEN could reduce diarrhea. Herein, Pectin is dietary fiber that changes to a solid in the stomach 3). Pectin-containing liquid enteral nutrition PCLEN would mitigate vomiting and diarrhea.
OBJECTIVES. This study compared PCLEN with traditional LEN TLEN for enteral feeding failure, diarrhea and vomiting rates in critical care.
METHODS. We used TLEN as the primary LEN at the emergency and critical care center in Hitachi General Hospital. We adopted PCLEN as the primary LEN from 2014. During 2012-2016, 954 patients admitted to intensive care units and emergency wards were given PCLEN or TLEN. We conducted propensity score matching for 693 eligible patients for age, sex, and organ dysfunctions for six organs.
RESULTS. We included 199 PCLEN patients and 199 TLEN patients. Severity was higher in the PCLEN group: APACHE2 15.3 ± 6.8 vs. 13.6 ± 5.4 ($p=0.0055$) and SOFA 6.2 ± 3.8 vs. 5.1 ± 3.3 ($p=0.0029$), respectively. The enteral nutrition failure rate was significantly lower for PCLEN: 10.6 % than for TLEN: 17.6 % (p=0.043). The GRV at 24 hr was slightly lower for PCLEN: 7.9 ± 24.3 ml than for TLEN: 25.1 ± 63.0

ml ($p=0.017$). Although the vomiting events were not different, the diarrhea incidence rates were 28.1% vs. 38.2% ($p=0.033$), and the incidence rates of nosocomial pneumonia were 4.5% and 9.6% ($p=0.048$). For PCLEN, the enteral nutrition failure rates were not different for patients with gastric acid inhibitors and without them.
CONCLUSIONS. PCLEN can be used effectively for critically ill patients irrespective of the use of gastric acid inhibitors. It can decrease the incidence of enteral nutrition failure and diarrhea in critical care.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1070

INTRODUCTION. Early goal-directed enteral nutrition protocol (EGDN NAGOYA) was created in 2010. EGDT might promote enteral nutrition in critical care patients.
OBJECTIVES. We aimed to investigate outcome of EGDN NAGOYA in the emergency and medical ICU.
METHODS. Patients hospitalized for 48 hours or more were retrospectively investigated rom May 2011 to June 2017 in Nagoya University Emergency and medical ICU. Patients were classified into the following three groups by the first nutrition method: oral intake group (PO), enteral nutrition group, and total parenteral nutrition group (TPN). Enteral nutrition group was classified into the following four groups, according to the time to initiate enteral feeding: within 6 hours(EN6), 6 hours or more, and less than 24 hours (EN6-24), 24 hours or more, and less than 48 hours (EN24-48) , and 48 hours or more(EN48). We evaluated APACHEII score and mortality in ICU of each group. For statistical multiple comparison, the Tukey-Kramer method and Fisher´s exact test were used.
RESULTS. There were 977 cases in the criteria of this study. Enteral nutrition according to EGDN NAGOYA were 470 cases (48.1%) were classified into enteral group: EN6 77 (7.9%), EN6-24 217 (22.2%), EN24-48 129 (13.2%) and EN48 47 (4.8%). The mean APACHE II score was 28.9, 29.9, 28.7 and 27.5, and the ICU mortality was 3.9%,10.1%,10.1%, 10.6%, respectively. On the other side, in TPN, the APACHE II score was 28.2 and its ICU mortality was 20.0%. EN according to EGDN NAGOYA showed the significantly better outcome than PN in spite of the similar ill severity.
CONCLUSIONS. This study showed that early beginning enteral nutrition with the protocol EGDN NAGOYAcould lead to good prognosis of critically ill patients from 2011 to 2017.

INTRODUCTION. Malnutrition is highly prevalent among older patients with type 2 diabetes in a hospital or geriatric care setting and is an important predictor for longer hospital stays and poorer clinical outcomes.
OBJECTIVES. In this study we aimed to investigate the effect of diabetes on nutrition status of patients in internal medicine intensive care unit.
METHODS. A total of 192 patients were enrolled in this retrospective study. The study group was comprised of 77 patients with diabetes and the control group was comprised of 115 patients without diabetes . Mini nutritional assessment (MNA), nutric score and the nutrition risk screening (NRS)- 2002 results of the patients were compared.
RESULTS. The groups were matched in terms of age and sex (68.6 ±13.4 vs. 71.6±14.6, p=0.091; female/male= 38/39 vs. 46/69, p=0.426). The APACHE II score of the groups were comparable (21.1±6.6 vs. 20.5±6.3, p=0.539). MNA, nutric score and NRS-2002 tests results were 8.0±3.1, 4.61±1.85 and 3.37±1.84, respectively in the study group while they were 7.1±3.2, 4.56±1.85 and 3.93±1.72, respectively in the control group. The differences were not statistically significant (p=0.068, p=0.869, p=0.075, respectively).
CONCLUSIONS. In this study we have found comparable nutritional scores in both of the groups. Concomitant diseases other than diabetes may have more effect on nutritional status of patients in intensive care units.

INTRODUCTION. Several factors are involved in ICU malnutrition, leading to longer ICU stay, longer dependence of mulitorganic support, and a higher number of nosocomial complications. Guidelines intend to reduce malnutrition and its associated complications.
OBJECTIVES. Describe the fullfillment of enteral nutritional requirements at 72 hours in a mexican intensive care unit before and after the implementation of ASPEN guidelines 2016 and the main factors involved in unfullfillment.

METHODS. A descriptive, retrospective study was performed analyzing medical files of patients admitted to ICU and without contraindication for enteral feeding.We analyzed first from january to december 2016, and then from january to december 2017;implementation of ASPEN 2016 guidelines in our ICU started on January 2017. A before-after compative analysis was performed.
RESULTS. 88 patients were included in 2016 analysis. 47 (53.4%) patients fullfilled at least the 60% of nutritional requirements estimated by Harris Benedict formula at 72 hours of ICU admittance. 27 (30.7%) patients not fullfilled the 60% of requirements at 72 hours,and 14 (15.9%) were overfeeded. In patients with BMI of 20-29 kg/m2 unfullfill-ment was present in 38% and overfeeding in 10%; in patients with BMI of 30-50 kg/m2 unfullfillment was present in 21.6% and overfeeding in 24.3%. In the group of BMI of 20-29 kg/m^2 the factors related to unfull-fillment were extremely high estimation of nutritional requirements by the first 24 hours, and lack of feeding progression at 48 and 72 hours; the main reason for unfullfillment in the group of BMI of 30-50 kg/m2 was the extremely high estimation of nutritional requirements at 24 (21%),48 (50%) and 72 hours (37.5%).110 patients were included in 2017 analysis. 82 (74.5%) patients fullfilled at least the 60% of nutri-tional requirements estimated by ASPEN 2016 Guidelines recomenda-tions at 72 hours of ICU admittance.20 (18.2%) patients not fullfilled the 60% of requirements at 72 hours,and 8 (7.3%) were overfeeded.In pa-tients with BMI of 20-29 kg/m^2 unfullfillment was present in 17% and overfeeding in 5.7%; meanwhile in patients with BMI of 30-50 kg/m^2 unfullfillment was present in 20.5% and overfeeding in 10.2%. The main cause for unfullfillment was high gastric residual volumen, present in the group of BMI of 20-29 kg/m^2 in 41.6%, and in the group of BMI of 30-50 kg/m^2 in 62.5%.
CONCLUSIONS. In our study we found a significant lower rate of unfullfillment and overfeeding when ASPEN 2016 guidelines recommendations were applied in comparation when Harris Benedict formula was applied. Overestimation of nutritional requirements is an usual problem related with Harris Benedict method, meanwhile high gastric residual volumen was the main problem in patients under ASPEN recomendations.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1073

INTRODUCTION. Malnutrition in critically ill patients was associated with an increase in mortality and morbidity. Despite having publication from many guidelines, feeding protocols varied among population and region. The protocol should be compatible with the characteristics of individual intensive care units (ICUs).
OBJECTIVES. To evaluate the efficacy of Siriraj Surgical ICUs feeding protocol and to compare the hospital mortality, hospital LOS and ICU LOS between protocol and non-protocol groups.
METHODS. A randomized control trial study was conducted in Surgical ICUs Siriraj Hospital. Nutritional administration in control group was depended upon attending physicians' discretion. In the intervention group, nutritional management was followed by the "Siriraj surgical ICUs nutritional protocol".
RESULTS. 170 patients were enrolled. Almost all patients in both group had risk of malnutrition described by Nutrition Risk Screening (NRS) 2002 (NRS score ≥ 3) and more than 50% of patients by NUTRIC score ≥5. Total median calories per day received in both group were not significantly different [760.1 kcal (494.6, 1047.8) in

protocol group vs. 754.6 kcal (444.6, 1092.9) in control group: p-value 0.773]. The median time to start enteral nutrition trended to shorter in protocol group [1.94 days in protocol group vs. 2.25 days in control group: p-value 0.503]. ICU LOS, hospital LOS, duration of mechanical ventilation and mortality were not significantly different between groups. The prevalence of nutrition related complication and rate of infection were similar in both groups.

CONCLUSIONS. The implementation of nutritional protocol showed no difference in the efficacy of nutrition management and clinical outcomes compared to standard treatment in surgical ICUs.

INTRODUCTION. Aiming do assess the compliance of current international nutritional guidelines, a Enteral Nutrition Protocol (ENP) was designed and applied in an Intensive Care Unit (ICU) at Centro Hospitalar Universitário do Algarve.

METHODS. We conducted an observational, retrospective study in a before-after design, corresponding to (group 1) the period of implementation of the ENP with several educational interventions (nutritionist monitoring and clinical discussion meetings) between April 2016 and May 2017, and (group 2) the period after the implementation between June 2017 and March 2018. All patients on full enteral nutritional support during ≥ 4 days in the ICU were included, and the protocol applied. Data was collected on nutritional intake value (initial and final caloric intake, with and without additives), biochemical markers (glucose, C-reactive protein, hemoglobin, total bilirubin, ALT / AST, total Proteins / Albumin, phosphorus, calcium magnesium) and the Simplified Acute Physiology Score (SAPS II). Data were analyzed using SPSS statistical program, version 22.0. Mann-Whitney test, Kruskal-Wallis and Wilcoxon test were used, statistical significance accepted at p< 0,05.

RESULTS. During the period of study, 590 patients were admitted to the ICU. 55 patients met the inclusion criteria, 32 (25,8% surgical, 61,3% medical and 12,9% trauma) in group 1 and 24 in group 2 (8,3% surgical, 79,2% medical, 12,5% trauma). The ICU length of stay were 19 days (SD ± 14) in group 1, and 18 (SD ± 14) in group 2. In group 1 SAPS II were 53 (SD ± 18,8) and in group 2 50,1 (SD ± 14,5). Statistically significant differences were found, with higher initial and final caloric intake without additives (p< 0,05), initial and final caloric intake with additives (p< 0,05), caloric value of additives (p< 0,05) in group 1. No difference was found concerning protein intake, but the nitrogen supply was significantly higher in group 1 (p< 0.05). Among biochemical markers analyzed, bilirubin was the only parameter

higher in group 1 (p< 0.05). Concerning the enteral nutrition timing of initiation, statistically significant differences were found on surgical patients, group 2 started enteral nutrition at 1,5 days (SD± 0,7), and group 1 started at 3,9 days (SD±3,7) (p< 0,05).

CONCLUSIONS. Implementation of the ENP associated with educational interventions, can improve compliance with current nutritional recommendations which are known to be associated with better clinical outcomes.

Enteral nutrition delivery in a tertiary cardiothoracic ICU: a quality improvement project

M. Sehmbhi, M.J. Rouhani, I. de Brito-Ashurst, A. Chan-Dominy, S.F.P. Ledot
Royal Brompton Hospital, Adult Intensive Care Unit, London, United Kingdom
Correspondence: M. Sehmbhi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1075

INTRODUCTION. Optimal caloric and protein intake reduces mortality risk in ICU (1), particularly among high nutritional risk patients (2), yet underfeeding remains a common problem.

We evaluated nutrition adequacy in our tertiary cardiothoracic ICU among elective admissions, ECMO admissions, and non-ECMO emergency admissions. Preliminary work found nutrition delivery was inadequate: a 5 day admission could result in a 5000 kcal deficit - the energy required to run two marathons. We performed a quality-improvement (QI) project to address this using the Plan-Do-Study-Act methodology, with a 1-month review to assess effectiveness of interventions.

OBJECTIVES.

1. To deliver >80% of each patient´s daily calorie/protein target
2. To assess adherence to QI interventions 1 month post-implementation

METHODS. We gathered data retrospectively from electronic records on all patients admitted to our ICU for >24 hours in two 6-week periods (n = 66), with QI interventions between the study periods. Interventions included: introduction of a "procedural NBM time" guideline, a nutrition checklist guiding daily nutrition rounds, increasing the gastric residual volume (GRV) cut-off threshold, and a "catch-up volume-based enteral feed (EF)" protocol. We studied compliance 1 month post-implementation.

Data collected included: calorie and protein delivery (first 5 days); reasons for delay in initiating EF; reasons for interruption of EF; adherence to the GRV and catch-up feed protocols.

RESULTS.

Caloric/protein intake

We achieved our objective. QI interventions resulted in >80% of target calorie/protein delivery by day 5 of admission (day 1: 19.8% cal target achieved, 18% protein target; day 5: 87.4% cal, 85% protein).

Delay in initiating feeding

Common reasons for delay included expectation of early extubation (particularly for elective surgical admissions), delays in confirmation of feeding tube position, and acute cardiovascular instability.

Feed interruptions

These were due to intended hold pre-/post-procedure, excessively high GRV, or inappropriate omission. Compliance with our procedural NBM time guideline increased from 32% to 39%. Compliance with our 400ml GRV cut-off was good, at 86.2%

Catch-up feeding

Compliance with catch-up feeding was poor at 1.5% of eligible cases.
CONCLUSIONS. Our QI interventions improved nutrition delivery to >80% of target by day 5 of admission, with some groups approaching 100%. Significant interventions were early initiation of EF, implementing an EF-hold time policy for high aspiration risk procedures (to maximise nutrition delivery while maintaining a safe feed-free interval), and a raised GRV cut-off.

Areas for attention in subsequent QI cycles include stricter enforcement of nutrition policies, particularly the catch-up feeding protocol, and further raising staff awareness with a Nutrition Awareness Week.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1076

INTRODUCTION. The management of nutrition along with the measures taken in terms of medical treatment and life support constitute one of the pillars for the treatment of sepsis patients. Therefore, the study of nutritional parameters on this group of patients is of high relevance.

OBJECTIVES. To evaluate the influence of routine nutritional parameters on the prognosis of a cohort of sepsis patients admitted to the ICU.

METHODS. Patients admitted for severe sepsis and septic shock (SS) were evaluated in this study. Levels of albumin, proteins, cholesterol (LDL and HDL), transaminases, ions, iron, bilirubin, CRP, glycemia, alkaline phosphatase and creatinine were measured on admission and at day 3 and 7. The [median ± IQR] was used to compare the quantitative variables. To evaluate the impact of the variables on patient mortality, the area under the ROC curve (AUROC) was used. A p value of < 0.05 was considered significant.

RESULTS. Data from forty-two adult patients were collected. Patients were an average age of 62 years old, of which 71.4% were males and 66.7% presented SS. Average albumin levels were of 2.6 gr / dl. When comparing survivors with deceased, statistically significant differences were found in the following variables [median ± IQR, p]: albumin day 1 (2.7 ± 0.8) vs (2.2 ± 0.9) p= 0,035; albumin day 3 (2.6 ± 0.75) vs (2 ± 0.55) p = 0.035; Albumin day 7 (2.6 ± 1.5) vs (1.9 ± 1.8) p = 0.035; Total proteins day 7 (5.5 ± 1.4) vs (4.6 ± 1.4) p = 0.025; HDL cholesterol day 7 (23 ± 9) vs (14 ± 21.5) p = 0.01; LDL cholesterol day 7(93.4 ± 48.9) vs (57.2 ± 37) p = 0.02. AUROC for UCI mortality prediction[95% CI, p], was 0.73 (0.54- 0.92) p = 0.036 for albumin on day 1; 0.73 (0.57 + 0.88), p = 0.036 for albumin on day 3; 0.76 (0.59 +0.929) p = 0.01 for albumin on day 7; 0.742 (0.56-0.925) p = 0.027 for total proteins on day 7; 0.792 (0.556-1) p = 0.043 for cholesterol on day 7, and 0.833 (0.614-1) p = 0.021 for LDL on day 7.

CONCLUSIONS. Sepsis patients presented low basal albumin levels, being significantly lower in the subgroup of non-survivors, both at admission and on successive days. The total protein levels at day 7 show a similar behavior. Based on AUROC both variables present good prognostic capacity. In contrast, LDL cholesterol levels are higher in the group of survivors, presenting an excellent AUROC for prediction of mortality. Further research in larger studies is needed to confirm these results.

Elemental vs polymeric early enteral nutrition in ICU patients: does elemental feeding improves tolerance and outcome?

M. Theodorakopoulou, F. Frantzeskaki, G. Skyllas, A. Diamantakis, E. Chrysanthopoulou, A. Armaganidis
University Hospital of Athens Greece Attikon, 2nd Critical Care Department, Athens, Greece
Correspondence: M. Theodorakopoulou
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1077

INTRODUCTION. Nutrition plays a significant role in achieving optimal health, but in certain high risk patients with significant systemic illnesses and/or organ dysfunction, achieving adequate nutrition maybe difficult. Elemental diet formulas are used to provide liquid nutrients in a form that is easily and readily assimilated. A large volume of clinical studies have demonstrated significant health benefits with semi-elemental diets and have been shown to reduce the degree of regurgitation, gastric emptying times, and improve tolerance.

OBJECTIVES. To examine whether elemental enteral feeding improves tolerance and outcome in Critically ill ICU patients.

METHODS. A total of 126 (75 men) consecutive, mechanically ventilated, critically ill patients with a mean (±SD) age of 65±22 years having various illnesses were included in the present study. Thirty two patients had sepsis. Mean APACHE II and SOFA scores were 17±10 and 7±3 respectively. Mean albumin upon admission was 3.0±0.7 g/dl. All patients were randomized to receive treatment with either elemental or polymeric diets for 10 days. EN treatment started within the first 48

hours of ICU admission. Patient's laboratory data was also recorded for 10 consecutive days. Twenty four-hours urine was collected for each patient to calculate nitrogen balance, while albumin level was recorded in days 1, 4, 7and 10. Results of enteral feeding of the two groups were subsequently assessed and analyzed.

RESULTS. Tolerance of enteral nutrition was significantly better in the elemental group. Laboratory values however had not significant difference between the two groups in the 10 days period. The mean nitrogen balance was more negative in polymeric group (p-value: 0.367) The mean serum albumin value was significantly higher in the elemental group. Nitrogen balance however seem to have no correlation with ICU mortality (p-value: 0.312) and incidence of sepsis (p-value: 0.422).

CONCLUSIONS. According to the results of this study, semi-elemental diet is better tolerated by the critically ill ICU patient. It seems that these population who have difficulty digesting or absorbing standard polymeric diets may be able to achieve improved nutritional outcomes through the use of semi-elemental diets.

Aplication of a protocol for the management of constipation in the intensive care unit of the General Hospital of Albacete: analysis and results

E. Simón Polo, J. De Capadocia, J. Pazos Crespo
Albacete Hospital, Anaesthesia, Albacete, Spain
Correspondence: E. Simón Polo
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1078

INTRODUCTION. Constipation is a common entity in critical care units. The omission in its treatment as well as the delay in the diagnosis can negatively affect in multiple clinical variables: delay in the respiratory weaning, increase of the rate of Infection, and even increased mortality.

Constipation is definited as the absence of bowel movements more than three days after starting enteral nutrition, having ruled out obstructive causes as an alternative diagnosis.

OBJECTIVES. The main objective of this study is to implant a protocol for the management of constipation in patients admitted in our intensive care unit, and to evaluate its efficacy in a preliminary way.

METHODS. An analysis was carried out in two phases: first a retrospective, in which we analyzed the magnitude of constipation in our unit, and a second prospective phase in which we studied the impact of the implementation of the protocol. It includes 40 patients (19 prospective) who were admitted between November 2017 and March 2018.

Patients were divided in two main groups: Group A, retrospective: we didn't applied the protocol, and prospective group B: the unit protocol was applied.

We analyzed the following variables: Day of first deposition, incidence of diarrhea, abdominal distention, intolerance and incidence of abdominal hypertension

RESULTS. There was a decrease in the incidence of constipation, reducing the day in which the first deposition occurs (day 7-8 vs 4-5 Day). There was an increase in the presence of diarrhea in 10% in the protocol group compared with the control group, as well as a decrease in 20% of abdominal distensión.

CONCLUSIONS. Constipation in the critical patient is a frequent and potentially serious entity. In our case the implementation of a protocol has shown a decrease in the incidence of constipation. We observed an increase of diarrhea in the protocol group, without clinical repercussion.

Prevalence of electrolyte disorders in ICU and its correlation with mortality

L. Bianchini[1], J. Gomez[2]
[1]Universidade de Passo Fundo, Passo Fundo, Brazil; [2]Hospital São Vicente de Paulo, Passo Fundo, Brazil
Correspondence: J. Gomez
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1079

INTRODUCTION. Electrolytes disorders are among the most common findings in critically ill patients. Furthermore, there is a well-established relation between some of these imbalances and mortality. However, whether an early correction of electrolytes disturbances decreases unfavorable outcomes remains uncertain.

OBJECTIVES. To assess the incidence of electrolyte disorders at Intensive Care Unit(ICU) admission, its relation with mortality and to evaluate if the correction of the disorder in 48 hours influences ICU an in-hospital mortality.

METHODS. We performed a retrospective observational study, including all patients >18 years-old admitted for more than 48 hours at the ICU of Hospital São Vicente in the first semester of 2017. Sodium, potassium, chloride, calcium, magnesium, phosphorus were measured at ICU admission and 48 hours after and evaluated regarding their possible association with mortality.

RESULTS. A total of 273 patients with a mean age of 52.94 years (18-94) and 60.8% of them male were included. In this sample, hypernatremia at admission was associated with a two-fold increase in the risk of in-hospital death (p=0.024) and hyperphosphatemia increased mortality by 2.4 times (p=0.001). For those who were hypernatremic on ICU admission, every within-subject 1mmol/L alteration was associated with 1.8 times higher mortality (p=0.028). In 48 hours, only hyperphosphatemia increased both ICU and in-hospital mortality (p< 0.001) and hyponatremia (p=0.003) and hypokalemia (p=0.07) were also related to ICU death. No differences both in ICU and in-hospital mortality were observed with correction of the evaluated electrolytes disorders within 48 hours of ICU admission.

CONCLUSIONS. The correction of measured electrolytes in the first 48 hours of ICU admission was not associated with decreased mortality, although a larger sample is needed to confirm these findings.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1080

INTRODUCTION. Sufficient energy and protein intake for intensive care patients can reduce infections, length of stay, mortality rate and increase health-related quality of life. Energy requirement recommended for ICU patients is 20-25kkal/kg/day and 1.2 - 2.0 g/kg/day of protein and should be started within 48 hours. Studies show that malnutrition is common and that nutritional support is often delayed in the ICU.

OBJECTIVES. To evaluate the route of feeding, time to initiation of nutritional support, the energy and protein intake in adult patients in the general ICUs at Landspitali the National University Hospital and analysing the results by length of ventilator treatment.

METHODS. Data was collected from medical journals of all patients, 18 years and older, with ICU´s length of stay > 72 hours, not receiving palliative care, during three 2-months' time periods, from 2014 to 2015. Patient demographics were collected, the nutrition and protein intake was recorded daily for the whole stay in ICU. Group A were patients with longer than 24 hours on mechanical ventilation, group B were not on mechanical ventilation or less than 24 hours. Descriptive statistics with anova test on difference between groups were applied.

RESULTS. Totally, 134 patients were evaluated for 1359 patient days (range 3-42). Group A, included 86 patients and group B 48. In group A the energy intake was 66% of the energy requirements versus 45% in group B (p< 0.05). Protein intake was 27% of the protein requirements in group A versus 11% in group B (p=0,631). Substantial proportion of energy intake, or 46% in group A and 23% in group B came from propofol. Nutrition was initiated on average in 45 hours in group A versus 25 hours in group B (P< 0,001). Enteral nutrition was used in 88% patients in group A, initiated on average in 56 hours, but in 15% in group B in average, initiated after 36 hours.

CONCLUSIONS. Energy and protein requirements were not reached in this study, especially in patients not on mechanical ventilation. Propofol was a large proportion of energy intake, especially among patients with longer ventilator treatment. The initiation of nutritional support was under 48 hours, but shorter delay for enteral nutrition may be encouraged, focusing on patients expected to receive longer ventilation support.

The relationship between base excess unmeasured anions and postoperative outcomes in living donor liver transplantation candidates

H.K. Atalan

Acibadem Mehmet Ali Aydinlar University School of Medicine, Istanbul, Turkey

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1081

INTRODUCTION. The liver has an important influence on normal acid-base homeostasis because of its metabolism of organic acid anions, primarily lactate and certain amino acids. It is also known that liver failure has multisystemic effects including metabolic perturbances. It is demonstrated that increased unmeasured anions (UA) are associated with higher mortality in critical ill patients (1). Base excess unmeasured anion (BEua) can be used to show the presence of UA and it's a component of standart base-excess (SBE). BEua can be calculated by using partitioned base-excess approach (2).

OBJECTIVES. The aim of this study is to investigate the impact of preoperative presence of UA on postoperative outcomes in living donor liver transplant patients.

METHODS. Living donor liver transplantations performed in 2016 and 2017 were investigated and 332 adult living donor liver transplantation patients were included. ABL-800 blood gase analyser was used to measure arterial blood gas samples. BEua was calculated in accordance with partitioned BE approach. Demographic data, blood gas parameters, length of ICU stay, length of hospital stay, duration of mechanical ventilation, postoperative first seven days serum creatinin levels and hospital mortality were recorded.

RESULTS. In this study, there were 229 (68.6%) patients with BEua< 0 in preoperative period. In patients with BEua< 0, postoperative 7th day acute kidney injury (AKI) was significantly higher than patients with BEua≥0 (15.3% and 5.7% respectively; p=0.013).

CONCLUSIONS. The preoperative presence of UA in living donor liver transplant candidates is associated with early postoperative AKI. Therefore, in this specific population acid-base status assessment should be done with this point of view to improve postoperative outcome.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1082

INTRODUCTION. The Sepsis-3 conference redefined clinical criteria for diagnosis of sepsis using measures of organ dysfunction. The qSOFA score was suggested to replace SIRS in screening for sepsis. The prognostic accuracy of suspected infection with either qSOFA or SIRS for predicting organ dysfunction, rather than mortality, has not been evaluated.

OBJECTIVE. To compare prognostic ability of qSOFA with SIRS for presence of organ dysfunction within 48 hours of triage in patients admitted through the Emergency Department with suspected infection.

METHODS. Single center retrospective cohort analysis of patients aged ≥18 admitted through ED with suspected infection 3/07-5/16. Presence of SIRS and/or qSOFA within 3 hours of triage were assessed. Suspected infection was defined as a combination of body fluid cultures and antibiotics within a 4-hour window, and both must have occurred within 6 hours of ED triage. Organ dysfunction was defined by both Sepsis-2 and Sepsis-3 criteria. Organ dysfunction at presentation was defined as presence of organ dysfunction within 3 hours of triage, and progression to organ dysfunction was defined as presence of organ dysfunction 3 - 48 hours post-triage. A third category included all patients with organ dysfunction either at presentation or at any time up to 48 hours after triage.

RESULTS. 13,749 patients with suspected infection that met inclusion criteria were identified. 6,113 patients presented with only SIRS (44.46%), 427 patients presented with only qSOFA (3.11%), 3,072 patients presented with both qSOFA and SIRS (22.34%), and 4,137 patients presented with neither qSOFA nor SIRS (30.09%).

Table 1 shows area under ROC curves for organ dysfunction at presentation, progression to organ dysfunction, and either, according to presence of SIRS or qSOFA at presentation.

Table 2 shows sensitivity and specificity for organ dysfunction at presentation, progression to organ dysfunction, and either, according to presence of SIRS or qSOFA at presentation.

CONCLUSIONS. A majority of patients who present to the ED with suspected infection present with ≥2 SIRS. There is a substantial overlap of patients with both ≥2 qSOFA and ≥2 SIRS. qSOFA shows a

significantly greater prognostic accuracy for Sepsis-2 and or Sepsis-3 Organ Dysfunction from presentation to 48 hours after ED triage. However, in each circumstance SIRS has higher sensitivity, while qSOFA has higher specificity.

Sepsis-3 definitions of septic shock are not only associated with higher disease severity but with differences in type and origin of infection

D. Thomas-Rüddel[1,2], H. Rüddel[1,2], K. Reinhart[1,2], F. Bloos[1,2], MEDUSA study group
[1]Universitaetsklinikum Jena, Center for Sepsis Control and Care (CSCC), Jena, Germany; [2]Universitaetsklinikum Jena, Anesthesiology and Intensive Care Medicine, Jena, Germany

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1083

INTRODUCTION. The new Sepsis-3 definition of septic shock includes a serum lactate level >2mmol/l [1] in addition to the established criterion of persistent hypotension. One validation study in 470 emergency room patients hinted at differences not only in disease severity and mortality but in infection characteristics between patients fulfilling the Sepsis-3 lactate criterion and those that did not [2].
OBJECTIVES. To assess differences in disease severity, mortality and infection characteristics in a large, mixed population of hospital and community acquired septic shock depending on the used definition.
METHODS. We present a post hoc analysis from a 4 year multicenter quality improvement study [3] where ICU patients with sepsis (all with organ dysfunction) were documented prospectively. The analysis was restricted to those with persistent hypotension, assessed by vasopressor support according to SOFA subscore. Differences between the patients with and without lactate >2mmol/l were assessed by Fisher´s exact test, Mann-Whitney U or Kaplan-Meier curve with Log rank test as appropriate.
RESULTS. 5144 patients fulfilled Sepsis-1 criteria for septic shock, of those 3524 (69%) had a lactate level >2mmol/L and therefore fulfilled also Sepsis-3 criteria. Patients fulfilling Sepsis-3 criteria had

significantly more community acquired septic shock, more frequent an abdominal focus and a higher rate of bacteremia (Table 1).
They also had a significantly higher disease severity, higher procalcitonin levels and higher mortality (Table 2). The mortality difference was mostly driven by early death within 14 days (Figure 1).
CONCLUSIONS. Using the Sepsis-3 definitions of septic shock is not only associated with higher mortality but with changes in infection characteristics towards more community acquired infections, more abdominal sepsis and more bacteremia. Early mortality, likely caused directly by septic shock, is much higher. This should be taken into account in the design and interpretation of future trials and epidemiological studies.

Comparison of capillary leak index versus traditional ICU scoring sistems

INTRODUCTION. Sepsis is a medical condition based on a hyperstimulation of the immune system, making a release of biochemical substances to the bloodstream triggering systemic inflammatory response.

Endothelium, under physiological conditions, is responsible for anticoagulant and anti-adhesive properties, also it regulates vaso-motor tone and vascular homeostasis. Endothelial dysfunction has been associated with inflammation, oxidative and nitrosative stress.

Impairment of endothelial function leads to phenotypic and physical changes of the endothelium, with deregulated release of potent vasodilators nitric oxide and prostacyclin, reduction of vascular reactivity to vasoconstrictors, leukocytes and platelet aggregation, and increase in inducible nitric oxide synthase expression that can exert a negative feedback on endothelial nitric oxide synthase expression, with subsequent deregulation of nitric oxide signaling.

Systemic capillary leak syndrome on sepsis is a serious condition with a high morbidity and mortality rate. On a previous trial, we validate the Capillary Leak Index (CLI) as a poor prognosis scale in septic patients. A cut-off point of 85.55 has a direct association with 28 days mortality.

OBJECTIVES. Compare Capillary Leak Index with common prognosis staging scales used on intensive care unit in septic patients.

METHODOLOGY. Observational prospective cohort trial including 62 septic patients. We analyzed CLI, SOFA, APACHE II, hospital length of stay, complications and mortality. T student test and ROC curves validated CLI as a poor prognostic factor. $(p > 0.05$ IC 95%).

RESULTS. 62 patients. 2 groups assigned, dead (22) clinical improvement (40). Mean age of 58.9 years, 72.58% males. We report a higher CLI (106 IC 94.91-118.42), SOFA (13.7 IC 12.14-15.31) and APACHE II (25.63 IC 23.33-27.93) on dead patients. $(p < 0.001)$.

We also performed ROC curves to compare sensibility and specificity of CLI (AUC0.822) versus traditional ICU scoring systems such as APACHE II (0.858) and SOFA (0.896). We obtained 86.36% and 72.50% of specificity and sensibility respectively to a cut-off point >85.55.

CONCLUSION. There is a directly proportional relationship between CLI and mortality. Comparative analysis between CLI and other scales (SOFA, APACHE II) show inferiority, however the simplicity, and lower costs make it an accessible scale. This index evaluates integrity of endothelium, not analyzed component in another scale. We differ cut-off point (85.4) in our trial from results in previous trials (>61).

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1085

INTRODUCTION. Prompt administration of antibiotics is associated with improved outcomes in sepsis (1). It is unclear whether using a prehospital sepsis screening tool provides significant clinical benefit (2). The PRESEP score [TABLE 1] was developed to identify sepsis in the prehospital setting, with high reported discrimination in the small derivation study with a sensitivity 0.85 and specificity 0.86 at a cut-off of 4 (3), but this has limited external validation to date.

OBJECTIVES. To evaluate whether in a cohort of patients transported by ambulance and identified in the ED as possibly septic, PRESEP would predict adverse outcomes when compared to National Early Warning Score (NEWS) and quick sequential organ failure assessment (qSOFA) scores in the prehospital environment.

METHODS. A dual-centre, prospective cohort (2015-16) of adult ED patients (n=1534), identified as potentially septic was analysed and prehospital observations and 30-day mortality data collected. 301 patients were excluded, 132 as not assessed pre-hospital, and 168 for missing as ambulance data not retrievable. Area under the receiver operator characteristic curves (AUROCs) for 30 day mortality and for ED physician diagnosis of sepsis were calculated for all 3 scores, together with sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for each.

RESULTS. Compared to the derivation group, our cohort had higher median age (79 vs 71) and a higher proportion of medical admissions (84% vs 55%), but similar rates of surgical admission and similar gender distribution. [TABLE 2]

PRESEP showed poor discrimination for 30-day mortality with an AUROC of 0.47 (95% CI 0.41-0.50) compared to NEWS of 0.61 (0.57-0.66) and qSOFA of 0.64 (0.60-0.68), though both had limited discrimination. [FIGURE 1]

Discrimination for an ED diagnosis of sepsis was poor for all three scores: AUROC of 0.5 (0.46-0.54) for PRESEP, 0.52 (0.48-0.56) for NEWS and 0.52 90.48-0.55) for qSOFA. [FIGURE 2]

At a cut off of 4, PRESEP demonstrated no better sensitivity and specificity, positive predictive value or negative predictive value than NEWS or qSOFA. [FIGURE 3]

CONCLUSIONS. In a large prospective cohort of patients with suspected sepsis, the PRESEP score in the pre-hospital environment did not discriminate for mortality or ED diagnosis of sepsis and was inferior to NEWS and qSOFA. Future research could assess performance of these screening tools in a larger cohort of patients with suspected infection in the pre-hospital environment.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1086

INTRODUCTION. Sepsis is a leading cause of mortality both locally and worldwide. Despite this, early diagnosis of sepsis remains difficult, with a significant number not fulfilling SIRS criteria. In 2016, the Sepsis-3 guidelines modified its definition to include qSOFA score.

OBJECTIVES. To compare the performance of the qSOFA versus SIRS in terms of earlier recognition of sepsis, to determine the sensitivity/specificity of qSOFA and compare with the SIRS criteria, to determine the positive/negative predictive value of qSOFA and compare with the SIRS criteria, and to use the AUROC to identify the overall predicitive accuracy of the qSOFA criteria versus the SIRS criteria.

METHODS. To compare the two, 295 adult patients in the emergency room with suspected infection were included in the study and simultaneously determined their qSOFA score and SIRS criteria. The presence of sepsis was adjudicated by three infectious disease specialists, and outcomes within the first 48 hours were acquired. Sensitivity, specificity, positive predictive and negativepredictive values for qSOFA and SIRS were computed using constructed confusion matrices,and overall predictive accuracy was measured by the AUROC.

RESULTS. The qSOFA score was specific (95.5%) but poorly sensitive (46.3%) test compared to the SIRS criteria (sensitivity 73.7% and specificity 60%). Both qSOFA and the SIRS criteria significantly co-related with sepsis positivity but the qSOFA score had superior overall predictive accuracy at 70.9% compared to the SIRS criteria. The adjudicators had moderate strength in agreement (Fleiss' kappa = 0.39) and a percentage agreement of 60%.

CONCLUSION. Based on our findings, we conclude that the qSOFA score is a more accurate predictor of sepsis, but should not be used as a preliminary sepsis screening tool. We recommend that the SIRS criteria be maintained as a screening tool and to use the qSOFA score simultaneously for timely management.

INTRODUCTION. The obesity paradox in critically ill patients, suggests a survival advantage with increasing body mass index (BMI), while underweight individuals exhibit the greatest risk of mortality, however the physiopathology underling of this phenomenon isn´t clear. The nature of the inflammation caused by obesity it's unique and include inflammatory mediators of immunity innate and adaptive.

OBJECTIVES. To evaluate risk for mortality and clinical outcomes and its correlation with body mass index (BMI) and lymphocytic count in septic patients in a critical care unit.

METHODS. We conducted an observational cohort with critical patients from a single center in an intensive care unit (ICU) in Mexico City, Mexico. Demographic, Clinical, laboratory data was collected for all patients. We estimated the following severity indexes on admission to ICU: sequential organ failure assessment (SOFA) score with acute physiology and chronic health valuation (APACHE) II score, Body Mass index (BMI) and the presence of lymphopenia on admission. Outcomes included mortality and length of stay (LOS) in ICU. Patients with prior therapy with immunosuppressive agents were excluded. less than 18.5 (underweight), 18.5-24.9 (normal weight), 25.0-29.9 (overweight), and 30.0 or more (obesity).

RESULTS. We included 83 patients, 53% male, with mean age 69 (SD±16) years and mean BMI 25.5 (SD ± 5.9) Kg/m^2. Median score for SOFA 5 (RIQ 3 - 9) and APACHE II 18 (RIQ 13 - 23). Proportion of patients with underweight, normal, overweight and obesity were 44.5, 8.4, 25.3 and 21.69%, respectively, lymphopenic 65.1%. Overall mortality 27 %, median LOS 7 (RIQ 4-12) days. BMI strongly correlated with lymphocytic count (r=0.65, p< 0.01) also Non-obese patients were more frequently lymphopenic 92.2 vs 7.8%, (p< 0.01). Obese patients showed lower mortality (4.3 vs. 28.3%, p=0.01) and higher LOS [10 (RIQ 7-14) vs. 7 (RIQ 4 -11) days, p=0.027]. Lymphopenia showed higher mortality (41.2 vs. 6.3% p=0.001). Mortality cases had lower lymphocytic counts [1.2(SD±0.82) vs 0.65 (SD ±0.78), p=0.004] Predictors for mortality were obesity HR = 0.09 (IC95% 0.01 - 74, p=0.025) and Lymphopenia HR = 7.7 (IC95% 1.8 - 33.4, p=0.006).

CONCLUSIONS. Non-obese and lymphopenic ICU patients showed worse outcome in sepsis. Chronic inflammation present in obesity may be protective in this setting, however further research is needed to describe the inflammatory responses with measurement of specific inflammatory mediators.

Comparison of sepsis biomarkers in critical patients upon admission to the emergency room

K. Katabami, M. Hayakawa
Hokkaido University Hospital, Sapporo, Japan
Correspondence: K. Katabami
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1088

OBJECTIVES. Early diagnosis and treatment of sepsis are important; however, sepsis is difficult to diagnose especially in critical situations upon arrival at the emergency room on. This study aimed to investigate sepsis biomarkers in critical patients upon admission and compare their diagnostic values.
METHODS. This was a single-center retrospective observational clinical study conducted on 53 patients admitted to our emergency room and critical care center. Presepsin, procalcitonin (PCT), and interleukin-6 (IL-6) levels were measured upon admission to predict its diagnostic value for sepsis. Receiver operating characteristic (ROC) curve analysis was performed to determine the diagnostic accuracy. The sequential organ failure assessment score was used to quantify the severity of patients' condition. Infections were diagnosed after reviewing the clinical, radiological, and microbiological data. The study was approved by the hospital's ethical committee.
RESULTS. Presepsin levels were significantly higher in sepsis than those in non-sepsis group, with significant differences according to Mann-Whitney test (P< 0.0297). ROC curve analysis and area under curve (AUC) were 0.896 for presepsin and 0.953 for IL-6 when differentiating sepsis from non-sepsis patients. The sepsis diagnostic accuracy of presepsin and IL-6 was higher than that of PCT (AUC, 0.527). The best cut-off values for presepsin and IL-6 were 516 pg/mL and 166.7 pg/mL, which were associated with negative predictive values of 96.4% and 100%, respectively. These biomarkers were not associated with the prognosis.
CONCLUSION. Presepsin and IL-6 levels on admission may contribute to rule out the diagnosis of sepsis in critical patients admitted to the emergency room. Large-scale studies are needed to reveal the importance of these biomarkers in the diagnosis of sepsis.

INTRODUCTION. Limited information exists about the epidemiology, management, and outcomes of severe sepsis in Japanese patients.
OBJECTIVES. To evaluate characteristics, clinical practices, and outcomes for patients with severe sepsis.
METHODS. This is a sepsis sub-study of the Focused Outcomes Research in Emergency Care in Acute Respiratory Distress Syndrome, Sepsis and Trauma (FORECAST) study, a multicenter, prospective cohort study. It was conducted in 59 ICUs from January, 2016 to March, 2017 in Japan. We included adult patients (≥16 years) with severe sepsis based on sepsis-2 criteria.[1]Demographic, physiological, therapeutic, sepsis care, and outcome data were collected. Primary outcome was in-hospital mortality. Secondary outcomes were dispositions after discharge, ICU-free days, ventilator-free days, and length of hospital stay (LOS).
RESULTS. 1,184 patients with severe sepsis admitted to ICUs. The median age was 73 (IQR: 64-81) and 719 (61%) were male. Majority

of patients (676 [57%]) came directly from emergency department. The most common comorbidity was diabetes (272 [23%]). 745 (63%) patients had septic shock. Median APACHE II score and SOFA was 23 (IQR, 19-29) and 9 (IQR, 6-11), respectively. The most common site of infection was lung 367/1,184 (31%), followed by intraabdominal (311 [26%]), and urinary tract (218 [18%]) infection. Rate of blood culture positivity was high (59%). In regard to antibiotics, carbapenem was the most commonly used (627 [53%]), followed by tazobactam/piper-acillin (238 [20%]) and vancomycin (203 [17%]). 413 (35%) patients were used antibiotics before diagnosis of sepsis. 663 (57%) patients received de-escalation of their antibiotics. In regard to adjunctive therapies, steroid (345 [30%]), continuous renal replacement therapy (302 [26%]), and recombinant human soluble thrombomodulin (242 [21%]), antithrombin (231 [20%]), and intravenous immunoglobulin (222 [20%]) were used. Compliance rate for entire 3-hour bundle was 65% (766/1,173), whereas compliance rates for entire 6-hour bundle including or excluding central venous catheter-related were 4% (41/1,164) and 54% (625/1,167), respectively. In-hospital mortality was 269/1,148 (23%). With septic shock, in-hospital mortality was 200/718 (28%). Post-acute mortality (death after 31 days) was 78/458 (17%). Median ICU-free days were 19 (IQR, 11-24), ventilator-free days were 21 (IQR, 0-28), and LOS were 24 (12-46). 323/879 (37%) patients were discharged to home after recovery.

CONCLUSIONS. Sepsis care in Japan characterized by high early use of carbapenem and low compliance rate of 6-hours bundles, especially, central venous catheter related. In-hospital mortality of our study was comparable among developed countries. A steady linear relationship between LOS and in-hospital mortality was seen. Our results may reflect an aging society.

The biological evidence for the use of SOFA score on sepsis definition

R. Costa, R. Salomao, O. Araujo, M. Brunialti
Universidade Federal de São Paulo (UNIFESP), Division of Infectious Diseases, São Paulo, Brazil
Correspondence: R. Costa
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1090

INTRODUCTION. The cytokines storm is essential on sepsis physiopathology and development of tissue damage. Sepsis-3 definitions are based on life-threatening organ dysfunction related to host immune response and results from epidemiological studies, without physiological basis.

Objective. The aim of this study was to evaluate the association between pro and anti-inflammatory cytokines kinetics and sepsis related organ dysfunction through the SOFA score analysis.

METHODS. We included 104 septic patients in this observational, prospective study from 4 brazilian centers. The plasma samples were collected in 3 time-points: ICU admission (D0), seventh (D7), and fourteenth (D14) from sepsis diagnosis. The cytokines IL1-β, IL2, IL6, IL8, IL10, IL17, IL12/23p40, IL 21, TNF, G-CSF, GM-CSF were analyzed by flow cytometry. Sofa score was assessed on ICU admission.

RESULTS. The cytokines were included in a factor analysis model comprising the three measurements and were grouped in 4 factors according to their kinetics over the 3 dosages (D0, D7, D14). Factor 1 (IL 6, IL 8, IL 10, IL 1 β and G-CSF) correlated with SOFA (D0) (p = 0.039), while factor 3 (IL 17 and IL 12 / 23p40) with SOFA (D0), p = 0.003. Factor 4 (IL21) and Factor 2 (IL-2, TNF-α and GM-CSF) did not show any correlation with the SOFA score.

CONCLUSION. There was a correlation between the kinetic of the most relevants cytokines and organ dysfunctions (SOFA score). This result could be the biological explanation for the statistical success of Sepsis-3 criteria.

Red-flag sepsis and SOFA identify different patient populations at risk of sepsis-related deaths on the general wards

M. Kopczynska, B. Sharif, T. Szakmany, Welsh Digital Data Collection Platform
Cardiff University, Anaesthesia, Intensive Care and Pain Medicine, Division of Population Medicine, Cardiff, United Kingdom

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1091

INTRODUCTION. Controversy exists regarding the best clinical diagnostic and screening tool for sepsis outside the ICU. SOFA score has been shown to be superior to SIRS criteria (1). NICE recommends the use of "Red-flag sepsis criteria" however the performance of this tool has not been tested formally (2).

OBJECTIVES. The aim of the study was to investigate the ability of Red-flag sepsis criteria and SOFA based sepsis criteria to identify the patients at high risk of sepsis-related death.

METHODS. Patients were recruited into a 24-hour point-prevalence study on the general wards and emergency departments across all Welsh acute hospitals. Inclusion criteria were: clinical suspicion of infection and NEWS 3 or above in-line with established escalation criteria in Wales. Data on Red-flag sepsis and SOFA criteria was collected together with qSOFA and SIRS scores and 90-day mortality.

RESULTS. 460 patients were recruited over a 24-hour period. 246 were positive for Red-flag sepsis, mortality 26.4% (65/246); 242 for SOFA based sepsis criteria, mortality 32.2% (78/242). Both Red-flag sepsis and SOFA based sepsis criteria were found in 140 patients, mortality 35.7% (50/140). 83 patients were positive for Red-flag sepsis criteria only, mortality 18.1% (15/83) in comparison to 102 patients positive for SOFA based criteria only, mortality 25.5% (26/102). 82 patients did not meet either Red-flag sepsis or SOFA based criteria, mortality 25.6% (22/82). SIRS based sepsis criteria identified 162 patients, mortality 27.2% (44/162) whilst qSOFA based criteria identified 56 patients, mortality 51.8% (29/56). 22/460 (4.7%) patients met every classification criterion at the same time.

CONCLUSIONS. Both Red-flag sepsis and SOFA based criteria identifies patients at high risk of sepsis-related deaths on the general ward. However, both failed to identify a population with similarly high risk of death, who had elevated NEWS and clinical suspicion of infection. Whilst SIRS and qSOFA based criteria were also able to identify at risk populations, their sensitivity was significantly lower. Our data suggest that the sequalae of infection related organ dysfunction cannot be reliably captured based on routine clinical and physiological parameters.

OBJECTIVES. To analyze if there is an association between the initial hyperprocalcitonemia and the development of poor clinical evolution, greater organic dysfunction and the need to enter the ICU in patients activated by the sepsis code (SC).

METHODS. Study of a cohort of patients with initial procalcitonin greater than 0.5 ng / ml activated by SC in our center during the period 2015-2017. We analyzed demographic variables, severity (APACHE II), organic dysfunction (SOFA), procalcitonin (PCT), cytokines (IL-6, TNF-α), admission to the ICU and in-hospital mortality. For the analysis of ICU admission, patients were classified into 5 groups based on PCT quintiles from a PCT cut of 5 ng / ml [PCT Q1 (0.253) -Q2 (2.52) -Q3 (11.45) - Q4 (36.64) -Q5 (235.67)]. The study was authorized by CEIC (PR (AG) 11/2016, PR (AG) 336/2016) and the patients or their representatives signed informed consent. The data have been expressed in the form of "n" (%) if they are categorical and on the average (± SD) if they are quantitative. The comparison of means was made with the Student´s T test.

RESULTS. During the study period, 434 patients activated with SC presented PCT levels greater than 0.5 ng / ml. Characteristics of the study population: 63.82% men, mean age 63.41 (± 16.16), SOFA 8.5 (± 3.0), APACHE II 21.3 (± 7.3), 90.2% septic shock and 9.8% sepsis. The most frequent sepsis focus was abdominal (31.6%) followed by urinary (29.3%) and respiratory (24.2%). PCT levels did not show significant differences depending on hospital mortality or admission to the ICU. PCT was correlated with SOFA (r = 0.177, p < 0.0001), with TNF-α (r = 0.580, p < 0.0001) and with IL-6 (r = 0.454, p < 0.0001). According to the quintile of PCT, the percentage of patients admitted to the ICU was: Q1 4.37%, Q2 20.96%, Q3 45.85%, Q4 75.55%, Q5 96.94%.

CONCLUSIONS. PCT is related to organic dysfunction and the inflammatory response. High initial levels of PCT could be useful for decision making regarding the admission to the ICU of the patient activated by SC.

The frequency and clinical significance of thrombocytopenia complicating sepsis: a meta-analysis

Y. Xie, Z. Zhou, R. Tian, W. Jin, H. Xie, J. Du, R. Wang

Shanghai General Hospital, Shanghai, China

Correspondence: R. Wang

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1093

BACKGROUND. Thrombocytopenia is a common feature of sepsis. This study aimed to perform a meta-analysis of thrombocytopenia *vs* without thrombocytopenia for sepsis to evaluate the incidence and prognostic value of thrombocytopenia.

METHODS. Databases including PubMed, EMBASE, the Cochrane Library, the Science Citation Index, and important meeting abstracts were searched and evaluated by two reviewers independently. The main outcome measures included: mortality, use of mechanical ventilation, Shock, and other complications. A fixed-effects model weighted by the Mantel-Haenszel method was used for pooling the odds ratio (OR) when heterogeneity was not significant among the studies. When a Q test or I^2 statistic indicated substantial heterogeneity, a random-effects model weighted by the DerSimonian-Laird method was used.

RESULTS. Thirteen studies involving 6676 patients were analyzed. There was significant heterogeneity for most results; we analyzed these using a random-effects model. Meta-analysis showed thrombocytopenia caused hihger overall mortality than without thrombocytopenia (OR =3.14, 95% CI: 2.36-4.17, P < 0.00001). Bleeding (OR = 4.44, 95%CI: 2.04-9.69, P = 0.0002), Shock (OR = 2.40, 95% CI: 1.49-3.85, P = 0.0003)and AKI increased (OR = 2.19, 95% CI: 1.77-2.71, P < 0.00001) in thrombocytopenia group. Use of mechanical ventilation (OR = 1.12, 95%CI: 0.93-1.35, P = 0.24) and ARDS (OR = 1.42, 95% CI: 0.96-2.09, P = 0.08) in the thrombocytopenia and without thrombocytopenia group showed no significant different.

CONCLUSION. Thrombocytopenia is associated with poor prognosis, causing more complications than without thrombocytopenia.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1094

INTRODUCTION. The high mortality of sepsis and need for swift treatment demand fast detection of patients with a risk of sepsis progression. Criteria for bedside detection have been derived and primarily validated towards death and prolonged intensive care [1].

OBJECTIVES. To evaluate established risk stratification scores for sepsis, such as quick Sequential Organ Failure Assessment (qSOFA) and National Early Warning Score 2 (NEWS2) towards severe sepsis, infection-related mortality or admission to intensive care and to develop and evaluate a candidate risk stratification score based on vital parameters and heparin-binding protein plasma levels (HBP) [2].

METHODS. Retrospective analysis of two prospective, observational, multicentre, convenience trials of sepsis biomarkers at emergency departments. A candidate risk stratification tool was constructed in a derivation cohort, using the least absolute shrinkage and selector operator (LASSO) method. Accuracy of evaluated risk stratification scores was evaluated in a validation cohort, compared to a composite of severe sepsis, infection-related mortality within 72h or admission to intensive care.

RESULTS. 506 patients were included in the derivation cohort and 435 patients, were included in the analysis (figure). qSOFA had lower AUC than in studies with in-hospital mortality as outcome (table 1) [1]. NEWS2 had significantly higher AUC than qSOFA, p =0.02. Addition of HBP analysis augmented the AUC for NEWS2 and the AUC for qSOFA, although not significantly.

A new screening score (table 2) with HBP levels had the highest AUC and differed significantly from the AUC of qSOFA p < 0.01.

CONCLUSIONS. qSOFA is a parsimonious screening score for sepsis, but was inadequate in patients at emergency departments for predicting severe sepsis, infection-related mortality or admission to intensive care. NEWS2 performed better, but is more extensive. The addition of HBP levels to qSOFA seems to increase its performance without renounce of simplicity.

With a new risk stratification score that includes HBP levels, severe sepsis, infection-related mortality or admission to intensive care were successfully predicted at emergency departments. The new score was signifikant better than qSOFA.

Biomarkers of infection versus systemic inflammation in burn patients

N. Valero[1], A. García de Lorenzo[2], R. Galeiras[3], M. Ugalde[4], S. López[1], L. Oteiza[1], J.A. Lorente[1,5,6]
[1]Hospital Universitario de Getafe, UCI, Getafe, Spain; [2]Hospital La Paz, UCI, Madrid, Spain; [3]Complejo Hospitalario de A Coruña, UCI, A Coruña, Spain; [4]Hospital Universitario de Cruces, UCI, Barakaldo, Spain; [5]Universidad Europea, Getafe, Spain; [6]CIBER de Enfermedades Respiratorias (CIBERES), Getafe, Spain
Correspondence: N. Valero
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1095

INTRODUCTION. Burn patients develop a systemic inflammatory response and have a high risk of infections due to burn-induced immunosuppression. Both the intensity of the systemic inflammatory response and the incidence of infections are associated with an increase in mortality. Biomarkers can be beneficial tools in clinical practice for the differential diagnosis between the systemic inflammatory response after injury and infection.
OBJECTIVES. To assess whether serum concentration of soluble triggering receptor on myeloid cells-1 (sTREM-1), C-reactive protein (CRP), procalcitonin (PCT), platelet blood count (PLT), and the sequential organ failure assessment (SOFA) score are of value for the diagnosis of infection in burn patients.
METHODS. A prospective multicenter observational study of consecutive patients admitted to four Burn Intensive Care Units(April 2010-May 2014) was conducted. Inclusion criteria: age >18 years, total body surface area burned (TBSA) >20% or full thickness body surface area burned (FTBSA) > 10%, expected ICU stay >3 days. Exclusion criteria: neutropenia < 500/mcl, immunosuppressive treatment, diagnosis of AIDS. Age, gender, TBSA, FTBSA, inhalation injury, requirement of mechanical ventilation, duration of mechanical ventilation, survival and length of ICU stay were recorded. Variables for SOFA calculation) and serum concentration of sTREM-1, CRP, PCT, and PLT were recorded every 3 days. Microbiological cultures and antibiotic treatment were ordered according to clinical criteria. Patients were classified into one of the following condition: No SIRS (if it does not meet SIRS criteria), SIRS without infection (meets SIRS criteria and no cultures have been obtained or are negative) and Sepsis (meets criteria for SIRS with positive cultures). The comparison of the diagnostic performance of the different markers between Sepsis and SIRS without infection was assessed by comparing the areas under the ROC curve. Statistical analysis was performed with SPSS version 20 statistical software. The study was approved by the Ethics and Clinical Research Committee of the participating hospitals.
RESULTS. The total number of patients included was 115. CRP, sTREM-1, PLT and SOFA (p < 0.001) as well as PCT (p = 0.018) differed between SIRS without infection and Sepsis. The areas under the ROC curve (95% CI) for the diagnosis of Sepsis for the different biomarkers were PCR 0.73 (0.66-0.81); PCT 0.75 (0.68-0.81); sTREM-1 0.69 (0.61-0.76); PLT 0.60 (0.53-0.68); SOFA 0.72 (0.66-0.79). Although the discriminative capacity was higher for CRP, procalcitonin and SOFA, differences did not reach statistical significance (the confidence intervals overlapped each other).
CONCLUSIONS. All markers studied were different in patients with Sepsis as compared to patients with SIRS without infection. However, their discriminative capacity was not significantly different from each other.

1096

Evolution in the identification and early treatment of critically ill septic patients at the emergency department of a Spanish tertiary hospital

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1096

INTRODUCTION. In 2005 the EDUSEPSIS Campaign was carried out in Spanish hospitals and in 2015 a protocol was implemented for the

detection and early treatment of sepsis in the emergency department (ED). There is controversy about whether early treatment improves outcomes.

OBJECTIVES. To compare the evolution of critically ill patients with sepsis (all of them finally requiring admission to an intensive care unit (ICU)) in two different periods at the same ED; a first period during the surviving sepsis campaign implementation (2005-2007) and a second period (2015-2017) with a specific early identification and management protocol.

METHODS. Retrospective observational study that evaluates at two different historical periods in septic patients requiring ICU admission the following; initial 3 hour bundle (lactate, cultures, and antibiotics) completion, correct fluid administration (30 mL/kg) within the first 6 hours in those patients who presented hypotension (SBP< 90 mmHg or MBP< 65 mmHg), and final outcome.

RESULTS. We collected 83 and 85 patients who presented sepsis at the ED and finally required ICU admission during 2005-2007 and 2015-2017 respectively. Differences between both groups (2005-2007 and 2015-2017) were: median age was 67 (53,76) and 65 (55,74), median SOFA score was 9 (5,11) and 10 (8,12), median time from the onset of sepsis to ICU admission was 3600 (1100, 12000) minutes (min) and 504 (245, 1500) min respectively (p=0.0001). Lactate determination and cultures (before antibiotics) within the first 3 hours from ED admission were performed in 10.7% and 69% of patients respectively in 2005-2007 period, compared to 71.7% and 53.7% of patients in 2015-2017 period (p=0.0001, p=0.08). Early antibiotic within the first hour of ED admission was administered in 47.1% patients (2005-2007) and 32.5% (2015-2017) (p=0.28). The complete bundle (3 measures) was completed in 6% (2005-2007) and 83.5% (2015-2017) (p=0.0001) of patients, with a mean time of 275±55 min vs 1050±4000 min. Correct fluid resuscitation with crystalloids (30mL/kg within the first 6 hours) in patients with hypotension (75% in both groups) was carried out in 51.7% of patients (2005-2007) and in 67.9% (2015-2017) (p=0.09). The requirement of vasoactive drugs was 66.3% (2005-2007) and 58.8% (2015-2017). Mortality during hospital admission, 28 days after admission, and 90 days after admission was 45.8%, 42.2%, 65.1% respectively (2005-2007), compared to 29.4%, 23.5%, and 31.8% (2015-2017) (p=0.04, p=0.01, and p=0.001). Overall mortality was 69.9% (2005-2007) compared to 32.9% (2015-2017) (p< 0.0001).

CONCLUSIONS. The implementation of a protocol in the emergency department for the detection and early treatment of sepsis may reduce mortality in those patients who finally require ICU admission.

1097

Sepsis-3 diagnostic criteria as a tool to predict hospital mortality in critically-ill patients: a validation study in developing country

P. Wacharasint[1], Y. Wittayawisawasakul[1], K. Aramsaowapak[2]
[1]Phramongkutklao Hospital, Department of Medicine, Bangkok, Thailand; [2]Fort Suranaree Hospital, Department of Medicine, Nakhon Ratchasima, Thailand
Correspondence: P. Wacharasint
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1097

INTRODUCTION. The European and American Society of Intensive Care Medicine recently redefined new concept of sepsis, or so-called "sepsis-3". New diagnostic criteria, quick sepsis-related organ failure assessment (qSOFA), was purposed to achieve better prediction of hospital mortality than systemic inflammatory response syndrome (SIRS) criteria in critically ill patients.[1] However, these criteria have not been validated in developing country where critical care resources are limited and the burden of mortality may be differed from developed countries.[2]

OBJECTIVE. To validate whether qSOFA better predict in-hospital mortality than previous criteria [i.e. SIRS, sepsis-related organ failure assessment (SOFA), and Acute physiology and Chronic Health Evaluation (APACHE) II scores] among critically-ill patients with sepsis and was admitted to medical intensive care unit (ICU) in Thailand.

METHODS. We performed a prospective observational study in patients with suspected infection with at least one organ dysfunction, and was admitted to the ICU of Phramongkutklao

hospital (University-based hospital) or Fort Suranaree hospital (non-University-based hospital) during July 2017 to December 2017. The primary outcome was difference in area under the ROC curves (AUROC) which predict hospital mortality compared among SIRS, SOFA, qSOFA, and APACHE II scores.

RESULTS. A total of 101 patients were included in this analysis. Average age of the patients was 71.3±14.5 years old, most common underlying disease was hypertension (66.3%), and most common source of infection was respiratory tract (47.5%). Average hospital LOS, and ICU LOS were 23 and 10 days, respectively. There were forty-one non-survivors (40.6%). In terms of prediction of hospital mortality, we found that SIRS (>2 points), SOFA (>8 points), qSOFA (>2 points), and APACHE II (>22 points) score had 78%, 88%, 61%, and 78% for sensitivity; 35%, 55%, 77%, 68% for specificity, and 0.59, 0.74, 0.68, 0.78 for AUROC, respectively (differences in AUROC between-group: SIRS vs. SOFA, p=0.016; SIRS vs. APACHE II, p< 0.001; and qSOFA vs. APACHE II, p=0.045). No difference of AUROC between SOFA and APACHE II (p=0.49).

CONCLUSIONS. Patients with sepsis and was admitted to medical ICU in Thailand, an increase in SOFA score (>8 points) or APACHE II (>22 points) had greater prognostic accuracy to predict hospital mortality than SIRS and qSOFA criteria. Our findings were aligned to previous study in developed countries which suggested that qSOFA criteria have limited power to predict hospital mortality in the ICU setting.[1]

Does peripheral circulating blood flow correlate with the quick SOFA score in emergency room patients?

INTRODUCTION. The quick Sequential Organ Failure Assessment (qSOFA) score was created as a screening tool for life-threatening organ dysfunction due to a dysregulated host response to infection outside the ICU. One cause of organ dysfunction in critically ill patients is thought to be peripheral circulatory failure. Laser Doppler flowmetry (LDF) is an easy way to assess the peripheral circulation and may have potential as a screening tool in patients with organ dysfunction; however, the relationship between the qSOFA score and circulatory failure has not been studied. We hypothesized that quantitative evaluation of the peripheral circulation correlates with the qSOFA score.

OBJECTIVES. To compare peripheral circulating blood flow and the qSOFA score in emergency room (ER) patients.

METHODS. The study included 42 ER patients. Peripheral circulating blood flow was measured for 3 min using LDF (Pocket LDF; JMS, Tokyo, Japan) and the average value over the last minute was used in the final analysis. The qSOFA score was determined using the Glasgow Coma Scale, respiration rate, and systolic blood pressure.

RESULTS. The median (range) blood flow measured by LDF was 36.4 ml/min (3.9-68.5), and the median qSOFA score was 1 (0-3). There was no correlation between LDF and qSOFA score (R^2= 0.06).We evaluated only those patients with a positive qSOFA score $\geq$ 2 (n=10), but there was no correlation between LDF and the qSOFA score (R^2= 0.05).

DISCUSSION. Decreased peripheral circulating blood flow is one cause of organ damage in septic patients, and the qSOFA score is

used to predict mortality in septic patients; however, we did not demonstrate a correlation between peripheral circulating blood flow, as measured by LDF, and the qSOFA score in ER patients. One of the reasons for the lack of correlation is that the peripheral circulation may not have a linear regression to the severity of organ damage, such as peripheral circulation in warm and cold shock. Another reason for the lack of correlation is that the study subjects included patients without sepsis, and the qSOFA may not have represented the severity of organ damage in such patients. To verify the peripheral circulation as a screening tool for organ dysfunction, a further study comparing the peripheral circulation measured in the ER and the development of organ dysfunction is warranted.
CONCLUSIONS. Peripheral circulating blood flow does not correlate with the qSOFA score in ER patients.

Patient ventilator interaction

1099
Prevalence of reverse triggering early after intubation

INTRODUCTION. Reverse triggering (RT) is a recently described type of patient-ventilator interaction where respiratory muscle contractions seem to be triggered by the ventilator. The aim of this study was to calculate the prevalence of RT early after initiation of mechanical ventilation using an automated detection.
OBJECTIVES. To determine the prevalence of RT early after intubation and describe parameters that are associated with it.
METHODS. This is a substudy of an observational trial (NCT02434016) to detect resumption of diaphragm activity after intubation with continuous electrical activity (Eadi) recording. A total of 75 patients were enrolled. A daily one hour recording of Eadi and ventilator waveforms was available for each patient.
1- Automatic detection algorithm: 3 reviewers assessed 2010 breaths in assist/control mode to derive an automatic method to detect RT with the use of Neurosync (Toronto, Canada). These breaths came from 10 patients in assist-control mode. Then the model was tested in 10 patients ventilated in pressure support and the algorithm was refined to reduce the rate of false positive and the results of the final algorithm in these 20 patients are presented. For the derivation of the algorithm, RT was considered only when agreement among all three reviewers was found. Inter-rater agreement by means of Fleiss kappa index was calculated.
2- After a suitable algorithm was identified, we analyzed a 1-hour strip (average breaths per patient 1787, SD 563) recorded for the 37 patients in assist/control mode after a median of 24 hours (IQR 22-26) after intubation.
For analysis of demographic data and ventilation parameters we split the cohort in two groups; one above the median RT and the other below or equal to the median RT.
RESULTS. Inter-rater agreement was 0.84. For Neurosync, the results for RT detection were: sensitivity 0.84, specificity 0.96, positive predictive value 0.75 and negative predictive value 0.98. The rate of patient-triggered breaths being misclassified as RT was 2%.2- The 37 patients were 60 ±13 years old, had a median APACHE of 25 (IQR 19-30) and 65% had a primary pulmonary reason for intubation. Median RT was 9% (IQR 5-32). For comparison between groups, see tables.

CONCLUSIONS. RT detected on Eadi is common after intubation. No differences in demographic data, sedation score, reason for intubation or ventilation parameters were apparent between groups. However, patients with more RT were more likely to be on an assisted mode or extubated the day after.

INTRODUCTION. Asynchronies are frequent during invasive mechanical ventilation (MV). Clinical management, as adjusting mechanical ventilator settings, affects patient-ventilator asynchronies. Adequate analgesia with slight sedation might enable more spontaneous breathing activity and might result in clinical advantages, such as improved patient-ventilator interaction. The effect of sedation, analgesia and level of consciousness is poorly understood.
OBJECTIVES. To analyze the association between patient-ventilator asynchronies, the treatment with sedatives and opioids, alone or combined, and its doses,the level of consciousness and the clinical severity.
METHODS. Multicenter prospective observational trial (4 ICUs) in patients undergoing invasive MV $\geq$ 24h. Do-not-resuscitate orders, admitted for organ donation, pregnancy and broncho-pleural fistula were exclusion criteria. Ventilator waveforms (flow, volume and pressure) were continuously recorded, stored and analyzed using dedicated software (BetterCare®, Spain). The software identified ineffective inspiratory efforts during expiration (IEE), double cycling (DC) and calculated the asynchrony index (AI). We registered the level of consciousness, severity, doses of sedation (midazolam, propofol, lorazepam), and opioids (morphine and fentanyl) which were reported as equipotent of morphine and midazolam. Linear mixed-effects models were used to analyze the relationships between variables.
RESULTS. We recorded 579 days of ventilatory support (14,166,469 breaths) in 79 patients. The overall AI, IEE and DC were similar in the sedation-only, opioids-only and sedation+opioids group. The no drugs group presented higher AI, IEE and DC than others. The mean level of consciousness (per day) in patients treated with opioids alone [3.13 (95%CI:2.84, 3.42)] was higher than in patients treated with sedation + opioids [2.44 (95%CI:2.22, 2.65); p< 0.001]. The dose of opioids was inversely associated with the AI, IEE, and DC (p< 0.01), but not with the level of consciousness.
CONCLUSIONS. Higher doses of opioids reduced asynchronies without lowering the level of consciousness. The combined use of sedatives plus opioids does not result in better patient-ventilator interaction than opioids alone. Adequate pain control can help improve patient-ventilator interaction and avoid the deleterious effects of sedation.

INTRODUCTION. During Neurally Adjusted Ventilatory Assist (NAVA), as NAVA support level (GAIN - cmH$_2$O/µVolt) increases, the electrical activity of the diaphragm (EAdi - µVolt) decreases, resulting in a constant tidal volume (Vt). In transplanted lungs (LTx), the neuro-mechanical coupling could be compromised beacuse of the absence of vagal innervation. Nevertheless, a protective ventilation is mandatory to reduce ventilator induced lung injury and the risk of primary graft dysfunction.
OBJECTIVES. To assess the EAdi variation to varying of NAVA GAIN and positive end expiratory pressure (PEEP) levels in the early post-operative period of LTx.
METHODS AND RESULTS. Four intubated (two males, median age 58 years old, IQR 49-60) and spontaneously breathing patients were admitted to Intensive Care Unit of ospedale Maggiore Policlinico di Milano (Italy), for post-operative monitoring of LTx. Sedation was titrated to obtain a Richmond Agitation Sedation Scale between 0 and -2. Through "NAVA preview" function, the "Baseline GAIN" level was chosen to obtain a Vt 6 ±2 mL/Kg/predicted body weight of the donor. The patients underwent to a random sequence of six steps, randomly mixing three NAVA gain levels (Baseline gain, 50% Baseline gain, 150% Baseline gain) and two PEEP levels (6 and 12 cmH$_2$O).
CONCLUSIONS. Preliminary data about the application of NAVA during the early post-operative period after LTx, showed that increasing NAVA support reduced the EAdi Peak. Nevertheless, the neuro-mechanical coupling might be partially impaired since the resulting mean Vt was not constant and tended to increase with the level of GAIN. Finally, double PEEP level was associated with slight increase in EAdi Peak and consequently in the mean Vt

Fig. 2 (abstract 1101). Ventilatory parameters and arterial blood gas values

with breaths delivered by MV, iatrogenic positive pressure may be reduced. (Reynolds et al., 2017).

OBJECTIVES. Due to the proximity of the pacing catheter to the vagus nerve, inadvertent stimulation is a likely side-effect of phrenic nerve pacing. As the sinoatrial node is primary vagus nerve target, study objectives include determining any changes in mean heart rate resulting from phrenic nerve pacing therapy.

METHODS. This is a pre-clinical, randomized, semi-blinded study in which a pig model is mechanically ventilated for 50 hours in a mock ICU environment. Control subjects undergo MV with no pacing therapy, while experimental subjects undergoing MV and adjunct pacing therapy receive regular bursts of current to both phrenic nerves on every second breath. Subject heart rate was recorded from an arterial line pressure transducer at 15-minute intervals throughout the duration of the study.

RESULTS. Results from within-subjects t-test reveal no significant difference in heart rate during paced breaths versus unpaced breaths in experimental subjects (p= 0.76). Conversely, between-subject t-test results indicate significant increase in heart rate in unpaced beats of experimental subjects compared to control subjects (p< 0.01), as well as between paced heart rate in experimental subjects versus heart rate of control subjects (p< 0.01).

CONCLUSIONS. Within-subject results illustrate the absence of significant changes in heart rate resulting from phrenic nerve pacing. As such, results of this study provide evidence supporting safe and efficacious use of this therapy in patients where hemodynamic instability is a concern. Between-subject results do not provide evidence for inadvertent vagus stimulation caused by phrenic nerve pacing causing a global change on heart rate.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1102

INTRODUCTION. During normal breathing, contraction of the respiratory muscles and diaphragm serve to create negative pressure inside the chest facilitating the passive flow of air into the lungs. In contrast, during mechanical ventilation (MV), the ventilator pushes a pre-determined pressure or volume of air into the lungs using positive pressure. As such, patients who undergo MV for prolonged periods of time are at risk for the development of ventilator-induced lung injury (VILI), as well as ventilator-induced diaphragmatic dysfunction (VIDD) (Slutsky et al., 2013).

A novel transvenous electrical pacing catheter that recruits the phrenic nerve bilaterally aims to mitigate the development of VIDD and VILI. By stimulating diaphragmatic contractions in synchrony

INTRODUCTION. Dead space ventilation is associated with ventilatory efficiency. Increased dead space fraction (V_D/V_T) is a negative prognostic factor in subgroups of ICU patients.

In chronic cardiac and pulmonary disease, however, another parameter of ventilatory efficiency, VE/VCO$_2$, has been recognized as a negative prognostic sign. Two alternatives are in use: VE/VCO$_2$-slope and the lowest VE/VCO$_2$-ratio, both measured during exercise.

In many ICUs, active mobilization of ventilated patients is commenced early. Using metabolic monitoring, parameters of ventilatory efficiency during exercise are readily obtained.

OBJECTIVES. To compare VE/VCO$_2$-slope and lowest VE/VCO$_2$-ratio, both during exercise, and V_D/V_T in rest, in their ability to separate critically ill patients from healthy volunteers.

METHODS. Intubated patients recovering from critical illness were submitted to an incremental resistance protocol on a bedside cycle ergometer (MOTOmed Letto2) as soon as they regained the ability to actively exercise (1).

After a period of rest, active cycling was started at resistance level one, which was increased by one level every minute until a stop criterion was reached.

Before, during and after exercise, heart rate, respiratory rate, tidal volume, VO$_2$ and VCO$_2$ were noninvasively monitored using indirect calorimetry (Cosmed Quark RMR), placed in the ventilatory circuit. Parameters of ventilatory efficiency were calculated offline.

Fractional dead space was calculated from VE/VCO$_2$ and P$_a$CO$_2$ by the equation:

$$\text{VE/VCO}_2 = 115/(P_aCO_2 \times (1 - V_D/V_T)).$$

Healthy volunteers aged > 50 years were subjected to the same protocol, using a face mask. A $V_{D,app}$ of 125 ml was used to correct V_D.

RESULTS. The protocol was completed by 14 patients and 11 volunteers. All patients were on a spontaneous ventilation mode. No adverse events occurred.

During exercise, the average VCO$_2$ in patients increased from 250.9 ml/min to 330.4 ml/min (p = 0.000).

VE/VCO$_2$-slope was 37.7 (± 13.3) for patients and 26.5 (± 4.2) for volunteers (Fig A).

Lowest VE/VCO$_2$-ratio was 44.1 (± 8.4) for patients and 30.3 (± 2.7) for volunteers (Fig B).

Resting P$_a$CO$_2$ was 5.6 (± 0.89) kPa for patients and 5.1 (± 0.28) kPa for volunteers (Fig C).

V_D/V_T-ratio was 0.53 (± 0.12) for patients and 0.20 (± 0.04) for volunteers (Fig D).

CONCLUSIONS. Fractional dead space performed best in separating spontaneously ventilated ICU patients from healthy volunteers.

P$_a$CO$_2$ in the patient cohort showed large variation, which may have an important influence on VE/VCO$_2$.

In patients recovering from critical illness, VE/VCO$_2$-slope and VE/VCO$_2$-ratio should be considered invalid parameters to represent ventilatory efficiency.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1104

INTRODUCTION. Evaluation of patient/ventilator synchronization is currently performed by direct visual analysis of ventilator´s curves at the patient´s bed side or by invasive methods like esophageal pressure. Curvex is a non-invasive tool based on these studies which allow to quantify and qualify asynchronies [1].

OBJECTIVES. The main purpose of this study was to assess where automated evaluation of patient/ventilator asynchronies was feasible and efficient.

METHODS. This project is based on a prospective physiological tracing data-warehousing program (Rea STOC, clinicaltrials.gov

#NCT02893462) that aims to record 1500 consecutive ICU patients, over a 3-years period. This study was approved by the local ethical committee of Brest university hospital - France.

All patients in ICU with mechanical ventilation (invasive or NIV) could be included. We realized a first analyze during 1 or 2 hours without changing ventilator´s settings. Then we looked curvex´s results: asynchrony index, number and type of asynchrony, correlation between curvex´s interpretation and direct analysis of ventilator´s curves at patient´s bed side. If there were asynchronies we modified ventilator´s settings in function of asynchrony type with a standardized protocol and we recorded another session, else we not performed another session. The main criteria was the diminution of the asynchrony index (AI) between the two sessions.

RESULTS. Between February 2017 and April 2018, 90 patients were included (age 61.6 ± 12.9 yr; 67 males / 23 females; SAPS II 53.2 ± 19.2). 84/90 patients had invasive mechanical ventilation. Main admission diagnosis were acute respiratory failure (49%), neurological failure (21%), shock (13%), cardiac arrest (12%), and ARDS (4%). AI was high in most patients with only 12.2% with AI< 10%. Correlation between visual and automatic detection was 82.2%. Main asynchrony type was ineffective effort (44 ± 3%), premature cycling (25 ± 3%), short cycle (14 ± 2%), double triggering (9 ± 1%), and prolonged inspiration (5 ± 1).

No correlation was observed between either the AI or the overall asynchrony number and mean ICU, hospital stay, or outcome. Correction measures were performed for 65 patients, according to a standardized protocol. However, no significant differences were observed after ventilatory settings modifications (p=0.76), whatever the asynchrony type.

CONCLUSIONS. A high level of asynchronies was observed over our ICU population. Automated evaluation of asynchronies was well correlated with direct visual observation of ventilator curves. However, we were not able to reduce asynchronies between the first and second analysis.

Intensive Care Medicine Experimental 2018, **6(Suppl 2)**:1105

INTRODUCTION. Experimental data show that the patient-ventilator breath contribution (PVBC) index can be used to estimate the relative contribution of the patient's inspiratory muscles versus that of the ventilator, during partially supported modes of ventilation.[1,2] PVBC can be estimated using the ratio of inspiratory tidal volume (Vt_{insp}) to peak electrical activity of the diaphragm (Edi_{peak}). If reliable in clinical practice, PVBC could help to titrate ventilator support such that the risks of both excessive support and high respiratory muscle effort can be reduced.

OBJECTIVES. To evaluate test-retest agreement of the PVBC index in clinical practice.

METHODS. This observational study was conducted in a heterogeneous group of ICU patients (n=31) ventilated in neurally adjusted ventilatory assist (NAVA) mode. PVBC repeatability coefficient (RC) was calculated using five repeated intra-subject PVBC measurements with a one-minute interval.

PVBC was measured as $(Vt_{insp}/Edi_{peak})_{no-assist}/(Vt_{insp}/Edi_{peak})_{assist}$. Unassisted breaths were obtained by reducing the NAVA level to zero. A PVBC index of 1.0 thus suggests that Vt_{insp} is fully generated by the patient. $(Vt_{insp}/Edi_{peak})_{assist}$ was calculated by using either Vt_{insp} and Edi_{peak} of one breath just prior to the unassisted breath (^{N1}PVBC), or mean Vt_{insp} and Edi_{peak} of five breaths prior to the unassisted breath (^{X5}PVBC). Thirdly, PVBC was computed as $Vt_{insp,no-assist}/$mean$(Vt_{insp})_{assist}$ by selecting those assisted breaths that matched respiratory drive of the unassisted breath, based on Edi-derived criteria (PVBCβ). At last, PVBC indices were squared (^{N1}PVBC^2, ^{X5}PVBC^2 and PVBCβ^2) as previous studies showed that this led to better agreement with inspiratory pressure measurements.[1]

RESULTS. Median ^{N1}PVBC was 0.80 [0.48-0.99]. RC of PVBC as calculated by the different methods is shown in Table 1. Estimating PVBC using assisted and unassisted breaths with matching respiratory drive resulted in the best test-retest agreement (RC PVBCβ: 25.2%). This implies that if a PVBC of 0.6 is measured in a patient, it is expected with a probability of 95% that the subsequent measured PVBC will be between 0.6 and 1.0.

As the SERVO-i ventilator always provides some inspiratory support, even at a NAVA level of zero, there might be a slight overestimation of the fraction Vt_{insp} that is generated by the patient, especially in those patients ventilated with low levels of support.

CONCLUSIONS. This study shows that the PVBC index exhibits moderate intra-subject variability in a heterogeneous cohort of ICU patients. Additional analyses will be performed to gain insight in the remaining variability. We believe that PVBC might be a potentially valuable index for bedside monitoring and titrating the patient's contribution to total mechanical inspiratory effort.

Fig. 1 (abstract 1105). Parameters used in PVBC calculation

the mean ratios of $P_{mus}:\Delta P_{occ}$ and $\Delta P_{es}:\Delta P_{occ}$ (termed K_1 and K_2, respectively) were computed in recordings from 10 randomly selected patients. Step 2: in the remaining patients, P_{mus} and ΔP_L were predicted in each recording from three measurements of ΔP_{occ} selected at random from the same recording. Predicted P_{mus} was estimated as $\Delta P_{occ}*K_1$; predicted ΔP_{es} was estimated as $\Delta P_{occ}*K_2$; predicted ΔP_L was estimated as the inspiratory pressure (peak pressure - PEEP) - predicted ΔP_{es}. Predictive accuracy was assessed by Bland-Altman analysis. Discriminative accuracy to detect threshold values for P_{mus} and ΔP_L was quantified. The cross-validation procedure (Steps 1 and 2) was repeated 100 times to estimate confidence intervals.

RESULTS. 82 daily recordings were collected from 20 patients. P_{mus} and ΔP_L were frequently excessive (P_{mus} median 14 cm H_2O, IQR 9-21 cm H_2O; ΔP_L median 17 cm H_2O, IQR 12-21 cm H_2O). K_1 was -0.70 (95% CI -0.65, -0.77); K_2 was 0.60 (0.56-0.63). Agreement between predicted and observed P_{mus} and ΔP_L was moderate (**Table**). Predicted P_{mus} and predicted ΔP_L accurately detected excessive respiratory effort and excessive dynamic lung stress across different thresholds (**Table**, **Figure**).

CONCLUSIONS. Respiratory effort and dynamic lung stress are often significantly elevated during assisted ventilation. Predicted P_{mus} and ΔP_L are not sufficiently accurate to replace direct monitoring but measuring ΔP_{occ} enables accurate non-invasive detection of excessive respiratory effort and dynamic lung stress (analogous to driving pressure in controlled ventilation). Routine measurement of ΔP_{occ} could be used to determine the need for more intensive monitoring or for adjustments to ventilation.

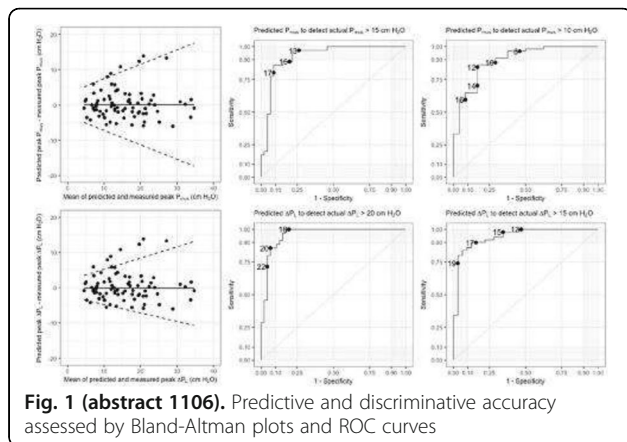
INTRODUCTION. Excessive respiratory effort during mechanical ventilation can injure the lung/diaphragm. Respiratory effort is not routinely monitored in the ICU.

OBJECTIVES. To determine whether the negative airway pressure deflection resulting from inspiratory effort during an end-expiratory occlusion (ΔP_{occ}) can detect excessive respiratory effort and dynamic lung stress in spontaneously breathing patients.


METHODS. Spontaneously breathing patients intubated for ≤36 hours were studied. Esophageal pressure (ΔP_{es}), peak inspiratory muscle pressure (i.e., effort or P_{mus}), and transpulmonary driving pressure (i.e., dynamic lung stress or ΔP_L) were recorded for 10 minutes daily. During each recording, 15-20 brief end-expiratory occlusions were applied to measure ΔP_{occ}. A method for predicting ΔP_L and P_{mus} from ΔP_{occ} was derived and validated by cross-validation. Step 1:

Table 1 (abstract 1106). Accuracy of predicted Pmus and ΔPL

	Measurement	Estimate (95% confidence intervals)
Predicted vs. measured Pmus	Bias	0.1 (-0.1, 0.3) cm H2O
	Limits of agreement (% of estimated value)	48% (33%, 59%)
Predicted vs. measured ΔPL	Bias	-0.2 (-0.3, 0.0) cm H2O
	Limits of agreement (% of estimated value)	33% (23%, 39%)
Discriminative accuracy (Area under ROC curve)	Measured Pmus > 10 cm H2O	0.90 (0.82, 0.87)
	Measured Pmus > 15 cm H2O	0.90 (0.83, 0.99)
	Measured ΔPL > 15 cm H2O	0.91 (0.84, 0.99)
	Measured ΔPL > 20 cm H2O	0.94 (0.87, 0.99)

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1107

INTRODUCTION. The Flow-Volume (FV) Loop has been used to identify the presence of secretions and Auto-PEEP during controlled ventilation. We have found FV Loop phenotypes that can be useful to discriminate different types of asynchronies during pressure support ventilation (PSV).

OBJECTIVES. Assess the efficiency of the FV Loop to identify asynchronies and to describe the different phenotypes during PSV.

METHODS. Prospectively collected data from January-2015 in 76 patients during PSV at different levels of assistance. We recorded the flow signals (V´), airway pressure (Paw), esophageal pressure (Pes) at 560 Hz during 30 min. FV Loop represented as usual. Demographics data was recording. The identification of the different phenotypes related to the different asynchronies were evaluated by visual examination. Each finding was considered positive. The results are expressed as mean±SD, median (IRQ), or percentage.

RESULTS. 44 patients had presented asincronies (57.9%). Age: 58.62±12.1 y. Male 44.2%. APACHE II: 19.92±5.9. PaO2/FiO2 277.78±112.7. Death 44.2%. Main diagnosis: Pneumoniae. Lung Transplantation. Trauma. A total of 80 asynchronies were identified (1.82/patient): Reverse Triggering (RT) 23, Failure of Cycling (ineffective efforts) 15, Inspiratory delay 12, Expiratory Delay 10, Autocycling 9, Double cycling 7, Early closure of Inspiration 3, and Double Cycle Failure 1.

RT was considered neural cycle induced by mechanical insufflation. Arrows blue (begin of reverse cycle) and red (end) in figure 3 (R1 to R12). Occasionally with Double cycling (black arrow).

Failure of cycling occurs usually at the end of expiration (red arrow), but occasionally not so late (blue arrows) and rarely occurs in both expiration and inspiration (black arrows). B1-B6 in figure1.

Delay of inspiration (blue arrow in figure 2) and expiration (red arrow) occurs when the neural cycle precedes more than 200 msec. to the mechanical time. In D2 panel (Pes vs V loop in black) the same arrows point delayed phases.

In Autocycling the inspiratory and expiratory phase of the FV Loop are identical mirror images (Figure 1A).

In the early closure of the inspiratory phase of the ventilator cycle, a notch appears in the early expiratory phase of the FV Loop that coincides with the neural end of the inspiration (red arrows in figure 1C1-C2) giving origin double cycling (black arrow) in figure 1C3.

The different phenotypes of FV Loop for each asinchrony are shown for the arrows in figures 1-3. Although the findings are not pathognomonic or specific, they are sufficiently suggestive to warn of the existence of asynchrony in PSV.

CONCLUSIONS. In our patients with asynchronies during PSV, the index of severity and mortality are high; we could speculate whether the asynchrony may be considered a marker of poor prognosis. The analysis of the morphology of FV Loop is very efficient and useful for detecting asynchronies even as complex as Autocycling followed by RT with Double cycled.

INTRODUCTION. Patient-ventilator asynchrony and, recently, clusters of them, have been associated with adverse physiological and clinical outcomes (1-4) in critically ill patients undergoing mechanical ventilation (MV). Optimizing patient-ventilator interaction to both, support the patient's ventilatory demand and to minimize the mismatch between the patient's breathing and the ventilator (1,5) is paramount in intensive care units (ICU).

OBJECTIVES. To develop a predictive model based on discrete-time series data useful to anticipate/alert the likelihood of occurrence of asynchronies in MV patients.

METHODS. We studied retrospective data of 51 critically ill patients underwent MV>24h in two ICUs. Patients were continuously monitored by Better Care® system (6). Most common asynchronies were identified and regularly indexed over time each 15 minutes. Four level of alerts, from the lowest (z_1) to the highest (z_4), based on the total count of asynchronies, were defined. A Poisson hidden Markov model was used to predict the probability of occurrence of each level of asynchronies at the next period. The model was trained on a subset of randomly patients and subsequently tested on the remaining ones.

RESULTS. A total of 12.7 million breaths were analyzed. On average, 52% of 15 min. periods corresponded to state z_1, 28% to z_2, 14% to z_3 and 6% to z_4. Thus, long periods without any asynchronous events were more likely than periods with high level of alert corresponding to a 52.8% of asynchrony incidence at a respiratory rate of 15bpm. Large shifts of states were unlikely, as the most probable switches (if occurs) were to neighboring states (Fig. 1). Moreover, states persisted over time, as reported by the diagonal elements of the transition probabilities matrix (Fig. 1). This can have serious implications in case of patients entering in a state with high number of asynchronies, since it is highly likely (79% for z_4 level) that they continue in that state for the next periods.

CONCLUSIONS. This study proposes a novel approach to deal with the problem of patient-ventilator asynchrony. This may be a first step in developing smart alarms which would be triggered when a patient entered at a state of high risk. These alerts may be useful to warn healthcare team about considering the need for actions to improve patient-ventilator interaction.

INTRODUCTION. Measurement of airway pressure 100 ms after airway occlusion (P0.1) has been initially described in normal subjects to quantify the intensity of the respiratory drive (1). At this time it was measured at the mouth of the subject (1). Its measurement has been implemented into ICU ventilators to make respiratory drive monitoring easily available at the bedside (2). It has also been shown reflecting the work of breathing (3). However, during mechanical ventilation P0.1 is measured upstream the ventilator circuit and hence may not reflect mouth P0.1 due to the compliance of the circuit.
OBJECTIVES. We aimed to compare P0.1 as commonly measured with the Evita XL ICU ventilator (P0.1,Evita) with airway (P0.1,aw) and esophageal P0.1 (P0.1,es) pressure in ICU patients, who were attempting a spontaneous breathing trial during weaning from mechanical ventilation.
METHODS. Measurement of P0.1 is part of an ongoing study comparing pressure support (PS) 7 cmH2O + PEEP 4 cmH2O (treatment A) to PS 0 cmH2O + PEEP 4 cmH2O + 100% automatic tube compensation (treatment B), each applied for 30 minutes, at the time of weaning from invasive mechanical ventilation. Before each treatment the baseline PS of each patient is applied for 30 minutes.
We ran the P0.1 built-in function available in the Evita XL ventilator. Paw and flow were measured at the proximal tip of the endotracheal tube. Pes was obtained from esophageal balloon whose right position and optimal volume were checked properly. Paw, Pes and flow signals were recorded with BIOPAC150 at 200 Hz. Three to ten P0.1 measurements were performed, each separated by 4-8 breaths, in each condition in each patient. P0.1,Evita was read at the ventilator screen and compared to P0.1,aw and P0.1,es. Values are expressed as mean±SD. The data were assessed by using Bland and Altman representation and linear mixed effect model with method of P0.1 measurement and rank of measurement used as the fixed variables and patient as the random variable.
RESULTS. Thirteen patients have been included totalizing 222 measures with each method. P0.1,Evita averaged 2.71±2.43, P0.1,aw 2.56±2.37 and P0.1,es 2.63±2.55 cmH2O.
The bias and limits of agreement for the relationship of P0.1,Evita to P0.1,aw and of P0.1,Evita to P0.1,es were 0.2 (-1.4;+1.7) (Figure 1 left panel) and 0.1 (-3.2;+3.3) cmH2O (figure 1 right panel), respectively.
The linear mixed model found that neither the method used nor the rank of the measurement had a significant effect on P0.1,Evita
CONCLUSIONS. P0.1,Evita provides reasonable estimate of P0.1 measured near the patient.

Hand hygiene compliance at intensive care units: a prospective observational study

M. Hoffmann[1,2,3], V. Gombotz[1], G. Pregartner[4], G. Brunner[3], G. Sendlhofer[1,3]
[1]University Hospital Graz, Executive Department for Quality and Risk Management, Graz, Austria; [2]Medical University of Graz, Division of Endocrinology and Diabetology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [3]Medical University of Graz, Research Unit for Safety in Health, c/o Division of Plastic, Aesthetic and Reconstructive Surgery, Department of Surgery, Graz, Austria; [4]Medical University of Graz, Institute for Medical Informatics, Statistics and Documentation, Graz, Austria
Correspondence: M. Hoffmann
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1110

INTRODUCTION. Healthcare associated infections (HAI) in intensive care units (ICU) are a leading risk for patient safety and cause a serious disease burden with economic impact. Hand disinfection is one of the most effective measures to reduce HAI [1,2,3]. To improve hand hygiene (HH) compliance in a university hospital, several measures of the German HH campaign "Aktion Saubere Hände" (ASH) were implemented and observed in terms of HH-compliance rates.
OBJECTIVES. To raise awareness for HH, healthcare experts were observed in order to assess if implemented measures of ASH influenced HH-compliance rates over a period of five years.
METHODS. ASH in-house training tools comprised face-to-face instructions by hygiene experts, a hand hygiene training clip, standard operating procedures, HH-conferences and an HH in-house newsletter for all healthcare

experts. Furthermore, to also raise awareness amongst patients and relatives, a patient information clip including sequences on HH, leaflets for patients, posters were implemented. To determine the effectiveness of all these measures, a prospective observational single-centre study to assess compliance rates of healthcare experts was performed between 2013 and 2017. HH compliance rates were observed by hygiene experts. Linear mixed models were used to estimate the compliance trend over time.

RESULTS. In total, 48 compliance measurements with 10,315 observed "My five moments for HH" (M5M) were conducted in 12 intensive care units. Overall, mean HH compliance rates increased from 76.9 ± 19.3% in 2013 to 88.6 ± 8.1% in 2017. The estimated increase per year was 3.3% (95% CI 1.8 - 4.8%, p< 0.001).

CONCLUSIONS. To assess the influence of implemented ASH-measures, 48 compliance measurements in 12 different ICUs were observed and showed an overall significant increase. Additionally, it is the aim to further increase HH-compliance rates in terms of patient safety. The major limitation of this study was that it was not determined which of these measures influenced HH-compliance rates. Therefore, a follow up study will address the questions if trainings or compliance measurements of healthcare experts influenced behaviors and/or if patient and relatives empowerment also influenced results.

INTRODUCTION. Ventilator-associated pneumonia (VAP) is a frequent infection in intensive care units (ICU), with a major impact on patient outcome. Tracheal microaspiration of contaminated oral or gastric secretions, a major factor in VAP pathogenesis, could be prevented by subglottic secretion drainage (SSD). Despite a strong rationale and robust data on the effectiveness of SSD, no study has evaluated its impact on microaspiration of secretions.

OBJECTIVES. To determine if SSD could reduce the incidence of tracheal microaspiration in mechanically-ventilated patients compared to standard tracheal tubes. Secondary outcomes included the incidence of airway colonization, ventilator-associated tracheobronchitis (VAT), VAP, and patient outcome.

METHODS. This prospective single-center observational study was performed from March 2012 through April 2013 and included adult ICU patients who had been mechanically ventilated for at least 24 hours and were expected to stay intubated for at least 24 hours. Patients intubated with SSD-ready tracheal tubes (TaperGuard™ Evac, Mallinckrodt; polyvinyl chloride (PVC) tapered cuff) were included in the SSD group, those intubated with PVC standard-shaped cuff tracheal tubes were included in the control group. To assess the incidence of microaspiration,

pepsin and salivary amylase, respectively for gastric and oral origin, were measured in endotracheal aspirates (ETA) for 24 hours following inclusion. ETA were considered as positive for pepsin or amylase at concentrations above 200µg/L, and 1685IU/L; respectively.

RESULTS. SSD group included 55 patients vs 45 in the control group. No significant difference was found between groups regarding male gender (73% vs 69% of in the SSD and control group respectively), age (62.5 vs 58.6), SAPS II (46 [36 - 60] vs 51 [39 - 69.5]) and LOD score (6 [3 - 9] vs 8 [4 - 10]). However, patients in the SSD group had a significantly lower mean cuff pressure (23 [21 - 30] versus 29 [22.5 - 30] cmH$_2$O, p = 0.015), received significantly higher enteral nutrition solution volumes (613 ± 453 vs 365 ± 462, p = 0.003) and were less likely to receive neuromuscular-blocking agents (3.6% versus 17.8%, p = 0.040). There was no statistically significant difference between groups regarding the median percentage of ETA positive for pepsin or amylase (81.4 ± 31.4% vs 75.6 ± 36.6%, p = 0.584), the median proportion of pepsin- (0 [0 - 50]% vs 0 [0 - 17.8]%, p = 0.152) or amylase-positive (88 [58.5 - 100]% vs 100 [33 - 100]%, p = 0.859) ETA, or incidence of VAP (16 (29.1%) vs 11 (24.4%), p = 0.656), VAT (7 (12.7%) vs 4 (8.8%), p = 0.750) and airway colonization (15 (34.9%) vs 8 (21.1%), p = 0.219).

CONCLUSIONS. SSD was not associated with reduced incidence of microaspiration, VAP, VAT or airway colonization in this study. Cuff shape (tapered or cylindrical) might be a confounding factor. Further randomized controlled studies are needed.

Comparison of hand rub with super-oxidised water & alcohol-based chlorhexidine for hand hygiene of healthcare workers in trauma ICU to prevent nosocomial infections: a single-centric, prospective, single-blinded, cross-over, clinical comparative interventional study

B.P. Das[1], G. Yadav[1], M. Gupta[2], S. Viswakarma[1]
[1]IMS-BHU, Anaesthesia and Critical Care, Varanasi, India; [2]IMS-BHU, Microbiology, Varanasi, India
Correspondence: B.P. Das
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1112

INTRODUCTION. In the era of antibiotic-resistance, hand-hygiene plays an important role in the prevention of nosocomial infections (NCI)[1]. Although many kind of hand-rub agents are used, ideal hand-rub for hand hygiene of health care workers(HCW) is still a matter of debate.

OBJECTIVES. We proceeded with an aim to evaluate the efficacy of invivo use of super-oxidized water (SOW) over alcohol-based chlorhexidine (ABC) as hand-rub for hand hygiene of HCW in a tertiary care trauma critical care setting to prevent NCI.

METHODS. After ethics committee approval and written informed consent from patients/relatives and HCWs, a single-centric, prospective, single-blinded, cross-over, clinical comparative interventional study was conducted from September2017-December2017 in the two ICUs, Department of Anesthesia, Trauma centre, IMS-BHU, where the HCW associated directly with patient care, were allotted into one of the 2 study groups based on the hand-rub used (ICU SOW or ICU ABC). 180 patients were admitted based on simple randomisation into both the ICUs. After a period of 2 months, the ICUs were crossed over wrt the use of study hand-rub. Primary outcome noted was incidence of nosocomial infections & secondary outcomes were cost effectiveness and adverse effects. Chi-square and student-t test were used for qualitative & quantitative data, respectively. Statistical significant difference was declared when p-value ≤0.05.

RESULTS. Demographic parameters were comparable (Table 1). Incidence of NCI were lower with SOW (VAP-28 out of 71 vs 62 out of 69,p=0.001) (Fig 1), with decreased MDR organisms (12 vs 28,p=0.002) & less fungal infections (0 vs 6, p= 0.02) (Fig 2). SOW was cost-effective as compared to ABC (Rs 08 prepared by 'Sterigen' vs Rs 200 (Bactorub) per patient during the stay, p=0.0001). Duration of hospital stay and mortality at 1 month were comparable (p=0.23) (Fig 3).

CONCLUSIONS. Use of SOW as hand-rub for hand hygiene of HCWs, not only, is safe and cost-effective, but also decreased the incidence of nosocomial infections & contributed to a favourable ICU flora.

INTRODUCTION. Colonization-Infections by multiresistant bacteria (BMR) are increasing in critical care units, so vigilance and control strategies are needed.

OBJECTIVES. The aim to this study is to determine the incidence of colonization in patients admitted in a intensive care unit and describe risk factors related.

METHODS. A prospective, observational, descriptive was conduced, including patients admitted in the unit from April 2016 to September 2017.

Risk factors were predefined and analysed (admitted to hospital for more than 5 days, institutionalized, previous colonization, renal failure, antibiotic more than seven days) and colonization controls were performed at admission and every 7 days.

Chi-squared test and logistic regression analysis was analysed to see if there was a relationship between risk factors and colonization when admission.Odds ratio was calculated to measure the strength of this association.

RESULTS. In this period, 969 patients were studied. The incidence of colonization is 5.9%, being Beta-lactamases Productors Enterobacterias (3.2%) and Methicillin Resistant Staphilococcus Aureus (2.2%) the most frequently microrganism founded in our results. Some risk factor associated was presented in 31% of them.

Logistic regression showed 3 risk factors as statistically significant result: Income greater than 5 days (OR = 1.99, CI 1.08-3.66), institutionalized (OR = 16.28, CI 1.001) -163.95) and present a previous colonization by BMR (OR of 3.85, CI 1.06-13.94)

CONCLUSIONS. Being admitted for more than 5 days, institutionalized or a previous colonization by BMR are factors related to a higher incidence of colonization when the patient is admitted in an intensive care unit. The implementation of this project is useful for the vigilance and control infections in critical patients

Collaboration between ward pharmacists and infection control team for the appropriate antimicrobial use in the emergency medical center

T. Tatsumichi, K. Yamaguchi, K. Takahashi, H. Tanaka, S. Kosaka, H. Houchi
Kagawa University Hospital, Kagawa, Japan
Correspondence: T. Tatsumichi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1114

INTRODUCTION. As stated in the Guidance for Implementing an Antimicrobial Stewardship Program in Japan, issued by infection-related eight societies in Japan in September 2017, pharmacists are expected to play a central role in the program.

Since assigned to the emergency medical center in our hospital in April 2016, its dedicated pharmacists have intervened in an appropriate use of antimicrobials in collaboration with the infection control team (ICT).

OBJECTIVES. We report the current status and challenges in the collaboration between ward pharmacists and ICT.

METHODS. Data were extracted from our pharmacy department system on the use of antimicrobials (injections) between April 2014 and September 2017 in the emergency medical center. We calculated defined daily dose (DDD) per 1000 bed-days (hereafter DDD measurement)[1] , days of therapy (DOT) per 1000 bed-days (hereafter DOT measurement)[2] , and DDD/DOT ratios[3] of specific antimicrobials (MEPM, IPM/CS, VCM, TEIC, LZD) in pre- and post-assignment periods of dedicated pharmacists. Pre-assignment period

was defined as April 2014 through September 2015 and post-assignment period as April 2016 through September 2017.

RESULTS. DDD measurements of pre- and post-assignment periods of dedicated pharmacists were 80.4 vs 81.0 for MEPM, 2.9 vs 0.2 for IPM/CM, 15.4 vs 15.3 for VCM, 2.1 vs 1.7 for TEIC, and 3.7 vs 6.1 for LZD, respectively. Specific antimicrobials accounted for 20.8% (104.5/501.) for pre-assignment period and 24.0% (104.3/434.1) of total antimicrobial injections. These results indicate decreases in DOT measurements for specific antimicrobials expect for LZD. The DDD/DOT ratio for VCM increased from 0.68 in the pre-assignment period to 0.86 in the post-assignment period.

CONCLUSIONS. Although total use of VCM remained unchanged between pre- and post-assignment periods, our results showed an increase in VCM dose per day and decreases in duration of VCM therapy and the number of patients receiving VCM, which suggests that VCM began to be used more appropriately. We consider that this resulted from our continuous intervention including development of protocols of loading-dose and TDM in cooperation between ward pharmacists and the ICT. No changes were found in dose per day, treatment duration, and the number of patients receiving MEPM, IPM/CIM, and TEIC therapies, suggesting that there is room for intervention. Aiming at the appropriate antimicrobial use, we will make intervention by further enhancing collaboration between ward pharmacist and ICT.

OBJECTIVE. To assess the value of enteral paromomycin to decontaminate patients with rectal colistin and / or carbepenemase (CPN) resistant microorganisms colonization in order to prevent the development of ICU-acquired infections.

METHODS. All consecutive patients admitted to the ICU from October 2011 to December 2016, requiring tracheal intubation for longer than 48 hours were given SDD with a 4-day course of intravenous cefotaxime, plus enteral colistin, tobramycin and nystatin in an oropharyngeal paste and in a digestive solution. Oropharyngeal and rectal swabs were obtained on admission and once weekly. Patients with rectal swabs colonized by colistin and / or carbepenemase resistant microorganisms were treated with enteral paromomycin 1 gr every 6 hours daily, in order to eradicate them and prevent nosocomial infections. Categorical variables were summarized as frequencies and percentages and the continuous ones as medians and interquartile ranges (IQR) or means and standard deviations. Statistical significance was set at $p \leq 0.05$.

RESULTS. Paromomycin was applied to 84 colonized patients with rectal colistin-resistant microorganisms (CRM). All of them but two had colonization by Extended Spectrum Beta-lactamases (ESBLs) producing *Klebsiella pneumoniae*. One patient was colonized by ESBL producing *Enterobacter spp* and another by ESBL producing *Escherichia coli*. Demographic data and type of admission are shown in Table 1.

Sixty-eight out of 84 (81.7%) eradicated the rectal swab after paromomycin. Twenty-six of them received concurrent susceptible antibiotics during paromomycin application. Five out of the seven CPN producing patients were decolonized. Twenty-eight patients died in the ICU and 15 of CRM colonized patients died without achieving negativization, being 2 of them CPN. Only 3 patients developed nosocomial infections after decolonization.

CONCLUSION. Our data show that enteral paromomycin could be effective in treating rectal colistin and / or carbapenemase resistant microorganism colonization allowing prevention of ICU-adquired infections.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1116

INTRODUCTION. In patients treated in intensive care units (ICU), infections are commonly observed due to severe illnesses, immune

supressive effects of drugs, surgical procedures, and usage of invasive equipment. In this respect ICU's should be inspected for nosocomial infections since resistant microorganisms can easily colonize.

OBJECTIVES: In this study we aimed to compare the surveillance results for ventilator associated pneumonia (VAP) before and after the use of closed aspiration system.

METHODS. Between September 2016 and April 2017 intubated or tracheostomized patients aspirated with conventional aspiration catheter and between May 2017 and December 2017 patients aspirated with closed aspiration system are enrolled to the study. Patients' VAP results depending on laboratory culture samples are assessed with active surveillance system. Patient day, days on ventilator, VAP rate, total number of infections were calculated.

RESULTS. Patient day in ICU for two groups were 5694 and 5866 days, respectively. For conventionally aspirated group ventilator day and ventilator usage rate were 3111 days and 0.55. For closed system aspiration group ventilator day and ventilator usage rate were 2967 days and 0.51. For the first 8 months VAP rate was 10.3 % and total number of infections was 32 while in the second 8 month, 10.8 % and 32.

CONCLUSIONS. VAP rate and number of infections were similar with two aspiration techniques. Ventilator use rate and days on ventilator decreased throughout the study. In ICU successful surveillance results can be achieved by isolation of the agents, appropriate antibiotic choice and obeying isolation rules.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1117

OBJECTIVES. To prospectively evaluate the impact of Selective Digestive Decontamination (SDD) application on colonization rates and nosocomial infections (NI), after 6 years, in a mixed ICU.

METHODS. This study was conducted in a 30-bed-medical-surgical ICU. All consecutive patients admitted to the ICU from October 1, 2011 to September 30, 2017 expected to require tracheal intubation > 48 hours were given SDD (SDD study group) with a 4-day course of intravenous cefotaxime, plus enteral colistin, tobramycin, nystatin in an oropharyngeal paste and in a digestive solution. Oropharyngeal and rectal swabs were obtained on admission and once weekly. We used ENVIN NI criteria. We compared all patients admitted to ICU with ICU NI from October 1, 2010 to September 30, 2011 (non-SDD group) to the SDD study group. Categorical variables were summarized as frequencies and percentages and the continuous ones as means and standard deviations (SD) when the data followed the normal distribution or medians and interquartile ranges (IQR) when they did not. The percentages were compared using the test of chi-square test or Fisher exact test, means with the t-test and medians with the

Wilcoxon test for independent samples. Those variables that showed statistical significance in the univariate analysis were introduced in a multivariate logistic regression analysis. For each one of the infections (catheter-related and other secondary bacteremias, pneumonia and urinary infections and antibiotic resistant bacteria (ARB) infections) the incidences per 1000 days of exposure in each cohort and the corresponding relative risks were obtained using the Poisson regression. Statistical significance was $p \leq 0.05$. We analyzed colistin- and tobramycin-resistant colonization and also antibiotic consumption as Defined antibiotics Daily Doses (DDD).

RESULTS. Results are shown in Tables 1

There were no statistical significant differences between both groups in type of admission or demographic data. Patients with SDD had significantly less Extended Spectrum Betalactamase (ESBL), Gram Negative Bacteria Multirresistant (GNB-MR) and *Acinetobacter spp* infections. We had also a significant reduction in ventilator associated pneumonia (VAP), urinary infections, other secondary bacteremias and ARB infection rates, in SDD group versus non SDD. There was no infection by *Clostridium difficile*. The exogenous infections were 73.9 %. Colistin-resistant colonization was 17.4% and tobramycin-resistant colonization was 25.7% of samples. There was a decrease on the DDD/100 ICU stays after SDD.

CONCLUSIONS. After 6 years applying SDD a significant reduction of infections by ESBL, GNB-MR and *Acinetobacter*, was observed. A significant decrease of VAP, secondary bacteremias, urinary and ARB infections rates was also shown. An antibiotic consumption reduction was found after SDD. Low rates of colistin- and tobramycin-resistant colonization bacteria have been persistently observed.

Compliance with hand hygiene guidelines in the context of glove usage

C. Siebers, M. Mittag, B. Grabein, M. Zoller, L. Frey, M. Irlbeck
Ludwig-Maximilians University of Munich, Munich, Germany
Correspondence: C. Siebers

INTRODUCTION. Hand hygiene is known to be the single most effective prevention measure of nosocomial infections. In a recent meta-analysis the pooled compliance rate (CR) was only 40% [1].
OBJECTIVES. Aim of this study was to determine the incidence of hand hygiene indications (HHI) with regard to the resulting CR in the setting of the treatment of critically ill patients (APACHE > 20 and mechanical ventilation). One special focus was put on glove usage to determine whether gloves were substituted for HD when an indication according to the WHO "my five moments" (M5M) occured.
METHODS. We performed a single-blinded direct observation on a mixed 24 beds ICU of a university hospital. To get reliable results we designed a 24/7 monitoring performed by an external, specially educated nurse experienced in working with ICU-patients suffering high contagious infectious diseases. To minimize the Hawthorne Effect the employees were told that observation was fulfilled to stratify recurrent procedures of their work with the goal to evaluate the possibility of reducing their workload. One single nurse was monitored in maximum over two shifts. In accordance to the concept of M5M all HHI and all HD were documented. Additionally, donning and doffing of gloves was recorded with regard to the different indications of HD. The CR is the quotient of HD and HHI.
RESULTS. In total, 21 shifts (168 h) spread over the whole week and divided to early, late and night shifts were accompanied. Over the entire examination period a total of 2036 indications for HD (12.1/h) per single patient were obtained. In fact, only 690 HD (4.1/h) were performed, which equates to a total compliance rate of 33.9%. The highest CR was observed for the indication "after patient contact" (nurses 50.0%, physicians 52.0%). CR was the worst for the indication "before aseptic measures" (nurses 22%, physicians 17%). Assuming that a glove change can replace a HD, the shame compliance rate in the total collective increased significantly to 72.1% (p< 0.0001; 64.5% nurses, 70.3% doctors, 89.1% other employees).
In regard to the group of nurses, there was an HHI around the clock on average every six minutes. About 17% of the total working time of a nurse would have to be applied for 100% correct hand hygiene application.
CONCLUSIONS. Our results show that compliance with hand hygiene in the ICU of a university hospital remains very low and requires constant optimization. HCW use gloves instead of performing adequate HD. Propably, alternative regimens for handling glove use, i.e. a clean your gloves campaign, should be discussed.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1119

INTRODUCTION. Hospital acquired infection (HAI) is a global healthcare issue and various methods have been used to reduce colonization of ICU without significant effect on outcome [1]. Disinfectant foot mat has been used to reduce colonization [2]. We studied the efficacy of use of disinfectant foot mat in ICU in reducing colonization and HAI.
OBJECTIVES. The aim of our study was to assess the impact of use of disinfectant foot mat to reduce the air, surface colonization and subsequently on HAI in ICU.
METHODS. Prospective observational study was performed in the ICU of tertiary care hospital with mixed population from April 2017 to March 2018 conducted in two phases of 6 months each. In phase one (April to September 2017), ICU staff and visitors were made to use dedicated ICU slippers or shoe covers. In phase two (October 2017 to March 2018) disinfectant door mat was placed at the entrance of ICU and the staff and visitors were allowed to use their own footwear.
Primary outcome: Number of colony forming units (CFU) from various ICU surfaces, air samples which were randomly collected and plated on blood agar.
Secondary outcomes: Impact on incidence of HAI, ICU length of stay (ICULOS), ICU mortality.
Everyday mat was washed with liquid soap, sprayed with 1% glutaraldehyde-dimethanol and changed 4 hourly or when visibly dirty. Every month floor swab was collected from 6 to10 feet away from the foot mat and air sample was collected from the centre of ICU. Visitor policies and mopping frequencies remained same in both the groups. Statistical data was analysed with SPSS 21 using z test and t-test.
RESULTS. Results were as per table 1 and 2 given below.
CONCLUSIONS. Use of disinfectant mat did not result in a significant reduction in colonisation and incidence of HAI, ICULOS and ICU mortality compared to shoe covers or dedicated slippers.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1120

INTRODUCTION. Mobile phones (MP) of health care workers (HCWs) are colonized by pathogenic bacteria[1]. Therefore, they can be vectors of nosocomial infections. An interventional program could reduce the contamination of MP and the transmission of these high risk microorganisms.
OBJECTIVE. The aim of this study was to determine the prevalence of bacterial colonization of MP carried by HCWs in the intensive care units (ICU) and operating room (OR), and to evaluate an interventional program designed to reduce bacterial colonization rates.
METHODS. The study was performed in three phases. In the first phase (September to October 2017) sixty MP samples were randomly collected at the end of HCWs duty and inoculated into blood sheep and eosyn methilene blue agar for culture. In the second phase an interventional program was performed (from November 2017 to January 2018). This program consisted in: 1) Reinforcement of the World Health Organization programs (handrub and handwash in the 5 moments for hand hygiene) and 2) The implementation of a periodic MP cleaning program using microfiber cloth (1 time each day with water and each 5 days with a 60% isopropyl alcohol). In the third phase (February to March 2018) sixty MP samples were collected of the same HCWs that were evaluated in the first phase. These samples were collected in randomly order and processed in the same way as the first phase. In addition, all microbiological samples taken from the patients admitted in the ICU and OR during phases 1 and 3 of the study were analyzed.
RESULTS. Overall bacterial colonization rates of MP in phase 1 and 3 were n=57 (95%) and n=35 (58%), p=0.001 respectively. The MP colonization rates according to the isolated bacteria are detailed in table 1.
Isolation of pathogenic bacteria in microbiological patient samples in phase 1 and 3 were n=13/81 (16%) and n=7/75 (9%) respectively (p=0.21). The same pathogenic bacteria was present in both, mobile phone and patient sample in 10/13 (76%) in phase 1 and 6/7 (85%) in phase 3 (p=0.90). Most common isolated pathogenic bacteria in MP and patient samples are detailed in table 2.
CONCLUSIONS. We found high rates of pathogenic bacterial colonization in the MP carried by HCWs. The interventional program performed in this study significantly reduced MP colonization rates and could reduce the nosocomial infections.

METHOD. Audit data was collected and managed using a purpose built REDCap™ (Research Electronic Data Capture) portal hosted at Queen Mary University of London (UK), designed to take 30 minutes per centre to complete. Units were given 30 days to collect data in April 2016, from 12-month ICNARC dataset (except St. Bartholomew's hospital who supplied 6-month data following recent merger). The audit was registered with the clinical effectiveness unit.

RESULTS. There was a varied mix of Level-3 patients across the units surveyed in keeping with their speciality areas. Table 1 shows characteristics of these units.

All 4 units used VAP care bundles with the same core components: head of bed elevation, sedation level assessment with daily sedation interruption (unless contraindicated), oral care with chlorhexidine mouthwash (0.125%), teeth brushing, ventilator circuit changes, hand hygiene using alcohol before airway management, tracheal tube cuff pressure control and daily review of stress ulcer prophylaxis.

Table 2 shows variance in the VAP care bundles. All 4 units audited compliance with their VAP care bundle with 2 units performing this continuously. Two units were aware of their VAP rate from local audits in the preceding 12 months (12 and 15 VAP cases per 1000 ventilator days). Three units had no strict VAP definition for audit and the remaining ICU used a simplified definition of a patient commenced on antibiotics for chest sepsis 48 hours or more after initiation of invasive mechanical ventilation. Two units audited frequency of causative pathogens, with Enterobacteriaceae being most prevalent in both cases. Two units had an antibiotic treatment policy for VAP. Two units had access to quantitative microbiological results (e.g. CFU/mL) and the remaining 2 used semi-quantitative results (e.g. +, ++, +++) from local laboratories.

CONCLUSIONS. This pilot study highlights considerable variation in the management strategies and active surveillance for VAP, even within the same NHS Trust. The methodology used showed good feasibility to carry out a wider national/international VAP study and identify areas of good practice.

INTRODUCTION. We hypothesised that management strategies and active surveillance for VAP varies widely across intensive care units, and that in clinical practice the criteria used for antibiotic treatment of chest sepsis differ from published definitions of VAP.

OBJECTIVES. To determine the management and prevention strategies, including active surveillance monitoring and diagnostic criteria, of VAP across four London ICUs (Barts Health NHS Trust, London, UK): The Royal London (RLH-trauma/neuro/general), St. Bartholomew's Cardiac ICU (SBH cardiac), St.Bartholomew's (SBH-general/oncology), and Whipps Cross University Hospital (WXH-general).

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1122

INTRODUCTION. The ZERO projects are a nation multimodal intervention based on the implementation of evidence-based bundle measures that have proven effective in preventing infections associated with healthcare in the ICU. There is little information on the effect of these programs on critically ill cardiac patients, traditionally considered as low risk patients.
OBJECTIVES. To Know the influence of ZERO projects on the incidence of VAP in the
subgroup of critically ill cardiac patients.
METHODS. Patients from the national registry ENVIN-HELICS were included in the period April-June, from 2007 to 2015, of those units that incorporated patients all theperiods ,the reason for admission being an acute cardiac process and subject to mechanical ventilation(VM) more than 24h. 4 periods are considered in relation to the ZERO projects: Previous, Bacteriemia Zero(BZ), Neumonia Zero(NZ) and post.The incidence rate (IR) is estimated in each period. A multivariate analysis was performed by Poisson regression using the statistical program SPSS 20.
RESULTS. The IR of VAP in the basal period was 16.35 episodes / 1000 days of MV and decreased to 12.48 in the BZ period, 10.56 in the NZ period and 7.72 in the post-intervention period. Tables I, II and III show the result of the multivariate analysis.

CONCLUSIONS. Multivariate analysis has shown the high effectiveness of ZERO projects in the reduction of VAP in critically ill cardiac patients.

Endotracheal tubes with sub-glottic suction ports to reduce suspected ventilator-associated pneumonia... are our ICU patients worth it?

R. Hart, C. Bradley, E. Black, R. Docking
Queen Elizabeth University Hospital, Anaesthesia and Critical Care, Glasgow, United Kingdom
Correspondence: R. Hart
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1123

INTRODUCTION. Ventilator-associated pneumonia (VAP) is the most common healthcare associated infection (HAI) in ventilated patients. VAPs are associated with an increased duration of mechanical ventilation and mortality. For this reason, VAP prevention bundles are commonly used in our ICUs. The Intensive Care Society (ICS) recommend the use of sub-glottic drainage endotracheal tubes (SGT) as part of this bundle.

OBJECTIVES. In this study, we aim to assess whether the introduction of SGT has any influence on the rate of suspected VAP.

METHODS. A two-month trial period of SGT was implemented in our unit. Education was delivered to our department to ensure all front line staff were aware of the practical differences between SGT and standard endotracheal tubes. A data collection tool was devised using Microsoft Excel to allow patients with SGT to be audited. All patients with a SGT were included in our data collection which gathered daily HAI data and patient demographics. If VAP was suspected, then further clinical information was obtained to determine if this episode could be formally diagnosed as a VAP according to our existing diagnostic criteria (HELICS).

RESULTS. During the trial period 26 patients received a SGT. Median patient age was 51. The most common admission diagnosis was pneumonia. Median duration of mechanical ventilation was 7 days. There was one episode of suspected VAP, which did not meet the HELICS criteria for a formal VAP diagnosis.

CONCLUSIONS. There is a strong evidence base supporting the use of SGT demonstrated by three meta-analysis and a recent RCT. A recent national audit by the Scottish Intensive Care Society also demonstrated a reduction in VAP rates in SGT patients. Given the health economic implications of VAP, there are public, political and regulatory interest to minimise the rate of VAPs in our units. SGT are more expensive than standard ETT. We estimate in our unit, adopting routine SGT would cost £3,400. A one week course of temocillin to treat VAP would cost £700 per patient, therefore we would only need to prevent 7 VAPs per year for routine SGT to be cost effective. This is in comparison to almost £30,000 per year spent on dexmedetomidine in our unit to prevent and treat delirium. We believe our ICU patients are worth the cost of SGT in order to prevent VAP. In the current climate of antimicrobial resistance, SGT may also be an economical approach to reduce the antibiotic burden in our patients.

Influence of the Zero protocols and their patient safety protocol in catheter-associated urinary infection

R. Fernandez[1], M.I. Ruiz[2], J.F. Machado[1], M. Guerrero[2], M. Gordillo[2]
[1]Hospital Universitario Virgen de las Nieves, Granada, Spain; [2]Complejo Hospitalario de Jaen, Jaén, Spain
Correspondence: M. Guerrero
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1124

INTRODUCTION. Patient safety is the fundamental principle of health care and a critical component of quality management. It depends on the interaction and the permanent balance of multiple actions of the health system and of its professionals.

Urinary tract infection is the most common nosocomial infection, accounting for 23 to 30% of all infections acquired during hospitalization, with a prevalence of 2%. Increases hospital stay and hospital costs. Mortality is low and is particularly associated with secondary bacteremia. Bladder catheterization (CV) is the most influential factor for developing an urinary tract infection (UTI).

OBJECTIVES.

– Evaluate if the application of zero projects can influence to reduce ITU
– Study ITU evolution

METHODS.

– Admitted to ICU more than 24 hours from 01.04.10, until 31.10.17.
– Rate per 100 patients admitted (N 3928 patients) and the incidence density (ID) per 1000 urinary catheter days (23288).
– Application of the Zero projects since April 2010 (Pneumonia Zero, Bacteremia Zero) and the patient safety protocol they associate.

RESULTS.
01.04.10-31.12.10- 2.96/admitted, 3.79/ catheter days
01.01.11-31.12.11- 3.32/admitted, 4.99/catheter days
01.01.12-31.12.12-2.46/admitted, 4.82/catheter days
01.01.13-31.12.13- 0.93/admitted, 3.1/catheter days
01.01.14-31.12.14- 6.22/admitted, 7.61/catheter days
01.01.15-31.12.15- 2.41/admitted, 5.56/catheter days
01.01.16- 31.12.16- 3.26/admitted, 5.56/catheter days
01.01.17-31.12.17- 2.37/admitted, 4.51/catheter days

CONCLUSIONS. In view of the results, we can see that the ITU figures have remained stable except for one year, in which there was a rebound. The protocol of patient safety, hand hygiene and the greater dedication to avoid infections involving the Zero projects, have helped to control the number of these infections.

INTRODUCTION. Colonization and microaspiration made the foundation of ventilator-associated pneumonia (VAP) pathogenesis. Koeman et al., found that topical decontamination of the oral cavity with chlorhexidine (CHX) reduced the VAP incidence from 18 to 13% [1]. The permanence of antiseptic effect in the oral cavity is doubtful due to dilution effect with salivary secretions; we hypothesize that continuous oral antiseptic infusion may offer a better decontamination.

OBJECTIVES. We developed endotracheal tube with additional port that allows continuous oral infusion of CHX, and we want to test the technique versus the slandered on bacterial colonization. (Provisional patent: 62359944)

METHODS. Two identical bio models for the upper airways were created by (3DX Diagnostics, USA) to admit the modified and the

ordinary endotracheal tubes (ETT). The two techniques tested were using six hourly CHX disinfection (group A) versus continuous disinfection over 24 hours infusion technique (Group B). Five microorganisms plus mixed bacteria were used and each was tested for nine times. Normal saline was used constantly to irrigate the biomodels and 10 ml aliquot was collected by the end of the experiment. The aliquots from decanted broth post disinfection was cultured. The time to apply CHX by practitioner was also compared
RESULTS: Lower bacterial growth trend was noted in group A in 5 experiments which reach statistical significance only with pseudomonas aeruginosa (p=0.05). In one experiment the growth was lower in group B. Additionally, time saving advantage was observed in group B (12±3.1 versus 3.9±1.1 min, p=0.01).
CONCLUSIONS: The novel technique got at least non inferior results, plus time saving advantage. These results may warrant future clinical trial.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1126

INTRODUCTION. The activation of "acute stroke protocols" (ASP) has proven to be effective in decreasing the latency time for starting therapy in emergency scenarios. The door-to-needle time (DNT) defined as the time from hospital admission to treatment, is often delayed for avoidable reasons. The standard recommendation in our health system for reference sites of ASP, is a median DNT< 35 minutes (m). Kaizen methodologies with real-time asset tracking technology have demonstrated its utility in developing more efficient workflows.
OBJECTIVES. Because the DNT in our hospital exceeded this time, we tried to implement Kaizen strategies within the Lean Healthcare Management System (LHMS) in order to identify improvement measures for shortening DNT.
METHODS. The Kaizen team was composed by a leader, an external methodological expert and a working team including a representative of the different professionals involved in the procedure (neurologist, emergency physician, intensive care specialist, emergency nurse, radiologist and auxiliary personnel). A simulation of the activation of ASP was videotaped and the time spent in the whole process was divided into different small activities (administrative tasks, transfers, material storage, circuits and medical/nursing actions). After analyzing these periods, several improving measures were suggested according to their value and necessity. Once evaluated, the new workflow was standardized and approved. Training was carried out for all the professionals involved.
RESULTS. From June 2016 to December 2016, the Kaizen methodology was implemented in our site in the ASP scenario. There were 6 discussion meetings, more than 50 identified activities and there were finally accorded among others, 13 main improving measures. After a training program, the new workflow was implemented. The median DNT felt from 48m in 2016 (22 patients) to 23m in the end of the year 2017 (30 patients). There also was a dramatic decrease in the inter-case time variability, estimated by the standard deviation (SD), which felt an 80% at the end of the period (57m to 11m). The course of the DNT and SD for each period is shown in the figure.
CONCLUSIONS. The application of Kaizen (LHC) methodology in the acute stroke program led to a reduction of the DNT and the inter-case variability. This methodology may be a reliable tool to improve the management of patients in acute clinical scenarios.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1127

INTRODUCTION. Endotracheal intubation (ETI) is a life-saving procedure for critically-ill patients in the emergency department (ED). However, several obstacles, including an uncontrolled environment, lack of skilled workforce and advanced equipment, and unstable patients with limited physiologic reserve are challenges associated with ETI in the ED. Difficult intubations during emergent ETI can occur up to twice as often compared to the operating room.[1] In addition, a number of life-threatening complications including failed intubation, severe hypoxemia, and severe hypotension are associated with emergent ETI.[1,2]
OBJECTIVES. We described our 3-year experience and evaluated endotracheal intubation (ETI) outcomes during a multi-disciplinary emergency department (ED)-based quality improvement (QI) program.
METHODS. This was a single-center, observational study taking place during a QI program. We used a registry for airway management performed in the ED from April 2014 to February 2017. The QI program focused on procedural standardization, airway management education, and comprehensive preparation of airway equipment. The primary outcome was the first pass success (FPS) rate. The secondary outcomes were multiple attempts rate and overall rate of complications.
RESULTS. A total of 1,087 emergent ETIs were included. The FPS rate significantly increased from 68% in the first year to 74% in the second year and 79% in the third year (P for trend < 0.01). The multiple attempts rate in the first year was 12%, followed by 7% and 6% in the second and third years, respectively (P for trend < 0.01). The overall complication rate was 16% in the first year, 8% in the second year, and 8% in the third year (P for trend < 0.01).
CONCLUSIONS. We observed improved outcomes of ETI in the ED, including FPS rate, multiple attempts, and overall complication rates during the multi-disciplinary QI program to enhance patient safety.

INTRODUCTION. Care of the patients under mechanical ventilation (MV) requires intensive human participation and teamwork. In this high-risk and high-stress care setting, human failures might play a significant role in the occurrence of adverse events.
OBJECTIVES. To investigate the human failures and ineffective communications in the reported patient safety events related to the use of MV for patients with respiratory failure.
METHODS. We conducted a retrospective analysis of the reported patient safety events related to the use of MV for patients with respiratory failure from the Incident Reporting System of a university-affiliated medical center from 2011 to 2017. The investigators analyzed all of the available descriptions by the reporters and comments from their supervisors to infer the possibility of human errors, focusing on unsafe acts and their preconditions of the related care and institutional processes.
RESULTS. From the 19,080 cases of reported patient safety events during the study period, we identified 474 (2.5%) MV-related events. Of these 474 events, 428 (90.3%) were artificial airway-related events, whereas 29 (6.1%) were concerned with ventilator management, and 17 (3.6%) were patient-care events. Patient harms presented in 223 (47.0%) cases, of which 192 (81.1%) were artificial airway-related events. Content analysis of the reporting descriptions and comments showed that 174 (36.7%) were deemed having unsafe acts as conditions with human failure, including 25 (14.4%) related to perceptual errors, 53 (30.5%) related to decision errors, and 97 (55.7%) related to action errors. Preconditions for these unsafe acts included adverse mental state (79, 45.4%), technological environment (42, 24.1%), physical/mental limitation (33, 19.0%), crew resource management (10, 5.7%), physical environment (5, 2.9%), and adverse physiological state (5, 2.9%). In the 145 cases related to artificial airway having unsafe acts, 83 (56.6%) were action errors, and the most commonly related care processes were artificial airway care (47, 32.4%), physical restraint (44, 30.3%), and patient positioning (33, 22.8%). Moreover, we found 27 (5.7%) cases with ineffective communications, of which 13 (48.1%) were artificial airway-related events.
CONCLUSIONS. Human failures and ineffective communications may play a significant role in the occurrence of patient safety events related to the use of mechanical ventilation. To improved the safety of care of mechanically ventilated patients, emphasis should be addressed to the prevention of action error, especially to the errors related to the processes of artificial airway care, physical restraint, and patient positioning.

Residents' and nurses' attitudes to a rapid response team in a tertiary hospital

D.S. Lee, S.Y. Lim, H.J. Min, Y.Y. Choi, M.A. Yun, B.N. Lee, Y.J. Lee
Seoul National University Bundang Hospital, Interdepartment of Critical Care Medicine, Seongnam, Korea, Republic of

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1129

INTRODUCTION. Residents and nurses are the main group of clinicians who activate the rapid response team (RRT), placing them in an excellent position to provide valuable insights regarding the effectiveness of this system.
OBJECTIVES. Purpose of our descriptive study is to assess whether residents and nurses value the RRT service and to determine barriers to calling the RRT exist in a 1400 bed teaching hospital.

METHODS. We conducted a modified personal interview, using a 17-item Likert agreement scale questionnaire from January to May 2017.
RESULTS. A total of 322 ward nurses and 30 residents (100% response rate) returned their completed surveys. Overall, the majority of nurses and residents were satisfied with the RRT, with suggestions for simplifying and educating the RRT activation criteria. Most responders suggested that they would make a call to RRT team even if the patient's vital signs were normal or the patients did not fulfill RRT criteria. However, both nurses and residents feared criticism of activating RRT from colleagues that the patient was not sufficiently unwell to transfer to ICU (76% and 83% respectively). Despite hospital RRT protocol, 95% of nurses would call the covering doctor and 67% of residents would discuss with other residents about patients' management, before activating the RRT for a sick ward patient.
CONCLUSIONS. Nurses and residents value the RRT service and appreciate its potential benefits. The major barrier to calling the RRT appears to be awareness of honor in Asian culture, and allegiance to the traditional approach of initially calling covering doctors, rather than fear of criticism for calling to the RRT team.

Golden hour for ICU admission - don't get late!

V. Loureiro[1,2], S. Castro[1], A. Marreiros[2], C. Granja[1,2,3]
[1]Algarve University Hospital Center, Intensive Care Unit, Emergency and Intensive Care Department, Faro, Portugal; [2]University of Algarve, Biomedical Sciences and Medicine Department, Faro, Portugal; [3]Center for Health Technology and Services Research, Porto, Portugal

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1130

INTRODUCTION. The delay in the recognition and early admission of critically ill patients to the ICU has been associated to an increase in the mortality (1). There is no consensus regarding the optimal time for ICU admission, as this may depend on specific organizational features. We conducted this study in order to understand if our own organization would need changes in the critical care patient circuit.
OBJECTIVES. To identify patients' clinical and demographic characteristics associated with the delayed admission to the ICU and if such delay is associated to worse clinical outcomes, namely ICU and hospital mortality and length of stay.
METHODS. Based on previous works (2), we defined that four hours would be the cut-off for delayed (DICU) or non-delayed ICU admission (NDICU). Exclusion criteria included scheduled admissions, transfers from other hospital, transfers from the wards, readmissions and organ donor patients. The clinical and demographic characteristics of both groups were compared, as well as their outcomes.
RESULTS. From a total of 592 ICU admissions, 443 were excluded. From the remaining 149 patients, 109 (71,8%) were on the DICU group. These patients were statistically significantly older (67 vs. 55, p=.001), with higher scores of SAPS II (59,40 vs. 47,24, p= .003) and SOFA (9,62 vs 7,76, p=.012), with more non-scheduled surgery patients (41 vs. 5, p=.002) and with septic shock (49 vs. 5, p=.000). The NDICU group had statistically significantly more cardiogenic shock

patients (12 vs. 8, p=.001). DICU patients had higher mortality rate (47,6% vs. 26,2%, p=.017) and more days of vasopressors support (3,94 vs. 2,38, p=.009). There was no statistically significant differences in ICU or hospital length of stay between the two groups. Patients with septic shock submitted to non-scheduled surgery had a delay of 22,19 h versus 14,29 h when compared to non-scheduled surgery patients without septic shock.
CONCLUSIONS. Delay to ICU admission was significantly associated with ICU and hospital mortality and significantly worse severity scores. Possible explanations for these findings include a deterioration of the clinical condition of patients during the time before ICU admission. Non-scheduled surgery patients presented a delay much higher than 4h that can't be fully explained by the surgery time. These findings may suggest that an improvement on the circuit of critical patients is needed.

Can we improve the quality of critical care referrals?

N. Robin, R. Gale, S. Singh
Countess of Chester Hospital, Anaesthesia & Critical Care, Chester, United Kingdom
Correspondence: N. Robin
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1131

INTRODUCTION. Selecting patients who will benefit from critical care treatment requires skill, judgment and experience. Poor selection subjects patients to potential harm, may prolong suffering and is not cost effective.
OBJECTIVES. To assess the quality of referrals to critical care in order to improve the referral pathway.
METHODS. Using the electronic patient record system (Meditech) we identified 107 sequential referrals to the ICU. For each patient the following information was recorded: Time of referral
Grade of the referring clinician
Most senior clinician involved in referral
Significant comorbidity and life limiting disease
Functional status (FS): good (G), independent (I), poor(P), very poor (VP)
Admission decision
Hospital outcome
Data was reviewed independently by 2 ICU consultants (blinded to the referring team and the duty critical care team) and graded as appropriate or inappropriate based on the following criteria:
Appropriate referral:
Severely unwell **and/or** at high risk of deterioration, **and** has no exclusion criteria (see below) **and** has a reversible condition which will benefit from an intervention or treatment strategy which can be delivered **only** in the critical care setting.
Inappropriate referral:
Presence of the following exclusion criteria:
Poor or very poor FS **and** significant comorbidities **and/or** an irreversible condition, **and/or** the presence of a terminal disease with a significantly reduced life expectancy **and/or** patient refusal.
RESULTS.
59/107 (55%) of referrals were made out of hours (between 18:00 and 08:00)
28/107 (26%) were considered inappropriate. Appropriateness did not vary with time of referral
Of the 28 inappropriate referrals, 20 (71%) had poor or very poor FS **and** comorbidities with a 60% hospital mortality. 6/28 (21%) had good FS with a 17% hospital mortality. 2 had unknown FS/comorbidities.

Of the 79 appropriate referrals 33(42%) were admitted to ICU with a 36% hospital mortality. 46/79(58%) were declined ICU admission and had a 28% hospital mortality.
CONCLUSIONS. Seniority had a positive effect on quality of referral, however even following senior discussion 23% of referrals were considered inappropriate.

The outcomes of the inappropriate referrals reflect the negative impact of a combination of poor FS and comorbidities. Appropriate referrals do not always need ICU admission either because the patient is too well, or too ill.

Collaborative work with clinicians referring to ICU aims to improve understanding of the rationale for decision making. Recording the FS of the patient using a recognized frailty score is as important as assessing comorbidity, when considering critical care referral.

Health professionals' perception of head-of-bed elevation in patients on mechanical ventilation

A.H. Furtado Jr, M.C.F. Albuquerque, L.R. de Araújo, A.M.H.P. Silva, L.O. Domingues, L.M. Rodrigues, K.P. Afonso, A. Aires Peixoto Jr
Universidade Federal do Ceará, Fortaleza, Brazil
Correspondence: A.H. Furtado Jr
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1132

INTRODUCTION. Ventilator-associated pneumonia (VAP) is the second most frequent pathology in the Intensive Care Units (ICU) and it is one of the most fearsome events, due to the high lethality and the high costs involved. The head-of-bed (HOB) elevation at an angle between 30° and 45° is one of the most effective measures to prevent VAP. The perception of health professionals is key to make sure the HOB is put at the right angle.

OBJECTIVES. We investigated the knowledge of ICU professionals at the Walter Cantidio University Hospital on the recommendation of HOB elevation and the methods that they use to routinely assess the elevation of HOB in the ICU.

METHODS. The setting of the study was the clinical and the surgical ICUs at the University Hospital Walter Cantídio in Fortaleza, Brazil. The sample was 65 health professionals who work at the ICUs. A model simulating a critical patient was created with a mannequin equipped with hospital vestments and devices on a bed frame. The HOB was inclined at 30 degrees and the angle was confirmed by an inclinometer before each session of surveys. A mark 60cm away from the bed was placed on the floor, where the participants had to stand and answer 3 questions, which were written in a simple way to facilitate standardization: 1 How many degrees do you think this head of bed is elevated at? 2 What is the elevation angle that reduces the chance of ventilator-associated pneumonia? 3 In your daily practice at the ICU, how do you verify the angle of elevation of the head of bed? The surveys lasted for 7 days in a row. The study was reviewed and approved by the hospital's ethics committee, report number 2.467.096.

RESULTS. The angle indicated for HOB elevation varied between 2° and 90° among the physicians and between 10° and 45° among other health professionals. The correct HOB angle was identified by 54.5% nurses, 89.0% physiotherapists, 30% physicians. The HOB elevation interval for VAP prevention (30 to 45°) was precisely mentioned by 73% nurses, 20%. The technique used to determine the HOB elevation was 41.6% in the bedside indicator, 40.2% in the guesswork, 6.5% in the external appliance, and 11.7% do not know how or do not measure it.

CONCLUSIONS. There is a tendency to underestimate HOB elevation among nurses and overestimating it among physicians. The nurses were the professionals who presented the highest percentage of the correct HOB elevation interval for VAP prevention, followed by nursing technicians and, later, by doctors. In addition, the most prevalent technique used to determine HOB elevation was the indicator of the bed.

Quality improvement project on patient diary in intensive care unit to build the picture on critical illness events for the road of survival and rehabilitation

A. Chan-Dominy, K. Liyanage, E. Forbat, T. Hart, J. Matemera, R. Peters
Royal Brompton and Harefield NHS Trust, Department of Critical Care, London, United Kingdom

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1133

INTRODUCTION. Physical sequelae such as weakness can be difficult to understand when patients report no existential memory of the critical care environment. Experiences of delusional and intrusive memories, nightmares and hallucinations constituting to post-traumatic stress disorder are reported by patients at critical care follow-up clinic. Patient diaries can be helpful to fill in gaps in patients' memories and equip patients with a better understanding of what has happened to them in critical care, as a strategy to set realistic goals for recovery [1]. Diaries are intuitively unstructured with entry on voluntary basis to reflect autonomy of their scribers. An audit at our unit showed first entry was over 10 days in 25% diaries, under 10% diaries had more than 2 entries including notes by family per 24-hour period.

OBJECTIVES. To promote quantity and quality of entries in patient diaries employing PDSA (plan-do-study-act) methodology [2]. Improvement by 6 months aiming for over 90% diary with entry of 12 key events identified based on follow-up clinic feedback and telephone interview of 6 past patients about diary.

METHODS. Interventions included front-page insert of 12 key events, staff education at bedside and nursing team days, 5 diary champions,

family guidance on diary as a communication tool, glossary of common monitoring and advanced organ support therapy, staff notice board on patient feedback from clinic, nurse observers at clinic.

RESULTS. Over a 6-month period from August 2017 to February 2018, 104 diaries were launched for the 154 patients who had over 3 days length of stay (average stay of 16 days). A total of 39 diaries were audited after patient discharge from intensive care unit (ICU). 97% diaries had entry within 10 days of ICU admission and 23% diaries had more than 2 entries per 24-hour period. ICU admission entry and ICU discharge entry were noted in 23% and 60% diaries respectively (unchanged from previous audit). Entries by family members featured in 59% diaries

CONCLUSIONS. Quality improvement on patient diary entries is about studying staff and environmental culture (for a voluntary non-clinical activity), nurture skills of communication, then adapting to overcome barriers (index prompt for diary). Patient feedback provides a powerful testimony to plan intervention for this initiative.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1134

INTRODUCTION. The general population is slowly increasing in age, this is thought to be due to a combination of improved mortality, health provisions, and lifestyles, and reduced fertility [1]. As a result, there is a perception that there will be an associated increase in the age of patients admitted to critical care.

OBJECTIVES. This study aimed to review age and length of stay (LOS) characteristics in a district general mixed medical and surgical intensive care unit (ICU).

METHODS. Data was obtained from our WardWatcher database for 12,294 patients aged over 16 from 1992 to 2017, and was presented as boxplots for each year.

RESULTS. Qualitatively, the median age [IQR] of admission has varied minimally over the last 25 years (see Figure 1). However, looking at the mean age of admissions, there is a weak positive correlation associated between the year of admission and average age (R^2 = 0.66). The rise in mean age has not been associated with a positive correlation in the mean length of stay for the same time period (R^2 = 0.06).

CONCLUSIONS. Despite the increasing age of the general population over the last 25 years, there has only been a weakly positive correlation with the age of patients admitted to our ICU. There has not been an associated increase in the mean length of stay. Further work is required to elucidate whether there has been a proportionate increase in the admission of older patients.

High frequency of severe burnout syndrome in health care professionals at ICU and stepdown unit

C.S.A.A. Castro[1], K. Timenetsky[2], R. Afonso Caserta Eid[2], A. Serpa Neto[2]
[1]Hospital Albert Einstein, Fisioterapia Pacientes Graves, São Paulo, Brazil;
[2]Hospital Albert Einstein, São Paulo, Brazil
Correspondence: C.S.A.A. Castro
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1135

INTRODUCTION. Burnout syndrome is a prolonged response to chronic emotional and interpersonal stress at work. Burnout syndrome is seen as a process over time, where increased efforts to meet external demands lead to emotional exhaustion, which is a trigger for frivolous interpersonal conviviality which, in turn, leads to a decrease in achievement increase emotional exhaustion and start a vicious cycle. Health professionals, more specifically those working in Intensive Care Units (ICUs), seem to be the most affected by the syndrome and the high prevalence of burnout was associated with negative outcomes, such as psychological problems, a higher incidence of heart disease, and less personal satisfaction. Their presence also worries the employer´s intuitions, since it is associated with the quality of care, patient safety and professional engagement.

OBJECTIVE. To evaluate the prevalence of burnout syndrome in nursing, physiotherapy and medical professionals in a stepdown and intensive care unit of a private hospital in São Paulo.

RESULTS. Between February 2017 and June 2017, 206 professionals (63.3%) answered the questionnaires, of which 55 were physicians (26.7%), 88 physiotherapists (42.7%) and 63 nurses (30.6% %). The prevalence of severe burnout syndrome in the participants was 34.3%, with no difference according to the professional class (34.1% vs. 33.9% vs. 35.3% for physiotherapists, nurses and physicians respectively, p = 0.986) or place of work (34.2% vs. 34.5% for ICU and stepdown unit, respectively, p = 0.960). The prevalence of severe or

very severe cases of depression, anxiety and stress was 12.9%, 11.4% and 10.5%, respectively. The median points observed in the Gallup questionnaire were 41 (34-48), with no differences in relation to the workplace (p = 0,239) or professional class (p = 0.403). In the multivariate analysis, moderate and severe levels of stress and work between 3 and 5 days a week in other services were independently associated with a higher risk of developing severe burnout syndrome. Although it did not reach statistical significance, there was a tendency of association between higher Gallup scores and a lower risk of severe burnout.

CONCLUSION. Severe burnout syndrome presents a high prevalence among physicians, nurses and physiotherapists working in ICU and stepdown units. Moderate and severe levels of stress and work between 3 and 5 days a week in other services were independently associated with a higher risk of developing severe burnout syndrome.

Table 1 (abstract 1135). Association of work days in other hospitals with severe burnout syndrome through the multivariate analysis

|	Odds Ratio (95%CI)	p value
Work days in other hospitals per week		
None	1 (Reference)

Characteristics and evolution of patients of long stay in a polyvalent ICU throughout 15 years

J. Ruiz Izquierdo, B. Sánchez González, S. Quintana Riera, J. Trenado Alvarez
Hospital Universitari Mutua Terrassa, Intensive Care Department, Terrassa, Spain
Correspondence: J. Trenado Alvarez
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1136

INTRODUCTION. Due to advancements in medical technology and management of illnesses, an increasing number of intensive care unit (ICU) patients are stabilized during acute illness following prolonged resuscitation and treatment.

OBJECTIVE. To describe the characteristics and evolution of long-stay (LS) patients in a polyvalent ICU over 15 years.

METHOD. Unicentric, observational and descriptive study conducted in the period January 2000-June 2015. LS is defined as a stay above the 95th percentile.

Descriptive statistics and Chi square were performed for intergroup comparison.

RESULTS. In the study period, a total of 11443 patients were admitted, of which 542 (4.74% of the income) exceed one 19-day stay (95th percentile of the average stay of the unit in the period).

Male sex predominates (5.2 vs 3.8% respectively, p < 0.001). There are no differences in the age between groups, 60.70 years ± 16.87 vs 60.65 years ± 15.85.

Regarding severity score, these are much higher in the group of LS: MPM 0 27.72 vs 43.56, MPM 24 20.49 vs 38.09, SAPS 2 35.15 vs. 48.70, Apache III 56.40 vs 81.04.

Medical patients are predominant between patients with LS: 73.5%, compared to the Surgical one's 17.6% or 9.0% among emergent surgery (p = 0,004)

When we analyze the procedures performed in LS patients, we observed that use of vasoactive drugs (76.5% vs. 28.3% p < 0.0001), hemodialysis (10.9% vs 3.0% p < 0.0001), hemofiltration (18.1% vs 4.0% p < 0.0001), ICP monitoring (15.0% vs. 2.5% p < 0.0001), mechanical ventilation 97.6% vs 42.4% (Chi square 633.96 p < 0.0001) and realization of tracheostomy (57.3% vs 2.3% p < 0.0001) are more common.

If we divide the global period of study in three five-year periods, we observed that the prevalence of LS patients decreases significantly from 6.4 to 4.5% and 4.0% from first to third quinquennium, p < 0.001.

The average stay of the group LS was 33 days, with a higher mortality (8.5 vs 4.2, p < 0.001).

CONCLUSIONS. In the group of patients with LS, men and medical admissions predominate.

Age is not a risk factor to belong to this group.

The severity of the illness at the time of admission to the ICU, reflected in greater use of invasive techniques and life support.

Mortality is higher in the LS group but does not exceed 10%.

Reliability of free open-access medical education for intensive care procedures

J. Braviner[1], M. Carpenter[2]
[1]Newcastle University, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom; [2]Sunderland Royal Hospital, Integrated Critical Care Unit, Sunderland, United Kingdom
Correspondence: J. Braviner
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1137

INTRODUCTION. FOAM is a new concept where freely accessible resources are created online. Concerns have been expressed that whilst FOAM is an easy way to access medical education, its lack of peer review may make its reliability uncertain.

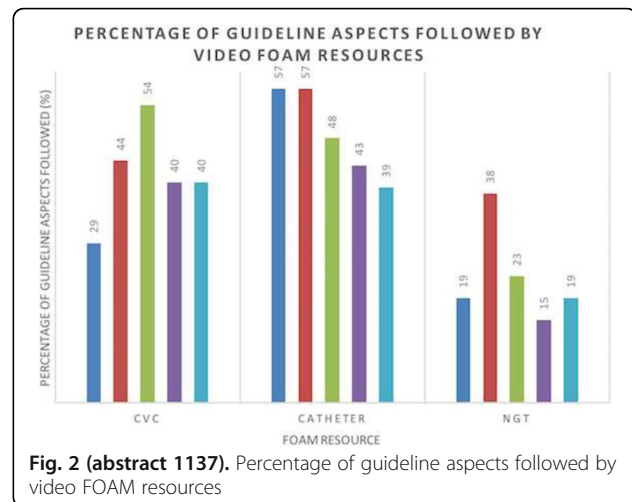
OBJECTIVES. Thirty FOAM resources related to three common intensive care procedures (central venous catheterisation, urinary catheterisation and nasogastric tube insertion) were reviewed to assess compliance with UK national and international guidelines. These procedures were chosen because the existence of international guidance, the frequency of their use in the ICU and the potential for significant harm from infection (CVC and catheter) and misplacement (NGT).

METHODS. The search strategy was predefined to gather five web and five video resources for each procedure.

The search terms "Central Line Insertion", "Male Urinary Catheterisation" and "Nasogastric Tube Insertion" were used (Google). Irrelevant, foreign language or paid resources were excluded.

Important elements within each guideline were pre-defined and their presence was compared to gauge compliance (CVC 28, NGT 22, catheterisation 28) [EPIC2 guidelines (Pratt, 2007) were used for specific guidance on CVC and catheter insertion. NPSA guidelines (National Patient Safety Agency, 2011) for NGT insertion].

RESULTS. 34% of guideline elements were included correctly, 64% were not included and 2% of elements were contradicted. Resources originated from a wide range of countries (CVC: 3 UK, 4 US, Canada, Australia, Pakistan, Catheterisation: 7 UK, 2 US, 1 Canada, NGT: 5 UK, 3 US, 2 Canada). In no single resource were more than 57% of elements correctly included (mean compliance per procedure CVC 36.2%, NGT 47.2%, catheterisation 29.6%).

Compliance with guideline elements ranged from only 17% for cleaning equipment to 100% for use of sterile drapes. The 19 contradictions included use of incorrect cleaning and flushing solutions, incorrect handling of sharps, contamination of sterile fields, incorrectly sized catheters and incorrect methods of confirming NGT placement (e.g. auscultation).


Due to incorrect placement of NGT being a UK 'never event' these incorrect placement methods give rise to significant patient safety concerns.

CONCLUSIONS. FOAM provides medical education in an easy to access format, but is not peer reviewed. We found substantial gaps in the information they conveyed. Contradictions to the guidelines were rare but clinically significant.

Correspondence: P. Vega Ocaña

INTRODUCTION. Healthcare workers are a key player in a pandemic, since they will be the first to expose themselves to it. Therefore, it is important to know their beliefs and attitudes when exposing them to it.

OBJECTIVES. The objective of this project is to analyze the beliefs and attitudes of healthcare workers and nursing students in an influenza pandemic, and their differences.

METHODS. A transversal and descriptive study was carried out, through a personal and anonymous inquest, among the healthcare personnel and students of the Degree in Nursing of the Las Palmas de Gran Canaria University (ULPGC), with a sample of 277 people. The instrument used to measure up the beliefs and attitudes of health workers before an epidemiological alert was the one published and validated by Professor Heather Draper of the University of Birmingham in June 2008, after obtaining the approval of the author to carry out this work (Draper H 2008, Damery S, Ives J 2009 & Damery S 2010).

The statistical analysis was carried out using the statistical package SPSS 15.0. Student-t and Chi-square tests were used to compare continuous and categorical variables, respectively.

RESULTS. 84.5% believe that a pandemic is likely to occur. Almost half do not believe there is a vaccine that protects them. And this percentage is much lower among students (52 versus 30.4%). In addition, students, unlike workers, fear that if there were an effective vaccine do not have access to it. 41.9% would not go to their workplace if their family had a higher risk of contracting the disease. But the most relevant fact is that only 5.8% have a high possibility of going to work, during a hypothetical pandemic, despite almost all adverse circumstances identified.

CONCLUSIONS. Almost everyone is aware that a possible influenza pandemic could happen and are willing to work for it, despite the personal risks they might be exposed. However, they place the family before work, since they would not be willing to fulfill their responsibilities if there was a greater risk than usual in infecting their relatives; being able to reach figures of absenteeism higher than 94%.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1139

INTRODUCTION. In recent years, the number of patients older than 80 years admitted to the Intensive Care Unit (ICU) has increased exponentially.
OBJECTIVES: To analyze the predictive capacity of SAPS-3 score in patients older than 80 years admitted to Intensive Cre Unit (ICU) and to evaluate the influence of the previous functional situation on the mortality.
METHODS. Multicentric prospective observational study in the ICU of 7 Spanish hospitals (Carlos Haya in Malaga, Cabra (Córdoba), Jaén, Burgos, Arnau Vilanova in Valencia, Clinic of Zaragoza, Ronda).
Data were expressed as the mean and standard deviation for quantitative variables and percentages for qualitative variables. For the comparison of two means we used the Student´s t-test and the chi-squared test was used to compare proportions and logistic regression for multivariate analysis. Statistically significant differences: $p < 0.05$.
RESULTS. 2008 patients in total. Of these, 181 (9%) between 80-85 years, 57 (3%) between 85-90 years old and only 4 patients were older than 90 years.
62% for medical pathology. Acute coronary syndrome (20% of all patients, 12% with ST-segment elevation myocardial infarction (STEMI), arrhythmias especially bradycardia with need for vigilance and / or pacemaker (17% of the total), 5% for sepsis and 4% for cardiac or respiratory arrest.
38% are surgical, of them 10% only for central venous catheterization, and 7% for emergency surgery. The most frequent were cardiac and maxillofacial surgery.
At admission, 26% required mechanical ventilation, with mortality of 40% and of non-ventilated patients of 17% (p=0.001). Previous functional situation (normal, self-sufficient but with dysfunction and not self-sufficient) was: 50%, 36% and 14%, with hospital mortality: 14.4%. 35.9% and 23.1% respectively.
SAPS-3 on admission of 53.83±12.71 points. The predicted mortality of 26% and hospital mortality of 23%, (ICU of 14%).
The multivariate analysis with logistical regression shows complementarity between SAPS-3 and previous functional situation to predict hospital mortality. OR: Normal = 1, Self-sufficient but with dysfunction = 2.9(1.25-7.13) and Not self-sufficient = 1.65(0.49-5.52).
In younger than 80 years, mortality was associated with previous functional situation and there was complementarity with SAPS-3. OR: (Normal = 1, Self-sufficient but with dysfunction = 1.57(1.1-2.24) and Not self-sufficient = 4.01(2.41-6.67)).

CONCLUSIONS. SAPS-3 is useful for predicting the mortality of elderly patients admitted to the ICU, the hospital mortality was similar to predicted mortality. The functional situation dysfunction is an independent factor associated with mortality, both in elderly patients and in those under 80 years.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1140

INTRODUCTION. Variation of outcomes in critically ill patients due to admission day was demonstrated in past studies [1]. Some studies suggested that an additional "off-hours" effect was also associated with unfavourable outcomes.
OBJECTIVES.

a) To assess, whether daytime of ICU admission is associated with variation in risk of death and chance of discharge.
b) To assess, whether time of day is associated with differences in the immediate risk of death and chance of discharge during ICU stay.
c) To assess, whether previously reported "weekend effects" occurred independently from possible "daytime effects".

METHODS. Retrospective study in the Austrian Centre for Documentation and Quality Assurance in Intensive Care (ASDI) database [2]. Adult patients admitted due to medical reasons or following emergency surgery to ICUs participating in the project between 2012 and 2016 were included. ICU readmissions during the same hospital stay were excluded.
Multivariable competing risk analysis using the Fine and Gray proportional subdistribution hazards model concerning ICU mortality and ICU discharge was performed [3]. The following variables of interest were included in the model: time of admission (4h blocks), time of event (4h blocks), weekend or working day, year of admission, month of admission. 08:00-11:59 was chosen as the reference range for all daytime variables. The model was adjusted using ICU as fixed effects, type of admission and SAPS3 score [4].
RESULTS. 146,004 patients were included in the analysis. Risk of death varied significantly with time of admission [HR (95% CI) for ICU admission time: 12:00-15:59 0.99 (0.92-1.07), 16:00-19:59 1.08 (1.00-1.16), 20:00-23:59 1.11 (1.03-1.19), 00:00-03:59 1.24 (1.14-1.36), 04:00-07:59 1.23 (1.11-1.36)]. Significant variation in the risk of death during ICU stay with regards to daytime was observed [HR (95% CI) for time of death: 12:00-15:59 1.06 (1.00-1.13), 16:00-19:59 0.94 (0.89-1.01), 20:00-23:59 0.92 (0.85-1.00), 00:00-03:59 0.50 (0.46-0.55), 04:00-07:59 0.53 (0.49-0.58)]. Chance of discharge was drastically lower in the afternoon and at nights [HR (95% CI) for time of discharge: 12:00-15:59 0.62 (0.54-0.72), 16:00-19:59 0.15 (0.12-0.18), 20:00-23:59 0.08 (0.06-0.10), 00:00-03:59 0.02 (0.02-0.03), 04:00-07:59 0.03 (0.02-0.03)]. Risk of death following weekend ICU admission was elevated nevertheless [HR (95% CI) 1.19 (1.06-1.35) compared to working days].
CONCLUSIONS. Daytime is associated with significant variation in both risk of death and chances of discharge in critically ill patients admitted to ICUs for reasons other than scheduled procedures and following adequate adjustment for severity of illness.

INTRODUCTION. The post-intensive care syndrome (PICS) is marked by physical, mental and cognitive disabilities that remain in survivors of critical illness. The epidemiology of PICS and its association with quality of life (QoL) among general ICU survivors are not clear.

OBJECTIVE. To evaluate the prevalence and associated factors of long-term physical, mental and cognitive disabilities, and their association with QoL among general ICU survivors in Brazil.

METHODS. A prospective cohort study was conducted in 10 Brazilian mixed ICUs. Post-ICU patients aged ≥18 years, and with an ICU stay >72h (for medical and emergency surgical admissions) or >120h (for elective surgical admissions) were followed by telephone interviews 3, 6, and 12 months after ICU discharge. The outcomes were moderate/severe physical dependence, evaluated by the Barthel Index; anxiety and depression, evaluated by the Hospital Anxiety and Depression Scale (HADS); posttraumatic stress disorder (PTSD) evaluated by the Impact Event Scale-6; cognitive dysfunction, evaluated by the Montreal Cognitive Assessment; and QoL, evaluated by the SF12v2 health survey.

RESULTS. From May 2014 to April 2018, 1,044 post-ICU patients were followed. The one-year mortality was 27.9% (n=291). At 3 months, 262/726 (36%) had moderate/severe physical dependence. At 6 months, 85/373 (23%) had anxiety, 75/373 (20%) had depression, and 57/374 (15%) had PTSD. At 12 months, 227/326 (69%) had cognitive dysfunction. Figure 1 shows the factors associated with post-ICU disabilities. At 3 months, Charlson comorbidity index ≥2 (PR, 1.74; 95%CI, 1.15-2.63), no higher education (PR, 1.89; 95%CI, 1.07-3.33), HADSa ≥8 at ICU discharge (PR, 1.68; 95% CI, 1.17-2.42), previous physical dependence (PR, 1.81; 95%CI, 1.16-2.83) and muscular weakness at ICU discharge (PR, 2.47; 95% CI, 1.70-3.60) were associated with moderate/severe physical dependence. At 6 months, HADSa ≥8 at ICU discharge (PR, 1.89; 95%CI, 1.28-2.79) and decrease in household income (PR, 1.50; 95%CI, 1.01-2.23) were associated with anxiety; HADSd ≥8 at ICU discharge (PR, 3.39; 95%CI, 2.24-5.12) and public health insurance (PR, 1.64; 95%CI, 1.08-2.50) were associated with depression; age per year (PR, 0.98; 95%CI, 0.96-0.99), HADSd ≥8 at ICU discharge (PR, 2.36; 95%CI, 1.42-3.94) and decrease in physical functional status (PR, 1.79; 95%CI, 1.07-2.98) were associated with PTSD. At 12 months, age ≥65 years (PR, 1.36; 95%CI, 1.17-1.58) and public health insurance (PR, 1.25; 95%CI, 1.07-1.46) were associated with cognitive dysfunction. Patients with post-ICU disabilities, with exception of cognitive dysfunction, had lower physical and mental SF12v2 scores in comparison to those without disabilities (figure 2).

CONCLUSION. The high burden of disabilities after ICU is a matter of high relevance for public health, given its impact on patients´ QoL. The network of potential risk factors for post-ICU disabilities is complex and involves factors of multiple domains.

Renal insufficiency in intensive care unit patients: clinical characteristics and outcome

M. Sousa, W.C. Baptista, R.S. Franco, A. Bemfica, A. Moreira, M.C. Cesar, I. Valade, M. Leite
Hospital Novo Atibaia, ICU, Atibaia, Brazil
Correspondence: M. Sousa
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1142

INTRODUCTION. Renal insufficiency (RI) is one of the main complications found in the intensive care unit. The risk factors and clinical evolution of the patients may contributes to increase the morbidity rate of critically ill patients.

OBJECTIVES. To characterize the clinical and laboratory profile as well as the outcomes of patients with acute (comparing acute or chronic with acute exacerbation) renal failure in an intensive care unit (ICU).

METHODS. Retrospective study from January 2013 to December 2016, with 106 patients hospitalized in an ICU who evolved with RI. The clinical characteristics, laboratory and evolution of the patients were compared according to type of RI (acute or chronic with acute exacerbation). For statistical analysis, a significance level of 5% was used and chi-square test, Kruskal-wallis test (when abnormal distribution of the sample) and t-student test (when normal distribution) were used.

RESULTS. The sample was 106 patients, 65 (61.3%) with acute and 41 (38.7%) with acute exacerbation of chronic. The group with acute had a mean age of 67.11 ± 17.20 years; 58.5% male; 70.8% clinical patients and 29.2% surgical; 51 deaths (78.4%). On the other hand, the group with acute chronic has a mean age of 72.24 ± 12.54 years; 68.3% male; 85.4% clinical patients and 14.6% surgical; 28 deaths (68.3%). In the statistical analysis, the variables with significant statistical difference between the 2 groups (acute and chronic acute exacerbations) were: SAPS III points (75.75 ± 16.38 X 67.51 ± 13.25 - p 0.008), SAPS III% in death (63.12 ± 24.02 X 51.72 ± 22.63 - p 0.01), diabetes (23.1% X 48.8% - p 0.006), vasoactive drug (81.5% X 46,3% - p 0.000), sepsis (80% X 58.5% - p 0.01), creatinine on admission (2.54 ± 2.74 X 4.39 ± 3.37 - p 0.00), creatinine on day 1 of hemodialysis (3.87 ± 2.49 X 8.95 ± 26.25 - p 0.016), urea on admission (93,47 ± 60.67 X 164.48 ± 114.27 - p 0.00) and urea on the 1st day of hemodialysis (149.86 ± 59.96 X 194.29 ± 96.53 - p 0.034). The predictors of acute and chronic morbidity are listed in TABLE 1.

CONCLUSION. RI has a high morbidity and mortality rate and the identification of risk factors for poor prognosis in patients with renal insufficiency allows for early diagnostic and therapeutic intervention to minimize and reverse unfavorable patient outcomes.

Table 1 (abstract 1142). Predictors of mortality in renal injury

	Acute renal injury	Acute deterioration in chronic kidney disease

Comparison between obese and non-obese populations who have undergone heart surgery regarding bleeding, polytransfusion and bleeding-related reoperation

E. Trujillo García, J. Muñoz Bono, E. Curiel Balsera, M.D. Fernández Zamora, H. Molina Díaz, G. Quesada García
H. R. U de Málaga, Intensive Care, Málaga, Spain
Correspondence: E. Trujillo García
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1143

OBJECTIVE. Evaluating the possible influence of obesity on the incidence of postoperative bleeding, need of polytransfusion, and bleeding-related reoperation, as well as their complications in patients undergoing cardiovascular surgery.

MATERIAL AND METHODS. Observational, prospective, multicentre and comparative study of all patients who have undergone heart surgery in Andalusian hospitals taking part in the ARIAM Project.

RESULTS. A total number of 7276 patients who had undergone heart surgery from March 2008 to July 2012 were analysed. 61.1% of the operated patients were males. 34.9% were obese with a BMI over $30Kg/m^2$.

Patients with BMI>30 Kg/m^2 showed significantly lower bleeding incidence than those with BMI< $30Kg/m^2$ (17.5%vs.13.1%, p=0.001), lower polytransfusion need (7.3%vs.5.5%, p=0.004), and lower bleeding-related reoperation figures (4.4%vs.3%, p=0.005).

In this analysis, high BMI was shown as a protective factor against mortality (OR 0.69, IC 0.51-0.93, p=0.015), adjusted by EuroScore, surgery type, and previous anticoagulant/antiplatelet treatment, since —when this duration is the same— obese patients show 30% lower bleeding and reoperation probability.

Regarding complications, no significant differences were observed in the incidence of postoperative kidney failure (worsening of the kidney function measured by the AKIN scale, or the need of renal replacement therapy during ICU admission). However, analysis of postoperative kidney failure patients showed significantly higher incidence of kidney failure among obese patients who had needed transfusion than among their non-obese counterparts (38.8% vs. 35.3%, p = 0.023).

Regarding respiratory complications, no significant differences were observed regarding the duration of mechanical ventilation (MV) after surgery, the need of reintubation, and the performance of tracheostomy to wean patients from MV between both groups. Patients whose BMI>30 Kg/m^2 showed significantly lower incidence of hemothorax (5.6% vs. 7.2%, p=0.014). However, obese patients can be observed to need NIMV with higher frequency and duration than their non-obese counterparts (7.2 vs. 5.6%, p=0.026).

Reoperated obese patients showed longer hospital stay relative to reoperated non-obese ones (19.68±17.5 days vs. 29.56±36.63 days, p< 0.043). No differences are observed in death rates between both groups.

CONCLUSIONS. Unlike what would be expected in patients who have undergone heart surgery (both coronary artery bypass and heart valve replacement), obesity (BMI>30) does not predispose patients to develop greater postoperative bleeding, bleeding-related reoperation, or greater need of postoperative transfusion of hemoderivatives. It can even be a protective factor against bleeding and reoperation after prolonged extracorporeal circulation.

Vascular closure device angioseal for femoral percutaneous catheterization: assessment of security

A.M. Garcia Bellon, A.M. Gonzalez Gonzalez, M. Cano García, M. De Mora Martin
Regional Hospital of Malaga, Cardiology, Malaga, Spain
Correspondence: A.M. Garcia Bellon
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1144

INTRODUCTION AND OBJECTIVES. Our aim was to determinate the prevalence of vascular complications with the use of vascular closure device AngioSeal after cardiac catheterization via femoral artery. We studied the overall prevalence of any vascular complication in this population, the epidemiological and clinical predictors of bleeding, the complication rate and the way of presentation.

METHODS. Between 2012 and 2016 we studied 1613 patients in whom, after catheterization via femoral artery, it was used an AngioSeal percutaneous closure system. We studied the predictors of complications, clinical profile of patients and its manifestations.
RESULTS. The study included 1613 patients with a mean age of 69.47 years. 57% were female, 52% had diabetes mellitus and 15% chronic renal failure. 74 patients (4.6%) in this serie had a complication related to AngioSeal. The procedure performed was coronary angioplasty with drugs eluting stents or bare metal stents in 1032 patients (64%), diagnostic catheterization in 420 patients (26%), and valve interventions in 161 patients (10%). 74 complications were observed, the most frequent was haematoma in 60 patients (81%), and most of them were small: 73% < 5 cm (44 patients). 57% of all haematomas appeared or worsened late (> 24 hours), presenting as a syndrome of acute bleeding (26 patients), coinciding with the primo-mobilization. The symptoms were acute groin pain, swelling and hypotensive or hemorrhage syndrome. 22 patients (29.7%) required transfusion for signs and/or hemoglobine < 9 mg/dl. 18 patients developed pseudoaneurysms, 12 of them were resolved with compression, 6 with embolization with surgery. 3 patients (4%) developed arterial ischemia resolved with endarterectomy. Independent predictors of bleeding were: coronary intervention (63%),dual antiplatelet therapy (76%), fibrinolysis (28%), previous oral anticoagulation (26%), prior anemia (6%).
CONCLUSIONS. Vascular complications resulting from the use of AngioSeal are rare, and many of them, have a presentation of acute bleeding possibly due to late inadequate apposition between collagen and vascular anchor. Coronary intervention and dual antiplatelet therapy are the most important independent predictors of bleeding associated with the use of this device.

Comparative study of three therapeutic strategies in patients admitted to the ICU due to symptomatic bradycardia: temporary transvenous pacemaker (TTVP) vs chronotropic drugs (C+) vs observation (OBS)

J. Romo[1], P. Gallardo[2], N. Arriero[1], Z. Eguileor[1], S. Saboya[3], J.A. Silva[1], C. Marian[1], M. Torralba[4], C. Benito[1], A. Albaya[1], Y. Elena[1], A. Estrella[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1145

INTRODUCTION. Admission for symptomatic bradycardia in the ICU is frequent and the initial therapeutic option, while waiting for permanent pacemaker implantation, depends on the severity of symptoms, the center´s infrastructure and the personnel who perform the care. This study tries to describe the clinical outcome of the three most frecuently used therapeutic options before definite pacemaker implantation: temporary transvenous pacemaker (TTVP), chronotropic drugs (C+) and observation (OBS).
OBJECTIVES. To analyze the characteristics and clinical outcome of three initial therapeutic options (TTVP, C+ and OBS) in patients admitted to the ICU due to symptomatic bradycardia.
METHODS. Retrospective cohort study of patients admitted to the ICU due to symptomatic bradycardia [symptomatic atrioventricular block (sAVB), sinus node dysfunction (SND), hyperkalemia (HK), drug overdose (OD), etc.] from January 2014 to December 2017.
We collected demographic data: age and sex; and clinical variables: APACHE ll, diagnosis at admission, low cardiac output, agitation, time from ICU admission to permanent pacemaker implantation (TPPM), length of stay in ICU (LSICU) and in hospital (LSH); the last three meassured in days.
The demographic variables were compared by χ2 and the quantitative ANOVA or nonparametric test (Kruskal-Wallis).

RESULTS. We analyzed 105 patients divided into 3 groups: TTVP: 70, C+: 11, OBS: 24. Of these 54.3% were men; median age 79.5 (IQR: 71.5-84).

The APACHE II median was 14 (IQR: 10-17) with no significant differences (NSD) between the 3 groups (p = 0.200).

The most frequent diagnosis was sAVB (83.8%), with NSD in the type of bradycardia between the 3 groups (p = 0.830).

There where NSD in low cardiac output between the 3 groups (p = 0.340).

Agitation was more frequent in the TTVP (25,7%) and C+ (27,3%) groups compared with OBS (4,2%), although with NSD (p=0,070).

The TPPM (days) was 1.42 (1.18-1.66) in TTVP; 2.11 (0.33 - 3.89) in C+; and 1.09 (0.72-1.45) in OBS; with NSD between the 3 groups (p = 0.700).

The LSICU (days) was 1.94 (1.63-2.25) in TTVP; 1.6 (1.0-2.20) in C+; 1.33 (1.01 - 1.65) in OBS ; with NSD between the 3 groups (p = 0.080).

The LSH (days) was 4.8 (3.91 - 5.69) in TTVP; 4.78 (1.96-7.6) in C+; 3.83 (3.03-4.63) in OBS; with NSD between the 3 groups (p = 0.334).

Four patients in the OBS group (16.7%) and two patients in the C+ group (18,2%) required urgent placement of TTVP.

CONCLUSIONS. In our series, there were no significant differences between the three groups in any of the studied variables. There was a higher incidence of agitation in the TTVP and C + group, although with no significant difference.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1146

INTRODUCTION. Excessive fibrinolysis remains a major component of acute coagulopathy in patients undergoing on-pump coronary artery bypass grafting (CABG). Desmopressin (DDAVP) (1) and tranexamic acid (TXA) (2) secure the formation of normal blood clots through different pathways (platelet adhesion and aggregation and inhibition of enzymatic degradation of fibrin blood clots respectively) .

OBJECTIVES. The objective of our study was to evaluate whether the efficacy of DDAVP is major when combined with TXA.

METHODS. We performed a randomized double-blind clinical trial to investigate the fibrinolytic activity, represented by D-dimers, in 57 patients who underwent primary and isolated on-pump CABG surgery and admitted in our cardiovascular intensive care unit between December 2017 and March 2018. The patients were randomized in two groups, group D (n=27) and group B (n=28) according to whether they received DDAVP only (0,6 γ/kg, divided in two doses, at the beginning and at the end of surgery) or TXA as well (20 mg/kg at induction of anesthesia,10 mg/kg during CPB and 30 mg/kg with protamine injection). The two groups were compared for pre and post-operative levels of D-dimers as well as visible blood loss defined as intra- and postoperative bleeding during the first 24 hours

RESULTS. Median age of the patients included to the study was 66 years and 65% were males. Production of D-dimers and visible blood loss was significantly lower in group B than group D (0.69 mg/L [+-0.49] vs 3.08 mg/L [+-2.05] , p< 0.05 and 855 ml [+- 330] vs 1491 ml [+- 495], p< 0.05, respectively). Stratified analysis revealed statistically significant association between D-dimers and blood loss (p< 0.01). An increase in D-dimers indicated an increase in blood loss (rho=0.343).

CONCLUSIONS. These results suggest that DDAVP must always be given concomitantly with TXA for maximum depression of fibrinolysis and minimum blood loss during and after CABG.

INTRODUCTION. Cardiogenic shock and advanced heart failure are causes of admission to the intensive care unit (ICU). Placement of mechanical circulatory assist devices (MCAD) must be considered as a salvage therapy when first-line therapies fail. It allows temporary bridging to recovery, decision or heart transplantation.

OBJECTIVES. Description of the most common causes, the type of device used and the kind of bridging therapy selected for MCAD positioning. Severity assessment of the cardiac failure before MCAD implantation and further mortality rate during the therapy will be presented.

METHODS. Prospective observational study from January 2012 to December 2017 in a third-level ICU. All patients that required short-term MCAD placement during ICU admission were included. All the devices were surgically placed in theatres and perioperative care was managed by the intensivist at the ICU. Demographic data, type of device, cause of heart failure, laboratory parameters, left ventricular ejection fraction (LVEF) before device placement, inotropic support and intra-aortic counterpulsation balloon pump (IAoB) requirement, type of bridging therapy and mortality on ICU were collected. INTER-MACS (Interagency Registry for Mechanically Assisted Circulatory Support) class was used to determine the severity of heart failure.

RESULTS. Fifty-nine patients were included. The average age was 50 years (IR 41-61) of whom 43% were males. Myocardial infarction was the main cause of MCAD positioning (36%) followed by non-ischemic dilated cardiomyopathy (22%). Peripheral venous-arterial (VA) ECMO (69%) was the most used, followed by central VA ECMO (15%), biventricular Levitronix Centrimag (9%) and univentricular Levitronix Centrimag (7%). MCAD positioning as bridge to transplantation therapy was practised in 43% of the patients, 32% as bridge to recovery and 25% as bridge to decision. Serum lactate level after 24 hours of MCAD support was 3,0 mmol/L (IR 1,4-5,2). Sixteen days was the average of days of stay in ICU (IR 6-31). Forty-two patients (64%) had INTERMACS class 1. Among survivors, 73 % of the patients had INTERMACS class 1.

Heart transplantation was the outcome in 20 patients (34 %), recovery in 11 patients (19 %), second MCAD positioning in 6 patients (10%) and 22 exitus cases (37 %).

An overall mortality after heart transplantation or second MCAD placement was 53 % (35 patients).

CONCLUSIONS. The most frequent cause of MCAD implantation was cardiogenic shock after myocardial infarction, followed by non-ischemic dilated cardiomyopathy. The most used device was VA ECMO. In most cases, MCAD implantation was used as bridge to heart transplantation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1148

INTRODUCTION. Patients after cannulation for venoarterial extracorporeal membrane oxygenation (VA-ECMO) can develop a sepsis like syndrome necessitating substantial fluid resuscitation. There are data suggesting a potential benefit of albumin fluid resuscitation in patients with septic shock.

OBJECTIVES. This study evaluates outcome of VA-ECMO patients with albumin versus saline fluid resuscitation.

METHODS. We performed a retrospective cohort study between October 2010 and October 2017 of all patients treated with VA-ECMO for shock or for extracorporeal cardiopulmonary resuscitation at a single center. At physician's discretion, patients received either albumin (local standard encouraged 10g albumin per liter fluid resuscitation) or saline only. Propensity score matching was performed to attenuate bias.

RESULTS. A total of 306 patients (age 58.7±14.6 years, 27.1% female, SOFA score 14.9±2.2, SAPS2 score 49.4±14.1) were included. 118 patients received albumin within 24 hours after cannulation (average 60.3±57.5g), 188 patients did not. Patients with albumin were sicker (SOFA-score 15.3±2.4 vs. 14.7±2.1, p=0.044, SAPS2-score 52.1±13.4 vs. 47.7±14.3, p=0.015) and had a higher net fluid balance after 12 hours (7.9±6.2 vs 6.2 ± 6.3, p=0.026). Hospital survival however was similar (albumin 37.3% vs. saline 29.8%, p=0.211). When excluding 18 patients with a negative net fluid balance 12 hours after cannulation, patients with albumin fluid resuscitation had a significant survival benefit (median survival 165h vs 99h, hazard ratio 1.36, 95% CI 1.03-1.82, Mantel-Cox p=0.033). After 1:1 propensity score matching (including age, resuscitation, norepinephrine, lactate, fluid balance, and SAVE, SOFA and SAPS2 score) we identified 79 matched pairs. Hospital survival was significantly higher in the albumin fluid resuscitation group (51.9% vs 26.6%, p=0.002) after matching.

CONCLUSIONS. In this retrospective registry of patients after va-ECMO cannulation, albumin fluid resuscitation resulted in a significant better hospital survival when compared to saline alone. These results have to be confirmed by a randomized trial.

Fig 1: Kaplan-Meier survival curves after cannulation for venoarterial extracorporeal membrane oxygenation (va-ECMO) in patient with and without albumin fluid resuscitation within the first 24 hours. Significance was calculated by log-rank (Mantel-Cox) test.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1149

INTRODUCTION. The central venous saturation (ScvO$_2$) had been advocated in intraraortic balloon pump weaning [1]. Some literature link the cardiac surgery outcome to high ScvO2 as well [2]

OBJECTIVES. We aimed to identify the IABP-induced changes in patients with impaired left ventricular function (LVF).

METHODS.

Design: A retrospective, observational, cross-sectional study.

Settings: Tertiary hospital 12-bed cardiothoracic intensive care unit (ICU). We examined arterial and venous blood gases through electronic medical records from 2012 to 2016.

Patients: We included patients with at least moderate impairment of LVF with ejection fraction (EF) < 40%.

Intervention: Patients were divided according to presence of IABP support into two groups:

1) group I with IABP and
2) group II without IABP.

RESULTS. Both groups were matched with respect to age, ejection fraction (EF) %, and hemoglobin and arterial saturation (SaO_2) in blood gases. Patients with IABP have a trend toward higher $ScvO_2$, which was significant in three out of seven samples screened from admission (71.47±12.5 versus 63.5±9.3, 68.3±12.6 versus 60.1±9.5, and 62.69±10.8 versus 55.63±8.1, p=0.04, 0.05, and 0.03 respectively).

CONCLUSIONS. In this study we found that patients with IABP had higher venous saturation in comparison with the matched group with moderately impaired left ventricular function after coronary revascularization. These results need to be addressed in interpreting ScvO2 data after cardiac surgery, especially when it is linked to outcome measures.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1150

INTRODUCTION. Previous reports

(1) have suggested a better outcome in fulminant myocarditis
(2) treated with mechanical circulatory support.

Only few studies have compared outcomes in fulminant myocarditis using pharmacologic therapy or mechanical circulatory support.

OBJECTIVES. To evaluate and compare mortality in patient with fulminant myocarditis requiring or not mechanical circulatory support.

METHODS. It was a retrospective, single-center, observational study. We analyzed data of all patients hospitalized at our institution for myocarditis from 1st January 2005 to 31 December 2016. We included only patients with fulminant myocarditis. Two groups were defined: patients with circulatory support (MF A+) and patients without circulatory support (MF A-). We evaluated mortality, morbidity, functional recovery in the 1, 3 and 6 months.

RESULTS. We analyzed data of 302 patients and we included 30 patients: 16 in MF A+ group and 14 in MF A- group. At day 28, MF A + group mortality was higher than MF A- group [50 vs 14% (p=0.007)]. The mean support time was 2.6 ± 3.5 days from the introduction of inotrope support. Myocardial recovery in MF A+ group was 41% at day 28 versus 60% in MF A- group and was not statistically different.

CONCLUSIONS. Mortality of fulminant myocarditis requiring mechanical circulatory support was significantly higher. Further studies would be needed to select patients who may require circulatory support.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1151

INTRODUCTION. Ventricular Assist Device (VAD) implantation in patients with Interagency Registry for Mechanical Assisted Circulatory Support (INTERMACS) Level I and II is accompanied with high early mortality and morbidity rates. In order to stabilize or discriminate inoperable patients, Extracorporeal Life Support (ECLS) is a promising new tool.

OBJECTIVE. Aim of this study was to compare early postoperative morbidity and midterm mortality in patients with cardiogenic shock and VAD-implantation with and without prior ECLS - implantation.

METHODS. Out of 116 consecutive patients with VAD implantation (continuous-flow devices) during 01/2012 and 07/2016, 50 patients were classified as INTERMACS I or II and analyzed retrospectively. Group 1: 24 ECLS patients, Group 2: 26 patients without ECLS. Primary outcome was 360 and 720 day mortality, secondary outcome was prolonged ICU stay (>7 days) and ventilation time (>3 days), renal replacement therapy (RRT), reintubation (RI) and re-thoracotomy (RT) after surgery.

RESULTS. In 12 patients, ECLS implantation was performed under cardiopulmonary resuscitation (ECPR). Mean time of mechanical support prior surgery was 8.1±6.5 days. Concerning age (52.4±12.9 vs. 58.5±11.3 years), gender (87% male73% vs. male), underlying disease, and destination or bridge to transplant indication there were no significant differences between groups. However, incidence of severe acute kidney injury requiring renal replacement therapy was higher in patients with preoperative ECLS (18/24 (75%) vs. 10/26 (38.5), p = 0.009) as well as the proportion of patients with INTERMACS level I (24/24 [100%] vs. 8/26 [31%], p < 0.01).

Using Cox regression analysis for primary outcome, 360-d-mortality (HR 0.83) and 720-d-mortality (HR 0.74); (p=0.65 / p=0.45) tended to be lower in the ECLS group without reaching statistical significance.

Using chi^2-test for secondary outcome parameters, ECLS implantation was not associated with a prolonged ICU stay (OR 1.2; p=0.75), ventilation time (OR 2.4; p=0.16), RI (OR 0.45; p=0.24) or RRT (OR 0.53; p=0.27). In contrast, ECLS therapy was a risk factor for postoperative RT (OR 4.9; p=0.048).

CONCLUSION. Despite unfavorable preoperative conditions, mortality and morbidity in patients with preoperative ECLS support was

comparable to patients without temporary mechanical support. Therefore, ECLS prior to LVAD as a bridge-to-bridge therapy may help to lower mortality in primarily unstable patients. However, attention has to be paid to the coagulation disorders of ECLS therapy with an increased risk of postoperative bleeding.

INTRODUCTION. Cardiorenal syndrome (CRS) type 2 is defined as heart disease primary chronic, responsible for kidney failure chronic secondary. Its prevalence varies by data of literature between 20 and 40% [1] and it constitutes an independent predictor of outcomes and mortality. Therefore, it is of the upmost importance to preserve the renal function in these patients.
OBJECTIVES. The objective of our study was to evaluate the therapeutic impact of CKD in patients followed for CHF.
METHODS. Our work was a retrospective study of 70 patients with CHF included in the cardiology department of the Marsa FSI Hospital. It compared between two groups: G1 group control: patients with renal clearance> 60 ml / min (N=30) and G2 group CRS: patients with renal clearance $\leq$ 60ml / min (N=40). For all the patients we recorded epidemiological, clinical, biological, echocardiographic and therapeutic data as well as major events during the follow-up.
RESULTS. Our patients had an average age of 58 and were predominantly male. The most common pattern of hospitalization was acute coronary syndrome in 33 (47%) cases, followed by congestive heart failure in 30 (43%). Thus, overload and renal congestion explain the use of diuretics. Furosemid was the most used, it was prescribed in 45 patients (64%) with no difference between the two groups (24 in G1 versus 22 in CRS, **p=0, 38**). The mean dose was 71 mg in group control and 53 mg in CRS group (**p=0, 36**). In Campbell´s study [2] loop diuretics were more used in the SCR group and at higher doses. For adjuvant therapy, the blockers of the Renin Angiotensin System, betablockers, digoxin and anticoagulants were used similarly in both groups, with no significant correlation. However, Isosorbide dinitrate was more used by the CRS group (n=6, (20%)) than in the control group (n=2(5%)), with a high correlation (**p=0, 05**).Our results were in agreement with those of Ahmed´s study [3]. In the current study, no patient had veno-venous ultrafiltration.
CONCLUSIONS. In addition to optimizing the management of heart failure and the prevention of cardiovascular risk factors, the main CRS treatment; which must be multidisciplinary; is based on optimal volume control using diuretics mainly. The place of ulrafiltration in this context remains to be clarified by complementary studies.

INTRODUCTION. Recent studies highlight a fall in the mortality in the ST-elevation miocardial infarction (STEMI) relate to an early reperfusion and the use of strong antiplatelet therapy. In spite of these results, in-hospital mortality persists high, around 4 to 12%.
OBJECTIVES. To describe the complications related to STEMI according to the inicial management adopted (conservative, fibrinolytic therapy or primary angioplasty) in our centre without 24h primary angioplasty availability.
METHODS. Descriptive restrospective study that incluyes 167 patients admitted in our ICU in the last year (2017) with the diagnosis of SETMI. We obtained demographic variabes, initial reperfusion therapy, complications and mortality.
Data analysis with SPSS program.
RESULTS. We describe 167 patients, 82% men with a median of age of 64 years old. In admítanse 77.2% presented Killip I, 12% Killip II, 6.6% Killip III and 4.2% cardiogenic shock.
38.2% had an anterior STEMI, 30.5% inferior STEMI, 24.6% infero-posterior/infero-lateral and 4% lateral STEMI.
Glotal mortality was of 6% (72% in women), being 4.2 % related to the initial Management and 1.8% with ICU admittance.
Angioplasty was performed in 44.3% of the patients (43.7% in anterior localisation, 49% inferior), fibrinolytic therapy in 38.9% and conservative Management in 16.8%.
According to the initial Killip, angioplasty was performed in Killip I cases 38.7%, Killip II in 47.6%, Killip III 81.3% and Killip IV 83.3%.
In total 58.7% of the patients did not present any complications. Between the patients undergoing fibrinolysis therapy, 41.4% had a complication (cardiorrespiratory arrest 9.2% (CRA), ventricular tachicardia with pulse 7.6% (VTWP), auriculo-ventricular block (7.6%) (AVB), hemorrhagic stroke, cardiac tamponade and cardiogenic shock (CS), 1.5% respectively.
Out of the patients undergoing angioplasty 51.4% suffered complications (CRA 5.4%, VTWP 1.3%, AVB 8.1%, CS 9.5%; no cardiac tamponade or hemorrhagic stroke were registered).
CONCLUSIONS. Despite the limited access to the hemodynamics unit, our in-hospital mortality is similar as those described in European series. There are more complications in pacients treated with angioplasty probably in relation with a higher initial Killip in admittance.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1154

INTRODUCTION. According to the latest clinical guidelines, primary percutaneous coronary intervention (PCI) is the reference reperfusion treatment in STEMI. In our daily practice the hemodynamics unit only performs primary PCI from Monday to Friday from 8AM-15PM, and in special cases such as contraindications to fibrinolytic therapy, failure in fibrinolytic therapy and extremely severe cases.

OBJECTIVES. Asses the management of those patients with STEMI diagnosis in our unit during the last year, and whose initial reperfusion treatment was fibrinolytic therapy.

METHODS. Retrospective observational study with 58 patients diagnosed of STEMI in 2017. Statistical analysis: cualitative variables expressed in percentages and cuantitative variables according to central trend and dispersion.

RESULTS. During the period of study a total of 54 patients with STEMI were admitted into the ICU, of which 52% were treated with in-hospital fibrinolytic therapy and 48% received pre-hospital therapy.

In the pre-hospital group, 76.9% were men with a mean age of 58.1 ±13.6 years. 96% had at least one cardiovascular risk factor (CVRF). Inferior STEMI was present in 35% and multiple localisation in 35%. Rescue PCI was performed in 46% of the patients, with mono-vessel disease in 58% of these. During ICU admittance, 58% had a torpid evolution with predominant cardiologic complications (93%). Mean ICU and hospital length of stay was 1.5 ± 0.7 days and 3.8 ± 3.5 days, respectively. Regarding clinical outcome, only one exitus was recorded (3.8%) and Ejection Fraction (EF) at discharge of the surviving patients was 43.5%± 12.7.

In the in-hospital group, 82% were men with a mean age of 53.8 ± 13.7 years old, 93% had CVRF. Anterior presentation occured in 54% of the the patients and in 29% of the cases rescue PCI was performed, being 68% of these mono-vessel disease. During ICU admittance, 50% had a torpid evolution with predominant cardiologic complications and only in one case a hemorrhagic complication occurred. Mean ICU and hospital length of stay was 1.5 ± 0.8 days and 3.9 ± 3.5 days, respectively. In this group two exitus were recorded (7%) and EF at discharge of the surviving patients was 44.9%± 9.7.

CONCLUSIONS. In spite of needing less number of rescue PCI and presenting less complications during the evolution, the in-hospital group had a higher mortality. However, there were no significant differences regarding lenght of stay in ICU/hospital or EF at discharge in the surviving patients.

Despite the limited number of analyzed cases and the limited access to the hemodynamics unit, we hightlight the reduced incidence of severe complications, translating into satisfactory results in terms of prognosis and mortality.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1155

INTRODUCTION. Patients with inhalation injury have a worse prognosis. One of the factors involved in this increase in mortality are the hemodynamic changes produced in the initial resuscitation phase and reflected the higher volume requirement during this phase.

OBJECTIVES. The aim of our study is to analyze the hemodynamic changes that occur in the patient with inhalation injury during the initial phase of resuscitation and its relationship with mortality.

METHODS. We conducted a three-year prospective cohort study of 362 consecutive critically burned patients admitted to a critical burn unit considered as a national burn reference center. We used in all patients admitted to our unit a resuscitation protocol guided by the parameters obtained with transpulmonary thermodilution and tissue perfusion data. Demographic data, TBSA, severity scores, mechanical ventilation, length of stay and mortality were collected, in addition to the data provided by thermodilution and lactate value, troponin and NTproBNP.

We compared the results obtained among critically burned patients with TBSA < 20% and patients with inhalation injury. Inhalation injury was defined with two or more of the following criteria: history of injury in an enclosed space, facial burns with singed nasal hair, carbonaceus sputum and stridor. If they were intubated it was diagnosed by bronchoscopy.

RESULTS. During this period 362 consecutive critical burns patients were admitted in our unit, 96 patients with a TBSA > 20%, 84 patients with inhalation injury. The majority were middle-aged males, although the patients with inhalation Injury were older. We did not find significant differences in the severity scores between both groups, except in APACHE II. Neither did we find differences in the amount of volume used during the initial resuscitation, nor in the average stay, although we found differences in the need for MV and in mortality, being significantly greater in patients with inhalation injury (Table 1)

The parameters obtained with the transpulmonary thermodilution are shown in the following graph (Graph 1).

CONCLUSIONS. In our study, the volume used during the initial resuscitation was similar in both groups, coinciding with those estimated by Parkland.

Patients with inhalation injury had a greater need for MV, which could be related to the increased mortality of these patients.

Mortality in patients with inhalation injury was associated with greater cardiac dysfunction, represented by lower cardiac index values and higher values in markers of myocardial damage (troponin and NTproBNP), greater tissue hypoperfusion (elevated lactic acid levels) and greater inflammatory response with more alteration of permeability (elevations of IAPEV).

and NE requirement (< 0.05 mcg/kg/min) in COM vs non-COM were: MA 48 vs 24hrs (Hazard ratio and 95% CI) (HR 0.87 (0.4-1.6), p=0.56), L 32 vs 16hrs (HR 0.85 (0.45-1.59), p=0.62), NE dose 54 vs 30hrs (HR 0.36 (0.21-0.62), p=0.0002). P values by log-rank test.

CONCLUSIONS. Clinicians selectively deployed cardiac output monitors in patients with vasopressor resistant septic shock. This cohort was more likely to need adjuvant therapies including inotropes, renal replacement therapy and concomitant shock steroids. Patients on COMs took longer to come off NE, however they resolve their acidosis and lactataemia within a time-frame which is not significantly different to the non-COM cohort, suggesting that COMs help drive appropriate decision making in managing complicated shock.

INTRODUCTION. The Surviving Sepsis Campaign recommends use of cardiac output monitors with dynamic assessment for fluid responsiveness[1,2] in patients with septic shock. Minimally invasive pulse contour analysis based cardiac output (CO) monitors (COM) are popular in many ICUs, but akin to the pulmonary artery catheter[3], determination of their clinical efficacy is compounded by questions about adequacy of training and (in)appropriate clinical responses to CO studies[4].
OBJECTIVES. To review practice, clinical and biochemical outcomes of patients with isolated severe septic shock admitted to a major tertiary academic ICU, between those patients who received a COM (either LiDCO or PiCCO) versus those who did not.

METHODS. Contemporaneous automated data recorded in an advanced electronic record system (Epic® Systems USA) was retrospectively interrogated and analysed. All patients admitted to ICU with isolated severe septic shock (norepinephrine (NE) >0.1 mcg/kg/min) over a period of 5 months were included. NE dose and biochemical parameters were recorded on 1 and 4 hourly intervals respectively. Data was collated on to an Excel database and analysed using appropriate statistical methods.

RESULTS. A total of 75 patients fulfilled selection criteria, of whom 34 (45%) had a COM used. Chest (60%) and abdomen (28%) were the commonest sources of sepsis. COM vs non-COM findings were as follows: median age 68 vs 62 yrs, crude in-hospital mortality 19/34 (56%) vs 15/41 (36%), median NE starting dose 0.17 vs 0.14 mcg/kg/min, p=0.0042 (Mann-Whitney U test), adjuvant vasopressor therapy 38% vs 5%, p=0.0003 (Fisher's exact test), inotropes 35% vs 2%, p=0.0002, shock steroids 85% vs 52%, p=0.003, and renal replacement therapy 68% vs 43%, p=0.04. Fluid balance between the groups was comparable.

Median time to resolution by survival analysis for metabolic acidosis (MA) (base excess better than -2), lactataemia (L) (< 2)

The prognostic value of cardiac power output in septic patients
M. Turker, B. Bilgili, Z. Aykac
Marmara University School of Medicine, Istanbul, Turkey
Correspondence: B. Bilgili
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1157

INTRODUCTION. Sepsis is one of the leading reasons for the hospitalization with high mortality and morbidity; there is still a search for predictive values for mortality. Recently, a new hemodynamic parameter "Cardiac Power Index (CPO)" has been proposed to determine prognosis in heart failure.
OBJECTIVES. We aimed to evaluate the prognostic power of CPO in sepsis and ICU survivals of patients with septic shock.
METHODS. Adult, sepsis and septic shock patients admitted in intensive care unit were included. Sepsis was defined as Sepsis 3 and patients were treated according to the recommendations in the Surviving Sepsis Guideline. Patients' age, gender, comorbidities, source of sepsis, pre-intensive care hospital admission, SOFA and APACHE II scores were recorded. Biochemical variables such as arterial blood gases, central venous oxygen saturation (ScVO2), leukocyte, procalcitonin (PCT), lactate, platelet, creatinine, brain natriuretic peptide (BNP) were followed daily. After excluding intravascular volume depletion by a passive leg-raising test, cardiac output volume, cardiac index, systemic vascular resistance, and stroke volume measurements were made and the measurements were repeated three times for every 12-hour. The cardiac power output (CPO) and cardiac power index (CPI) were calculated. Patients were grouped as survivors and non-survivors due to sepsis and ICU survivals.
RESULTS. Survivor and non-survivor patients were comparable in demographic data, APACHE II, and SOFA scores, and the changes in biochemical variable according to sepsis and ICU survivals. The CPO values survivors according to sepsis survival were as followed: M1= 0.89, M2= 0.99, M3= 0.9, and M4= 1.05 (p1= 0.16, p2= 0.31, p3= 0.08, and p4= 0.07, respectively). The CPI values for survivors according to sepsis survival were as followed: M1= 0.48, M2= 0.49, M3= 0.45, and M4= 0.56 (p1= 0.124, p=0.521, P00.08, and p4= 0.09, respectively).
CONCLUSIONS. CPO and CPI values did not predict mortality in sepsis patients. The reason why these values failed to predict mortality in sepsis could be due to the differences in the pathophysiology of cardiogenic and septic shocks. In the early phase of septic shock the CO is normal or high, whereas in cardiogenic shock it is reduced. Septic shock causes LV systolic dysfunction, LV diastolic dysfunction, and right ventricular (RV) dysfunction and only the diastolic dysfunction is the strongest independent predictor of early mortality in septic patients, whereas left ventricular systolic dysfunction is the most frequent cause and mortality predictor of cardiogenic shock.

Hemodynamic response of fixed-dose dobutamine in patients with severe cardiogenic shock
P. Ostadal, A. Kruger, D. Vondrakova, M. Janotka, J. Naar, P. Neuzil
Na Homolce Hospital, Dept. of Cardiology, Prague, Czech Republic
Correspondence: P. Ostadal
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1158

INTRDUCTION. Dobutamine is widely used as an effective positive inotropic agent in severe cardiogenic shock. However, the precise effect of dobutamine on the hemodynamic variables is not fully understood.
OBJECTIVES. The aim of our study was, therefore, to assess the hemodynamic response on the administration of dobutamine in cardiogenic shock.
METHODS. Twelve patients with severe cardiogenic shock required inotropes were recruited into the study. Hemodynamic variables including cardiac output, heart rate, dP/dt max and blood pressure were measured from arterial line (using pressure waveform analysis) before and 30 min after the administration of dobutamine 5 mcg/kg/min.
RESULTS. Mean age of the study group was 57 years, 10 of 12 were males, the most frequent cause of cardiogenic shock was acute myocardial infarction (9 of 12) and all subjects were concomitantly treated with norepinephrine (mean dose 0.13 mcg/kg/min). Administration of dobutamine resulted in an increase of cardiac output by 23% from 3.5 to 4.3 L/min (P=0.0014), heart rate increased by 6% from 61.8 to 65.4 beats/min (P=0.0006), mean arterial pressure increased by 23% from 62.5 to 77.0 mmHg (P˂0.0001), and the most pronounced effect of dobutamine was observed on the rise of dP/dt max by 45% from 715.7 to 1036.0 mmHg/s (P˂0.0001).
CONCLUSIONS. Administration of dobutamine 5 mcg/kg/min was associated with slight increase of heart rate and marked rise of cardiac output and mean blood pressure. However, the most sensitive parameter to the effect of dobutamine was dP/dt max.

1159

Heamodynamic effects of disconnection from the "advanced organ support" (ADVOS): the HAEMADVOS-II-study evaluating the "re-transfusion volume challenge option" (REVOLUTION)
W. Huber, M. Leinfelder, T. Lahmer, U. Mayr, A. Herner, G. Batres-Baires, S. Schreiber, M. Häberlein, L. Habenicht, S. Roland

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1159

INTRODUCTION. Multi-organ support provided by *one* single device is intriguing. The "advanced organ support" (ADVOS) procedure provides liver support, renal replacement, CO_2-elimination and acid-base modulation. To improve toxin elimination, the device is equipped with two dialyzers. This results in an inreased 500mL-volume of the extracorporeal circuit.
OBJECTIVES. After treatment, disconnection from the circuit with re-transfusion of 500mL within five minutes can be used as an option for a post-therapeutic volume challenge. This concept of a "re-transfusion volume challenge option" (REVOLUTION) has been recently introduced after dialysis (1). It might optimize fluid management and help to define filtration goals for subsequent therapies. Our study analyzed haemodynamic effects of disconnection during 25 ADVOS (HepaWash; Germany) therapies in six patients with PiCCO monitoring.
METHODS. Thermodilution with the PiCCO-device (Pulsion; Germany) was performed immediately before and after connection (T1, T2) and disconnection (T3, T4) with a blood flow of 100mL/min and stable

dosages of vasopressors. During the 5-minutes disconnection pulse-contour-derived cardiac index CI_PC, MAP and cardiac power index CPI were recorded in intervals of 30s. Data on effects of connection to ADVOS (T2 vs. T1) were analyzed for a separate study (HAEMAD-VOS-I; A-0978-0022-00719).

RESULTS. Indication for ADVOS: 3 cirrhosis, 1 alcoholic steatohepatitis, 2 sepsis. 65±18 years, SOFA 11±3, mechanical ventilation 24/25 (96%); vasopressors 20/25 (80%). Net Filtration: 931±698mL.

Disconnection resulted in increases in MAP (83±9 vs. 76±7mmHg; p= 0.005), global end-diastolic volume index GEDVI (922±244 vs. 907 ±259 mL/m²; p=0.031) and CPI (1.00±0.25 vs. 0.92±0.32 W/m²; p=0.009). Increases in CVP (21.4±6.3 vs. 18.8±5.9mmHg; p=0.075) and stroke volume index SVI (55.3±12.1 vs. 53.5±13.8mL/m²; p=0.82) slightly failed significance. Heart rate HR, systemic vascular resistance index SVRI, dPmax, global ejection fraction GEF and extravascular lung water index EVLWI did not change during disconnection. Disconnection resulted in maximum increases of 15% (primary end-point), 10% and 5% in 10 (40%), 16 (64%) and 23 (92%) of treatments for MAP, 7 (28%), 9 (36%) and 15 (60%) of treatments for CI_PC and 17 (68%), 20 (80%) and 23 (92%) of treatments for CPI, respectively. Among the parameters recorded immediately before disconnection, GEDVI (AUC=0.917; p=0.003) and CPI (AUC=0.811; p=0.024) significantly predicted increases in CI_PC of a least 15% during disconnection, whereas CVP and MAP were not predictive.

CONCLUSIONS. Disconnection after ADVOS with re-transfusion of 500mL blood resulted in significant increases of MAP, GEDVI and CPI. Increases of ≥15% in CPI, MAP and CI_PC were found in 68%, 40% and 28%.

Due to the larger extra-corporeal volume of 500mL, the REVOLUTION-manoeuvre might be even more useful after ADVOS than after dialysis.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1160

INTRODUCTION. Given the ageing of the world's population, the number of patients aged 80 years and older admitted to the intensive care unit (ICU) has increased during the past decade. The appropriateness of care for those patients in ICU might be questionable especially with the limited healthcare resources available in low income countries. Knowing more about the outcome of those patients in ICU allow a better allocation of resources and help clinicians in decision making.

OBJECTIVES. The aim of the study was to assess the characteristics of very elderly patients (≥80 years) and to identify factors predicting ICU mortality.

METHODS. It is a retrospective study conducted in the medical ICU of Farhat Hached teaching hospital between January 2013 and December 2017. All very elderly patients (≥80 years) were included. Underlying condition, severity of illness, diagnostic at admission, management and outcomes were recorded. Variables found to be statistically significant in univariate analysis were included into a multivariate regression model to identify factors independently associated to poor prognosis. For all tests, a P value of less than 0.05 was considered statistically significant.

RESULTS. During the study period, 1378 patients were admitted, of whom 93 (6.7%) were older than 80 years. Patients' characteristics were : mean age, 83.27±2.6years ; male, 53(57%) ; median Charlson co-morbidity score, 2[1-3]; Knauss C or D, 39(41.9%); MacCabe≥2,

88(94.6%); mean SAPSII, 44±15.7; invasive mechanical ventilation (IMV), 58(62.4%) and vasopressors use, 60(64.5%). The main reasons for admission were respiratory disorders, 50(53.8%) ; shock, 15(16.1%) ; neurological disorders, 11(11.8%) and miscellaneous, 17(18.2%).The median duration of IMV was 2[1-6]days. The median length of ICU stay was 5[3-8]days. Mortality rate was 52.7%.

The univariate analysis identified the following respectively for deaths and survivals : Knauss D, (12.2% vs zero, p=0.028) ; SAPSII, (50.9±17.9 vs 36.3±7.5, p=0.000) ; use of vasoactive drugs, (89.8% vs 36.4%, p=0.000), mechanical ventilation, (79.6% vs 43.2%, p=0.000), nosocomial infection, (34.7% vs 4.5%, p=0.000) and ICU acquired kidney injury, (59.2% vs 18.6%, p=0.000).

Multivariate regression model identified the following factors as independently associated to fatal outcome: SAPSII, (OR, 1.1 ; 95%CI, [1.04-1.18] ; p=0.001) ; nosocomial infection (OR, 9.18 ; 95%CI, [1.53- 55] ; p=0.015) and vasoactive drug use (OR, 6.9 ; 95%CI, [1.8- 25.8] ; p=0.004).

CONCLUSIONS. In this study, predictors of fatal outcome in very elderly patients were severity of illness, nosocomial infection and vasoactive drug use.

Prevalence and impact of frailty on intensive care unit outcomes

L. Hodgson[1,2], J. Warren[2], D. Hunt[2], A. Allen[2], R. Venn[2]
[1]University of Southampton, Southampton, United Kingdom; [2]Western Sussex Hospitals Foundation NHS Trust, Worthing, United Kingdom
Correspondence: L. Hodgson
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1161

INTRODUCTION. The clinical syndrome of 'frailty' is one of the most-challenging consequences of population ageing. Data which could aid prediction of quality of life, survival, functional dependence and resource requirements following intensive care unit (ICU) admission in older patients are essential for informed discussion and decision-making. The validated clinical frailty scale (CFS, scored 1-9 points) is electronically recorded at admission for patients over 65 years in our Trust whose catchment is one of the oldest populations in England, (25% of the population >65 years), a demographic closely resembling projections of the rest of England by 2035.(1)

OBJECTIVES.

- Determine the prevalence and impact of frailty on outcomes from patients admitted to ICU (incorporating level 2 and level 3 care) and the general hospital wards and,
- Assess discrimination of the CFS to predict mortality in those aged >65 admitted to ICU and general wards.

METHODS. We interrogated a 1-year prospectively gathered, dual-centre data-set (n=55,848 hospital admissions January-December 2017). All patients admitted to ICU with a CFS score recorded at admission were included.

RESULTS. 59% of ICU admissions (n=733/1,242) were over 65 years of age, of whom 76% (n=556) had a CFS recored at hospital admission (median 4 [interquartile range 3-6]) with an in-patient mortality of 12% (Figure 1 shows distribution and associated in-patient mortality). Almost half the patients (n=256) had significant frailty (CFS ≥5 points), yet were not at higher risk of mortality (13% vs 12% for those with a CFS < 5 points, odds ratio (OR) 1.11 [95% CI 0.70-1.85], P=0.67). This was in contrast to the overall hospital population where a CFS ≥5 points was strongly associated with mortality (11% vs 2% OR 6.2 [95% CI 5.4-7.2], P< 0.001). Discrimination to predict mortality of the CFS assessed using area under the receiver operating characteristic curves (AUROCs) was poor in ICU patients - 0.58 (95% CI 0.50-0.65), in contrast to acceptable discrimination - 0.75 (95% CI 0.73-0.76) - when applied to all hospital admissions >65 years (n=18,434) (Figure 2).

CONCLUSIONS. In a dual-centre ICU study with a high proportion of elderly frail patients, the CFS did not predict short-term mortality in contrast to its good predictive performance in the overall population of patients admitted to hospital.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1162

INTRODUCTION. Outcome predictors are an essential aspect of Intensive Care Unit (ICU) management and performance evaluation. The Sequential Organ Failure Assessment score (SOFA) is based on the degree of organic dysfunctions and can be used to predict mortality in critically ill patients[1]. Although used in trauma patients[2], there is a lack of studies comparing its performance as a mortality predictor among trauma to non-trauma patients.

OBJECTIVES. To compare initial SOFA and peak SOFA performance in predicting mortality among trauma and non-trauma patients.

METHODS. A retrospective cohort of adult patients admitted to the ICU of a tertiary university hospital between 2012-2016. The SOFA for the first 14 ICU days was recorded. Multivariate logistic regressions were used to estimate the association of risk factors and ICU mortality. We compared ICU mortality among trauma and non-trauma patients utilizing the SOFA at admission and accessed the ability of initial vs. peak SOFA in the first 14 ICU days for predicting ICU mortality using the difference between the area under the Receiver Operating Characteristic curves (AUC).

RESULTS. We included 1870 patients in the analysis. Patients characteristics and outcomes are shown in the table. Trauma patients were younger, had higher admission SOFA and ICU length of stay, while non-trauma patients had higher peak SOFA and ICU mortality. Multivariate analysis showed in trauma patients SOFA, SAPS 3, gender and shock were associated with mortality, while in non-trauma patients, factors associated with mortality were SOFA, SAPS 3, and gender.

When admission SOFA was categorized, non-trauma patients had significantly higher mortality for the same SOFA category when compared with trauma patients, as shown in the graphic. The AUC for mortality prediction in trauma patients was 0.903 when using admission SOFA, and 0.904 when using the peak SOFA, the curves did not differ statistically (p=0.99). For non-trauma patients, the AUC was 0.88 for admission SOFA, and 0.924 for peak SOFA (p< 0.001).

DISCUSSION. Our results show essential aspects of SOFA dynamic in both trauma and non-trauma patients. Although with higher mean SOFA at admission, trauma patients had lower ICU mortality when compared with non-trauma patients, this difference was significant within most SOFA categories, as showed in the graph. Non-trauma patients had higher peak SOFA when compared to trauma patients. Therefore, although with more severe organic dysfunctions at admission, their progression in trauma patients are less pronounced than in non-trauma patients. There was no difference in accuracy whether using admission SOFA or peak SOFA for trauma patients, however, for non-trauma patients, the peak SOFA showed better accuracy predicting ICU mortality than admission SOFA.

Assessment of lactate concentration as a co-predictor with the APACHE-IV scoring system

M. de Boer, M.W.N. Nijsten

University Medical Centre Groningen, Intensive Care, Groningen, Netherlands

Correspondence: M. de Boer

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1163

INTRODUCTION. Many variables measured in critically ill patients have been used to estimate the severity of their disease and prognosticate patient mortality. Accurate prediction models are essential for establishing and comparing effective treatments in the care of intensive care unit (ICU) patients. The Acute Physiology and Chronic Health Evaluation -IV (APACHE-IV) scoring system is a clinical standard for ICU mortality prediction [1]. Lactate levels are known to be the single strongest outcome predictor of all routinely performed laboratory measurements [2,3]. However, lactate is not included in APACHE-IV.

OBJECTIVES. We investigated whether combining lactate concentration with the APACHE-IV score leads to an improved prediction model.

METHODS. We analyzed data from patients who were admitted for >12h to the ICU from 2009 through 2014. Arterial lactate was routinely determined together with glucoses for glucose control and blood gas analysis. Using this dataset we calculated the area under the receiver operating characteristics curve (AUROC) with hospital mortality as outcome for APACHE-IV, mean lactate ($[Lac]_{mean}$) during the first 24h and a linear combination of APACHE-IV and lactate generated by logistic regression analysis.

RESULTS. We included 12,619 patients with a hospital mortality of 12%. During the first 24h 9.0 ± 4.5 lactate measurements were performed. Mean ±SD APACHE-IV was 52 ± 28. $[Lac]_{mean}$ and $[Lac]_{max}$ were 1.8 ± 1.6 and 2.9 ± 2.5 mmol/L respectively. The AUROCs (95% CI) of APACHE-IV, $[Lac]_{mean}$ and $[Lac]_{max}$ were 0.88 (0.87-0.89), 0.67 (0.66-0.69) and 0.66 (0.64-0.68) respectively. When APACHE-IV and $[Lac]_{mean}$ were combined in logistic regression, both were highly significant (P< 0.0001). The AUROC of this combined score was 0.88 (0.87-0.89).

CONCLUSIONS. Combination of APACHE-IV with lactate did not improve the predictive ability of APACHE-IV alone. Apparently the lactate blood concentration is not independent with respect to the variables already incorporated in the APACHE system.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1164

INTRODUCTION. Several prognostic indices have been employed to predict the outcome of surgical critically ill patients. Among them APACHE II, SOFA and SAPS 3 are widely used. CRP is an acute-phase protein that correlate with the degree of inflammation during the early postoperative phase. Furthermore, we hypothesized that CRP/Albumin ratio could be a superior marker of mortality than CRP or albumin alone.

OBJECTIVES. The objective of this study is to compare the predictive values of SOFA, SAPS 3, CRP/Albumin ratio and blood lactate level in the outcome of these patients.

METHODS. Eight hundred forty seven surgical patients admitted to the ICU in the post-operative phase were retrospectively studied. Cardiovascular, digestive system, neurological and orthopedic elective or emergency surgery accounted for 85% of cases. The patients were divided into survivors (n=765, 57.5% males, mean age of 60.1 ± 17.0 years) and nonsurvivors (n=82, 57.3% males, mean age of 68.0 ± 15.1 years). SOFA, SAPS 3, blood lactate level, CRP/Albumin ratio were recorded on ICU admission. The capability of each index (SOFA, SAPS 3, lactate, CRP/Albumin ratio) to predict mortality was analyzed by receiver operating characteristics (ROC) curves. The area under de curve (AUC) and the respective confidence interval (CI) were used to measure the index accuracy. Comparison among these curves was tested. The level of significance was set at p< 0.05. ROC curves analyses were performed using the software MedCalc v. 14.

RESULTS. The mean SOFA, SAPS 3, lactate and CRP/Albumin ratio were 4.5 ± 2.7, 37.0 ± 12.5, 11.2 ± 23.0, 2.8 ± 1.6 for survivors and 8.3 ± 3.7, 56.1 ± 15.9, 31.8 ± 38.6 and 3.9 ± 3.4 for nonsurvivors, respectively. The area under the ROC curve for SOFA, SAPS 3, CRP/Albumin ratio and lactate and the respective CI data between survivors and nonsurvivors are showed in table 1. The comparisons of ROC curves for these indexes are depicted in graph 1. The overall mortality was 9.7%.

CONCLUSIONS. Even though SOFA and SAPS 3 were the most effective indices to predict mortality in the surgical critically ill patients, the CRP/Albumin ratio on admission may also play a role as predictor of outcome.

Table 1 (abstract 1164). SOFA, SAPS 3, CRP/Albumin and lactate of surgical patients survivors and nonsurvivors *p<0.05

| Patients (n=847)	Survivors (n=765)	Nonsurvivors (n=82)	AUC	IC
SOFA	4.5±2.7	8.3±3.7*	0.880	0.856-0.901
SAPS 3	37.0±12.5	56.1±15.9*	0.874	0.850-0.896
CRP	29.4±55.7	68.4±73.5*	0.672	0.639-0.703
Albumin	3.2±0.6	2.7±0.8	0.653	0.619-0.685
CRP/Albumin ratio	11.2±23.0	31.8±38.6*	0.691	0.658-0.722
Lactate	2.8±1.6	3.9±3.4	0.658	0.625-0.690

Fig. 1 (abstract 1164). Comparison of ROC curves of SOFA, SAPS 3, CRP/Albumin and lactate of surgical patients.

The worst physiological data within the first 24 hours of ICU admission of each score were collected to calculate the scores. The primary outcome was hospital mortality and the secondary outcomes were ICU mortality or composite of hospital mortality and ICU length of stay (LOS) ≥ 72 hours.

RESULTS. The number of sepsis patients diagnosed by Sepsis-3 criteria was 1,589 and 925 patients (58.2%) were classified as septic shock. The mean age was 60.3±20.5 years and mean APACHE II was 23.6±9.8. A total of 1,069 patients (67.3%) had community-acquired infection. The common sources of infection were respiratory tract (51.4%), gastrointestinal (13.3%), and urinary tract (9.8%). Mechanical ventilation was used in 1,427 patients (89.8%). The ICU and hospital mortality rates were 31.9% and 46%, respectively. The number of patients died in the hospital or had ICU LOS ≥ 72 hours was 1,284 patients (80.8%). The distribution of MEWS, NEWS, and SOFA scores correlated with hospital mortality (Figure 1). The SOFA score presented the highest discrimination with an area under the receiver operating characteristic curve (AUC) of 0.880 (95% CI 0.863-0.896) followed by MEWS, qSOFA and NEWS (Table 1). The discrimination of hospital mortality using the SOFA score was significantly greater than the qSOFA (P< 0.001), MEWS (P=0.03) or NEWS (P< 0.001) (Figure 2). The AUC of qSOFA for hospital mortality was not significantly different from the MEWS and NEWS. However, SOFA and MEWS showed similar performance to predict ICU mortality and both scores provided better discrimination than the qSOFA and NEWS (P< 0.001 for both). Nevertheless, the AUC for secondary composite outcome was significantly higher for NEWS (Table 1) than either MEWS (P=0.003), qSOFA (P< 0.001) or SOFA (P< 0.001).

CONCLUSIONS. The SOFA score provided significant accuracy to predict ICU and hospital mortality among sepsis patients admitted to the ICU. Our results also supported the application of SOFA score for screening and clinical criteria of ICU sepsis by the Sepsis-3 consensus.

Table 1 (abstract 1165). The AUC of MEWS, NEWS, qSOFA and SOFA scores to predict outcomes.

Scores	Hospital mortality	ICU mortality	Combines hospital mortality and ICU LOS≥72 h
MEWS	0.858 (0.840-0.876)	0.861 (0.842-0.879)	0.820 (0.797-0.843)
NEWS	0.833 (0.813-0.852)	0.825 (0.805-0.846)	0.845 (0.824-0.866)
qSOFA	0.847 (0.829-0.864)	0.812 (0.794-0.830)	0.768 (0.746-0.791)
SOFA	0.880 (0.863-0.896)	0.867 (0.849-0.885)	0.782 (0.757-0.807)

INTRODUCTION. Early warning scores were developed for bedside early identification of physiological deterioration and allow early discrimination of high risk critically-ill patients.

OBJECTIVES. To compare the accuracy of the Modified Early Warning Score (MEWS) and National Early Warning Score (NEWS) with the quick Sequential Organ Failure Assessment (qSOFA) and SOFA scores to predict outcomes in sepsis patients admitted to the intensive care unit (ICU).

METHODS. A retrospective study was conducted in a single medical ICU of a tertiary university teaching hospital in Thailand over a 7-year period.

The role of platelet distribution width in predicting mortality in critically ill patients

A. Fogagnolo[1], S. Spadaro[1], M. Lazzeri[1], M. Albanese[1], G. Benetto[1], F.S. Taccone[2], C.A. Volta[1]

INTRODUCTION. Platelet distribution width (PDW) is a parameter which reflects variation of platelet size distribution. While the red blood cell distribution width has recently gained importance as a prognostic tool in intensive care unit (ICU), only few data are available about the role of the PDW in this setting.(1) However, due to the high platelets susceptibly to inflammation and infection, it is reasonable that PDW values increase in sickest patients, especially in those with sepsis or septic shock.

OBJECTIVES. The aim of this study is to identify if PDW can be useful in predicting 90-day mortality in an unselected cohort of ICU patients.

METHODS. We enrolled consecutive patients who needed at least 72 hours of ICU stay. Exclusion criteria were: age < 18 years, pregnancy, hematologic disorder or history of platelets disease. Clinical and laboratory data were recorded daily. Due to the lack of knowledge about normal range of PDW in ICU, we decided to divide our population in terciles according to the PDW value at admission. Primary outcome was 90-day mortality; a pre-planned sub-group analysis was performed in patients admitted for sepsis or septic shock.

RESULTS. A total of 106 patients have been included; of those 32 (30%) were septic. (Table 1) Ninety-day mortality was 40% (42/106), being higher in the third PDW terciles (PDW>12.8%) than in the second and first one (56%, 40% and 24%, respectively; p=0.02). The ROC curve for 90-day mortality in the whole population was 0.72 [0.65-0.82], while it increased to 0.86 [0.73-0.96] when the analysis was restricted to septic patients. (Figure 1) Patients with higher PDW had also higher mean platelet volume (MPV) while no differences were found in platelet count. However, when the population was stratified for PDW terciles,

the MPV values did not change between survivors and non-survivors (Figure 2).

CONCLUSIONS. PDW values at admission is a useful and widely available prognostic tool in ICU, in particular in patients with sepsis or septic shock. The association between PDW and 90-day mortality seems not to be influenced by MPV or platelet count.

(CI) were used to measure the index accuracy. Comparison among these curves was tested. The level of significance was set at p< 0.05. ROC curves analyses were performed using the software MedCalc v. 14.

RESULTS. The mean SAPS 3, SOFA and GCS on D1 were 13.5 ± 12.7, 3.1 ± 2.4 and 13.7± 2.8 for survivors and 32.5 ± 28.0, 5.6 ± 4.9 and 13.5 ± 1.9 for nonsurvivors, respectively. The area under the ROC curve for SAPS 3, SOFA and GCS and the respective CI data between survivors and nonsurvivors are summarized in table 1. The comparisons of ROC curves for these indexes are depicted in graph 1 and 2. The overall mortality was 27%.

CONCLUSIONS. .Even though SAPS 3 predicted better on admission, SOFA was the most effective index to predict mortality in SAH patients when performed on D3. However, the GCS on D3 may also be used as predictor of outcome.

Table 1 (abstract 1167). SAPS 3, SOFA and GCS scores on day 1 (D1) and day 3 (D3) of patients survivors and nonsurvivors of SAH *p<0.05

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1167

INTRODUCTION. Guidelines for SAH management and several grading systems or prognostic indices have been used not only to improve the quality of care but to predict also the outcome of these patients. Among them the gold standards Fisher, Hunt-Hess and the World Federation of Neurological Surgeons (WFNS) are the most employed. On the other hand, although the GCS is critical in the neurological patients with acute brain disorders, including SAH, this scale measurement loss its accuracy on day 1 (D1) when the patient is sedated, e.g. the day after de surgical procedure.

OBJECTIVE. The objective of this study is to compare the predictive values of SAPS 3, SOFA and Glasgow Coma Score (GCS) on D1 and D3 (SOFA and GCS) in the outcome of patients with SAH.

METHODS. Fifty-one SAH patients (33 % males and 67% females; mean age of 54.1 ± 10.3 years) admitted to the ICU in the post-operative phase were retrospectively studied. The patients were divided into survivors (n=34) and nonsurvivors (n=17). SAPS 3, SOFA and GCS were recorded on ICU admission (day 1 - D1), and 72-h (day 3 - D3) SOFA and GCS. The capability of each index (SAPS 3, SOFA and GCS (D1 and D3) to predict mortality was analyzed by receiver operating characteristics (ROC) curves. The area under de curve (AUC) and the respective confidence interval

Is there a decrease in the amount of in-hospital cardiac arrest (IHCA) after the instauration of an activation score for the Rapid Response Team (RRT) in a tertiary hospital?

A. Sánchez Ginés, C. Lorencio Cárdenas, J. Gonzalez Londoño, P. Loma-Osorio, S. Martin Hernandez, J. Lopez Fernandez, R. Arcega Sainz, J.M. Sirvent, Comission for Prevention and Attention of IHCA
Josep Trueta Hospital, Girona, Spain
Correspondence: A. Sánchez Ginés
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1168

INTRODUCTION. Several studies show that IHCA is usually preceded by objective signs of deterioration. This is why RRT are part of the security network of patients at risk of deterioration, as well as global hospital security.

OBJECTIVES. To study the impact on the incidence of IHCA and hospital mortality on a tertiary hospital after the implementation of an activation system for the RRT based on a severity *score* (EWS).

METODOLOGY. The amount of IHCA between the years 2010-2014 was registered, during this period the RRT did not have a specific activation system. In 2017, an activation system based on the EWS was implemented and the IHCA were also registered. We also analyzed the hospital mortality during the years 2016 and 2017.

RESULTS. During the period 2010-2014, 125 IHCA were registered; corresponding to 31,25 IHCA/year (0,16 IHCA/1000 hospital discharges). During the year 2017, there were 19 activations of IHCA, meaning a reduction of 39% in the incidence of IHCA (0,09 ACIH/1000 hospital discharges). The hospital mortality during the year 2016 was of 619/18.043 hospital discharges (34,3 deaths/1.000 hospital discharges (4%)). During 2017, the hospital mortality was of 633/18.861 hospital discharges (33,56 deaths/1.000 hospital discharges (3,9%)).

CONCLUSIONS. The implementation of an activation system for the RRT based on a severity scale of the hospitalized patient (EWS) decreased the number of IHCA and the global hospital mortality.

RRT based on alert systems that recognize patients that are deteriorating are a fundamental part of global hospital security. It will be necessary to see if these results will remain in time and if changes will be required in order to improve the functioning of the RRT and the quality of care to the hospitalized patient.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1169

INTRODUCTION. Coronary artery bypass graft surgery is a well-established therapeutic option for treatment of patients with coronary artery obstructive disease [1, 2]. Studies suggest that non-cardiac diseases and patient clinical status are main determinants of mortality after coronary artery bypass grafting that may be overlooked by traditional ICU scores [3-5]. Moreover, scores developed to predict mortality that are derived from specific cohorts and clinical settings, may lose accuracy after extrapolation to different populations [5]. Simplified Acute Physiology Score (SAPS 3), Sequential Organ Failure Assessment (SOFA) and Acute Physiology and Chronic Health Evaluation II (APACHE II) scores are well-validated predictive models for mortality in critical care setting [3-5].

OBJECTIVE. To evaluate accuracy of general critical care models for mortality prediction of patients in early postoperative period of CABG surgery in ICU.

METHODS. This was a retrospective cohort study including elective CABG surgery patients enrolled from January 2013 and December 2017 in the postoperative ICU of a university hospital. Scores discrimination was assessed through the area under the receiver operating characteristic curve (AUROC) and calibration was evaluated by a goodness-of-fit test with intra-ICU mortality as outcome. A p value < 0.05 was considered statistically significant. Local and national ethics committee approved the study's protocol.

RESULTS. There were 407 patients included in this study. The observed mortality was 3,44%. Discrimination was fair for all tested scores. AUROCs were 0,641 (95% CI 0,592 to 0,688) for admission SOFA, 0,747 (95% CI 0,702 to 0,789) for SAPS 3 and 0,714 (95% CI 0,667 to 0,757) for APACHE II. Pairwise evaluation achieved no significance between differences among AUROCs of assessed scores. All prognostic models showed acceptable calibration.

CONCLUSION. SAPS 3, APACHE II and admission SOFA are fair scores for intra-ICU mortality prediction in early postoperative period of CABG surgery patients. However, discrimination improvements may be necessary to increase their accuracy in this setting.

The C-reactive protein/albumin ratio as a predictor of mortality in critically ill patients

A.Y. Leem
Yonsei University College of Medicine, Seoul, Korea, Republic of
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1170

INTRODUCTION. The C-reactive protein (CRP)/albumin ratio has recently emerged as a marker for poor prognosis or mortality across various patient groups. However, there are relatively few studies conducted focusing on critical care patients in the ICU.
OBJECTIVES. This study aimed to identify the association between CRP/albumin ratio and 28-day mortality and predict the accuracy of CRP/albumin ratio for 28-day mortality in medical intensive care unit (ICU) patients.
METHODS. This was a retrospective cohort study of 875 patients admitted to the medical ICU. We evaluated the prognostic value of CRP/albumin ratio to predict mortality at 28 days after ICU admission, using Cox proportional hazard model and Kaplan-Meier survival analysis.
RESULTS. The 28-day mortality was 28.0% in this study. In the univariate analysis, the Acute Physiology and Chronic Health Evaluation II (APACHE II) score (P< 0.001), CRP level (P=0.045), albumin level (P< 0.001), and CRP/albumin ratio (P=0.032) were related to 28-day mortality in ICU patients. Following the receiver operating characteristic (ROC) analysis and calculating the area under the ROC curve (AUC), the AUC of CRP/albumin ratio was higher than that of CRP for mortality in ICU patients (0.594 vs. 0.567, P< 0.001). The cut-off point for CRP/albumin ratio for mortality in ICU patients was 3.43. On Cox proportional-hazard regression analysis, APACHE II score (hazards ratio [HR]=1.05, 95% CI=1.04-1.07, P< 0.001) and CRP/albumin ratio (HR=1.68, 95% CI=1.27-2.21, P< 0.001 for high CRP/albumin ratio) were independent predictors of 28-day mortality.
CONCLUSIONS. Higher CRP/albumin ratio was associated with increased mortality in critically ill patients. Therefore, clinicians might predict poor prognosis through the initial assessment of CRP/albumin ratio.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1171

INTRODUCTION. Sepsis and septic shock are major causes of ICU admission and mortality. Organ dysfunction associated with sepsis is quantified by the SOFA score. Patients developing new onset organ dysfunction or worsening of existing organ dysfunction are more likely to not survive. We studied the effect of worsening of SOFA score from day 1 and day 3 in predicting outcomes in patients with sepsis.
METHODS. A prospective observational study was undertaken in our tertiary level medical- surgical ICU (15 bedded) from October 2017 to January 2018. All adult patients (Age> 18 years) with a diagnosis of sepsis were included in the study. Demographic data, diagnosis on ICU admission, SOFA score on Day1 and Day3, Difference of SOFA score from Day 1 to Day 3 (Delta-SOFA score) and outcome of patients (ICU stay, days on mechanical ventilation, mortality) was noted. Univariate and multivariate analysis of predictors of mortality was done.
RESULTS. Of the 406 patients admitted to the ICU during the study period, 80 patients (19.7%) had sepsis. The mean age of the patients was 50.41(SD 30.56) years and 57% were males. The most common causes of sepsis were tropical infections (38.35%) followed by respiratory (20.73%) and abdominal infections (11.16%). The common tropical infections were Dengue (40.15%), Malaria (15.12%), Leptospira (8.9%), and rickettsial infections (5.6%).
The mean hospital mortality was 62.34%. The mean SOFA score was 9.32 (SD 3.6) on Day 1 and 11.55 (SD 4.5) on Day3. The mean SOFA score on DAY1 for survivors and non-survivors was 8.3 and for non-survivors was 13.8. An increase in the SOFA score by 5 during the ICU stay (Delta-SOFA score) was associated with mortality in 88% of these patients. SOFA score (p=0.0026), Delta-SOFA score>5 (p=0.002) and Mechanical ventilation (p=0.001) were independently associated with mortality.
CONCLUSIONS. Sepsis is seen in 19.7% of all ICU admissions in our setting and tropical infections are the most common cause of sepsis. An increase of SOFA score (Delta-SOFA) > 5 during ICU stay can be used to predict mortality in patients with sepsis. Further and larger studies in our setting are needed.

How effective are metabolic markers in predicting mortality and length of stay in patients admitted into intensive care in comparison to existing scoring tools APACHE II and ICNARC?

T. Khan, O. Boyd
Brighton and Sussex Medical School, Brighton, United Kingdom
Correspondence: T. Khan
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1172

INTRODUCTION. Being able to identify the sick patients that are likely to deteriorate further is crucial to planning the nature and urgency of treatments. Early and accurate detection would enable patients to receive the most appropriate treatment preventing morbidity and mortality. Metabolic markers (lactate, pH, PaCO2, and BE) from arterial blood gases were examined because this investigation is performed frequently and easily in newly admitted patients. In addition, their results are returned quickly as compared to scoring tools APACHE (Acute Physiology and Chronic Health Evaluation) II and ICNARC (Intensive Care National Audit & Research Centre) which require 24 hours.
OBJECTIVES. There were many aims: firstly, to determine the effectiveness of metabolic markers (lactate, pH, PaCO2 and BE) in predicting mortality and length of stay in patients admitted to intensive care; secondly, to identify the cut-off values for the metabolic markers for both mortality and length of stay; thirdly, to determine the effectiveness of lactate clearance in predicting mortality and length of stay and finally comparing the above with APACHE II and ICNARC.

METHODS. An observational retrospective study was performed. The inclusion criteria were all patients ≥18 years old admitted to intensive care during 2017. 100 patients were chosen at random and their ROC (receiver operator characteristic) curves were plotted for each of the 4 metabolic markers to examine how effective they were at predicting mortality and length of stay (defined as < 4 or ≥4 days) on admission and 6 hours post admission. The AUC (area under the curve) was calculated so that the results could be compared. This was repeated for lactate clearance, APACHE II and ICNARC.

RESULTS. Admission Lactate was the best metabolic marker for predicting mortality with an ROC AUC of 0.79 and the optimum cut-off was 2 mmol/L. Admission BE was the best metabolic marker for predicting length of stay (LOS) with an ROC AUC of 0.69. Lactate clearance predicting both mortality and LOS gave an AUC of 0.68 and 0.61 respectively and the optimum cut-off was 30.0%. The scoring tools performed better than the metabolic markers at predicting mortality and LOS: the best was the ICNARC mortality predictor for both mortality and length of stay with an AUC of 0.83 and 0.76 respectively.

CONCLUSIONS. Metabolic markers can be helpful at predicting mortality at admission and soon after. Different markers are better suited for different outcomes. Predicting length of stay is more challenging - especially at 6 hours. Lactate clearance was found to be inferior to admission lactate at predicting both mortality and length of stay. The scoring tools, in particular the ICNARC mortality predictor, performed better than the metabolic markers at predicting mortality and LOS suggesting they are worth the wait. Nevertheless, the admission lactate is still useful and should not be ignored.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1173

INTRODUCTION. Coronary artery bypass graft (CABG) surgery is a well-established therapeutic option for treatment of patients with coronary artery obstructive disease [1, 2]. Non-cardiac diseases and clinical status are main determinants of mortality in CABG postoperative period that may be overlooked by Sequential Organ Failure Assessment (SOFA) score [3-5]. Studies suggest that age may increases SOFA's accuracy for intra-ICU mortality prediction in general critical care patients [3-5].

OBJECTIVES. To test whether age improves SOFA's intra-ICU mortality prediction accuracy in patients at CABG surgery early postoperative period.

METHODS. This was a retrospective cohort study including elective CABG surgery patients enrolled from January 2013 and December 2017 in the postoperative ICU of a university hospital. SOFA score and other relevant data were calculated at admission. To analyze the relationship between age, SOFA score and intra-ICU mortality, a logistic regression model was used. After, model's accuracy for intra-ICU mortality was evaluated calculating its discrimination and calibration properties. A p value < 0.05 was considered statistically significant. Local and national ethics committee approved the study's protocol.

RESULTS. A total of 408 patients were eligible for further analyzes. Observed mortality was 3,43%. SOFA and age contributed significantly to predict intra-ICU mortality. The area under the receiver operating characteristic curve (AUROC) was 0,767 (95% CI 0,723 to 0,807) for the SOFA/Age model and 0,641 (95% CI 0,592 to

0,687) for SOFA alone with intra-ICU mortality as the dependent outcome. Pairwise comparison showed a difference between ROC curves areas of 0,126 (95% CI 0,0128 to 0,239) with a p value of 0,0291. Both models showed a good calibration assessed through the Hosmer-Lemeshow test with p values of 0,8646 for SOFA/Age and 0,2786 for SOFA alone.

CONCLUSIONS. Associating age with SOFA score may improves its prediction accuracy for intra-ICU mortality of CABG surgery patients in early postoperative period.

INTRODUCTION. Early warning scores (EWS) are increasingly embedded in hospitals worldwide since their use has shown to reduce adverse events such as cardiopulmonary arrest, unplanned intensive care unit (ICU) admission, emergency surgery, unexpected death.(1) Additionally, recent advances in automated notification systems assessing EWS further improve the outcomes of medical patients.(2)

OBJECTIVES. The aim of this study was to evaluate and compare patient outcomes before and after the implementation of an automated EWS after major surgery.

METHODS. A before-and-after retrospective study was performed in a surgical high dependency unit where patients are admitted following postoperative ICU stay after major surgery. During the control period from January 2012 till March 2013, vital signs and EWS were collected and manually registered in the electronic medical record. Subsequently, staff was trained to collect vital signs with the automated EWS system the Guardian®, Philips (Figure 1), from June 2013 till August 2015. Two types of outcomes were defined: clinical outcomes, like length of stay, ICU readmission and mortality, and operational registration outcomes measuring the recording of the vital signs and calculating EWS.

RESULTS. A total of 593 patients were selected, consisting of 320 patients in the control group and 273 patients in the intervention group, including 7837 and 3418 documented assessments respectively. Using the electronic scores improved registration of respiratory rate by 94% and level of consciousness by 92% (Figure 2). However, no significant differences were found in clinical outcomes like hospital length of stay, mortality and ICU readmissions (Table 1), even though patient characteristics were similar. Subgroup analysis for patients requiring readmission at the ICU did not show significant differences in terms of age, gender, APACHE-IV scores, ICU and hospital length of stay and mortality between the control and intervention group.

CONCLUSIONS. Implementation of an automated EWS on a surgical high dependency unit improves electronic registration of vital signs and calculated EWS. This positive effect did not lead to a significant decrease in mortality, hospital length of stay or ICU readmissions. In this study, the EWS system lacked a connection to the EMR. Nonetheless, an improved adherence to the EWS protocol was observed.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1175

INTRODUCTION. Complete video-assisted thoracoscopic surgery (cVATS) has become popular for patients with a lung tumor because of the development of many new versatile devices that can be used through smaller incisions than those in conventional video-assisted thoracoscopic surgery (cvVATS). However, patients who undergo cVATS frequently suffered breakthrough pain in the intensive care unit (ICU) even when potent analgesics were repeatedly used for post-surgical pain.

OBJECTIVES. The aim of the present study was to evaluate clinical factors for breakthrough pain after video-assisted thoracoscopic surgery and to determine the optimal analgesia.

METHODS. We retrospectively analyzed data for 231 patients who had undergone video-assisted thoracoscopic surgery from January 2016 to December 2017. The patients who underwent cVATS and those who underwent cvVATS were allocated to a cVATS group (n = 85) and a cvVATS group (n = 146), respectively. We obtained data for age, sex, use of epidural analgesia, total dose of fentanyl during surgery, total dose of remifentanil during surgery, use of acetaminophen, and use of NSAIDs. After the surgery, all of the patients were admitted to an ICU. A nurse recorded intensity of pain using a 0 to 10 numerical rating scale (NRS) at regular intervals after ICU admission. An NRS of more than six was defined as breakthrough pain. Differences in clinical variables between the two groups were analyzed by the Mann-Whitney test or the chi-square test. Logistic regression analysis was used to assess the relationships of clinical variables with incidence of breakthrough pain. P values of less than 0.05 were considered to indicate statistical significance.

RESULTS. Epidural anesthesia was used in 58% (49/85) and 84% (123/146) of the patients in the cVATS and cvVATS groups, respectively (chi-square, p=0.0000043). The doses of fentanyl used during surgery were 4.9 (5.5) μg/kg [median (interquartile range)] and 3.9 (2.3) μg/kg in the cVATS and cvVATS groups, respectively (Mann-Whitney, p=0.06). Logistic regression analysis showed that the use of epidural analgesia was an independent factor for prevention of breakthrough pain (odds ratio: 0.08; 95% confidence interval: 0.003-0.20) and that total dose of fentanyl during surgery was also an independent factor (odds ratio: 0.75; 95% confidence interval: 0.64-0.89). However, choice of cvVATS was not an independent factor (odds ratio: 1.27; 95% confidence interval: 0.62-2.61).

CONCLUSIONS. The findings suggest that the incidence of breakthrough pain after cVATS is similar to that after cvVATS and that both the use of epidural analgesia and the use of a high dose of fentanyl during surgery reduce the incidence of breakthrough pain in patients undergoing video-assisted thoracoscopic surgery..

INTRODUCTION. We have released the protocols for the management of pain, agitation, and delirium in the intensive care units (ICUs) in 2012. It included the practical content of pharmacological and non-pharmacological guideline for sedation, agitation, and delirium for mechanically ventilated patients in the ICUs. The intensivists practically applied them to the patient and educated the physicians and nurses and monitored and provided feedback to them.

OBJECTIVES. To compare the clinical outcomes including the ventilator days, length of stay in the ICU and hospital, and mortality before and after the implementation of the ICU sedation and analgesia guidelines.

METHODS. A retrospective study was conducted reviewing the electronic medical records of patients who were mechanically ventilated in the ICU of Seoul National University Bundang Hospital from January 2008 to August 2017. Age, sex, APACHE 2 score, the sedatives, the neuromuscular blockers, the types of ICUs, the ventilator days, length of stay in the ICU, and mortality of the patients were collected via electronic medical records by the medical research collaborating center and two intensivists.

RESULTS. During the study period, 10,515 inpatients were mechanically ventilated (pre-intervention: 3426 patients, post-intervention: 7089 patients). In the protocol application group, ventilation days decreased significantly compared to that before protocol application (7.33 ± 11.12 vs 6.15 ± 8.3, p = 0.000). After protocol application, ICU length of stay (9.89 ± 13.34 vs 8.94 ± 10.59, p = 0.000) and 90-day mortality rates (32.3% vs 27.4%, p = 0.000) also decreased significantly.

CONCLUSION. Our findings suggest that establishment and implementation of the guideline for sedation and pain control of mechanically ventilated patients would be associated with reduced ventilation days, ICU length of stay, and mortality.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1178

INTRODUCTION. Sedatives and opioids are often used In the Intensive Care Unit (ICU) to mitigate anxiety and pain. However, heavy sedation prolongs durations of mechanical ventilation (MV) and ICU length of stay, and increases incidence of delirium. International guidelines on pain, agitation and delirium management make recommendations to avoid unnecessary deep sedation in attempts to reduce adverse patient outcomes [1]. Despite these recommendations, there is the perception of large international practice variation.

OBJECTIVES. To describe the incidence of sedative and opiate use (calculated as patients days receiving propofol, benzodiazepines or opiates) in ICU patients reported in literature.

METHODS. We searched MEDLINE (March 1999-March 2018) for surveys, point-of-prevalence studies, or audits on ICU sedation and analgesia practices in mechanically ventilated patients. A meta-analysis

for proportions was performed (© 2018 MedCalc Software bvba) to assess variation in practice, and proportions of usage of different sedatives and opioids. The primary outcome was the use of sedatives and opioids; calculated as the proportion of ICU patient days. Variation was assessed by examining the confidence intervals of the estimates and heterogeneity using the I^2 statistic.

RESULTS. We identified 10 studies; 8 reported on our primary outcome with 25876 subjects [2-9]. None of the studies included Low- and Middle-Income Countries (LMICs). The pooled analysis estimated: use of propofol 32% patient-days (95%CI 22-43%), benzodiazepines 42% (32-53%) and opiates 66% (54-78%) (Figure 1-3, Table 1). Heterogeneity tests were statistically significant for all medications (p< 0.0001) indicating large variation in practices.

CONCLUSIONS. Our preliminary results confirm the perception of a large variation of practice for sedatives and opioids in ICU. Overall, opiate and benzodiazepine use were very common, and propofol use less so. Larger international cohort studies, including LMICs, are necessary to confirm these findings.

The effect of melatonin administration on sedation level as adjuvant to propofol in traumatic brain injury patients

M. Soliman, T. Radwan, S. Osman, E. Mansour, R. Samir, M.M. Ghada, A.M. Ahmed
University, anaesthesia and critical care, Cairo, Egypt
Correspondence: M. Soliman
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1179

INTRODUCTION. *Sedatives are commonly used in the intensive care units ,suboptimal sedation practices may prolong mechanical ventilation, increase delirium and long-term cognitive impairment, especially in the acute phase following the initial injury(1). Bispectral index is Important monitoring for achievement of optimal sedation,*
Melatonin by virtue of its multiple functions can be an attractive option for pre-medication as an anxiolytic and sedative, Many studies showed that premedication with melatonin is associated with sedation without impairment of cognitive and psychomotor skills and without prolonging recovery(2). To the best of our knowledge there is no previous study determines the effect of the oral administration of melatonin on the dosage of propofol infusion in a mechanically ventilated patient with traumatic brain injury monitored by bispectral index .

OBJECTIVES. *Our purpose was to assess the effect of administration of exogenous melatonin as adjuvant to propofol on the level of sedation and consequently the rate of propofol infusion.*

METHODS. *38 patients with traumatic brain injuries requiring mechanical ventilation and sedation were randomly allocated to two groups (melatonin group)19 patients and (control group)19 patients. In both groups a bolus of propofol 1mglkg was given by titration till the patient reached a sedation level value of (60-70) on the bispectral index (BIS), Then propofol infusion started at a rate of 1mglkglhr as a maintenance and rate adjusted according to our targeted sedation level, melatonin 10 mg tablet was crushed and mixed with 20 ml of water and administrated through a nasogastric tube followed by another 20 ml to flush out the residue for (melatonin group). While (control Group) received a placebo tablets by the same way.BIS value and propofol infusion rate were recorded over a 12 hours.*

RESULTS. administration of exogenous melatonin resulted in a significant reduction in the rate of infused propofol required to achieve the same sedation level .rate of propofol infusion were 4.87(2.91)ml/hr. and 6.37(2.87)ml/hr. in melatonin group and control group respectively.p. value< 0.001. there was no significant changes regarding monitored hemodynamic parameters namely heart rate and blood pressure.

CONCLUSIONS. administration of exogenous melatonin has an adjuvant effect on propofol regarding sedation as decreasing the required dose of propofol infusion without compromising any of hemodynamic parameters.

Depth of long term ICU sedation under 0,5 MAC isoflurane, sevoflurane or desflurane using MIRUS, an automated delivery system for volatile anaesthetics

A.I. Georgevici, L. Procopiuc, D. Drees, J. Herzog-Niescery, P. Gude, H. Vogelsang, T.P. Weber, M. Bellgardt
St. Josef-Hospital, Ruhr-University of Bochum, Department of Anaesthesiology and Intensive Care Medicine, Bochum, Germany
Correspondence: A.I. Georgevici
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1180

INTRODUCTION. The MIRUS system (TIM, Andernach, Germany) uses a reflector to conserve volatile anaesthetics (VA) [1-3]. Both systems can be paired with ICU ventilators, but MIRUS features an automated control of end-tidal VA concentrations (etVA). We compare the depth of 0.5 MAC inhalational long-term sedation with Isoflurane (ISO), Sevoflurane (SEVO) or Desflurane (DES).

METHODS. Thirty ASA II-IV patients admitted to the ICU after elective or emergency surgery under general anaesthesia were included and randomized into three equal groups: ISO, SEVO or DES. We used MIRUS, a gas delivery system with a VA reflector that can be paired with common ICU ventilators just like the AnaConDa. In addition, MIRUS features the unique ability to maintain the end-tidal concentration (etVA) in target by automatically adjusting the delivery rate. Every 8 hours, the RASS was assessed by the nurse. The log of the EEG-Narcotrend Index (NI) was also included in the study.

RESULTS. Patients were comparable in demographics, tidal volume, respiratory rate and sedation time: total 1515h, ISO 35±44h; SEVO 81 ±135h; DES 35±35h; p=0.39. In all patients, a MAC of 0.5 was reached: mean±SD etVA [vol%]: ISO 0.64±0.07 SEVO 0.85±0.15, DES 3.71±0.40: ANOVA p< 0.001. The analysis of the depth of sedation showed comparable results: [1.Q/median/3.Q] RASS: ISO -3/-3/-2, SEVO

-3/-3/-2, DES -3/-2/-2; NI: ISO 36/39/50, SEVO 31/39/44, DES 36/39/47. 10 minutes after stopping VA, most patients reached RASS -2. EtVA was significantly associated with the RASS during the wake-up phase (Spearman-Rho: r=0.802 ISO, r=0.697 SEVO, r=0.720 DES; p< 0.001).

CONCLUSIONS. MIRUS maintained the etVA of ISO, SEVO and DES in target, independently from the breathing pattern. Using 0.5 MAC as default value, the RASS was -2 or -3 in 82% of the total sedation time, 1515 h. After 10 minutes the majority of patients were responsive and opened their eyes.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1181

INTRODUCTION. Sedation and analgesia are the integral part in treatment of patients on mechanical ventilator. Dexmedetomedine incorporates most of the properties of an ideal sedative agent by preserving arousability ,good analgesia, predictable hemodynamic effects and it does not cause respiratory depression.

OBJECTIVES. To evaluate the efficacy of dexmedetomedine compared to fentanyl in achieving adequate sedation, 24 hour midazolam requirement and also the effects on hemodynamics

METHODS. We conducted a prospective ,randomised ,double blind study in patients on mechanical ventilator admitted in ICU. Institution review board and ethics committee approval was taken.Patients between 20-60 yrs with SAPS II score < 59 who are mechanically ventilated ,with a RASS ranging +4 to 0 were randomly allocated using sealed envelopes.Both the groups received loading dose followed by maintainance infusion.The sedation level was assessed by RASS score recorded hourly for first six hours and then every 6 hrs for next 24 hrs and the doses were titrated to achieve a RASS score -1 to -3. If the sedation was not achieved with maximum dexmedetomedine (0.7 mcg/kg/hr) or fentanyl (3 mcg/kg/hr) then midazolam 0.02 mg/kg bolus was given as rescue sedation.Total doses of study drugs and the rescue dose of midazolam were recorded along with their haemodynamic effects.

RESULTS. Total 62 (n)patients (confidence level of 95%and power of 80%), 31 recieved dexmedetomedine and 31 recieved fentanyl infusion. The mean infusion rate for dexmedetomedine to achieve effective sedation (RASS of -1) was 0.5 - 0.6 mcg/kg/hr compared to fentanyl 1.5- 3 mcg/kg/hr. The hemodynamic effects between the groups were minimal and didnt require any intervention. Dexmeditomedine required 87% less midazolam as rescue sedation (0.39+-1.202 mg/24 hrs) and the mean time required to achieve RASS of -1 was 2.97 +-1.278 hrs at a clinical dose range of 0.5-0.6 mcg/kg/hr which was statistically very significant as compared to the fentanyl group which requIred higher dose of midazolam as rescue sedation (2.29 +-1.657mg/24 hrs) with p< 0.01 and the mean time to achieve RASS of -1 was 6.29+-3.388 hrs (p< 0.01) at dose range of 1.5-3 mcg/kg/hr

CONCLUSION. Dexmedetomedine when compared to fentanyl as a short term sedative in mechanically ventilated patients needs shorter

time to achieve adequate sedation in doses within the prescribed clinical range and also lesser 24 hour midazolam requirement. Whereas its hemodynamic profile is comparable with that of fentanyl.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1182

INTRODUCTION. Pain is a very prevalent problem in the Intensive Care Unit (ICU). Inadequate assessment and therapeutic management have been associated with increased morbidity and mortality. Pain monitoring tools, such as the Critical-Care Pain Observational Tool (CPOT), have been developed, despite they are rarely used in clinical practice
OBJECTIVE. To compare subjective evaluations of pain made by physicians, nurses and physiotherapists with an objective pain quantification scale (CPOT) in critically ill patients.
METHODS. A prospective cohort study in a general ICU from September to October 2017. Included patients were followed up during a maximum of 5 days. Pain was monitored daily through CPOT, and the results were compared with subjective assessments made by physicians, nurses and physiotherapists, who were systematically interviewed. To evaluate the association between interprofessional pain assessments, the correlation coefficient was obtained by the tau b statistic of Kendall. The professionals´ agreement with the CPOT index was measured through the gross coefficient of agreement and the Kappa Index (IK). The generalized Kappa Fleiss index was calculated for the concordance analysis, which included cases involving more than two evaluators (judges).
RESULTS. Of the 111 patients admitted, 101 were included in addition to 47 professionals from the multidisciplinary intensive care team. Mean age was 71.50 ± 17.21 years, 56 (55.4%) were women, median ICU length stay was 4 days (IQR = 2.0-8.0). A total of 336 pain evaluations were performed. Analyzes of the correlation between the results from subjective pain evaluations of professionals with CPOT indicated statistically insignificant correlations ranging from negligible (14%) to weak (86%). There was no evidence of moderate or strong relation between medical evaluations and CPOT, with a higher correlation presented on day 05 ($\tau = 0.36$; P = 0.017). The daily evaluation of the physical therapist with CPOT had a lower correlation variation with CPOT than evaluations by the other professionals. No correlation between subjective evaluation of any class of professionals and CPOT was observed. The daily comparison of the global agreement about presence of pain between the subjective assessment of the professionals and the CPOT revealed a slight to moderate concordances, with the highest agreement occurring on the first day (Kappa Index = 0.36, 95 %: 0.28-0.33, p< 0.001).

CONCLUSION. There is a positive correlation between CPOT and subjective pain assessments by the multidisciplinary team, in spite of a weak correlation. There was a weak agreement between interprofessional subjective evaluations, when defining if pain was present or not.

Implementation of a new sedation hold protocol

S. Shankla, A. Trimmings
Sussex Healthcare NHS Trust, Hastings, St Leonards-on-Sea, United Kingdom
Correspondence: S. Shankla
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1183

INTRODUCTION. Sedation in the ICU is primarily used to facilitate endotracheal tube tolerance and ventilation[1]. Over-sedation is associated with well-recognised complications. Regular sedation holds have been demonstrated to decrease weaning times, ICU[2] and hospital stays, and one-year mortality[3].
Objectives. To introduce a protocol across both our local NHS Trust ICUs to ensure that all eligible patients have a daily sedation hold with documented target sedation score (Richmond Agitation and Sedation Score (RASS)) and titration of sedation. This follows recommendations from the Guidelines for the Provision of Intensive Care Services (GPICS) 2016[4] (nil audit standards set).
METHODS. A retrospective audit was carried out 18th-31st Dec 2017, the new protocol implemented and a re-audit conducted 12th-25th Mar 2018. The protocol was adapted from the Spontaneous Awakening Trial (SAT) of the "Wake Up and Breathe" protocol by the ICU Liberation Initiative[5]. All ventilated patients who passed the SAT safety and failure screens were eligible. The first 24 hours of admission were discounted unless a hold had specifically been requested. We collected data on whether eligible patients had had a hold requested and completed, or a contraindication documented; a target RASS documented; the protocol for stopping and restarting the propofol infusion followed; changes in RASS and propofol infusion rates.
RESULTS. The retrospective audit had 31 patient-days of data and the prospective re-audit 65. Extubated patients or those with a documented contraindication other than in the SAT screen were excluded. Our results demonstrated:

- An improvement in holds requested (55% retrospective / 62% re-audit) and completed (59% / 75%)
- An improvement in documentation of contraindications (55% / 79%)
- Poor documentation of target RASS (0% / 8%)
- No change in the proportion of holds where sedation was stopped rather than reduced (50% / 50%)
- An improvement in restarting the sedative infusion at a lower rate (33% / 53%)
- An improvement in the number of patients with an improved sedation score (33% / 56%)

Retrospective: median pre-hold RASS of -4 (range -3 to -4) and median post-hold RASS of -3 (range -2 to -4)
Re-audit: median pre-hold RASS of -4 (range -3 to -5) and median post-hold RASS of -3 (range -1 to -5).
CONCLUSIONS. Education about sedation holds and implementation of a new protocol has increased both our ICUs' compliance with GPICS. Target RASS documentation and sedation titration is lacking. Moving forwards, we will continue the new protocol and will look to extend to the Spontaneous Breathing Trial of the Wake up and Breathe protocol[5].

Factors associated with probable withdrawal syndrome in trauma intensive care unit patients

C.M. Arroyo-Novoa[1], M.I. Figueroa-Ramos[1], K.A. Puntillo[2]
[1]University of Puerto Rico, Medical Sciences Campus, School of Nursing, Graduate Department, San Juan, Puerto Rico; [2]University of California San Francisco, San Francisco, United States

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1184

INTRODUCTION. The management of analgesia and sedation in ICUs has evolved to promote a lower level of sedation and prevent or minimize the associated negative effects of both opioids (OPs) and benzodiazepines (BZDs).[1] However, patients admitted to trauma ICUs (TICU) may require higher or prolonged doses of OPs along with BZDs. These medications may contribute to drug physical dependence, a response that may be manifested in withdrawal syndrome (WS).[2]
OBJECTIVES. To identify the factors associated with probable WS among TICU patients exposed to OPs and/or BZDs.
METHODS. An OP/BZD-WS checklist was developed from research in adult ICU patients, the DSM-5, and the ICD-10. Fifty patients were evaluated at baseline (4th day on OPs and/or BZDs), then were evaluated twice a day upon start of a BZD and/or OP weaning trial for up to 72 hours. If drug doses were increased, WS measurement was stopped and restarted at the next weaning. If patient presented with 3 or more signs and symptoms (s/s) for OP-WS and/or 2 or more s/s for BZD-WS, it was identified as probable WS. Any s/s present at baseline was not counted as withdrawal s/s during measures and if did not comply with the minimum s/s requirements, these measures were identified as questionable WS. A mixed-effects logistic regression model was developed to assess whether cumulative dose amounts of both OPs and BZDs prior to assessment, days on both OPs and BZDs, previous drug use, Richmond Agitation Sedation Scale (RASS) score, and presence of delirium were significantly associated with the occurrence of probable WS [odds ratios (ORs) and 95% confidence intervals (CIs)].
RESULTS. Majority of patients were male (88%) with a median age of 37 (IQR, 27 49), 90% were on mechanical ventilation, and 66% were OP/BZD/illicit drug naïve. Probable WS occurred in 44% and questionable WS in 20% of the patients. Cumulative dose amounts of OPs (OR=1.10; CI, 1.02- 1.19), RASS score (OR=3.89; CI, 1.87- 8.10), and previous drug use (OR=4.69; CI, 1.43- 15.41) were associated with odds of developing WS, while the number of days on OPs (OR=.73; CI, .54- .99) was protective for the odds of WS after adjusting for cumulative dose of BZDs, days on BZDs, and delirium.
CONCLUSIONS. We found an association between increase in the cumulative dose amounts of OPs, higher RASS scores, and previous drug use with WS developing. Special attention to significant factors associated with WS found in this study should be considered when caring for patients receiving OP/BZD. Further validation of OP/BZD-WS checklist is recommended.

Sevoflorane sedation in ICU ward using a Mirus™ system: an innovative methodology

R. Varutti, F. Bassi
AAS5 Friuli Occidentale, Emergenza, SOC Anestesia e Terapia Intensiva 2, Pordenone, Italy
Correspondence: F. Bassi
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1185

INTRODUCTION. Intravenous sedation is standard practice in the Intensive Care Unit (ICU[1]). Sevoflurane has some potential advantages over intravenous drugs: rapid elimination and few interactions. The optimal role of sevoflurane in ICU is unknown.
The Mirus[TM] system (Pall Medical, New York) is a new inhalational device for sedation in ICU. The system delivers volatile anesthetics in mecanically ventilated patients. A dedicated gas filter and a open reservoir scavenger permit an alogenate reabreating and avoid residual volatil anesthetic into the room air[2]
OBJECTIVES. The aim of this study, approved by the Institutional Ethics Committee, is to present our initial experience with sevoflurane in ICU.
METHODS. We performed a prospective study on adult patients who required sedation for mechanical ventilation. We used sevoflurane to achieve a RASS score of 0 to -2 using a maximal mean alveolar concentration (MAC) of 0.8% . The MIRUS [TM] system device was used along with the Servo-i ventilator (Maquet, Gothenburg, Sweden) gas monitor. CAM-ICU score was used for testing delirium. Data were obtained from patients' medical records.
RESULTS. We collected data from 24 patients (pt) admitted to our ICU from August 2017 to March 2018 for postoperative monitoring (2 pt), thoracic trauma (1 pt), sepsis (4 pt), acute respiratory distress or asthma (5 pt), acute coronary syndrome (6 pt), psychosis (1 pt), epilepsy (3 pt), coma (2 pt). Mean age was 62 y (+/-15 y), 11 was male. 50% of patients required temporary adjunctive sedation with remifentanil and dexmedetomidine or midazolam for develop of hyperactive delirium.
Hypotension was the most common symptom and it was rapidly solved with fluid administration or a low doses of vasoactive agents infusion. No metabolic syndrome or organ dysfunction was noted after a sevoflurane inhalation longer than 48 h. No malignant hyperthermia was done.
CONCLUSIONS. At the beginning there was a reduced compliance of the medical /nursing staff towards the use of the device due to lack of training, difficulty overcoming established sedative habits, skepticism. The learning curve allowed to reduce progressively the halogenate dose administered (mean MAC of 0.2-0.3%) and allowed become more confident with the methodology. Our initial experience, according to literature3, shows that Mirus[TM] device, used in a mixed pool of patients, is effettive, simply and safe.

Iatrogenic opioid withdrawal syndrome in critically ill patients: a retrospective cohort study

D.-G. Hyun, C.-M. Lim, J.W. Huh, S.-B. Hong, Y. Koh
Medical Center, University of Ulsan College of Medicine, Pulmonary and Critical Care Medicine, Seoul, Korea, Republic of
Correspondence: D.-G. Hyun
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1186

INTRODUCTION. In critically ill patients, especially those receiving mechanical ventilation, the use of opioid analgesics is recommended. However, there is a lack of detailed studies regarding opioid withdrawal syndrome (OWS), which may occur during reduction or discontinuation of opioid analgesics [1].

OBJECTIVES. To investigate the incidence, risk factors, and clinical features of OWS in an intensive care unit (ICU).

METHODS. A retrospective study was conducted; the analysis cohort comprised 126 patients who received intensive care unit treatment for ≥3 days, using only one type of opioid analgesic agent, in the medical ICU of Asan Medical Center. The presence of OWS for a certain period (2 hours for remifentanil, 10 hours for fentanyl, 8 hours for morphine) was assessed from when continuous infusion of opioid analgesic was discontinued or reduced by >1/2 dose. OWS was defined as satisfying ≥2 central nervous symptoms or autonomic symptoms.

RESULTS. OWS occurred in 21 patients (16.6%). There was no statistically significant difference in incidence of OWS among remifentanil, fentanyl, and morphine (19.0% vs. 19.1% vs. 4.8%, p=0.333), or in duration of ICU stay, duration of mechanical ventilation, and duration of opioid analgesic use between OWS (+) and OWS (-) groups. There was a significant difference in cumulative opioid dose (7437.08 mg vs 5051.54 mg, p=0.023) between OWS (+) and OWS (-) groups, but no significant differences in the frequency of extubation (61.9% vs 52.4%, p=0.424), tracheostomy (23.8% vs 27.6%, p=0.720), and mortality in ICU (38.1% vs 21.0%, p=0.092). In multivariate analysis, heavy alcoholics, presence of septic shock, and < 16 days of ICU stay were associated with OWS. Among the 21 patients, central nervous symptoms occurred in 12 (57.1%) and autonomous symptoms occurred in 20 (95.2%). The most common symptom was change of respiratory rate (n = 18, 85.7%).

CONCLUSIONS. Incidence of OWS did not differ among types of opioid analgesics; however, it was associated with heavy alcoholics, patients with septic shock, and those who stayed in ICU for < 16 days. Therefore, caution should be exercised when reducing or stopping opioid analgesics. Further prospective studies with larger sample sizes are needed to determine whether OWS affects the prognosis of ICU patients.

INTRODUCTION. Acute respiratory distress syndrome (ARDS) is a serious complication of surgery. Although the assessment of perioperative risk factors for ARDS has been described in various surgical populations, there is only limited data among patients undergoing liver transplantation (LT), particularly regarding the potential influence of intraoperative ventilation parameters.

OBJECTIVES. In the present study, we sought to determine the incidence of ARDS following LT in a large tertiary referral center, and to identify preoperative and intraoperative risk factors associated with its development. Also, we aimed to identify the impact of ARDS on clinical outcomes (mortality, hospital and ICU length of stay).

METHODS. This is a single center, retrospective cohort study of adult patients who underwent LT at a tertiary level academic medical center between January 1st, 2006 and January 31st, 2016. Postoperative ARDS was identified using the Berlin definition. Multivariate logistic analysis was used to identify preoperative and intraoperative risk factors for ARDS.

RESULTS. Of 817 eligible patients who underwent a LT during the study period, 20 (2.45%) developed postoperative ARDS. In the preoperative model, higher MELD score (per 1 unit increase, odds ratio [OR], 1.65; P< 0.01), higher INR (per 0.1 unit increase, OR, 1.69; P=0.03), and ongoing dialysis (OR, 5.23; P=0.03) were identified as independent risk factors associated with the development of ARDS post-LT. Intraoperatively a higher mean peak inspiratory pressure (OR, 1.32; P< 0.01) was recognized as the only independent risk factor. Patients with ARDS postoperatively had significantly greater intensive care unit and hospital stay than non-ARDS. There were no significant differences in the 30-day and 1-year mortality between the groups.

CONCLUSIONS. Acute respiratory distress syndrome occurred at a rate of 2.45% following LT in adult patients. Higher preoperative MELD score, higher INR and ongoing dialysis as well as elevated intraoperative mean peak inspiratory pressure were associated with the development of ARDS. In addition, ARDS post-LT was associated with increased length of ICU and hospital stay, but not in mortality.

Intraoperative use of 6% hydroxyethyl starch (130/0.4) and outcome in patients with major surgical haemorrhage: a retrospective study

J. Divatia, A. Daga
Memorial Hospital, Anaesthesiology, Critical Care and Pain, Mumbai, India
Correspondence: J. Divatia
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1190

INTRODUCTION. The use of 6% hydroxyethyl starch 130/0. 4 (HES) in patients with severe sepsis is associated with increased acute kidney injury (AKI), coagulopathy and mortality. [1,2] However fluid resuscitation with HES in relatively healthy surgical patients may not be associated with adverse short-term outcomes.[3,4]

OBJECTIVES. In this retrospective study, we aimed to compare the incidence of AKI, coagulopathy, and mortality during the hospital stay as well as mortality at 90-days in patients who received HES with those who did not receive HES for major hemorrhage during surgery for pelvic bone tumors.
METHODS. Records of 102 patients who underwent hemipelvectomy for pelvic bone tumors between January 2011 and June 2016 were reviewed. The Institutional Ethics Committee approved this retrospective analysis with a waiver of written, informed consent. Patients were classified as those who received HES during surgery (HES patients) and those who did not (No-HES patients). The primary outcome was a composite end-point of the number of patients developing postoperative AKI (RIFLE Stage Injury or Failure by creatinine criteria) OR coagulopathy (platelet count < 80,000/cu mm or international normalised ratio (INR) > 1.5 or activated partial thromboplastin time (APTT) > 1.5 times control value) OR death prior to hospital discharge. Secondary outcomes included serum creatinine values and mortality at 90 days after surgery. Data were analyzed using Chi-square test / Fishers exact test, independent "t" test and multivariate binary logistic regression analysis were planned. P< 0.05 was considered statistically significant.
RESULTS. There were 42 HES patients and 60 No-HES patients. Twelve HES patients and 52 No-HES patients received gelatins. Mean age was 35.9 ±15.6 years, median volume of HES infused was 1000ml [interquartile range (IQR) 500-1500ml] and median intraoperative blood loss was 3500ml [IQR 1700-6850ml]. The composite end-point occurred in 62% HES patients and in 63% No-HES patients (P=0.9). There was no difference in individual components of the composite end-point. Hospital mortality (HES patients, 1/42 vs. No-HES patients, 1/60) was similar (P=0.8). At 90 days after surgery, 2/33 HES patients and 1/50 No-HES patients had died (P=0.35). No differences were observed in other secondary outcomes.
CONCLUSIONS. In this retrospective study, young cancer patients who received limited amounts of 6% HES (130/0.4) during hemorrhage in the intraoperative period did not have an increased occurrence of AKI, coagulopathy, and mortality in hospital or mortality at 90 days, compared to patients who did not receive HES. A large randomized controlled trial is essential to establish the safety of 6% HES (130/0.4) for fluid resuscitation during major surgical hemorrhage.

Cerebral oxygenation evaluated by spatially resolved near-infrared spectroscopy shows a clinically small decrease during arthroscopic shoulder surgery with the patient in the beach chair position

Y. Itosu, S. Harada, N. Tanaka, R. Kato, Y. Morimoto
University Graduate School of Medicine, Department of Anesthesiology and Critical Care Medicine, Sapporo, Japan

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1191

INTRODUCTION. There have been many reports demonstrating that cerebral oxygenation evaluated by near-infrared spectroscopy dramatically decreases during arthroscopic shoulder surgery with the patient in the beach chair position (BCP) [1]. In these reports, almost all the near-infrared spectroscopes used for the studies mainly adopted the modified Beer-Lambert law (MBL). It was reported that cerebral oxygenation (rSO2) determined using the MBL was more affected by extracranial contamination than was cerebral oxygenation (TOI) determined using spatially resolved spectroscopy (SRS) methods [2]. However, few studies have evaluated the changes in TOI during this type of surgery. Accordingly, we evaluated the changes in TOI using the NIRO-200NX (Hamamatsu Photonics, Japan). We estimated the mean arterial pressure (MAP) in the temporal artery and observed early neurological outcomes.
METHODS. After obtaining institutional review board approval (014-0473), we performed an observational prospective study of 21 patients (ASA physical status1-2) scheduled for arthroscopic shoulder surgery with the patients in the BCP. One minute before the BCP (T1), TOI was measured as a control. Subsequently, TOI was obtained at 1, 5, 10, 15, and 30 minutes after the BCP (T2-6) and 1 minute before and after return to the horizontal position (T7, 8). At the same points, MAP in the temporal artery was estimated from the distance between the cuff and external auditory meatus. Neurological outcomes, including delirium, were observed until discharge. To analyze the changes in TOI and MAP, one-way repeated-measures analysis of variance (ANOVA) was performed followed by the Bonferroni multiple comparison test for each time point. Data were expressed as mean ± standard deviation. P < 0.05 was considered significantly different.
RESULTS. Twelve male and 9 female patients were enrolled. Their mean age was 64 ± 10 years. At T1, TOI (%) was 75.8±8.4 and MAP (mmHg) was 62±10 (Fig.). After the BCP, TOI significantly decreased to 70.5±8.8 and the values were maintained at 69 while in the BCP. At T8, TOI returned to 72.7 ±6.7. MAP decreased to around 30 during the BCP. No neurological complications were observed until discharge (14.7 days after surgery).
CONCLUSIONS. The decrease in cerebral oxygenation evaluated by SRS methods was significant, but clinically small during arthroscopic shoulder surgery with patients in the BCP, although MAP in the temporal artery was below the lower limit of cerebral autoregulation (= around 50 mmHg). A recent review indicated that the frequency of neurological complications such as cerebral infarction was around 0.004% in this type of surgery [3]. Accordingly, intracerebral oxygenation may not deteriorate much while patients are in the BCP.

Operation time of 15 hours or more increases postoperative complications: a retrospective study on extra-long hepatectomy

M. Nagata, Y. Hara, N. Kuriyama, T. Nakamura, T. Kawaji, D. Hasegawa, C. Yamashita, J. Shibata, H. Komura, O. Nishida
Health University School of Medicine, Anesthesiology and Critical Care Medicine, Aichi, Japan

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1192

INTRODUCTION. In hepatectomy, it has been suggested that an excessive operation length is related to an increased rate of postoperative liver failure and surgical site infection. These reports mostly investigated hepatectomy cases with a relatively short operating time, and there is no report on hepatectomy that exceeded 12 hours. However, it is possible that a long operation that could increase the incidence of life-threatening complications is disadvantageous to patients.

OBJECTIVES. With extra-long hepatectomy that exceeds 12 hours, we aimed to evaluate if the operation time is correlated with postoperative complications and postoperative liver failure, and identify the "limit of operating time (OT)" that could increase postoperative complications.

METHODS. We examined patients aged ≥18 years, for whom hepatectomy was performed at Fujita Health University (FHU) Hospital, Japan, between January 2014 and December 2017. Hepatectomy cases with an OT of ≥12 hours were selected. Postoperative complications were defined as those that were class III or higher in the Clavien-Dindo classification. In this study, Grades B and C of ISGLS criteria[1] that had impact on clinical management were defined as the clinical liver failure (CLF) group. Data are presented with the median and interquartile range, and were analyzed by using the multiple logistic regression analysis, and receiver operative curve (ROC). We used EZR for the statistical software. This study was approved by FHU Ethics Review Committee.

RESULTS. There were 94 patients (65 men), with an age of 67.5 (62-73) years, height 165.0(156.9-170.0) cm, weight 61.9(51.1-68.6) kg, body mass index (BMI)22.5 (21.0-24.9) kg/cm^2, and ICGR15 of 10.2 (7.2-13.7)%. Preoperative Child-Pugh (CP) classifications included 72 cases with five points, 18 with six points, 2 with seven points, and 2 with eight points. OT was 14.2 (13.0-16.7) hours. There were 33 patients who experienced CLF and 38 patients who experienced postoperative complications. The result of the multiple logistic regression analysis showed that factors contributing to postoperative complications were BMI (Odds ratio [OR] 0.78, 95% confidence interval [CI] 0.65- 0.96, p = 0.02), CP score (7.32, 1.90- 28.2, p = 0.004), ICGR15 (1.11, 1.01- 1.22, p = 0.02), and OT (1.27, 1.08- 1.50, p = 0.003). Factors contributing to CLF were BMI (0.77, 0.64- 0.95, p = 0.01), CP score (7.31, 2.02- 26.44, p = 0.002), ICGR15 (1.09, 1.00- 1.19, p=0.04), and OT (1.20, 1.04- 1.37, p = 0.01). ROC analysis showed that the cutoff value for OT that predicts occurrence of postoperative complications was 15.3 hours (Area under the curve 0.697, 95% CI 0.583-0.811).

CONCLUSIONS. In extra-long hepatectomy, OT was an independent factor for postoperative complications and CLF. It was indicated that when the operation exceeds 15 hours, the incidence of postoperative complications increases.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1193

INTRODUCTION AND OBJECTIVES. Some intra-operative variables may significantly affect patient outcomes after major pancreatic surgery. The identification of one or more of them could be very useful for choosing the best intra-operative management and for planning the best measures to be taken in the post-operative period.

METHODS. We collected data of patients operated for major pancreatic surgery during 12-month period from two clinical databases (Verona University Hospital and Peschiera Pederzoli Clinic).
We took into account the following preoperative variables: BMI, smoking habitus, presence of jaundice, pre-operative drainage of jaundice, recent chemotherapy, anamnesis positive for cardiovascular, pulmonary, renal, neurological disease and the American Society of Anesthesiologist (ASA) score. Recorded outcome data included incidence of postoperative abdominal surgical-related complications, systemic complications (infectious, respiratory, cardiovascular, nefrologic and neurologic), in-hospital mortality, ICU admission and days of hospitalization.

RESULTS. A total of 638 (320 women and 318 men, aged 61.4±12.5 years, mean + SD) were operated of major pancreatic surgery during 2013 and 2014 in the two hospitals. ICU admission was 8.9%. Total of post-operative complications were 57.6%,in-hospital mortality was 2.2%. We observed abdominal surgical-related complications in 43.5% and general complications (cardiac, respiratory, infectious and renal) in 34.1% of total patients. Mean ± SD surgical time was 333 ±106 minutes, and mean hospitalization was 16±18 days. Ten patients (1.6%) needed intraoperative infusion of inotropes or vasopressors and 72 (11.4%) received blood products. Colloids were administered to 221 patients (34.9%), and 179 patients (28.2%) received more than 4500ml of cristalloids.
The multivariate analysis showed that the incidence of abdominal complication was higher in group who received colloids (42.1%vs52%, p 0.017, O.R. 1.49 C.I.95% 1.073-2.069) and that the development of tachyarrhythmia in post-operative period was higher in the patients who received colloids (4.1%vs10%, p0.017, O.R. 2.245 C.I.95% 1.153-4.372) and when surgery time was longer than 300 minutes. The incidence of cardiac ischemia (0.3%vs10%) and hearth failure (0.3%vs10%) was higher in patients who needed infusion of inotropes or vasopressor during the surgery. All the analisys were adjusted for sex, age and preoperative physical status.

CONCLUSIONS. Our data suggest that the use of colloids, administration of cristalloids >4500ml and the infusion of inotropes or vasopressor can be related to development of post operative complication. These complications seem to be indipendent from pre-operative physical status and not influenced by sex and age. Also a time of surgery >300 minutes can be considered a risk factor for post operative complications.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1194

INTRODUCTION. Sometimes, patients undergoing head and neck surgery admit in intensive care unit (ICU) with nasotracheal intubation. For prolonged mechanical ventilation, a proper endotracheal tube depth is important component to prevent complications such as inadvertent extubation, or endobronchial intubation. However, we have often experienced the patients who showed shallow nasotracheal tube (NTT) depth in the ICU after surgery.

OBJECTIVES. To evaluate risk factors associated with improper NTT depth among the patients undergone prolonged mechanical ventilation after head and neck surgery.

METHODS. We retrospectively investigated all adult patients (age ≥ 18 years) who admitted the ICU with NTT after surgery between January 2008 and December 2016. The patients were divided into two groups according to distance from carina. Proper depth group consisted of patients that distal tip of NTT located 2 cm - 7 cm above the carina on

postoperative chest radiography (CXR). Improper depth group consisted of patients that distal tip of NTT located < 2cm or > 7cm above the carina on postoperative CXR. We collected patients' perioperative data from medical records and CXR. Risk factors for improper tube depth were evaluated using univariable and multivariable logistic regression analyses. **RESULTS.** Of the total 133 patients, 55 patients showed postoperative shallow NTT depth and none showed deep tube depth. The patients were divided into 78 patients of proper depth group and 55 patients of shallow depth group. The male sex, tall and heavy patient, low carina level on preoperative CXR, prolonged anesthesia duration, right side surgical field, postoperative restriction of position, and deep postoperative tube fixation were significant factors in univariable analysis. Multivariable analysis revealed that tall stature (OR 1.16, 95% CIs 1.08 - 1.25, P < 0.001), prolonged anesthesia duration (OR 1.16, 95% CIs 1.02 - 1.32, P = 0.026), and right side surgical field compared to left or median (OR 0.36, 95% CIs 0.14 - 0.93, P = 0.034, OR 0.25 95% CIs 0.07 - 0.85, P = 0.027, respectively) were independent risk factors.
CONCLUSIONS. The shallow NTT depth after head and neck surgery were present in 41% of patients. Tall stature, prolonged anesthesia duration, and right side surgical field were independent risk factors of postoperative shallow tube depth. Our study suggests that the patients with risk should select appropriate tube in advance and check tube depth on postoperative CXR.

Incidence and associated factors of successfully immediate extubation after liver transplantation

A. Suphathamwit, O. Pongraweewan, S. Lakkam
of Medicine Siriraj Hospital, Department of Anesthesiology, Bangkok, Thailand
Correspondence: A. Suphathamwit
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1195

INTRODUCTION. Liver transplantation is the definitive treatment of acute liver failure and end-stage liver cirrhosis. In the past, post liver transplant patients were remained intubated and stayed in the ICU because of prolonged period of surgery and massive blood and fluid administration. Nowadays, the evidence that spontaneous breathing provides better liver circulation and venous drainage without compromising postoperative patient status, thus, there is an increasing trend to extubate the patient immediately after liver transplantation.
OBJECTIVES. To determine the incidences and associated factors for immediate extubation of post-liver transplantation patient in Siriraj hospital.
METHODS. This is a retrospective descriptive study performed on 262 liver transplantation patients in Siriraj hospital between 2004 and 2016. The primary outcome is the incidence of successful immediate extubation post liver transplantations. Secondary outcome includes factors associated with successfully immediate extubation, pulmonary complications (including re-intubation rate, pneumonia, ARDS), acute kidney injury, graft failure rate, length of hospital and ICU stay and post-operative death.
RESULTS: A total of 239 patients were analyzed after exclusion according to exclusion criteria. The incidence of successfully immediate extubation after liver transplantation is 32.2 %. Factors significantly associated with successfully immediate extubation from multivariate analysis included diagnosis of hepatocellular carcinoma (adjusted OR 2.01, 95%CI 1.09-3.74, p = 0.026), amount of blood transfusion < 1,600 ml (adjusted OR 5.18, 95% CI 1.49 - 18.02, p = 0.010) and no post-operative vasopressor or inotropes requirement

(adjusted OR 18.43, 95%CI 2.43 - 140.08, p = 0.005). Postoperative pulmonary complications, acute kidney injury, length of hospital and ICU stays and postoperative death were lower in immediate extubation group.
CONCLUSIONS. The incidence of successfully immediate extubation in post-liver transplantation patients in Siriraj hospital was 32.2%. Factors associated with successfully extubation included hepatocellular carcinoma, less amount of blood transfusion and no inotropes or vasopressors requirement at the end of surgery. The patients in immediate extubation group had significantly less postoperative pulmonary complication, acute kidney injury and overall hospital stay.

Cardiopulmonary exercise testing as a predictor of hospital stay in patients undergoing oesophagogastrectomy

M. Gerstman, G. Friedlaender, J. Batty, M. Hacking, T. Wigmore
Royal Marsden, Anaesthetic Department, London, United Kingdom
Correspondence: M. Gerstman
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1196

INTRODUCTION. Oesophagogastrectomy surgery is high risk oncological surgery associated with high morbidity and mortality. Cardiopulmonary exercise testing (CPET) is used to risk stratify patients being considered for this surgery. Both V02 max and FVC have been identified as independent variables for predicting hospital length of stay however these results have not been consistent in all studies [1,2].
OBJECTIVES. Our aim was to analyse whether preoperative CPET in patients undergoing oesophagogastrectomy is predictive of hospital length of stay in our institution.
METHODS. This is a retrospective observational analysis of patients undergoing oesophagogastrectomy at the Royal Marsden between September 2010 and December 2015. Variables studied included anaerobic threshold oxygen consumption (AT VO2), maximal oxygen consumption (VO2 MAX), ventilatory equivalents for CO2 at AT (AT VE/VCO2), as well as forced expiratory volume in first second (FEV1), forced vital capacity (FVC) and peak flow.
RESULTS. Of the 157 patients who underwent oesophagogastrectomy surgery during this period 105 underwent cardiopulmonary exercise testing and 120 had their peak flow recorded. See the Table 1 below for results.
CONCLUSION. There was a weak negative correlation between peak flow and hospital length of stay in patients undergoing oesophagogastrectomy in our institution. CPET variables did not predict hospital length of stay in our study population.

REFERENCE(S)

2. Tan B, et al Cardiopulmonary exercise testing predicts prolonged hospital stay following oesophago-gastric cancer surgery. Gut 2015;64:A120.

There was negative linear relationship between peak flow and hospital length of stay (p=0.007) with a corresponding correlation of (r=-0.246) (Fig. 1). All other variables indicated weak negative linear relationship (r=-0.117 and r=-0.009) and correlation p-values of > 0.1

Table 1 (abstract 1196). CPET and peak flow results

Variable	Result mean (SD)
AT VO2 (ml/kg/min)	12.2 (3.0)
VO2-MAX (ml/kg/min)	19.1 (4.3)
Work at AT (Watts)	71.8 (27.9)
AT-VE/VO2	32.2 (5.2)
FEV1 (L)	3.2 (0.7)
FVC (L)	4.3 (1.0)
Peak flow (ml)	477.2 (107.7)

Evolution and complications in the inmediate postoperatory of citorreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC)

E. Rosas Carvajal, A. Vidal González, V.A. Hortigüela Martín, D.C. Robaglia, L.M. Polanco Mahecha, J.J. Páez Vargas, M.Á. Alcalá Llorente, C. Pérez Calvo
Jiménez Díaz, Intensive Care Unit, Madrid, Spain
Correspondence: E. Rosas Carvajal
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1197

INTRODUCTION. The CRS-HIPEC surgery is an essential therapeutic alternative in the management of the abdomino-peritoneal cancer locally advanced. Its postoperatory management is a challenge for the intensivist for its high risk of complications among which Acute Kidney Injury (AKI) stands, with rates that oscillate between 40.4% and 21.3% in the available literature.

OBJECTIVES. Analyze the evolution and complications in the immediate postoperatory of patients undergoing a CRS-HIPEC surgery.

METHODS. Observational and retrospectively all the patients admitted in a polyvalent ICU during the immediate postoperatory of a CRS-HIPEC surgery, between the years 2016 and 2017, were collected. All the patients were treated following a protocol planified in advance that included agressive intravenous hydratation to maintain a diuresis of 3-4 ml/kg/h, albumin administration and early start of parenteral nutrition.

RESULTS. A total of 39 patients were analyzed, 64.1% women, with a mean age of 57.5±10.52 years. The most common types of cancer were digestive in the 87.2% and primary peritoneal in the 12.8% of the patients, with an average PCI of 8.43±7.37.

Most of the procedures were realized in surgical second look, a 94.39%. The complete cytoreduction (CC-0/1) was achieved in the 97.4%.

Hyperthermic intraperitoneal chemotherapy was administrated adjusted to corporal surface, in digestive tumors with Oxaliplatin 460mg/m2, 31.2% of them with dose reduction of 400-430mg/m2; and in the primary peritoneal tumors with Cisplatin 75mg/m2.

The most frequent complications were the cytopenias (87.7%), presenting anemia in the 79.5%, trombopenia in the 53.8% and neutropenia in the 15.4%. We didn't find a relationship within the different types of chemotherapy nor the doses.

According to KDIGO criteria, AKI was presented in 7.7% of the patients, of which 66.3% were stage 1 and 33.7% stage 2, and none of them needed substitutive renal therapy.

Other severe complications occurred in the 35.9% of the patients, such as ARDS, pericardial effusion, pancreatitis, rebleeding, septic shock, paralytic ileus and hepatitis.

The mean ICU stay was 4±3.86 days with a mean of 0.5±3.20 days of mechanical ventilation, and a global intra ICU mortality of 3.2% (only 1 patient due to ARDS).

CONCLUSION. Although the rate of complications after this procedure remains high, we find our rate of AKI much lower than in other series published, a low mortality and stay in the ICU due to the procedure, what we relate to our protocolized postoperatory approach.

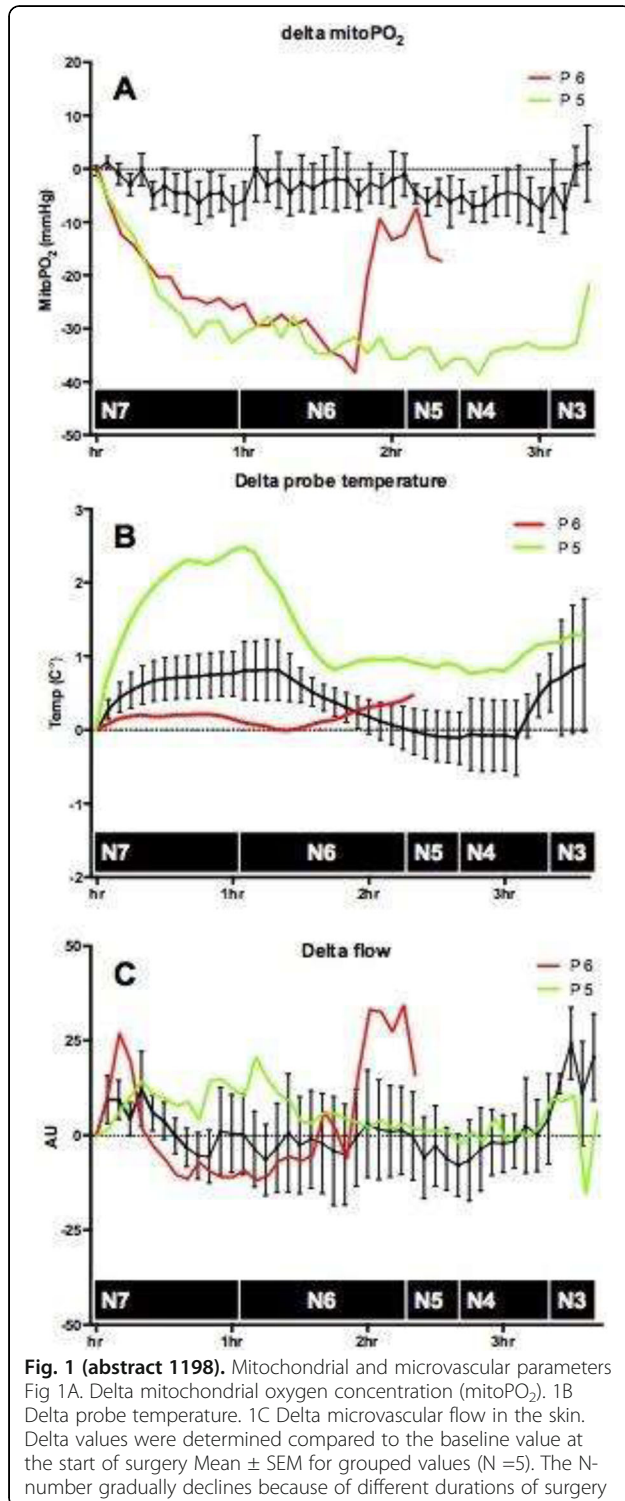
Monitoring of mitochondrial oxygen tension in the operating theatre: first experiences with the novel COMET monitor

M. Wefers Bettink, R. Ubbink, R. Jansen, T. van der Ende, F. Harms, B. Mik
MC University Medical Center, Anesthesiology, Rottedam, Netherlands
Correspondence: M. Wefers Bettink
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1198

INTRODUCTION. A novel non-invasive method of measuring mitochondrial oxygenation ($mitoPO_2$) in the skin has recently been implemented in the COMET (Cellular Oxygen METabolism) monitor (1). The $mitoPO_2$ reflects the balance between oxygen supply and demand.

For example, in a preclinical study $mitoPO_2$ appeared to be a potential parameter for personalized blood transfusion trigger (2).

OBJECTIVE. The COMET monitor was applied for the first time in the operating theatre during surgery under general anesthesia to test the feasibility of the measuring concept and the stability and response of $mitoPO_2$ during general anesthesia.


METHODS. A single centre observational study in 16 patients undergoing neuro surgery. The study was approved by the IRB of the Erasmus MC. After informed consent, pre-operatively a plaster containing 5-aminoluvelinic acid was placed on the sternum 5-8 hrs before induction of general anesthesia, to induce mitochondrial protoporphyrin IX for measurement of oxygen-dependent delayed fluorescence. $MitoPO_2$ was measured at a rate of 1 measurement every 5 minutes using the COMET (Photonics Healthcare B.V., Utrecht, The Netherlands). Additionally, micro-vascular haemoglobin saturationand flow in microcirculation were measured with the O2C (LEA Medizintechnik, Giessen, Germany). For standardisation purposes the start of surgery was chosen as first time point in the analysis.

RESULTS. The first 6 inclusions let to a software update to solve signal instability due to excessive infrared light in surgical lamps, 2 were excluded because of unavailability of the O2C monitor, 1 patient signal quality was insufficient. In the remaining 7 patients, ASA 1-2 and 56,5± 10,8 years of age, mean arterial pressure at start surgery was 78,3 ± 10,4 mmHg and remained above 60 mmHg. No significant blood loss or hemodynamic alterations were observed. $MitoPO_2$ started at 57,1 ± 16,5 mmHg andstayed stable in 5 out the of 7 patients, figure 1A. In patient 5 (p5) a decrease of $mitoPO_2$ of -30 mmHg was seen form baseline in half an hour, in correlation with a change in probe temperature, Figure 1B. In patient 6 (p6) a decrease in $mitoPO_2$ was seen followed by a normalization of $mitoPO_2$ at the end of surgery. This change in $mitoPO_2$ was correlated with a change in microvascular blood flow in the skin, Figure 1C.

CONCLUSION. COMET was able, after a software update, to measure mitoPO$_2$ in patients in the operating theatre. No significant changes of mitoPO$_2$were measured when the patients were stable in both hemodynamics and temperature.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1199

INTRODUCTION. Cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC) is an emerging treatment option for selected patients with peritoneal carcinomatosis. It has been linked to high rates of morbidity (12-15%) and mortality (1-5.8%) and patients are frequently admitted to an Intensive Care Unit (ICU) following it.
OBJECTIVES. To study the patients admitted to an ICU after CRS with HIPEC, its morbidity and mortality.
METHODS. Retrospective observational study performed in an Oncological ICU. All patients admitted in and between 2013 and 2017 after CRS with HIPEC or within one month were included. Data analysis was performed using descriptive statistics and hypothesis tests.
RESULTS. The study included 111 patients, accounting for 6.4% of all admissions to the ICU; 65.8% were female and the median age was 61 years. The primary tumors were located in the appendix (38.7%), colon/rectum (36%), ovary (15.3%), stomach (5.4%), peritoneum (3.6%) and jejunum (0.9%). Median Peritoneal Cancer Index (PCI) was 15. APACHE II and SAPS II mean score were 10.3 and 28.4.
Intra-abdominal complications were present in 7.2%: peritonitis and abdominal sepsis (4.5%), deep wound infection (1.8%), anastomotic dehiscence (1.8%), gastro-intestinal leakage (1.8%), intra-abdominal hematoma (1.8%) and ileus (0.9%). These complications were observed more often in men than women (p=0.02), and 37.5% occurred in patients with gastric cancer - 50% of all patient with gastric cancer developed complications. There were no statistically significant differences in mean age (p=0.478) and mean PCI (p=0.271) between the patients that developed intra-abdominal complications and the ones that did not.
Infections other than intra-abdominal occurred in 5.4% of patients: respiratory (3.6%), genitourinary (1.8%), central venous catheter-related bacteremia (1.8%), skin and soft tissue (0.9%), infective endocarditis (0.9%) and bacteremia (0.9%). Septic shock with multiple organ dysfunctions was present in 6.3% and hypovolemic shock in 3.6%. Acute respiratory failure was seen in 44.1% and 9% needed mechanical ventilation. Surgical reintervention was performed in 4.5%. Median ICU length of stay was 2 days, readimission rate was 6.3% and mortality was 1.8%.
CONCLUSIONS. In our study, 50% of patients with gastric cancer had intra-abdominal complications. Conclusions are difficult to draw because of all patients only 6 had gastric cancer, but there seems to be a tendency for complications in this group. Overall, during ICU stay, morbidity with intra-abdominal complications and other infections was low (9%) and so was mortality (1.2%). These findings and the long survivals associated with the procedure suggest its benefit in the management of well-selected patients.

INTRODUCTION. Preoperative risk stratification can be useful in choosing the whole therapeutical strategies for patients(pts) with pancreatic disease and allows to calculate the risk-benefit balance of surgery. A prediction of the postoperative risk is fundamental for planning the post-operative measures to be taken.

OBJECTIVES. The aim of our study was to identify the more important pre-operative variables that affect pts outcome after major pancreatic surgery.

METHODS. We collected the data of pts operated for major pancreatic surgery during a 12-month period from two clinical database (University Hospital of Verona and Peschiera Pederzoli Clinic). Outcome data included incidence of postoperative complications, hospital mortality, ICU admission and days of hospitalization. The level of risk was determined by considering BMI, smoking habitus, presence of jaundice, pre-operative drainage of jaundice, recent chemiotherapy, anamnesis positive for cardiovascular, pulmonary, renal, neurological disease and an American Society of Anesthesiologist (ASA) score ≥ 3.

RESULTS. A total of 638 pts (320 women and 318 man, mean±sd age 61.41±12.52 years) were operated of major pancreatic surgery in the two hospitals. 18.8% of these patients were ASA ≥ 3 pts. ICU admission was 8.9%. Total post-operative complications were 57.6%, mortality was 2.2%. We observed abdominal complications and general complications (cardiac, respiratory, infectious and renal) in in 43.5%and 34.1%, respectively. Mean surgical duration was 332.81 ±106.05 minutes, and mean duration of hospitalizations was 15.94 ±17.83 days. ASA≥3 patients presented higher peri-operative complications and in-hospital mortality than low ASA group, (5.8%vs1.3%, p. < 0.01, chi-square test). Intraoperative blood losses, the need of ICU admission (26.7%vs4.8%, p.< 0.01) and the mean length of in-hospital stay (20.90±25vs14.81±15.55 days, p.< 0.01) were higher in high ASA group as well. The percentage of complication with DGE, biliary-fistula (7.1%vs 3.8%, p. < 0.01), mean duration of surgery, ischemic cardiovascular complications were higher in group with pre-operative jaundice.

CONCLUSIONS. We found good correlation between ASA status and development of peri-operative general complications. Also intraoperative blood losses and length of hospitalization was well related to ASA status. Presence of pre-operative jaundice is strongly related to development of post-operative abdominal complications like enteric or biliary fistula. Overall mortality was higher in high ASA status group. Our data enforce the utility of the development of an easily applied scoring system with convincing accuracy for identifying high-risk patients, based on preoperatively assessable characteristics, which could be very useful in choosing the right therapeutic strategy, expecially for low-malignant risk lesions.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1201

INTRODUCTION. The choice of fluids in critically ill patients has been a long-debated subject, with recent evidence from SMART suggesting that the use of unbalanced fluids such as saline 0.9% is associated with hyperchloraemia, reduced plasma bicarbonate, & worse renal outcomes[1]. During liver transplants (LT), patients undergo complex physiological changes in the preanhepatic, anhepatic, & post-reperfusion phases[2], & these patients often require careful post-op ICU management. At our centre, LTs are a subset known to receive large volumes of fluid intra-op; majority being gelatine 4% (Gelofusine®) and saline 0.9%, in addition to blood products.

OBJECTIVES. We sought to investigate the association between intra-op fluid administration & post-op acid-base status, particularly post-op pH, chloride (Cl⁻) levels & incidence of AKI.

METHODS. Medical records of adults (over 18yrs) who received a LT from 1 Jul to 31 Dec 2017 were identified by their contemporaneous electronic medical records (Epic Systems®, USA). Patients missing more than 10% of their intra-op records (due to any cause) were excluded.

We examined the relation to total fluid administration (Gelofusine & saline 0.9%) of 3 parameters: Post-op serum Cl⁻ levels, intra-op change in pH (ΔpH = pre-op pH - post-op pH), & intra-op change in base excess (ΔBE = pre-op BE - post-op BE). The latter derivations were used to overcome the variability in pre-op pH. There was insufficient data on pre-op Cl⁻ to calculate ΔCl^-. Data were plotted against each other for linear least-squares regression analysis, & correlation strength was assessed by means of a Pearson Rank Correlation test.

RESULTS. 58 patients were initially identified, & 2 were excluded due to insufficient intra-op data. The average age was 54.8 yrs (SD 10.1), & 34/56 were male. Most LTs were for chronic liver failure, with 5 being for acute liver failure. The mean volume of IV fluid given was 4.8L (SD 2.6L), which was exclusively Gelofusine & saline 0.9%. There was a significant positive correlation between intra-op fluid volume & post-op absolute chloride level (R=0.352, p=0.008), & a significant negative correlation between intraoperative fluid & ΔBE (R=-0.283, p=0.03), & ΔpH (R=-0.387, p=0.003). The incidence of AKI up to 30 days post-op was 64.3% in our series.

CONCLUSIONS. In this small single-centre retrospective study of LTs receiving high volumes of chloride-rich fluid, the total volume of unbalanced fluid administered was associated with a post-op lower pH, bigger base deficit & increased absolute serum Cl⁻. Further study is required to establish associations with patient-centred outcomes in LTs.

INTRODUCTION. Delayed graft function in renal transplant patients might be affected by fluid therapy in the perioperative period. Cardiac output-directed strategies with minimally invasive hemodynamic monitoring has been recommended for fluid therapy guidance in critically ill patients. Fluids are a cornerstone for the management of kidney transplant patients, but overload should be avoided. There are, however, insufficient data to acknowledge the role of fluid administration guided by cardiac output monitoring in this specific population.

OBJECTIVES. Clinical evaluation of a strategy of perioperative fluid administration guided by minimally invasive hemodynamic monitoring and echocardiography in patients submitted to renal transplantation.

METHODS. 22-bed level III ICU, tertiary university-affiliated urban referral hospital. Outcomes from 34 kidney transplant recipients treated with a standard of care strategy, that included fluid administration guided by fluid balance and diuresis, were compared with outcomes from 19 patients prospectively treated by a clinical protocol that included fluid therapy guided by cardiac output monitoring with FloTrac™ and echocardiography.

RESULTS. Standard of care and protocol-driven patients had similar demographic and morbidity characteristics. Both groups had been transplanted by the same surgical team, and there were no differences regarding donor serum creatinine level, warm and cold ischemia periods. Cardiac index at admission was 4.3 ± 0.8 L/min/m^2. Patients from the protocol-driven group had a statistically significant higher SAPS II score (20.9 vs. 28.0; *p=0.001)*. Day 1 and day 3 cumulative fluid balance was higher in the standard of care group. Renal transplant outcomes did not differ, with similar incidence of graft survival and delayed graft function. Creatinine at 6 months showed no statistically significant difference. Standard of care patients showed statistical nonsignificant increased incidence of lung oedema, arterial hypertension requiring medication and haemodialysis; length of stay was similar.

CONCLUSIONS. To our knowledge, this is the first preliminary study comparing cardiac output monitoring to guide fluid therapy in renal transplant patients. We showed that a protocol-driven strategy to support fluid administration in these patients might be associated with less fluid overload when compared with standard of care. Furthermore, this restrictive fluid strategy does not compromise renal transplant outcomes at 6-month.

Table 1 (abstract 1202). See text for description.

	Standard of Care (n=34)	Protocol-Driven (n=19)	p value
Fluid balance (D3) (mL)	3342.7 ± 2165.8	1985.3 ± 2167.7	0.038
Creatinine (1week) (mg/dL)	3.3 ± 2.9	2.6 ± 2.1	0.338
Creatinine (6 months) (mg/dL)	1.5 ± 0.6	1.6 ± 0.5	0.609
Length of stay (LOS)	3.9 ± 1.3	4.5 ± 1.1	0,11
Delayed graft function	7 (20.6 %)	3 (15.8 %)	0.669
Graft survival	33 (97.1%)	18 (94.7%)	0.67
Haemodialysis (ICU)	4 (11.8%)	0 (0%)	0.12
Hypertension	21 (61.8 %)	11 (57.9 %)	0.782
Lung oedema	4 (11.8 %)	1 (5.3 %)	0.437

INTRODUCTION. The early postoperative period after liver transplantation is characterized by a complex hemodynamic situation, due to the interaction of multiple factors, as the persistence of the hyperdynamic circulation or the increase of lactate blood levels because of the impaired hepatic clearance. In the present study, we addressed the question of whether the PcvaCO2/ CavO2 ratio is useful in predicting the persistence of tissue hypoperfusion and anaerobic metabolism.

OBJECTIVES. To analyze the ability of the PcvaCO2/CavO2 ratio in the hemodynamic management after liver transplantation.

METHODS. Prospective observational study including all patients admitted to the ICU after liver transplantation over a 12-months study period. Demographic variables (sex, age, cause of transplantation and severity scores), hemodynamic variables, and those related to graft function and postoperative complications were recorded. Patients were classified according to the existence of a PcvaCO2/CavO2 ratio over 1.4 over the first 6 hours after the liver transplantation.

Data statistical analysis was done using SPSS software. Quantitative variables are expressed as mean with standard deviation (SD) and qualitative variables as absolute and relative frequencies. The statistical significance of the proportion comparison was addressed by the chi-square test, Mann Whitney U test or Student´s t-Test with a statistical significance p < 0.05.

RESULTS. During the study period, 45 patients were admitted to the ICU after a liver transplantation (84% male) with a mean age of 56 ± 9 years. The main causes of the liver transplant were alcoholism (53%), hepatocellular carcinoma (44,4%) and hepatitis C virus infection (44,4%). Mean MELD score was 16 ± 9; Median ICU stay was 6 days (IQR 4-10), with an overall ICU mortality of 13%.

Twenty one patients presented early tissue hypoperfusion defined as a PcvaCO2/CavO2 ratio over 1.4 during the first 6 hours after the liver transplantation; When compared with patients with a PcvaCO2/ CavO2 ratio under 1.4, they presented significantly higher mean SOFA score at 24 hours (7,68+/-4,3 vs 4,5+/-1,5, p=0.008).

Non-significant differences were observed comparing reintubation rate (4 vs 1; p=0,409), prolonged mechanical ventilation (5 vs 0;p= 0,67), acute renal failure incidence (14 vs 6;p=0.34) or ICU stay (6 vs 5; p=0,076).

CONCLUSIONS. In the early postoperative care after liver transplantation, the PCVACO2 gap is a feasible hemodynamic parameter that could predict a worse clinical outcome.

INTRODUCTION. Every year more than 200 million noncardiac surgeries are performed around the world and approximately 5-10% of them are vascular procedures. They are associated with high risk of perioperative complications, both arterial and venous.[1] These complications are closely related to activity of coagulation and fibrinolysis systems. Unfortunately, reliable studies assessing influence of vascular procedures on mentioned systems are lacking.

OBJECTIVES. Main goal of our study was to assess the impact of vascular procedures on activity of hemostatic and fibrinolytic pathways.

METHODS. We enrolled 29 patients ≥45 years old undergoing surgery for abdominal aortic aneurysm or peripheral artery disease under general or regional anesthesia, hospitalized at least one night after the procedure. Patients undergoing carotid artery surgery and those who had bypass graft thrombosis, cancer, renal failure defined as eGFR < 30 ml/min/1.73 m^2, venous thromboembolism 3 months

prior to surgery or acute infection were excluded from the study. We measured levels of markers of hemostasis (Factor VIII, von Willebrand Factor:CoR, antithrombin), fibrinolysis (D-dimer, tissue plasminogen activator, plasmin-antiplasmin complexes) and soluble CD40 ligand levels before and 6-12h after vascular procedure.

RESULTS. Significant differences between preoperative and postoperative levels of FVIII (152.1 vs. 117.6 %, p< 0.001), vWF:CoR (138.5 vs. 158.1 %, p=0.045), antithrombin (92.1 vs. 74.9 %, p< 0.001), D-dimer (889.0 vs. 1897.0 ng/ml, p=0.002), tPA (9.7 vs. 13.0 ng/ml, p=0.001) and sCD40L (9064.3 vs. 1786.7 pg/ml, p< 0.001) were observed. There were no significant differences between pre- and postoperative levels of plasmin-antiplasmin complexes (738.2 vs. 829.5 ng/ml, p=0.38).

CONCLUSIONS. Vascular surgery leads to activation of hemostatic system but its effect on fibrinolytic pathway remains unclear. Further studies utilizing dynamic methods of coagulation and fibrinolysis assessment, performed on larger study group are necessary to precisely address this issue.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1206

INTRODUCTION. Red blood cells (RBC) are one of the key element of the microcirculation (1). The ability to pass through capillaries and to deliver oxygen to cells, is due to its extreme capacity of deformability (2). Nevertheless, alterations in RBC deformability are observed in several diseases like in sepsis, and could contribute the altered microcirculation observed in these pathologies (2). The hyperbaric oxygen therapy (HBOT) with inhalation of 100% oxygen is proposed in several acute or chronic pathologies including carbon monoxide poisoning.

OBJECTIVE. We investigated the effects of HBOT on RBC deformability in healthy volunteers (n= 10), in patients with acute carbon monoxide poisoning (n= 10) and in patients with acute or chronic inflammation (n=10).

METHODS. After approval by the ethical committee, RBCs deformability was assessed before and after HBOT by ektacytometry technique (Laser-assisted Optical Rotational Red Cell Analyzer - LORRCA) in the various populations. Elongation index (EI) was defined as (L-W)/(L+W), where L is the length and W is the width. At constant temperature of 37°C, EI values were determined in the function of shear stress (SS) in a range of 0.5 - 50 Pa, based upon the laser diffraction pattern changes. A higher EI indicates greater RBC deformation.

RESULTS. Before HBOT, EI was significantly lower for the majority of SS studied in patients with acute or chronic inflammation compared to healthy volunteers and patients with acute carbon monoxide poisoning.

HBOT improved significantly the EI only in patients with acute or chronic inflammation.

CONCLUSIONS. Our results confirmed the altered deformability in patients with inflammation. HBOT could improved it and perhaps by this way the microcirculation in this particular population. This link need to be confirmed in a larger population.

Advanced glycation end products and new-onset atrial fibrillation in sepsis

E. Rodriguez-Ruiz[1], R. Hernández-Vaquero[1], I. Granja Gómez[1], J.L. García Allut[1], A. López Lago[1], A. Estany Gestal[2], M.Á. García González[3]

Correspondence: E. Rodriguez-Ruiz
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1207

INTRODUCTION. Sepsis has been shown to trigger atrial fibrillation (AF), the most common sustained arrhythmia in critically ill. A growing body of evidence indicates that inflammation and oxidative stress contribute to its pathogenesis. Advanced glycation end products (AGEs), stable products generated by non-enzymatic glycation of proteins and lipids, are driven by oxidative stress. AGEs are implicated in atrial fibrosis. New-onset AF (NAF), AF episode lasting > 30 seconds, has been associated with increased risk of in-hospital mortality. We wanted to investigate the implication of AGEs in sepsis-related NAF.

OBJECTIVES. Our aim was to determine the incidence of AF and NAF in patients with severe sepsis and septic shock, and to study their association with AGEs levels in plasma (pAGE) and 28-day mortality. Also, we wanted to analyze the relationship between NAF, medical history, MOF, severity scores and inflammatory mediators.

METHODS. We included 90 consecutive patients with the diagnosis of severe sepsis or septic shock according to 2001 Sepsis Consensus Conference. We checked in their medical history for age, sex, smoking habit, diabetes mellitus (DM), dyslipidaemia (DLP), arterial hypertension (aHT), chronic kidney disease (CKD), heart failure (HF) and myocardial infarction (AMI). At day 1, pAGE levels were measured by quantitative fluorescence spectroscopy. Also, we measured some inflammatory mediators: TNF-α, IL-1β, IL-6, IL-8, CRP and PCT. Moreover, Pro-BNP levels at admission were measured. APACHE-II was calculated at admission; meanwhile, daily SOFA was

calculated during the first five days. 28-day mortality was assessed during the follow-up. Chi-square was performed to determine the relation between AF or NAF and sex, medical conditions and 28-day mortality. Mann-Whitney U was applied to study the association between AF or NAF and pAGEs, inflammatory mediators, Pro-BNP, APACHE-II and SOFA.

RESULTS. In our cohort of septic patients (mean age 68±13), we detected AF in 11 patients (12,2%) at admission and 79 patients (87,8%) were in sinus rhythm (SR). From those in SR, 13 patients (16,5%) developed NAF during the septic process. Significant association was found between AF at admission and pAGE (p=0.013), but not between NAF and pAGE. We found that NAF was more frequent in patients with septic shock (p=0.032) compared with those with severe sepsis. NAF was also associated with MOF (SOFA day1: p=0.022, SOFA max: p=0.004). No relationship was found between age, sex, smoking habit, DM, DLP, aHT, CKD, HF, AMI, APACHE II score, inflammatory biomarkers, NT-Pro-BNP and NAF. We could not find association between NAF and 28-day mortality (p = 0,428).

CONCLUSIONS. In this study, sepsis-related NAF showed a high incidence. pAGE was associated with AF at admission, but not with NAF. NAF was more frequent in septic shock and MOF, but we could not find association between NAF and 28-day mortality.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1208

INTRODUCTION. Cardiac function is known to be negatively impacted by sepsis. Stroke volume change in response to Passive Leg Raise (PLR) is an effective method to predict fluid responsiveness (FR) or cardiac response to preload expansion.

OBJECTIVES. To evaluate preload functional status and trending cardiac output to identify patient phenotypes with varying cardiac reserve, dysfunction and outcome.

METHODS. Patient data were analyzed from a currently enrolling prospective randomized controlled study, evaluating the incidence of FR in critically ill patients with sepsis or septic shock (FRESH study, NCT02837731). Patients randomized to PLR guided resuscitation were classified as PLR+ (fluid responsive / preload dependent) if stroke volume (SV) increased $\geq$ 10% when measured with a non-invasive bioreactance device (Starling SV, Cheetah Medical). Independent evaluators categorized patients into 5 different phenotypic cohorts based on changing physiology exhibited on PLR and trending cardiac output over the initial 72 hours of therapy. Groups 1 (initial PLR +) and 2 (initial PLR-) both demonstrated fluid responsiveness and improvement in CO over the 72 hour assessment period. In contrast, Groups 3-5 did not exhibit an overall improvement in CO regardless of initial PLR response.

RESULTS. A total of 311 PLR assessments were performed in 43 patients. Overall, 39% (122/311) of assessments demonstrated PLR positive responses after receiving initial resuscitation fluid of 2.2 (+/- 0.6) L. There were no differences among the 5 groups with respect to age, gender, or QSOFA score (**Table 1**). Patients within the 5 groups exhibited distinctly different patterns of fluid responsiveness (**Table 2**).

Fluid responsiveness was dynamic, changing over the 72 hours of the study. Significant differences were noted in the incidence of fluid responsiveness between patient groups on Days 1-3 of treatment (p< 0.0001). Notably, patients in Groups 3-5 exhibited a higher incidence of a negative change in stroke volume with PLR (22%) compared to patients in Groups 1&2 (11%, p < 0.0001). Groups 1 &2 had a significantly shorter ICU stay (102 hours +/- 56 SEM) compared with Groups 3-5 (263 hours +/- 43 SEM, p=0.017) (**Figure 1**). Additionally, Groups 1&2 exhibited a notable but non-significant reduction in 30 day mortality (6.7%) compared with Groups 3-5 (28.6%, p=0.09).

CONCLUSIONS. Short-term sepsis resuscitation phenotypes based on SV and CO responses to PLR identify discrete and significantly different patient sub-groups. Patients who are FR, and augment CO in response to resuscitation experienced decreased length of stay and a trend to decreased mortality. A negative change in SV in response to PLR indicates impaired cardiac function that should prompt further early evaluation. Periodic dynamic monitoring may predict patient outcome and guide treatment for sepsis-associated cardiac dysfunction.

Table 1 (abstract 1208). Phenotype Cardiac Output Groups

Phenotype Cardiac Output Groups	72 Hr Assessment
Group 1: PLR+ stays PLR+, CO Improved	19%
Group 2: PLR- becomes PLR+, CO Improved	16%
Group 3: PLR- becomes PLR+, CO Not Improved	30%
Group 4: PLR- stays PLR- CO Not Improved	14%
Group 5:PLR+ CO Not Improved	21%

Bedside echocardiography to predict 28-day mortality in sepsis: the value of day 1 MAPSE

P. Cavaleiro, S. Castro, S. Pina, T. Salero, C. Granja

Correspondence: P. Cavaleiro
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1209

INTRODUCTION: Sepsis-induced myocardial dysfunction is present in over 40% of all cases and, when present, mortality rates are increased up to 70%. Several patterns of dysfunction may be present[1]. Mitral annulus plane systolic excursion (MAPSE) is an echocardiographic marker of left ventricle (LV) longitudinal function that correlates well with other markers of global LV function[2]. It can be obtained from patients with sub-optimal acoustic windows, by operators with limited training and is easily reproduced[3]. It has also been shown in a small study than shock non-survivors have lower MAPSE on day 1, when compared with survivors[2].

OBJECTIVES: The purpose of this study was to evaluate the correlation of MAPSE measurements obtained in the first 24h of ICU admission with 28-day all-cause mortality and whether it has prognostic value in septic patients.

METHODS: We prospectively enrolled consecutive adult patients with sepsis admitted to our general ICU. We collected demographic and medical data and performed echocardiography examinations during the first 24h of sepsis evolution, after initial resuscitation. Measurements obtained were averaged over 3 consecutive beats (or 10 beats if atrial fibrillation was present).

Univariate and multivariable analyses were used to assess the relationships between variables and 28-day mortality. Two different operators collected data and a reproducibility evaluation using Bland-Altman analysis was performed.

RESULTS: Eighty-five patients (67.1 ± 16.4 years; 58 men) were enrolled (tables 1 and 2). All-cause 28-day mortality was 35.3%.

When comparing survivors with non-survivors, we found significant differences in MAPSE ($p = 0.006$), SAPS II ($p < 0.001$) and SOFA ($p = 0.002$) scores. We categorized MAPSE in 3 categories (corresponding to tertiles: MAPSE < 11.5; 11.5 - 14.2; > 14.2 mm). In a multivariate model, including both scores, we identified SAPS II (adjusted OR 1.1, 95% CI 1.03 - 1.14) and lower MAPSE as predictors for mortality at 28 days, when compared to higher MAPSE (adjusted OR 5.3, 95% CI 1.24 - 22.46).

Bland-Altman analysis yielded a bias below 0.5 mm and limits of agreement of ± 0.76 mm.

CONCLUSIONS: Sepsis patients with lower day 1 MAPSE (< 11.5 mm) may have a significant higher risk of mortality than those with higher MAPSE, even when adjusted for severity of illness.

INTRODUCTION. Coagulation abnormalities and thrombocytopenia are common in sepsis, up to 40%.[1] Despite the clinical relevance of sepsis induced thrombocytopenia, few studies have focused on the prediction of thrombocytopenia in this setting.

OBJECTIVES. The aim of this study is to identify if platelets aggregometry can be useful in predicting sepsis induced thrombocytopenia in patients with septic shock and normal platelet count on the day of diagnosis.

METHODS. We enrolled consecutive patients with septic shock on ICU admission or with diagnosis of septic shock during ICU stay. Exclusion criteria were: age < 18 years, platelet count < $150*10^3$/mL; therapy with antiplatelet drugs within the 8 days from ICU admission. Aggregometry test were performed daily from admission to day 5 using adenosine diphosphate (ADP), arachidonic acid (AA) and thrombin receptor-activating

peptide-6 (TRAP). Maximal rate of aggregation (Agg_{max}) was recorded for all tests. Sepsis-induced thrombocytopenia was defined as a platelet count $< 150*10^3$/mL within 5 days, while moderate or severe thrombocytopenia as a platelet count $< 100*10^3$/mL or $50*10^3$/mL, respectively. 90-day mortality and hemorrhagic complications were also collected.

RESULTS. A total of 26 patients have been included. (Table 1) Sepsis-induced thrombocytopenia occurred in 10 (38%) patients; of those, 6 (17%) developed moderate/severe thrombocytopenia. Time to thrombocytopenia was 3 [2-5] days. Daily changes in Agg_{max} are shown in Figure 1. Patients with thrombocytopenia had lower Agg_{max}, than others, regardless the agonists that were used, in particular when thrombocytopenia was moderate to severe. (Figure 2) Hemorrhagic complications occurred in 15% of patients and 90-day mortality was 35%. Patients with hemorrhagic complication had lower Agg_{max} (ADP: 15.5 [5 – 47] vs 72 [65 – 78] %; p< 0.001 AA: 6.3 [3 – 18] vs 65 [54 – 74]; p=0.002; TRAP: 45 [23 – 60] vs 74 [62 – 78], p=0.004) but not lower platelets on admission (335 [214 – 377] vs 230 [176 – 368], p=0.47) than others. Also, non-survivors showed lower Agg_{max} (ADP: 68.2 ± 14 % vs 46.2±20 %; p=0.02 AA: 56.9 ± 11% vs 31.7 ± 17%; p< 0.001 TRAP: 69.2±10% vs 58.3±15%; p=0.10) than others.

CONCLUSIONS. Altered aggregometry test is common in septic shock even with normal platelet count, in particular in patients who will develop sepsis-induced thrombocytopenia. Altered aggregometry can also have prognostic value for both hemorrhagic complication or 90-days mortality.

Acoustocerebrography in septic patients: first clinical results

M. Sauer, G. Richter, A. Sievert, T. Mencke, J. Ehler, P. Schmude, D.A. Reuter
University Hospital Rostock, Anesthesiology and Intensive Care Medicine, Rostock, Germany
Correspondence: M. Sauer

INTRODUCTION. The sepsis-associated encephalopathy (SAE), as clinical sign of acute brain injury in septic patients, has a high incidence and is associated with increased mortality (1). The diagnosis remains an exclusion-process; none of the available measurements are specific for SAE (1).

OBJECTIVES. To verify the possible role of molecular acoustic for determining injury of brain in septic patients using an acoustocerebrography (ACG)-system. The ACG is a transcranial ultrasonic method enabling the data interpretation of absorption coefficient, frequency dependent attenuation, speed of sound and tissue elasticity, recorded from the transmitted multispectral ultrasound signals propagating through the brain tissue (2).

METHODS. After approval from the local research ethics committee 20 patients were included in a prospective clinical study in two study-groups: septic shock group (SG) and control group (CG; postoperative non-septic patients). All patients were measured with the ACG-method at inclusion, after 3, 7 and 14 days and blood parameters of organ-function, as well SOFA-score and delirium scores (CAM-ICU, ICDSC) were obtained to the same time-points. At inclusion a neurologist examined all patients. The results of the ACG-measurements were compared with Pearson correlations of the dimensionality parameter with the principal components derived by the genetic algorithm with medical parameters.

RESULTS. All patients of the SG were CAM-ICU positive at inclusion (ICDSC: in mean 4.0) and had clinical signs of SAE (according to clinical examination of a neurologist); in contrast, all patients of the CG were CAM-ICU negative und the values of the ICDSC were zero to all time points. In the ACG measurements significant differences between the CG and SG were obtained. Correlation between ACG results and the SOFA- and ICDSC-scores (0.74 and 0.60) were seen. In addition, correlations between ACG results and some clinical parameters were also found: lactate (0.5), procalcitonin (0.5), creatinin (0.45) and bilirubin (0.6).

CONCLUSIONS. The ACG-method may helpful for the diagnosis of acute brain injury; however, the results of this first report should verify in further studies. Following investigations should include more classical instruments of SAE diagnosis, e.g. EEG, MRI and biomarkers to compare the results with the ACG-measurement.

INTRODUCTION. Septic shock produces an aggression to the organism, presenting an increase of the muscular protein catabolism with rapid atrophy of the musculature in the first days.
OBJECTIVES. To assess muscle wasting in rectus femoris muscle in patients admitted to the ICU due to sepsis requiring mechanical ventilation during the first week of admission.
METHODS. Our sample includes 11 patients admitted to the ICU due to sepsis with respiratory support. We used ultrasound with 7.5MHz linear probe, assessing the rectus femoris muscle, measuring cross sectional area. Measurements are taken on day 1 and 7 after the start of respiratory support. Demographic variables, duration of mechanical ventilation, ICU and hospital stay, ICU and hospital mortality were collected.
RESULTS. Average age: 61.64 years. 72.7% males. 72.7% respiratory sepsis. MV Days: 16.8 days. Average stay in ICU: 28.36 days. When we analyzed muscle wasting measured in muscle rectus femoris, we found significant correlation (Spearman test p 0.005) with prolonged mechanical ventilation. We did not find significant differences with mortality, stay in ICU, APACHE II at admission or SOFA.
CONCLUSIONS. In our sample, we found a relationship between muscle wasting and prolonged mechanical ventilation. However, we did not find a significant relationship with mortality or ICU stay. It is a small sample, so a larger study is necessary to draw conclusions.

MAP versus SBP - which parameter is more sensitive to determine an early decline in the clinical status of hospitalized patients with hypotension and comparison of hemodynamic characteristics of septic versus non-septic patients

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1213

INTRODUCTION. Systolic blood pressure (SBP) has historically been used to score perfusion pressure in early warning systems (1), whilst mean arterial pressure (MAP) is used for sepsis definitions, is the determinant of organ perfusion, and the most accurate pressure measurement made by automated machines (2). There have been no studies to our knowledge addressing whether MAP or SBP is the more sensitive method of determining early decline of septic patients.

OBJECTIVES. This study aimed to review whether MAP or SBP is the more sensitive method of determining an early decline in the clinical status of septic patients referred to ICU.
METHODS.
Retrospective Chart review July 2015-June 2017
Mixed medical/surgical Intensive Care Unit, adult tertiary care hospital, Singapore.
Subjects: all patients fulfilling:
Inpatient referral to ICU and code blue events
Sepsis cohort identified by:
Keyword mining of ICU referral for "sepsis"
$\geq$ 2 SIRS criteria
Intravenous antibiotics
Blood culture collected
Non-sepsis cohort:
no sepsis positive criteria
Blood pressure data:

- Time of ICU referral/code blue
- Hourly SBP/MAP upto 48 hours before referral
- In patients with both low SBP and MAP, the time relationship between MAP and SBP was defined by subtracting time of SBP hypotension event from time of MAP hypotension event (MAP-SBP).
- ICU & hospital length of stay, mortality
- Statistical analysis Excel, one-factor ANOVA alpha 0.05,X^2 test for independence.

RESULTS. From 2648 unique ICU referrals we found 212 septic and 218 non-septic patients for analysis.
Our study found hemodynamic compromise in severe sepsis is variable, with significant proportion of patients manifesting isolated SBP or MAP hypotension prior to ICU referral. Up to 15% of 'septic' patients experienced only MAP hypotension, occurring on average 11 hours before 'ICU referral event' (formal ICU referral or deterioration to the point of code blue), 6.8 hours earlier than patients with isolated SBP hypotension. Our data supports added clinical value in monitoring both MAP and SBP for septic patients at risk of deterioration for earlier ICU review.
In both cohorts, we found a majority (70-82%) of patients were referred for ICU review within 48hrs of admission. In late referrals (referred beyond 48hrs of admission), low MAP precedes low SBP by up to 4.68 hours in septic patients with SBP+MAP hypotension, a trend not evident in non-septic cohort.
CONCLUSIONS. In considering the above findings, we believe incorporating routine monitoring of MAP and automated MAP hypotension triggers would increase clinical sensitivity in identifying deteriorating septic patients, as well as earlier detection of deterioration, facilitating timely intervention including earlier escalation of care.

*Intensive Care Medicine Experimental* 2018, **6**(Suppl 2):1214

INTRODUCTION. Initial distribution volume of glucose (IDVG) indicates central extracellular fluid (ECF) volume and IDVG has been reported to be a surrogate indicator of cardiac preload in animal bleeding models and in patients in ICU[1, 2]. Patients with sepsis develop distributive shock due to vasodilation and increased vascular permeability. Fluids management for septic patients has been still controversial. It has been unknown whether IDVG in septic patients reflects cardiac preload or not.
OBJECTIVES. The aim of this study is to investigate changes in IDVG in endotoxin-induced pig septic models
METHODS. After obtaining an approval of Hirosaki University ethical committee, we anesthetized 13 pigs with ketamine, pentobarbital, remifentanil and vecronium. Tracheostomy was established and the lung was mechanically ventilated. Physiological saline solution had been infused through the experiment (4ml/kg/hr). Sepsis was induced with endotoxin (ET). We used PiCCO® to measure CO, intrathoracic blood volume (ITBV) and so on. IDVG was measured with 2g glucose injection, as previously reported[3]. Five pigs were used to investigate chronological changes in IDVG following ET-injection (ET group) and three pigs were used for the control (C group). The other five pigs were used for fluid resuscitation with 30ml/kg Ringer's lactate solutions over 60 min, 4 hours after ET injection (RL-group). Dobutamine was continuously infused to maintain hemodynamics if needed. Hemodynamics, IDVG and other parameters were measured before and 1, 2, 4, 5 hours after ET injection for ET- and C-groups and before and 4, 5, 6, 7, 8 after ET injection for RL-group. Data are expressed as mean ± SD and the statistical analysis was performed with repeated measures of ANOVA, followed by Dunnett's test or Fisher's LSD test. P< 0.05 was considered as a significant.
RESULTS. Chronological changes in hemodynamics, IDVG index (=IDVG/Kg) and other parameters in both ET- and C-group were shown in table 1. Cardiac output (CO) and systolic BP significantly decreased and lactate levels significantly increased 4 hours after ET administration, suggesting that septic states were produced in pigs by ET infusion. Then, IDVG-index and ITBV significantly decreased, but CVP did not change 4 hours after ET. IDVG-index and CO were significantly increased with volume loading but those effects disappeared by the next one hour (Figure 1).
CONCLUSIONS. It was found that IDVG decreased in ET-induced septic state and increased with volume resuscitation. IDVG indicated the changes in the central ECF volumes and can be an indicator of cardiac preload in septic state.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1215

INTRODUCTION. Central venous minus arterial PCO$_2$ ($P_{cv-a}CO_2$) and the ratio of $P_{cv-a}CO_2$ to arterial minus central venous O$_2$ content difference ($P_{cv-a}CO_2/C_{a-cv}O_2$) are used as surrogates for mixed venous minus arterial PCO$_2$ ($P_{mv-a}CO_2$) and the ratio of $P_{mv-a}CO_2$ to arterial minus mixed venous O$_2$ content difference ($P_{mv-a}CO_2/C_{a-mv}O_2$). The interchangeability of these variables, however, has never been demonstrated.
OBJECTIVES. To assess the agreement between $P_{cv-a}CO_2$ and $P_{mv-a}CO_2$, and between $P_{cv-a}CO_2/C_{a-cv}O_2$ and $P_{mv-a}CO_2/C_{a-mv}O_2$, and their relationship to mortality.
METHODS. This is a secondary analysis of a previously published study (1). In 23 patients with septic shock and invasive hemodynamic monitoring with a Swan-Ganz catheter, we measured central venous and mixed venous gases, oxygen saturation, and hemoglobin. Sublingual microcirculation was assessed by SDF-videomicroscopy. The different gradients and ratios were calculated and compared by means of Bland and Altman analysis.
RESULTS. Panel A and B of Figure 1 respectively show the bias and 95% limits of agreement for $P_{cv-a}CO_2$ and $P_{mv-a}CO_2$, and for $P_{cv-a}CO_2/C_{a-cv}O_2$ and $P_{mv-a}CO_2/C_{a-mv}O_2$. Survivors and nonsurvivors showed similar values of $P_{cv-a}CO_2$ (6 ± 2 vs 6 ± 3 mm Hg, P = 0.82), $P_{mv-a}CO_2$ (6 ± 2 vs 6 ± 3 mm Hg, P = 0.66), $P_{cv-a}CO_2/C_{a-cv}O_2$ (1.17 ± 0.65 vs 1.30 ± 0.68, P = 0.65). $P_{mv-a}CO_2/C_{a-mv}O_2$ (1.22 ± 0.56 vs 1.28 ± 0.72, P = 0.65). Sublingual perfused vascular density was higher in survivors (16.0 ± 3.5 vs. 12.5 ± 4.5 mm^2, P < 0.05). A multiple linear regression model found Hb, lactate, and mixed venous PCO$_2$ as $P_{mv-a}CO_2/C_{a-mv}O_2$ determinants (Adjusted R^2 = 0.64, P < 0.0001). Hb was the explanatory variable with the highest independent contribution to prediction (highest t-ratio).
CONCLUSIONS.

1) $P_{cv-a}CO_2$ and $P_{cv-a}CO_2/C_{a-cv}O_2$ are poor surrogates for $P_{mv-a}CO_2$ and $P_{mv-a}CO_2/C_{a-mv}O_2$.
2) Unlike sublingual microcirculation, neither of these variables is an outcome predictor.
3) Hb is a main determinant for $P_{mv-a}CO_2/C_{a-mv}O_2$.

Sepsis-induced myocardial dysfunction as a predictor of mortality in the adult septic patient in the intensive care unit: a prospective cohort study

V. Fraile-Gutiérrez[1], D. Pérez-Torres[1], J.M. Ayuela-Azcarate[2], A. Mayo-Iscar[3], A.I. Rodríguez-Villar[1], P. Blanco-Schweizer[1], E. Prol-Silva[1], J.Á. Ayala-Fernández[1], C. Díaz-Rodríguez[1], J. Blanco-Varela[1]

Correspondence: D. Pérez-Torres
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1216

INTRODUCTION. Sepsis-induced myocardial dysfunction is a common entity complicating the course of sepsis or septic shock, with a negative impact on patient's survival. This myocardial depression comprises impairment of both ventricles and both systolic and diastolic dysfunction.

OBJECTIVES. To describe the incidence and mortality association of the different subtypes of sepsis-induced myocardial dysfunction (SIMD). To develop a SIMD-based mortality prediction model for septic patients admitted to the Intensive Care Unit (ICU).

METHODS. We conducted a single-centre prospective observational cohort study. Patients admitted to the ICU with sepsis over a 20-month period were enrolled, excluding those with ischemic or valvular heart disease and pacemakers. Transthoracic echocardiogram (TTE) was performed on Days 1, 3 and 7 of evolution. Left ventricular systolic (LVSD) and diastolic dysfunction (LVDD), and right ventricular systolic dysfunction (RVSD) were defined as recommended on ASE/EACVI Guidelines. Student's T, Mann-Whitney U and Fisher´s exact tests were applied as appropriate. A principal components analysis (PCA) with varimax rotation was conducted using mortality-associated variables on Day 1. A logistic regression model was developed based upon the factors obtained in the PCA.

RESULTS. 94 patients were enrolled, 55% male, aged 63±12, APACHE-II 23, 67% mechanically ventilated, ICU mortality 23%, 90-day mortality 29%. 217 TTE were performed. SIMD distribution by subtype and outcome is shown in the Table.

PCA identified two factors, which were used to develop a logistic regression model to predict mortality, with an AUCROC 0.85 (sensitivity 87%, specificity 84%). Factor 1 included age and diastolic function variables (septal e' wave; and septal, lateral and mean E/e' ratio), OR 3.2 (95%CI: 1.52-6.72, p=0.001). Factor 2 included clinical severity variables (SOFA, lactate, norepinephrine dose, weight gain, mechanical ventilation and LVOT VTI), OR 5.43 (95%CI: 1.97-14.92, p=0.001).

CONCLUSIONS.

- LVDD is the most common subtype of SIMD, and its detection within the first 24 hours of admission in an adult septic patient is an independent predictor of mortality.
- A prediction model based upon two factors, namely diastolic function factor and clinical severity factor, is able to successfully predict mortality in adult septic patients admitted to the ICU.

Table 1 (abstract 1216). SIMD distribution by subtype and outcome

	SIMD (%)	Subtype	Global (%)	Survivors (%)	Deceased (%)	p
Day 1	50	LVSD	18	11	41	0.003
		LVDD	40	13	59	0.05
		RVSD	21	15	36	0.02
Day 3	47	LVSD	10	5	26	0.02
		LVDD	38	32	58	0.02
		RVSD	17	8	42	0.003
Day 7	43	LVSD	2	0	8	NS
		LVDD	37	40	25	NS
		RVSD	10	8	16	NS

Decreased endothelial glycocalyx thickness is an early predictor of mortality in sepsis

M. Bol[1], D. Beurskens[2], M. Suverein[1], B. Broddin[1], C. Reutelingsperger[2], T. Delhaas[3], M. van de Poll[1], J. Sels[1], G. Nicolaes[2]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1217

INTRODUCTION. Microcirculatory alterations occur early and play an important role in systemic inflammation, such as in sepsis[1-3]. Reduction of the endothelial glycocalyx thickness, also described as glycocalyx shedding, is regarded as a primary cause of microvascular dysfunction and may contribute to multiple organ failure and death. Glycocalyx shedding leads to an increase in the size of the perfused boundary region (PBR) of sublingual microvessels (5-25 µm) that can be visualized using side stream darkfield (SDF) imaging.

OBJECTIVES. The objective of this study was to investigate the endothelial glycocalyx thickness in septic patients at ICU admission and its relation to outcome. We hypothesize that measured PBR thickness is inversely related to mortality in sepsis.

METHODS. The sublingual endothelial glycocalyx thickness was studied in septic patients within 24h of ICU-admission by SDF imaging. GlycoCheck software was used to automatically calculate the PBR for all recorded images. The results of 3 consecutive measurements were averaged to calculate a reliable PBR value per patient[4]. Patients were divided in two groups according to hospital mortality. Results are presented as mean (SD) and statistical analysis was performed using an independent t-test. A receiver operating characteristic (ROC) curve was generated to evaluate the discriminative ability of PBR for predicting survival to hospital discharge.
RESULTS. We included 22 patients, with an average age of 66 (12) years and a mean APACHE IV score of 98 (40). The mortality rate was 9/22 (41%). The PBR was significantly lower in septic patients who ultimately survived to hospital discharge compared to non-survivors (1,79 (0,21) µm, vs 2,02 (0,23) µm,; p=0,027). The PBR at admission can be considered a predictor of hospital mortality based on the ROC curve with an AUC of

0.778. A cutoff value of 1,88μm gave a sensitivity of 78% and a specificity of 77%.

CONCLUSIONS. Endothelial glycocalyx loss at ICU admission is an early predictor of sepsis mortality. Preservation of the endothelial glycocalyx may thus be an important goal in the early treatment of sepsis.

Real time assessment of tissue perfusion markers with fluid bolus in sepsis: time to change our targets???

J. Nikhilesh, T. Apurv
CHL Hospital, Dept of Critical Care Services, Indore, India
Correspondence: J. Nikhilesh
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1218

BACKGROUND. There is enough literature emphasizing value of tissue perfusion markers and their response to volume administration. However there is significant variation in how they behave in different patient subsets especially sepsis. We have had different assessments in past comparing the above and this communication delineates an attempt to correlate tissue perfusion markers values variations to fluid boluses.

OBJECTIVES. Validating change in tissue perfusion markers in response to fluid bolus in septic shock patients.

SETTING. A thirty five bedded multidisciplinary CCU of a tertiary care unit.

STUDY MODULE. Consecutive patients presenting with septic shock were included for the duration dated Oct 2015 to Feb 2017.All the patients were evaluated at baseline for demographics, SOFA scores, Lactate levels (L1), Central venous oxygen saturation(Scvo2[1]), Mean arterial pressure(MAP1) and base excess(BE1).They were all given fluid boluses of one liter balanced crystalloid and the above measurements were repeated after the same (L2,Scvo2[2],MAP2 and BE2 respectively).A variation of two or more was considered significant. Patients with chronic renal failure and cardiac dysfunction were excluded. Statistical analysis was done using SPSS.

RESULTS. Fifty one patients were included (n=51, M:F-30:21).Mean age of patients was 44.7+15 years(Range(R)=20-79).SOFA scores were 14.2+2.5(R=10-18).L1,Scvo2[1],BE1 and MAP1 levels were 10.9+3.9(R=5-22),62.2+6.3(R=50-75),-10.2+3.4 (R=-4—18) and 56.4 +3.9(R=48-62)respectively. The corresponding values post fluid bolus were L2 =9.4 + 3.6(R=4-20), Scvo2 [2] = 62.9+5.1(R=52-73), BE2= -7.6 +3(R=-2-15) and MAP2 = 58.9+ 4.3 (R=50-66) respectively. P values using a T test were significant for Lactate and Base excess (< .05) after computing variations and in terms of correlation with MAP the quantum of change in values was most significant for BE (56.9%) vis-à-vis L and Scv02 (15.7% and 17.7% respectively).

CONCLUSION. In terms of defining therapeutic end points of fluid resuscitation and response to fluid boluses base excess variations perform better vis-à-vis lactate and central venous oxygen saturations for sepsis patients. In addition their variation is more likely to be congruent with improvement in mean arterial pressures for patients with septic shock. There are no disclosures to declare.

INTRODUCTION. Persistent, profound hypotension is a common phenomenon in sepsis. Aggressive fluid resuscitation to restore tissue perfusion is considered a cornerstone of early sepsis &septic shock management .Arterial blood pressure(ABP) results from interaction between arterial system & blood ejected by the heart, thus the response of ABP to fluids continues to be a challenge[1]. Assessment of preload dependency was extensively studied in recent years, a few studies focused on ABP prediction to intravascular volume expansion.[2]

OBJECTIVES. Functional assessment of arterial load by dynamic arterial elastance (Ea_{dyn}), to predict ABP response to fluid challenge(FC) in hypotensive, preload-dependent septic patients.

METHODS. A cohort study conducted at Trauma & Surgical Intensive Care Unit (SICU) of Cairo University hospital. Enrolled patients were both spontaneously breathing & mechanically ventilated adults admitted with

sepsis according to 2016 Surviving Sepsis Campaign criteria, excluding patients younger than 18 years, Pregnant females, trauma patients, history of vasodilator therapy or arrhythmias. Preload dependency was defined if stroke volume variation(SVV) ≥10 % (obtained from cardiometry) or pulse pressure variation(PPV) ≥ 13% (obtained from invasive blood pressure monitoring). Two sets of hemodynamic measurments were obtained, the 1st on admission & th^{en} after an FC(200 ml normal saline).These included Heart rate (HR), systolic arterial pressure (SAP), mean arterial pressure (MAP), diastolic arterial pressure (DAP)& PPV. Cardiac output (CO), stroke volume (SV), SVV & systemic vascular resistance (SVR) were obtained from electrical cardiometry. Ea$_{dyn}$ (PPV/SVV) was calculated. Patients were classified after FC as MAP responders (≥10% increase in MAP) & MAP non-responders (< 10%increase in MAP).
RESULTS. Out of 58patients, 21(36%) were MAP responders. At baseline, Ea$_{dyn}$ was significantly higher in responders(0.93 ± 0.2) vs. nonr-esponders(0.79 ± 0.3). The Area under Curve(AUC) for preinfusion Ea$_{dyn}$(0.687 ± 080; 95% CI: 0.530 - 0.843;) was higher than PPV(0.613± 0.077; 95% CI 0.462 - 0.763) & SVV (0.595±0.076; 95% CI 0.445 - 0.744). An optimal cutoff of 0.80 to predict 10%MAP increase after FC in septic patients (91.0%sensitivity & 47.8%specificity) .
CONCLUSIONS. Ea$_{dyn}$ may predict arterial pressure response to FC in hypotensive, preload- dependent septic patients with fair sensitivity but poor specificity. It can be interpreted as a dynamic index of arterial load.

Factors influencing carotid blood flow measurements in ICU patients

G. Gursel[1], B.S. Kalın[2], M. Çimen[3], S. Eyüpoğlu[3]
[1]Gazi University School of Medicine, Department of Pulmonary Critical Care Medicine, Ankara, Turkey; [2]Gazi University School of Medicine, Department of Internal Medicine Division of Critical Care Medicine, Ankara, Turkey; [3]Gazi University School of Medicine, Department of Anaesthesiology Division of Critical Care Medicine, Ankara, Turkey
Correspondence: G. Gursel

INTRODUCTION. As a feasible, non-invasive, and reproducible bedside estimates of CO, carotid Doppler imaging is promising but still it is unclear whether measuring carotid blood flow by the velocity time integral using Doppler ultrasound can be used to monitor cardiac output and volume responsiveness.

OBJECTIVES. Aim of the study was to investigate the relationship between carotis blood flow(CBF) and cardiac output(CO) and other parameters that would influence CBF in ICU patients.

METHODS. 59 patients were included in the study. Patients' demographics, ventilation situations, arterial blood gase results and hemodynamics were recorded. In all patients echocardiographic measurements (such as CO, SV), and carotid doppler measurements were performed during the same time period. Velocity time integral (VTI) of the Doppler signal was measured using manual tracings . Intimal-to-intimal carotid diameter was measured at the level of the sample gate. All carotid measurements were measured on a single waveform by one investigator. Carotid blood flow was calculated as blood flow = $\pi \times$ (carotid diameter) $2 /4 \times$ VTI $\times$ heart rate. Measurements were obtained using a single carotid waveform and an average of three carotid waveforms for both measures.

RESULTS. Mean age and APACHE II scores of the patients were 72±13, 24 ±11 respectively. 42% of the patients were intubated and 53% of them had COPD. While there were no significant correlation between CO and CBF(r:0.18, p:0.59). There were weak but significant correlation between mechanical ventilation(r:0.31, p:0.024), tidal volume(r:-0.38, p:0.047) and CBF. Patients with COPD had significantly higher CBF than the others(627±280 versus 478 ±160, p:0.024). CBF was significantly correlated with paO2(r:0.53, p:0.006) and PaCO2(r:0.46, 0.018) especially in patients with COPD.

CONCLUSIONS. These results suggest that CBF may not reflect CO in all patients and it may be influenced by many other factors. Further studies are necessary to standardized CBF as a surrogate measurement of CO.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1221

INTRODUCTION. Sepsis is life-threatening organ dysfunction caused by a dysregulated host response to infection. Sepsis affects both heart and circulation, causing dysfunction in their interaction. One approach to detect this interaction is to examine ventriculoarterial coupling (E/A), which is defined by the ratio of arterial elastance (Ea) to left ventricular end-systolic elastance (Ees). In this study, we investigate time-course of E/A in a cohort of patients admitted to ICUs who presented sepsis.

OBJECTIVES. We aim to investigate time-course of E/A as an hemodynamic tool, such as Mean Arterial Pressure (MAP) and Cardiac Index (CI), in order to optimize cardiovascular function leading the therapy with inotropes (Levosimendan, Dobutamine) and vasopressor agents (Dopamine, Norepinephrine).

METHODS. In this study we measured, in patients with sepsis, SOFA score, routine hemodynamics using Pulse contour method and transthoracic echocardiograms from baseline (T0), every day at the same time for 7 days. Parameters were calculated using data gathered from the echocardiographic examination included Left Ventricular Ejection Fraction (LVEF), Stroke Volume (SV), Preejection time and

Systolic time. Ventricular Elastance Single Beat (EesSB) was estimated by using the method of Chen. (1). Arterial Elastance (Ea) was calculated as 0.9 × (systolic arterial pressure/SV), and the Ea/EesSB ratio was then calculated (2). Ea/EesSB ratio between 0,8 and 1,36 is considered normal value of E/A. In patients with Ea/EesSB ratio>1,36, low values of EesSB (< 1,4 mmHg/ml) and MAP>65mmhg Levosimendan was administered.

RESULTS. 28 patients were enrolled,18 patients were uncoupled (Ea/EesSB ratio >1,36), 10 patients at T0 and 8 patients in the first 72 hours. Patients with higher SOFA Scores had an higher Ea/EesSB ratio. Following the E/A monitoring, 8 patients were treated with Levosimendan and vasopressors and 10 patients with vasopressors. 87.5% (7 patients) in group treated with Levosimendan improved their hemodynamics (E/A, MAP, CI). In the other group, 50% (5 patients) improved their hemodynamic status. The mortality was 50% in the group treated with levosimendan while 60% in the group treated with vasopressors only.

CONCLUSIONS. Time-course of E/A could be an important tool to evaluate hemodynamic conditions in septic patients as a supplement to standard monitoring, related to patient clinical conditions, aimed to improve cardiovascular efficiency.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1222

OBJECTIVE. Analyzing the application of the preventive isolation protocol after ICU admission of postoperative elective surgery in our hospital, taking in consideration some risk factor for multirresistance colonization, and its necessity of continuation.

METHODS. A retrospective observational study with hospitalized patients admitted in ICU after an elective surgery from January to September 2017, choosing those who accomplished the requirements of preventive isolation, and fllowed up until the obtention of the surveillance culture results, as it was agreed upon our unit and preventive medicine unit. This protocol included throat and rectal swab samples for every patient who was hospitalized more than 5 days, came from North Africa or assisted residence or hospitalization within the previous 3 months (table 1).

RESULTS. A total number of 580 post-operative patients addmitted in ICU during the period of the study, 228 (36,89%) complies preventive isolation criteria. 24,76% (53 cases) of all the patients with preventive isolation indication admitted in our unit, with the surveillance culture previously drawn, avoiding an unnecessary isolation. However, from 161 patients who admitted without a test taken and were isolated preventively, only 92 (57,14%) were cultured. Besides, from the whole of the surveillance cultures taken, both in ICU as previously, only 1 was positive for multi-resistant germ. The direct cost (the cost of the consumable material in every isolation) of every culture taken in ICU, because it was not taken previously during the hospitalization, was 21.481,23€ approximately.

CONCLUSIONS. Based on this data, it seems necessary to become more flexible with the preventive isolation criteria in elective post-operative patients admitted in ICU (only one positive result for multi-resistant germ) and, in every case, obtaining the cultures previously to the surgery. Maybe, we have to analize another risk factors for multirresistence colonization.

Table 1 (abstract 1222). Requirements of preventive isolation

Patients admitted more than five days at Hospital.
Patients who came from North Africa.
Patients who came from assisted residence.
Patients with an hospitalization within the previous 3 months.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1223

INTRODUCTION. Several systematic review and meta-analyses have demonstrated that prolonged prone positioning can reduce the mortality associated with acute respiratory distress syndrome (ARDS). However, the effectiveness and optimal duration of prone positioning was not fully evaluated.
OBJECTIVES. To systematically review and meta-regression analysis is to investigate the duration of prone positioning needed to improve outcomes using sensitivity analyses and meta-regression.
METHODS. Electronic searches were performed in MEDLINE via Ovid, EMBASE, Cochrane Central Register of Controlled Trials and International Clinical Trials Registry Platform. Published and unpublished RCTs and randomized crossover trials (the first period only) between January 1980 and September 2017 were included. Included articles were independently assessed by two researchers. Quality of the articles was determined using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) system. Meta-regression analyses and subgroup analyses were employed to investigate potential sources of heterogeneity between studies.
RESULTS. We included twelve studies matched the inclusion criteria, comprising data for 2,789. Prone positioning reduce short term mortality (odds ratio, 0.82; 95% CI, 0.64-1.05; p= 0.004; I^2 = 71%).
Although there was no significant difference from the meta-regression model, there was a heterogeneity between duration of prone positioning and short term mortality, there was an apparent decrease in trend of correlation between duration of prone positioning and short term mortality (β=-0.04; 95% CI,-0.08-0.005; p=0.08). In this analysis, we determined 10 hours as a threshold. The effects were marked in the subgroup in which duration of prone positioning was greater than 10 hr, compared with a short time duration of prone positioning (odds ratio; 0.68: 95% CI, 0.49-0.95; p = 0.06; I^2= 60%).

CONCLUSIONS. We reconfirmed that long-term prone positioning of more than 10 hours affects prognosis, but the optimal threshold of its efficacy and hazard was not able to to get an answer in this meta-analysis.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1224

INTRODUCTION. The role of videothoracoscopic lung biopsy in acute respiratory distress syndrome (ARDS) has been questioned due to possible complications.
OBJECTIVES. The goals of this study were to better define the frequency of unexpected diagnoses made by videothoracoscopic lung biopsy, the frequency biopsy results lead to a change in clinical management, and the frequency of procedural complications.
METHODS. All individuals with available records undergoing videothoracoscopic lung biopsy between 2007 and 2017 for evaluation of ARDS based on the Berlin definition were analyzed.
RESULTS. The mean age in this cohort of 20 patients was 55.6 years (SD, 15 years) with PaO2/fraction of inspired oxygen ratio of 144 mm Hg (SD, 72 mm Hg) at the time of biopsy. A pathologic diagnosis other than diffuse alveolar damage or fibroproliferation was found in 75% of patients. The most common alternative diagnoses were alveolar hemorrhage (n = 4) and carcinomatous lymphangitis (n = 2). Biopsy results led to a change in management in the majority of patients, with addition of specific therapy in 65% and withdrawal of unneeded therapy in 35%. No one presented complications associated with the procedure.
CONCLUSIONS. In selected patients with clinical ARDS, videothoracoscopic lung biopsy can be performed safely, often reveals an unsuspected diagnosis, and frequently leads to alterations in therapy.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1225

INTRODUCTION. The use of neuromuscular blocking agents has been advocated as adjuvant therapy in patients with severe acute respiratory distress syndrome (ARDS) to improve mechanical ventilation support and outcomes. However, due to lack of robust evidence paralyzing patients with ARDS is still a controversial issue.
OBJECTIVES. We aimed to determine whether treatment with adjuvant neuromuscular blocking agents compared to standard care led to a reduction in the risk of death as well as its effect on plateau pressure, PEEP requirement, fraction of inspired oxygen, driving pressure, partial pressure of carbon dioxide and tidal volume in patients with severe ARDS.
METHODS. We searched MEDLINE, EMBASE and CENTRAL, from inception to February 2018. Pairs of reviewers identified

randomized controlled trials (RCTs) comparing neuromuscular blocking agent adjuvant therapy to standard care for patients with ARDS. We followed the Cochrane Handbook for systematic reviews and meta-analysis; two reviewers abstracted data independently. Main Outcomes and Measures Outcomes of interest included death and the effect of neuromuscular blocking agents on mechanical ventilation data as plateau pressure, PEEP requirement, fraction of inspired oxygen, driving pressure, partial pressure of carbon dioxide and tidal volume. We report risk ratios (RR) as the standard effect measure for mortality and mean differences for mechanical ventilation outcomes.

RESULTS. We identified 5 RCTs (503 participants). Moderate quality evidence suggested that adjuvant use of neuromuscular blocking agents probably reduces mortality (RR 0.72; 95%CI 0.57 to 0.91). Based on low quality evidence, the plateau pressure was reduced in patients who received neuromuscular blocking agents (mean difference -1.60; 95%CI -2.92 to -0.27). We found no significant difference in PEEP requirement, fraction of inspired oxygen, driving pressure, partial pressure of carbon dioxide and tidal volume.

CONCLUSIONS. Administration of adjuvant therapy with neuromuscular blocking agents reduces mortality in patients with ARDS. This reduction may be partially explained by a reduction in plateau pressure and consequently less lung injury related to invasive ventilation.

INTRODUCTION. Most patients presenting with Acute Respiratory Distress Syndrome (ARDS) have significant comorbidities, yet many of these patients are excluded from clinical trials, limiting our understanding of this cohort. We wished to explore the influence of comorbidities on outcome in this secondary analysis of the LUNG SAFE patient cohort (1-3).

OBJECTIVES. Our primary objective was to determine the effect of comorbidities on outcomes in ARDS patients diagnosed on days 1-2 of acute hypoxaemic respiratory failure and undergoing invasive or non-invasive ventilation

METHODS. The large observational study to understand the global impact of severe acute respiratory failure (LUNG SAFE) was an international, multicenter, prospective cohort study of patients with severe respiratory failure. LUNG SAFE was conducted during 4 consecutive weeks in winter 2014, in a convenience sample of 459 intensive-care units in 50 countries across six continents. Inclusion criteria were admission to a participating intensive-care unit within the enrollment window and receipt of invasive or non-invasive ventilation. In the current analysis, the study population was confined to patients developing ARDS within the first 2 days of acute respiratory failure. Major comorbidities analyzed included chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), chronic kidney disease (CKD), chronic liver failure (CLF) and immune incompetence (see Table).

RESULTS. Among 2813 patients in the study population, 60% had at least one major comorbidity. All patients with at least one comorbidity but CLF were older compared to patients with no comorbidities. Patients with CKD or CLF at admission had more severe Sequential Organ Failure Assessment scores compared to patients with no comorbidities. Hospital LOS in survivors was shorter in patients with COPD and CHF, but not different in the other comorbidity groups, compared to the no comorbidities group. The presence of at least one comorbidity was correlated with both high ICU and hospital crude mortality (see Table).

CONCLUSIONS. Most patients with ARDS have significant comorbidities. These comorbidities are strongly associated with outcomes in patients with ARDS. These findings might modify the current interpretation about the generalizability of findings from current clinical trials.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1227

INTRODUCTION. Several lines of evidence suggest that mechanical ventilation and acute respiratory distress syndrome may have adverse effects on renal function. This points out the harmful interactions between pulmonary and renal dysfunctions. And the importance of knowing its scope.

OBJECTIVES. To examine the relationship between positive intrathoracic pressure and the development of acute renal failure in patients with ARDS.

METHODS. Between 2015 and the present, 44 consecutive patients presenting with ARDS, according to the Berlin definition, were studied. The sample group was subdivided according to AKIN criteria. Pressure data (peak, plateau, PEEP, driving pressure, compliance and CVP) and analytical data (creatinine, urea, sodium, potassium and glomerular filtrate) were collected. Urine output, the use of hemodiafiltration and noradrenaline, age, sex, number of days on mechanical ventilation, admission to ICU, SOFA score and mortality were also recorded.

RESULTS. 39.1% of patients with ARDS in our polyvalent unit presented with AKI, of whom 32.47% developed AKI stage I, 14.4% AKI stage II and 53.09% AKI stage III (p = 0.001). 79.8% of the AKI patients were male, compared with 20.2% female (p = 0.001). Age difference was not noted. AKI was most common in ARDSexp, with 50%, compared with 30.6% in ARDSp (p = 0.004). The need for noradrenaline was associated with AKI in 55.3%, (59.6% AKIN III (p = 0.001)).

Differences were observed relating to pressure. Peak pressure in AKI was 34.04 ± 7.242 vs 31.16 ± 9.09 mmHg in patients without AKI (p = 0.012). Plateau pressure with AKI was 27.67 ± 4.76 vs 24.38 ± 7.30 mmHg without AKI (p = 0.001). PEEP with AKI was 14.30 ± 4.16 vs 12.91 ± 4.01 mmHg without AKI (p = 0.017). Driving pressure with AKI was 13.01 ± 4.75 vs 11.54 ± 5.10 mmHg without AKI (p = 0.017). VT with AKI was 7.00 ± 1.12 vs 7.59 ± 1.47 ml/kg without AKI (p = 0.002). Mean SAP with AKI was 77.71 ± 14.82 vs 85.52 ± 12.45 mmHg without AKI (p = 0.000). CVP with AKI was 14.94 ± 4.9 vs 12.66 ± 5.38 without AKI (p = 0.002).

Remedial measures such as pronation and corticosteroids were not associated with increased AKI. Neither were the number of days on ventilation, nor the number of days admitted to the unit. The mortality rate with AKI was 50%, this was higher for patients with AKIN III at 52.8% (p = 0.001).

CONCLUSIONS. There is an adverse relationship with the kidney in ARDS, although it is a separate organ, primarily relating to intrathoracic pressure, as we have demonstrated. Consequently, the use of lung protective mechanical ventilation should prevent decreased blood flow, and maintain an adequate gas exchange.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1228

INTRODUCTION. Mechanical power (MP) is a new concept to explain ventilator induced lung injury (1). It involves all the mechanical components of the energy load transferred from the ventilator to the respiratory system. The reference method. is assessed as the product of respiratory rate (RR) to work of breathing, this latter being obtained from the area subtended by airway pressure and volume during insufflation (MParea) (1). MP can also be computed according to the following equation (MPeq):

RR. $\{ \llbracket \Delta V \rrbracket ^2.[1/2. \llbracket EL \rrbracket \_rs+RR.((1+I:E))/(60.I:E). Raw]+\Delta V.PEEP\}$ with RR respiratory rate, ΔV tidal volume, ELrs elastance of respiratory system, Raw airway resistance, PEEP positive end expiratory pressure. We were wondering whether the following simplified equation (MPeqsimp), which is easy to obtain at the bedside, would predict MP accurately: $RR.\Delta V.[\vdash PEEP +\Delta P/2+(Ppeak-Pplat)]$ with Ppeak,Pplat and ΔP are maximal, plateau, and driving pressures of the respiratory system. This method requires variables that are used routinely at the bedside. OBJECTIVES. To compare MPeqsimp and MPaera to MPeq in patients with acute respiratory distress syndrome (ARDS). METHODS. We measured MParea, MPeq and MPeqsimp according to the above mentioned methods in 40 ARDS patients previously reported (3). Measurements were done breath by breath in the supine position. MP was expressed as J/min. The data were analyzed by using linear regression and Bland-Altman representation between methods.

RESULTS. The figure 1ABC displays the linear regression between the 3 methods while the corresponding Bland-Altman analyses are reported in Figure 1DEF. The coefficients of determinations were statistically significant.

The mean of the difference (continuous horizontal lines) between MPeq and MParea was 2.4 J/min. Between MPeqsimp and MParea the mean of the difference was 1.8 and the mean between MPeq and MPeqsimp was 0.5 J/min. In this last case upper and lower limits of agreement (broken horizontal lines) were (1.6; -0.5) J/min.

CONCLUSIONS. MPeqsimp can be used to compute MP accurately.

INTRODUCTION. The weak correlation between acute respiratory distress syndrome (ARDS) and its pathological hallmark, the Diffuse Alveolar Damage (DAD), has been proposed for explaining the failure of almost all pharmacological treatments to improve patient outcome.
OBJECTIVES.

(a) To identify clinical variables associated to DAD, and
(b) explore the impact of DAD on the hospital mortality risk.

METHODS. We conducted a retrospective multicenter study including adult patients with ARDS (Berlin definition) undergoing open lung biopsy (OLB) from France, Taiwan, Swiss and Colombia. Patients were splinted in a trainee then in a validation cohort. Data were recorded the day of ARDS and the day of OLB. Missing data (NA) was completed using a multiple imputation by chained equation procedure. Five dataset for each cohort were created with the aim to reflect the NA uncertainty. In each dataset of the trainee cohort, univariate analysis was performed. All variables with a P < 0.1 in at least one dataset were included in the pooled logistic regression model (PLRM). The discriminatory capability of the PLRM was calculated in each dataset AUROC. Mean of the five AUROC (95% confidence intervals CI) from the trainee and the validation cohort was compared with the aim to estimate the over-fitting of the model. P < 0.05 was considered significant.
RESULTS. There were 258 patients included (n=193 trainee and n=65 validation cohort). The following variables recorded the day of ARDS predicted DAD: respiratory rate (OR 0.95; 95%CI 0.91; 0.99; P =0.03) and coronary ischemia (OR 5.97; 95%CI 1.67; 21.39; P < 0.01). Average AUROC was 0.64 (95%CI 0.56; 0.72) in the trainee cohort and 0.56 (95%CI 0.42; 0.71) in the validation cohort. The following variables recorded the day of OLB predicted DAD: PEEP (OR 1.13; 95%CI 1.05; 1.22; P< 0.01) and coronary ischemia (OR 6.82; 95%CI 1.86; 25.06; P< 0.01). Average AUROC was 0.70 (95%CI 0.62; 0.77) in the trainee cohort and 0.58 (95%CI 0.44; 0.72) in the validation cohort. The following variables recorded the day of ARDS predicted mortality: DAD (OR 2.29; 95%CI 1.23; 4.29; P < 0.01), diabetes mellitus requiring insulin (OR 0.08; 95%CI 0.01; 0.71; P 0.02) and respiratory rate (OR 1.01; 95%CI 1.01; 1.09; p 0.04). Average AUROC was 0.66 (95%CI 0.58; 0.73) in the trainee cohort and 0.51 (95%CI 0.36; 0.66) in the validation cohort. Finally, the following variables recorded the day of OLB predicted mortality: DAD (OR 2.08; 95%CI 1.05; 4.11; P=0.03), diabetes mellitus requiring insulin (OR 0.09; 95%CI % 0.01; 0.95; P= 0.04), PaCO2 (OR 1.05; 95%CI 1.02; 1.08; P< 0.01) and platelets count (OR 0.99; 95%CI 0.99; 0.99; P< 0.01). Average AUROC was 0.65 (95%CI 0.56; 0.72) in the trainee cohort and 0.63 (95%CI 0.48; 0.78) in the validation cohort.
CONCLUSIONS. This study confirms that DAD can only be predicted using data from the day of OLB and is associated with a twice higher risk of hospital mortality.

INTRODUCTION. In ARDS, the heterogeneity of lung lesions results in a mismatch between ventilation and perfusion, leading to the development of significant hypoxia. It has been reported that prone ventilation may potentially improve this ventilation-perfusion mismatch, but this hasn´t been fully investigated.
OBJECTIVES. To investigate the association between computed tomography (CT) findings for patients who had developed ARDS after abdominal surgery and improvements in hypoxia and mortality as a result of prone ventilation.
METHODS. The study subjects were intra-abdominal infection-induced ARDS patients who had undergone lung CT in the period from 2004 to 2014. The patients were allocated to a prone group that underwent prone ventilation within 24 h of the start of mechanical ventilation following ICU admission and a supine group that did not. Patients were categorized as showing either increasing ground glass opacity (GGO) or alveolar shadow with predominantly dorsal lung atelectasis (DLA) by a single radiologist.
In the prone group, PaO$_2$/FiO$_2$(P/F ratio) was determined before patients were moved to the prone position and 12 h later and at 24, 48, and 72 h after the start of prone ventilation. In the supine group, the ratio was determined 12 h after the start of mechanical ventilation and at 12, 24, 48, and 72 h after the initial measurement. P/F ratios at the start of initial measurement and 72 h later were compared in patients with GGO and DLA in both the prone and supine groups, and the number of ventilator-free days (VFD) and outcomes 28 days later were also compared.
RESULTS. In total, 53 patients with ARDS following abdominal surgery were admitted to the ICU during the study period. Twenty-five of them underwent prone ventilation and 28 did not.
There was no significant difference between the two groups in patients' characteristics. CT showed GGO in 6 patients in the prone group and in 10 patients in the supine group, DLA in 18 and 14patients, respectively, and both (GGO + DLA) in 1 patient and 4 patients, respectively.
Prone ventilation significantly improved the impaired P/F ratio from 12 h after prone positioning compared with that in the supine position. VFD in the prone group was significantly higher than that in the supine group. However, there was no significant difference in 28-day mortality between the two groups.
Weaning from mechanical ventilation was significantly earlier in patients in the prone group with DLA than in patients in the supine group with DLA, but there was no significant difference between the two groups for patients with GGO
The mortality rate after 28 days in patients in the prone group with DLA was significantly lower than that in patients in the supine group with DLA, but there was no significant difference between the two groups for patients with GGO.
CONCLUSIONS. The results suggest that prone ventilation may be an effective method for treatment of patients with intra-abdominal infection who develop ARDS.

INTRODUCTION. ARDS is a frequent and severe pathology in ICUs regardless of the cause of admission, with high costs to society and no specific treatment, for this reason is important to know the specific characteristics of these patients in order to approach to the best supportive management.
OBJECTIVES. Describe the epidemiological characteristics, ventilatory parameters and hemodynamic data of all the patients admitted in a polyvalent ICU of a third level hospital with the diagnosis of moderate - severe ARDS.
METHODS. Retrospectively, all patients diagnosed with ARDS according to Berlin criteria in moderate- severe range between 2015 and 2017, were taken into account in this study.
Epidemiological, gravity, admission causes and ARDS were collected; also ventilation data (mode, PEEP, volume, plateau, peek and driving

pressure), rescue manoeuvres (prone, corticothetapy) and hemodynamics (invasive monitoring, need of noradrenalin, CVP, MAP). We also analysed need of reintubation and tracheostomy; and complications such as acute renal failure, barotrauma and ICU mortality.

RESULTS. A total of 44 patients were analysed (65% males), the average age was 63.03±13.9 years, the APACHEII gravity score at admission was 19.59±8.5, the ICU admission most frequent causes were respiratory (52.2%), post operatory (17.4%) and abdominal (8.3%). The ARDS most frequent etiology was respiratory (60.9%), abdominal (26.1%) and sepsis (6.5%).

The ventilatory modes used more frequently have been: VC (49.6%), PC (19.1%) y VCRP (10%). The average PEEP was 13.43±4.11 cmH2O, the driving pressure 12.22±5.1 cmH2O and compliance 36.9±27.8 cmH2O. The average tidal volume adjusted to ideal weight has been 7.36±1.39 ml/kg.

A 40% of the total patients were monitored with serial TTE diagnosing right ventricle failure in the 8.3%; and a 3.9% was monitored with pulmonary artery catheter.

Nearly half of the patients, a 48.7% needed Noradrenalin to maintain an average MAP of 82.47±13.9 mmHg and a CVP of 13.56±5.3 mmHg. Acute renal failure was found in the 36.5%, of which 48.7% needed extra renal depuration therapy.

Prone manoeuvre was used in a 43.5% of the patients, neuromuscular relaxation in a 50.4%, and corticotherapy in a 35.7%. Failure of weaning with needing of reintubation occurred in the 17.8% of the patients, and the 37% of the total were tracheostomized. The average of admission in the ICU has been 22.65±14.4 days, with 19.17±12.9 days of invasive mechanical ventilation. The percentage of mortality in our patients was 52.2% with respiratory (64.08%) and multiorgan failure (32%) as main causes.

CONCLUSIONS. The rise of life expectancy in the population leads to and increase in the average age.

The most commonly used ventilatory mode is volume control. The tidal volume is remarkably higher than expected, what could be related to the increasing rise of obesity in the population and the trend to adjust upwards the ideal weight. More hemodynamic monitoring should be done.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1232

INTRODUCTION. The impact of gender on the management and outcome of patients with Acute respiratory Distress Syndrome (ARDS) is relatively poorly understood. Given the potential for important gender-based differences in incidence and management of ARDS, we wished to address these issues in this secondary analysis of the LUNG SAFE patient cohort (1-3).

OBJECTIVES. Our primary objectives were to examine the influence of gender on the ventilatory management and the outcomes in patients with ARDS.

METHODS. The large observational study to understand the global impact of severe acute respiratory failure (LUNG SAFE) was an international, multicenter, prospective cohort study of patients with severe respiratory failure. LUNG SAFE was conducted during 4 consecutive weeks in winter 2014, in a convenience sample of 459 intensive-care units (ICUs) in 50 countries across six continents. Inclusion criteria were admission to a participating intensive-care unit within the enrollment window and receipt of invasive or non-invasive ventilation. A secondary aim of trial was to characterize if there was a gender variation in the demographics, management, and outcome of patients with ARDS.

RESULTS. Among 2377 patients included in the analysis with diagnosis of ARDS on day-1 or day-2 of acute hypoxaemic respiratory failure and undergoing mechanical ventilation, 38% were female and 62% were male. Females had higher BMI compared to males. ARDS severity profile or Sequential Organ Failure Assessment scores were not different among the genders at ICU admission. According to the ventilator setting, females were ventilated with higher tidal volume per predicted body weight and higher plateau pressure compared to males. Female patients had a lower duration of mechanical ventilation and ICU and hospital stay compared to male patients. Despite this, there appeared to be no difference in crude mortality rates between the genders (see Table).

CONCLUSIONS. Gender appears to influence the management and outcomes of patients with ARDS. These data suggest a need for greater vigilance in the approach to the ventilator management in females.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1233

INTRODUCTION. Moderate to severe ARDS is linked to high mortality rates, despite improvement in lung support(1). Inflammatory ARDS phenotype has been linked to a worse prognosis(2). Prediction of prognosis in ARDS can help to allocate treatment, namely corticosteroid use. None of the biomarkers identified so far are easy to use or clinically available.

OBJECTIVES. We aimed to identify markers linked to prognosis in ARDS patients among variables collected on daily basis in ICU.

METHODS. We performed a retrospective study of patients with ARDS treated in an university hospital, where protective mechanic ventilation protocol is used. We included patients with moderate to severe ARDS, and retrospectively reviewed time of ARDS diagnosis. We excluded patients that died in the first 24 hours of ICU admission. We collected demographic data, laboratory data, and ventilator setting data. Statistical analysis was performed using STATA.

RESULTS. We identified 130 patients with ARDS in a 3 year period, with a mean age of 56.6 (±17.8), 69.2% were male. They featured a mean SAPS II of 47.1(±19.41) and 55% had sepsis. Of note, 80.8% had severe ARDS, with a mortality of 44.6%. Patients were ventilated for a mean of 13.3(±12.1) days, and had a median length of stay of 14 days.

Using non-adjusted logistic regression albumin levels in the first 48 hours (odds ratio: 0.44; P= 0.02) and C-reactive protein (CRP) above 20 on the third day (OR: 1.86, P=0.08) were the only factors related to prognosis. Tidal volume (6.5±1.5 in survivors vs 6.5±1.6 in non survivors, mL/kg ideal body weight, P= 0.92), PEEP (9.0 vs 8.5, P=0.41), or having sepsis (P=0.47) were not linked to mortality rates. We forced into the multivariate analysis other variables with a P value below 0.15 (bilirubin and respiratory rate), and adjusted for extracorporeal oxygenation support as possible confounder to high CRP levels in the first days of ARDS. After adjusting for these variables, CRP levels above 20mg/dL (OR: 2.4, P=0.04), as well as albumin levels (OR: 0.41; *P*=0.03)were still linked with ICU death. Of note, CRP/albumin ratio was also significantly linked with ICU mortality (P=0.01).

CONCLUSION. Inflammation is a major trigger of ARDS, and previous reports have linked higher inflammatory profiles to mortality(2). Using a simple approach towards inflammation assessment we linked high CRP levels in the third day of ARDS to a high mortality, which might be a more available marker to guide the institution of immunomodulatory treatment.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1234

INTRODUCTION. Although the Acute Respiratory Distress Syndrome (ARDS) is common in medical-surgical intensive care units (MSICU) and is associated with significant morbidity and mortality, it is frequently unrecognized, especially in its mild forms, resulting in sub-optimal management.

OBJECTIVES. We sought to assess how well ARDS was being diagnosed, based on the Berlin definition, and whether an evidence-based algorithm for the management of ARDS was being followed in our tertiary care MSICU.

METHODS. Over a 28-day period in the ICU, we assessed all admitted patients daily for the diagnosis of ARDS, using the Berlin criteria. Paper and electronic charts of those fulfilling criteria were audited for the documentation of the ARDS diagnosis. Various aspects of the management of ARDS were assessed.

RESULTS. Over a 28-day period, 90 patients were screened and 13 (14.4%) met Berlin criteria for ARDS. A total of 101 patient-days of ARDS management were assessed. Documentation of the diagnosis did not differ significantly between mild, moderate, or severe ARDS (p=0.217), but none of the diagnoses were missed on the 9 patient-days of severe ARDS. While ARDS was documented in physician charting in 77% of patient-days, a lung-protective ventilation strategy was utilized during only 33% of patient-days. Targets for low tidal volumes and high PEEP were met 17% and 55% of patient-days, respectively. During over half (53%) of patient days, patients were in an undesirable positive 24-hour fluid balance. Appropriate sedation targets were achieved 59% of the time. While NMB was initiated at 5 of the 7 times (71%) when it was warranted, there were a total of 11 patient-days (11%) of inappropriate use of NMB. Appropriate use of NMB did not differ based on the severity of ARDS (p=0.416), but during the 9 patient-days of severe ARDS, 8 had appropriate use of NMB. While no patients were proned inappropriately, there were 23 patient-days (23%) when proning should have been initiated, but wasn't. Appropriate use of proning was significantly different between the mild, moderate, and severe ARDS groups (p=0.004). The local spontaneous breathing trial protocol at our center was followed during only 44% of appropriate patient-days.

CONCLUSIONS. At a tertiary care MSICU, recognition of ARDS seems to be improving as compared to previously published rates, however many evidence-based elements of ARDS management were still not adhered to at acceptable rates.[1] Further research is required to look into the factors involved in decreased adherence to ARDS management practices. Results from this medical audit of clinical practice will be used to guide future quality improvement initiatives in the diagnosis and management of ARDS.

Moderate and severe ARDS: hemodynamic and cardiac effects of an open lung strategy with recruitment maneuver analyzed using echocardiography

P. Mercado[1], J. Maizel[1], L. Kontar[1], M. Nalos[2], S. Huang[2], S. Orde[2], A. McLean[2], M. Slama[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1235

INTRODUCTION. Open lung ventilation with a recruitment maneuver (RM) could be beneficial for ARDS patients. However, the increased airway pressures resulting from the RM may induce cardiac dysfunction, limiting the benefit of this maneuver.

OBJECTIVES. We analyzed the effect of a RM and decremental PEEP titration on cardiac function.

METHODS. Twenty patients hospitalized in our ICU (Medical ICU Amiens, France) with moderate to severe ARDS were included. Patients underwent a stepwise RM with respiratory evaluation and echocardiography assessment of cardiac function including longitudinal strain (LS) at baseline, peak PEEP of RM (PEEP 40cmH$_2$0) and at 'optimal' PEEP. The patients were divided into two groups based on change on the P/F ratio (non-responders < 50%; responders≥50%).

RESULTS. At peak PEEP during the RM, the arterial pressure, cardiac output, left ventricular size decreased and right ventricular size increased. The left ventricular ejection fraction decreased from 60±13 to 48±18% (p,0.05). Both left and right ventricular global LS were impaired (-15.8±4.5 to -11±4.7% and -19±5 to -14±6% [p,0.05] respectively). Fifty percent of patients were non-responders, and demonstrated a lower hemodynamic tolerance to the RM than responders. Optimal PEEP was 14±5 cmH$_2$O (vs 11±4 cmH$_2$O at baseline) and P/F ratio increased from 111±25 to 197±89 mmHg (p< 0.0001). All hemodynamic parameters returned to their baseline value after the RM despite a higher PEEP.

CONCLUSIONS. An open lung strategy with a stepwise RM permitted a higher PEEP and improved oxygenation without any cardiac impairment. The RM was associated with mild, and transient, cardiac dysfunction, with non-responders demonstrating poorer tolerance.

Ultrasonographic assessment of lung recruitment with two different positive end-expiratory pressure strategies in moderate to severe acute respiratory distress syndrome

A. Bagheri Moghaddam, M. Khorsand, S. Amini
University of Medical Science, Mashhad, Iran, Islamic Republic of
Correspondence: A. Bagheri Moghaddam

INTRODUCTION. The positive or negative effects of PEEP in patients with ARDS is a result of its effect on the opening the collapsed alveoli and its effect on excessive distention of the lung tissue. These effects have a direct correlation with the amount of lung recruitable tissue.Therefore, an accurate assessment of this recruitable pulmonary volume can be considered a key step in using the optimal amounts of PEEP in ARDS patients.

OBJECTIVES. Assessment of lung recruitment with aid of ultrasonography after two methods of PEEP titration in moderate to severe ARDS patients.

METHODS. This quasi-experimental study with "before and after"design was done in Mashhad University of medical sciences, Emam Reza hospital.mashhad.Iran

In this study,15 patients with moderate to severe ARDS who need invasive mechanical ventilation were selected. Initially, patients were ventilated according to ARDS net protocol and positive end-expiratory pressure (PEEP) selection were based on the lowest recommended level in the "low PEEP table", then lung aeration was assessed by ultrasonography.After 30 minutes, PEEP level was adjusted according to EXPRESS trial and assessment of lung aeration by ultrasonography were repeated. Both types of PEEP selection were applied to each patient and in fact, control and intervention group were the same.

Inclusion criteria: Moderate to severe ARDS patients (based on Berlin criteria), older than18 and under invasive mechanical ventilation

Exclusion criteria: Known heart failure or acute ischemic heart disease, chronic respiratory disease, increased intracranial pressure, morbid obesity

RESULTS. 15 patients were included, of which 6 (40%) were male and 9 (60%) were female. The mean age of the patients was 46.13(±9.9). The frequency of patients with the acute respiratory syndrome (ARDS) with moderate and severe severity was 1 (6.7%) and 14 (93.3%) respectively. The average PO2 / FiO2 ratio of patients was 80.13 (±19.26) when entering the study. Positive end-expiratory pressure (PEEP) used in EXPRESS method (Mean = 16.73 cmH20) was higher than LOW PEEP method (Mean = 10.67 cmH20) (P < 0.001).

Loss of aeration scores were significantly lower in the EXPRESS method (Mean = 23) compared to the LOW PEEP method (Mean = 27) (P < 0.001).

The ratio of PO2 / Fio2 was significantly higher in the EXPRESS method (Mean = 104.6) than in the LOWPEEP (Mean = 87.27) method (P = 0.002)

CONCLUSIONS. The lung sonography can help selecting the appropriate PEEP for ARDS patients by identifying the lung recruitable tissue. An important limitation is the inability to detect lung overdistention.

INTRODUCTION. Regional strain is non-uniformly distributed in the mechanically ventilated, healthy and injured lung, and it has been spatially correlated with regional inflammation (1). Prone positioning decreases the dynamic strain (end-expiration to end-inspiration) gradient between dependent and nondependent lung regions in healthy lungs (2). However, the effect of prone on PEEP-induced static strain has not been explored in ARDS.

OBJECTIVES. The aim of this study was to explore the static strain induced by high PEEP on the regional level using computed tomography in moderate-severe ARDS patients in supine and prone.

METHODS. 5 mechanically ventilated patients (VT 6 ml/kg ideal body weight) underwent whole-lung computed tomography (CT) during breath-holding sessions at airway pressures of 5 and 15 cm H$_2$O. CT images were repeated in supine and prone positioning. A recruitment maneuver at 45 cm H$_2$O was performed before each PEEP change. Low radiation CT protocol was applied. Using Nifty-Reg package (3), a transformation mapping was generated between a fixed image (end of inspiration) and a target image (end of expiration), which calculates an estimated displacement of every point inside the lung from inspiration to expiration. Following, a biomechanical analysis method was used (4) to construct 3D maps of the volumetric strain distribution for each patient´s lungs. Strain maps were divided into 10 isogravitational horizontal regions-of-interest (ROI) from CT images obtained in supine and prone positioning. To assess the gradient between dorsal and ventral regions, we considered the extreme ROI 2,3 versus ROI 8,9

RESULTS. Global static strain induced by high PEEP was not different between supine and prone positioning (44±20% versus 41±12%, p=0,68). However, the gradient of PEEP-induced regional static strain between ventral and dorsal regions (ROI 2,3 versus ROI 8,9) was significant lower in prone (33±23% versus 48±20%, p=0,049)

CONCLUSIONS. Prone positioning attenuates the gradient of static strain induced by high PEEP between dependent and nondependent regions

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1238

INTRODUCTION. In a metanalysis conducted by Tonelli on 2014, they concluded that prone position, protective low tidal volumes and early use of neuromuscular blockers, are the only 3 interventions that have shown lower mortality rates in ARDS patients. patient´s response to prone withdrawal only can be known until change of position is performed. The Driving pressure/Static compliance (DP/Cstat) Index correlates the airway pressure with the lung static compliance, as an indicator of stretch.
OBJECTIVES. Identify the ability of the DP/Cstat Index to predict the success of prone position withdrawal.
METHODS. An analytical restrospective study was performed of the data base of Severe ARDS patients who were in Prone position (PP) during January to December 2017.The demographic variables included were age, sex, height, body mass index (BMI) and the etiology of SDRA. We calculated the DP/Cstat index before the prone position withdrawal, at time to supine position, 6,12 and 24 hours. A contingency tables 2x2 and square chi, were calculated for each one of the variables comparing them with the success of prone withdrawal at 24 hours.
RESULTS. 23 patients were included in the study, 21 males and 2 females, the average age was 35.4 yrs (15 - 58 yrs), average weight was 79.5 kg (55-115 kg), 28.5 kg/m2 was the average BMI (21.1 - 42.2). ARDS´s origin was pulmonary in 22 cases, and only 1 was extrapulmonary due pancreatitis. The average of length in continuous prone position strategy time was of 122.2 hours. Before prone position withdrawal, the PaO2/FiO2 average was 237.9, PaO2 88.2, CO2 36.3, Cstat of 33.7, driving pressure of 13.5 and DP/CStat of 0.5. 22 of the 23 patients accomplished with the criteria for prone positioning withdrawal, 15 patients had success of prone withdrawal at 24 hours, and 8 patients needed repositioning in prone. 6 hours after prone position withdrawal using a DP/Cstat cut-off < 0.51, we obtained 100% of sensitivity along with 100% of negative predictive value, 94% of positive predictive value and specificity of 88% with a strong association of 99% and Pearson R of 0.9 with prone position withdrawal success.
CONCLUSIONS. DP/Cstat index < 0.51 strongly correlated with success for prone position withdrawal with statistical significance. We consider the ability of this index to predict the success of prone position withdrawal is because the integration of these variables lead us infer lung stretch. Our study has several limitations, and a larger population is needed to corroborate the results of our investigation.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1239

INTRODUCTION. Source containment is essential in the treatment of intra-abdominal infections (IAI) in critically ill patients. However, there is a general lack of epidemiological data describing the types of interventions being performed, as well as their diagnostic yield, failure rate, and association with clinical outcome.
OBJECTIVES. To provide descriptive data that may aid physicians in making better informed decisions during the treatment of patients with severe IAI.
METHODS. We enrolled patients undergoing at least a single source control intervention because of presumed IAI during their stay in the Intensive Care Unit (ICU) of two university medical centres in the Netherlands between 2011 and 2015. Subsequently, we performed in-depth case reviews on these subjects and evaluated both procedural adequacy and clinical recovery after 14 days. Outcome was considered favourable if the anatomical infectious substrate was contained and the patient had been discharged alive from the ICU, both at day 14 after the first procedure.
RESULTS. In 353 ICU patients with presumed IAI, 496 surgical and 289 percutaneous procedures were performed. Overall, 178 (50%) patients required more than a single source control intervention (median 2 (IQR 1-3)). The initial substrate of infection was of gastrointestinal origin in 194 (57%) subjects (Table 1). Other sources

included the biliary tract (15%) and pancreas (8%). In 24 (7%) patients no infectious source was identified during the first procedure, but in 7 cases subsequent procedures yielded positive findings. First procedures mainly aimed for restoration of anatomy and function, whereas repeat procedures frequently concerned drainage. Microbiological specimens were obtained during 386 (55%) procedures, and led in 28% of the occasions to modifications of the therapeutic regimen. In 236 (67%) patients, ICU-admission occurred immediately prior to (29%) or directly after (38%) their first source control procedure. Among this subgroup, adequate source control was achieved using a single procedure in 106 (45%) patients. In an additional 65 (29%) patients multiple procedures were required to obtain containment of the anatomical source of infection by day 14, whereas in the remaining 65 (28%) subjects source control was still inadequate. Favourable clinical outcome was observed in 97 (41%) of these patients. Persistence of organ failure in the first 7 days after the intervention was associated with unfavourable outcome, whereas trends in CRP seemed non-predictive (Figure 1). Although effective source control was eventually achieved for 227 (64%) of all included 353 patients with presumed IAI, hospital mortality remained high at 42%.

CONCLUSIONS. Approximately half of the ICU-patients with presumed IAI require more than a single intervention, yet successful source control is eventually achieved in a majority of them.

Patients with their index procedure at ICU-admission (n=236) were divided based on outcome status after 14 days. Daily clinical parameters presented are: a) CRP, b) Sequential organ failure assessment (SOFA)-score, c) Septic shock, and d) Gastro-intestinal failure (i.e. insufficient enteral feeding, use of prokinetic medication, severe diarrhea/ vomiting, or increased abdominal pressure). Results are presented as proportion or median with Q1-Q3. Missing values were replaced with estimates derived from multiple imputation.

Influence of fluid administration in the first ICU day on septic patients mortality. Analysis of an electronic database

A. Naharro-Abellan[1], D. Domínguez Barbero[2], P. Matía Almudevar[1], A. Pérez Lucendo[1], A.P. Rodriguez Villamizar[1], S. Alcántara Carmona[1], J. Veganzones Ramos[1]

Correspondence: A. Naharro-Abellan

INTRODUCTION. Sepsis is a major cause of mortality in the ICU with fluid resuscitation being an important part of its treatment. Although it appears that positive fluid balance is associated with an increase in mortality, two recent large cohorts studies[1,2] have produced contradictory results.

OBJECTIVES. Our objective was to replicate the analysis of Marik et al[1], which demonstrated that administration of ≥5L of fluid during first ICU day lead to an increase in mortality, but using the actual Sepsis-3 definition[3] and SOFA score for the adjusted mortality analysis.

METHODS. We constructed a study cohort from the Medical Information Mart in Intensive Care (MIMIC)-III database v1.4[4] We identified infected patients adhered to the original Sepsis-3 study[3]. We included only the first ICU admission of adult patients with a SOFA score ≥2. We recorded the total amount of IV volume administered during the first 24 hours since ICU admission and the SOFA score.

RESULTS. A total of 5728 first admissions met our inclusion criteria. Demographic data are represented in Table 1.

The ability of SOFA to predict mortality had an AUC of 0.743. The actual vs. predicted mortality and the distribution of cases by Day 1 fluid administration groups are represented in Figure 1. In the overall analysis there was an association between fluid intake and mortality (OR 1.07;Cl95 1.05-1.09;p< 0,0001), but after adjusting by SOFA the association became negative (OR 0.97;Cl95 0.95-0.99;p=0.022). The same results were found dividing patients by < 5L or ≥5L: unadjusted (RR 1.55; Cl951.32-1.82;p< 0.0001) and adjusted (OR 0.87;Cl95 0.72-1.04;p=0.13).

CONCLUSIONS. In our study the amount of IV fluid administered during the first ICU day was associated with higher mortality, but after adjusting by SOFA, it turned protector. Higher fluid intake were correlated with higher SOFA scores. This was probably due to a relationship between severity and the need for a more aggressive resuscitation, but it could also be the result of a worsening state secondary to a generous fluid intake.

Our data suggest that a hight fluid intake is beneficial in those cases were it does not increase the SOFA score, and it turns harmful when it leads to an increase of this score. This might reflect a physiologically situation where fluid administration exerts a hemodynamic benefit until an inflection point beyond after which it becomes detrimental.

Sepsis-related deaths in the at-risk population on the wards: attributable fraction of mortality in a large point-prevalence study

M. Kopczynska, B. Sharif, T. Szakmany, Welsh Digital Data Collection Platform University, Anaesthesia, Intensive Care and Pain Medicine, Division of Population Medicine, Cardiff, United Kingdom
Correspondence: M. Kopczynska

INTRODUCTION. Sepsis mortality is reported to be high worldwide, however recently the attributable fraction of mortality due to sepsis (AFsepsis) has been questioned [1]. If improvements in treatment options are to be evaluated, it is important to know what proportion of deaths are potentially preventable or modifiable after a sepsis episode.

OBJECTIVES. The aim of the study was to establish the fraction of deaths directly related to the sepsis episode on the general wards and ED.

METHODS. Secondary analysis of patient episodes was performed on patient population recruited into two annual 24-hour point-prevalence studies on the general wards and ED across all Welsh acute hospitals in 2016 and 2017 [2]. Inclusion criteria were: clinical suspicion of infection and NEWS 3 or above in-line with established escalation criteria in Wales. Sepsis was defined according to Sepsis-3 definition based on SOFA and qSOFA scores. Clinical Frailty Scores and basic demographic information were also analysed. Deaths attributable to sepsis were evaluated based on microbiological, radiological and laboratory evidence. In addition, mortality was not attributed to sepsis if the patient has been discharged form hospital more than 7 days before death.

RESULTS. 791 patients were recruited over the two 24-hour periods in 2016 and 2017. 514 patients fulfilled Sepsis-3 criteria. 142 patients (27.1%) with sepsis and 47 patients (16.9%) without sepsis died within 90 days. Out of the 142 sepsis deaths 19 (13.4%) could have been directly related to sepsis, 41 (28.9%) possibly related and 82 (57.7%) were not related to sepsis. Overall AFsepsis was 30%. Upon analysis of the 60 deaths likely to be attributable to sepsis, we found that 48 patients had the Clinical Frailty Score >6, 40 had existing DNA-CPR order and 30 had limitations of care orders.

CONCLUSIONS. We are the first to report in a well-defined at-risk group outside critical care, that AFsepsis is only 30% and even this could be an overestimation due to the pre-illness trajectories and expectations, based on the frailty scores and limitation of care orders. Our results are similar to those reported in the ICU population [1]. The low proportion of preventable and modifiable elements of sepsis deaths should inform the design of interventional studies. More appropriate identification of patients who could actually benefit from aggressive interventions should be considered not just based on acuity, but also on pre-admission trajectories.

The comparison of infection prevelance, sepsis development, mortality and morbidity rates in traumatic brain injury

I. Saydere[1], A. Sagün[1], M. Azizoglu[1], A.A. Altunkan[2]
[1]Mersin University Medical Faculty, Anestehesiology and Reanimation, Mersin, Turkey; [2]Mersin University Medical Faculty, Intensive Care Unit, Mersin, Turkey

INTRODUCTION. Systemic infections and sepsis in severe head trauma are more frequent when compared to patients without trauma. In this study, we aimed to compare infection incidence and related sepsis development, morbidity and mortality rates in patients with head trauma.

OBJECTIVE AND METHODS. In this retrospective study, we included 80 patients aged 18-80 years who had traumatic brain injury between 2013 and 2016, at least one of peripheral, central blood, tracheal aspirate, and urine cultures to the intensive care unit.

RESULTS. The incidence of infection, sepsis development, morbidity and mortality rates were compared in these patients. In addition, the most commonly used scoring systems such as SOFA and APACHE II have been evaluated in intensive care unit. In our study, SOFA was found significant in terms of evaluation of organ dysfunction and early sepsis. Acinetobacter was the most frequent cause of nosocomial infections in the patients and the lungs were the most frequently isolated organ.

CONCLUSION. We would like to emphasize that our results from our study suggest that patients with head trauma are at high risk for sepsis development and mortality. Therefore it is clear that these patients need clinical follow-up and follow-up from the time of admission.

CRP, procalcitonin, lactate levels were assessed in the patients and it may be appropriate to use these laboratory tests as an indicator of sepsis progression but it was thought that these tests alone would not be enough. Scoring systems such as APACHE II, SOFA are also considered to be used as supportive diagnostic parameters in relation with these laboratory tests.

KEYWORDS. Head Trauma, Sepsis, C-Reactive Protein, Procalcitonin, Lactate, SOFA

INTRODUCTION. There is scarcity of information about sepsis epidemiology in LMICs. Moreover, big contrasts in outcomes and processes of care might occur in different healthcare settings within the region.

OBJECTIVES. To analyze differences in mortality between public and private hospitals in Argentina, using the Sepsis-3 definitions.

METHODS. Multicenter, national prospective cohort study performed during 7/1-9/1/16 including consecutive patients admitted to 49 Argentine ICUs with suspected infection, which prompted taking blood cultures and antibiotic administration. Considered groups were Infection; Sepsis (infection+change in SOFA≥2) and Septic shock (vasopresors+lactate ≥2 mmol/L. Epidemiological, clinical, infectological, and human-resource data were recorded. Hospital mortality was the main outcome variable. A p< 0.05 was considered statistically significant.

RESULTS. 809 patients were admitted to 23 ICUs in the public health system and to 26 in the private. Comparisons are shown in Table 1.
CONCLUSIONS.

- – Compared to patients from private hospitals, patients admitted to public hospitals exhibited profound and significant differences:
- – They were younger, sicker and had more frequent comorbidities; yet their autoperceived previous health status as measured by Euro-QoL visual analogue scale was not different from that of patients admitted to private hospitals.
- – They had less years of education and, notably, the duration of symptoms of their present disease doubled that of the patients in the private sector.
- – These issues point to a lack of awareness of the severity of the disease in patients admitted to from public hospitals-possibly aggravated by similar unawareness in the physicians that had evaluated them previously.
- – Thus, septic shock and higher SOFA on admission were more frequent in patients admitted to public hospitals, and mortality was higher. Patients were admitted later in the course of disease.
- – Regarding sepsis management, the only difference was in the presence of more frequent infections by multi-resistant microorganisms in the public sector. Human resources were greater in public hospitals.

Correspondence: C. Sánchez Ramírez
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1244

OBJECTIVES. To analyze the mortality risk factors in patients with nosocomial infections (NI), in a mixed ICU with selective digestive decontamination (SDD).

METHODS. Prospective study in patients who developed NIs were included from October 1st, 2010 to September 30th, 2017 in a 30-bed ICU. SDD was applied to patients requiring mechanical ventilation for more than 48 hours. An enteral solution and a paste with colistin, tobramycin and nistatin given every 8 hours until ICU discharge, was applied. Also intravenous cefotaxime was administered during the first 4 days. Rectal and pharyngeal exudates were requested on admission and weekly. The categorical variables were summarized in frequencies and percentages and the numerical variables in means and standard deviations or in medians and interquartile ranges. The percentages were compared with the X2 test or the Fisher exact test, the means with the t-test and the medians with the Wilcoxon test for independent data. A multidimensional logistic analysis was carried out. It was considered significant if p ≤.05.

RESULTS. Among 6291 admitted patients, 194 (36.44%) out of 532 patients with NI died. In a univariate analysis, APACHE II. age, type of admission, inflammatory response, traumatogic patient, immunosuppression, neutropenia, parenteral nutrition, presence of ventricular device catheter, renal replacement therapy, malnutrition, diabetes mellitus, chronic obstructive pulmonary disease, renal failure, cirrhosis, neoplasm, nosocomial pneumonia, antibiotic 48 hours previous to admission, Extended Spectrum Beta-Lactamase (ESBL) producing bacteria (p= 0.04) and multiresistant (MR) Pseudomonas (MR) (p= 0.024) were statistically significant. Among the patients who died versus survivals, ICU stay was not significantly different (Table 1)

The independent factors associated with mortality were: APACHE II, neoplasm, renal replacement therapy, septic shock, parenteral nutrition and COPD (Table 2)

CONCLUSIONS. In a ICU with SDD, factors that were independently associated with mortality were: APACHE II, neoplasm, renal replacement therapy, septic shock, parenteral nutrition and COPD. Also, MR Pseudomonas infections and ESBL were associated with greater mortality.

Correspondence: E. Vesteinsdottir
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1245

INTRODUCTION. Sepsis that requires an admission to intensive care is a rare complication of elective surgery and is associated with a high mortality and morbidity. Many previous studies on post-operative sepsis focus on specific types of surgery or patient groups in tertiary referral settings.
OBJECTIVES. To describe the incidence, etiology and outcomes of patients admitted to intensive care with sepsis after elective surgery.
METHODS. All adult admissions to all Icelandic intensive care units (ICU) during six whole calendar years (2006, 2008, 2010, 2012, 2014 and 2016) were screened for severe sepsis or septic shock using the ACCP/SCCM criteria. Demographics and clinical course of patients with severe sepsis or septic shock after hospital admission for elective surgery were compared with data from 564 patients admitted to the ICUs because of sepsis unrelated to surgery.
RESULTS. 88 patients were admitted to the ICUs with severe sepsis or septic shock after elective surgery during the study period. The mean age was 66.1 year and 65% were male. The most common surgical procedures were abdominal (64%), cardiothoracic (9%) and urologic (8%). The median ICU admission day was the 6th post-operative day. The infection site was most commonly the abdomen (59%), lungs (22%) and urinary tract (5%). The median ICU and hospital length of stay was 5.5 and 26 days, respectively. This was longer than for the comparison group (3 and 13.5 days respectively (p< 0.05)). The hospital mortality was 26% and the 1-year mortality was 41%, which did not differ from the comparison group (30% and 41% respectively (NS)). After excluding those who died in hospital only 48% of the group could be discharged directly home from the surgical ward. This was lower than in the comparison group (68% (p< 0.05)). 72% of patients in the study group had positive cultures and they had a higher incidence of multi-resistant pathogens compared with other septic patients (24% vs. 5% of patients with positive cultures (p< 0.05)). The initial empirical antibiotic therapy covered all cultured micro-organisms in only 43% of patients in the study group who had positive cultures, which was lower than in the comparison group (85% (p< 0.05)).
CONCLUSIONS. The most common cause of sepsis requiring ICU admission after elective surgery are infections complicating abdominal procedures. The ICU and hospital length of stay is long in this patient group and mortality rates are high. The initial antibiotic therapy needs careful evalulation given the increased frequency of multi-resistant pathogens.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1246

INTRODUCTION. Sepsis-related acute respiratory failure is common and associated with increased mortality (1). Initiation of intubation in sepsis cases with circulatory failure raises concern for hemodynamic deterioration (2) and there is currently no definitive recommendation (3).
OBJECTIVES. To evaluate the impact of invasive mechanical ventilation on outcome in patients with sepsis.
METHODS. We reviewed the electronic records of medical ICU patients with sepsis onset defined by lactate >4 mmol/L, mean arterial pressure < 65 mmHg or vasopressor use after 30 mL/kg fluid boluses, prospectively collected from 04/30/2014 to 12/31/2017. Patients who remained hospitalized at 24 hours following sepsis onset were divided into two groups defined according to whether the patient received mechanical ventilation in the initial 24 hours versus not. The main outcomes were hospital mortality and 28-day hospital-free days. Univariate and multivariate analyses were used, adjusted for admission characteristics and resolution of symptoms within 6 hours. The study was approved by our local Institutional Review Board (#14-008754).
RESULTS. Out of 1,335 encounters, we analyzed 1,052 single patients with research authorization: 345 (33%) patients were intubated and ventilated within 24 hours and 707 (67%) were not. Those ventilated were younger, originated more often from a referring facility, had higher APACHE III (92 [74-115] vs. 68 [57-82], p< 0.001) and SOFA score (10 [8-13] vs. 6 [4-8], p< 0.001), and within 6 hours, mean arterial pressure goals were achieved more often while lactate normalization occurred less often. Their hospital mortality was higher (89 (26%) vs. 82 (12%), p< 0.001) and they stayed more days in hospital (10.3 [6.6, 20.6] vs. 6.8 [4.5, 11.4], p< 0.001). After adjustment, invasive mechanical ventilation showed no effect on hospital mortality (OR 1.00 [95% CI 0.65 to 1.55], p=0.99) or hospital-free days through day 28 (estimated difference in hospital-free days -1.24 [95% CI -2.55 to 0.08], p=0.07).
CONCLUSIONS. Our findings suggest no significant association between invasive mechanical ventilation within 24 hours of sepsis onset and either hospital mortality or hospital-free days. These results should render the clinician more confident in initiating intubation in septic shock.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1247

INTRODUCTION. Sepsis is one of the major reasons for intensive care unit (ICU) admissions worldwide. Studies in several countries showed that mortality and resource utilization were, respectively, higher and greater in hospital-onset sepsis than those in community-onset sepsis [1-5]. However, whether the same situation is observed in Japan remains to be elucidated.

OBJECTIVE. To describe mortality and resource utilization in patients with community- or hospital-onset sepsis admitted to ICUs in Japan.

METHODS. Study design: A retrospective cohort study using data from the Diagnosis Procedure Combination (DPC) database, a nationwide discharge and administrative claim database in Japan
Setting: Hospitals participating in the DPC database in Japan, from April 2014 to March 2016
Participants: Patients admitted to the ICU with sepsis, which was defined as any sepsis-related diagnosis code in the International Classification of Diseases 10th Revision (ICD-10), plus combination of procedure codes for any antibiotic administration and any body fluid culture within 3 consecutive calendar days, from 1 day before to 1 day after ICU admission.
Exposure: Patients were dichotomized to those with community- or hospital-onset sepsis, defined as ICU admissions ≤2 or ≥3 calendar days following hospital admission, respectively.
Variables: Baseline characteristics of the patients and outcomes such as hospital mortality, length of hospital stay after ICU admission, length of ICU stay, duration of mechanical ventilation, and duration of renal-replacement therapy, were investigated. Data were demonstrated descriptively.

RESULTS. Among the 24,609 patients with sepsis admitted to ICUs in 521 hospitals, 16,419 (66.7%) and 8,190 (33.3%) had community- and hospital-onset sepsis, respectively (Table 1). Hospital-onset sepsis demonstrated higher mortality rate (community- vs. hospital-onset sepsis; 30.2% vs. 41.7%) and longer hospital stay after ICU admission (median, 26 days vs. 33 days). Table 2 shows detailed results.

CONCLUSIONS. Patients with hospital-onset sepsis had higher mortality rate and greater resource utilization than community-onset sepsis had. The results in this study would provide fundamental data for healthcare policy making on intensive care in Japan.

INTRODUCTION. New echocardiographic techniques such as speckle tracking have proven to show early myocardial dysfunction that could be overlooked by conventional methods. Myocardial dysfunction may be an early marker of mortality in sepsis patients.

OBJECTIVES. To assess the correlation between left ventricular circumferential vs. global longitudinal strain by speckle tracking with mortality and hospital stay in patients with sepsis admitted to an ICU unit.

METHODS. We conducted a prospective study in patients evaluated from January to March 2018 in an ICU unit from a single center in Mexico City. Sepsis was defined according to Surviving Sepsis criteria.

Echocardiogram evaluation that included left ventricular global longitudinal strain (GLS) and circumferential strain (CS) by certified personnel according to American Society of Echocardiography criteria. We evaluated global diagnostic performance and cox regression analysis of CS and GLS, using death during the ICU stay as our end-point.

RESULTS. We included 20 adults, 55% females (n=11), with a mean global age of 67.5 (±19) and length of stay of 12.9 days (CI 95%, 6.8-18.9). Sepsis origin was: 50% abdominal (n=10), 35% pulmonary (n=7) and 15% (n=3) urinary. Mortality rate was 25% (n=5). Non-survival vs. survival-groups baseline characteristics are outlined in table 1. CS was slightly superior to GSL and to SOFA, SAPS II and APACHE II scales for discriminating non-survivors vs. survivors (Fig.1) [AUC: 0.78 (CI 95%, 0.56-1), 0.66 (0.37-0.94), 0.64 (0.33-0.96), 0.68 (0.42-0.94), 0.59 (0.29-0.88), respectively]. Survival analysis revealed that CS for patients with a selected cutoff point ≥-15.5 was highly predictive for mortality [HR: 12.1, (CI 95% 1.3-112), p=0.022] (Fig. 2).

CONCLUSIONS. Myocardial dysfunction assessed by CS can be an early predictor of mortality in Mexican patients with sepsis. Results from non-conventional echocardiographic measurements add prognostic value to their outcome.

Influence on septic shock outcome of previous use of statins

R. Zaragoza[1], S. Sancho[1], V. Ramirez[1], D. Illa[1], C. Ibañez[1], R. González[1], R. Badenes[2], J.J. Camarena[1]
[1]Hospital Universitario Dr. Peset, Valencia, Spain; [2]Hospital Clinico Universitario de Valencia, SICU, Valencia, Spain
Correspondence: R. Zaragoza

INTRODUCTION. The role of previous use of statins before admission remains controversial in septic shock patients.

OBJECTIVES. The aims of this study were to know the prevalence of previous use of statins in patients with septic shock detected by a Sepsis unit, to know their updated prognosis and specially to analyze the influence on global mortality of previous statins use in these septic patients.

METHODS. During a four years and a half period (October-2012-March 2017), 2405 severe sepsis and septic shock patients detected by a sepsis unit form ICU using an electronic automatic alert in a teaching hospital were prospectively evaluated. Clinical and microbiological variables were recorded. Any patient with a confirmed septic shock (sepsis 2.0) was potentially eligible through the whole hospital. Previous use of statins was defined as the intake of statins 3 months previous admission. Several multivariate analysis was performed to describe independently factors associated to global mortality in these patients using SPSS package (16.0).

RESULTS. Among 2405 electronic activations 667 of them corresponded to septic shock (27.7%) Their mean APACHE II and SOFA score were 20.5±7.22 and 7.81±3.35 respectively. The most frequent sources of infections were the respiratory focus (31.2%), intraabdominal (29.1%) and urinary (26.6%). Global mortality was 35.2%. The majority of episodes were community adquired (54.1%). Associated bacteremia was present in 29.5% of episodes. Microbiological documentation was achieved in 56.7 %. Previous use of statins was documented in 17.7% of the episodes. Statistical significant factors associated to Global Mortality in univariate analysis (p< 0.05) were: nosocomial infection (45% vs 34%), respiratory focus (46.6% vs 33.7%), adequate empirical antibiotic treatment (32.2% vs. 65.3%) and 6h bundle adherence (28.1% vs 48,9%). Previous use of statins was not associated to global mortality in univariate analysis (33.8% vs. 35.6%). Factors independently associated to Global mortality were SOFA score (OR 1.25; CI95% 1.17-1.32) and 6h bundle adherence (OR 3.3; CI95% 2.10-5.18) but not previous use of statins (OR 1.12; CI95% 0.7-1.81)

CONCLUSIONS. Previous use of statins was present in almost one out five episodes of septic shock but had no influence on global mortality

Correspondence: R. Cicuéndez Ávila
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1250

INTRODUCTION. Clinical profile of Hospital Acquired Sepsis (HAS) patients is poorly known. HAS is associated with high mortality, and is considered a major preventable cause of admission to Intensive Care Unit (ICU).

OBJECTIVES. We sought to compare and contrast ICU, surgical and medical wards acquired sepsis in a major university hospital.

METHODS. Retrospective study of patients with HAS in a major Spanish Hospital from 2011 to 2015. Those patients fulfilling the SEPSIS-2 definition (Severe Sepsis or Septic Shock) with no evidence of infection the first 48 hours of hospital admission and over 18-years-old were included. Patients were grouped according to the place of sepsis acquisition (ICU, surgical wards and medical wards). ICU include medical, surgical and cardiac ICUs.

STATISTICAL ANALYSIS. Differences between groups were assessed using the χ^2 test for categorical and Kruskall -Wallis test for continuous variables. Mortality risk were evaluated using Cox regression univariate analysis. Finally Kaplan-Meier curves were plotted to show survival at 28 days. The log-rank test was used to compare the survival curves.

RESULTS. A total of 146 patients were included. Half (50%) present ICU acquired sepsis, while 31% acquired episode in surgical wards

and 19% in medical wards. ICU acquired sepsis patients were older (median) (74 years[66.5-79.0], compared to surgical (73 years[66.5-80]) and medical (63.5 years[51.5-75.0] p=0.012.Patients with history of immunosuppression predominate in medical 42.9% (surgical 17.8%, ICU 21.9%), p=0.040. Septic shock at diagnosis were more frequent in medical:75.0% (ICU:53.4%, surgical:73.3%), p=0.035. Urinary source predominate in medical 25% (ICU:5.5%, surgical 6.7%), p=0.008, and also primary bacteraemia 17.9% (ICU:17.8%, surgical:2.2%), p=0.035, while device-associated infection were higher in ICU:38.4% (Surgical:13.3%, medical:17.9%), p=0.006. HAS hospital mortality were higher in medical wards compared to surgical ones and to ICU (64.3% vs 55.6% and 45.2% respectively), p=NS. Patients from medical wards acquired sepsis showed higher risk of 28 days mortality: HR 1.77[1.02-3.07],p=0.042, while ICU acquired sepsis behaved as protector factor: HR 0.56 [0,34-0.91],p=0.018.

CONCLUSIONS. Many clinical differences were founded between ICU, Surgical and Medical wards acquired Sepsis. HAS acquired in the ICU presents a significantly lower mortality than that acquired in the hospital ward, probably due to earlier detection and treatment. These patients showed more survival time than patients with medical and surgical wards acquired sepsis. New studies are needed to confirm these findings.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1251

INTRODUCTION. Patients who are admitted to the ICU due to Influenza A are still at risk of high mortality, especially if they require mechanical ventilation. Despite advances in clinical research, risk prediction remains difficult in those patients.

OBJECTIVES. The aim of our study was to identify the risk factors for in-hospital mortality of patients suffering from respiratory insufficiency due to Influenza A, emphasizing the evaluation of laboratory data during first 48h.

METHODS. Prospective,observational study at our institution from 2012 to 2016.Baseline characteristics, laboratory data and outcomes were analyzed. Univariate and multivariate analysis was performed(SPSS 20.0).

RESULTS. 64 patients were included, 61.2%(43) were male, age was 54.8±14.5 years and APACHE II was 19.19±8.17. 46.8%(30) suffer from respiratory confection on ICU admission. In-hospital mortality was (25%;16). We did not show differences in previous comorbidities.

None of the non-survivors received previous Influenza vaccine whereas 29.1%(P=0.014) of the survivors received it. PaO2/FiO2 on admission (182±183vs.84±77;P=0.012), Platelets on admission (192 ±137vs.130±91×109·L-1;P=0.04), PaO2/FiO2 at 24h (183±100vs.114 ±60:P=0.008), Lymphocytes at 48h (943±659vs.469±317;P=0.02), Urine output first 24h (1874±1383vs.984±791mL) were different among subgroups. Non-survivors needed higher Invasive Mechanical Ventilation needs (41,67%vs.81,25%;P=0.009) and survivors higher hospital length of stay (38.5±58.6 vs.15.93±17.53days;P=0.022). All patients received similar regimens of Oseltamivir and other types of therapies (i.e. Renal Replacement Therapy, Antibiotics, Vasopressors). Lower PaO2/FiO2 at 24h (OR:0.958;95% CI:0.923-0.995;P=0.010) and higher APACHE II (OR:1.928;95% CI:1.081-3.438;P=0.026) were associated with higher in-hospital mortality.

CONCLUSIONS. Mortality remains high in patients suffering from Influenza A admitted to the ICU and prognosis assessment remains difficult. It seems that respiratory dysfunction during the first 24h may be helpful for this purpose.

Bacteraemia and its treatment in sepsis on the wards: results of a large point-prevalence study

P. McNulty, S. Kulikouskaya, T. Grother, H. Al Hassan, J. Abreu, S.Y. Heng, S. Ng, N. West, M. Kopczynska, B. Sharif, T. Szakmany, Welsh Digital Data Collection Platform
University, Anaesthesia, Intensive Care and Pain Medicine, Division of Population Medicine, Cardiff, United Kingdom

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1252

INTRODUCTION. Bacteraemia has been linked to increased mortality in sepsis, depending on the causative organism [1]. Quality improvement projects aimed to increase frequency and reliability of blood cultures obtained from this population revealed mixed results. Currently there is little known about the frequency and causative organisms of bacteraemia on the general wards and emergency departments (ED) in confirmed sepsis.

OBJECTIVES. The aim of the study was to establish the rate and organisms of bacteraemia related to the sepsis episode on the general wards and ED.

METHODS. Secondary analysis of patient episodes was performed on patient population recruited into two annual 24-hour point-prevalence studies on the general wards and ED across all Welsh acute hospitals in 2016 and 2017 [2]. Inclusion criteria were: clinical suspicion of infection and NEWS 3 or above in-line with established escalation criteria in Wales. Sepsis was defined according to Sepsis-3 definition based on SOFA and qSOFA scores. Microbiology data on collected blood cultures within 48 hours of the index episode were collected, together with data on antimicrobial regime.

RESULTS. 791 patients were recruited over the two 24-hour periods in 2016 and 2017. 514 patients fulfilled Sepsis-3 criteria. 321 (63.6%) patients had blood cultures taken. 16 blood cultures (4.9%) were positive with likely significant results: 6 Escherichia Coli, 1 Pseudomonas aureginosa., 2 Klebsiella pneumoniae, 1 Proteus mirabilis, 1 Gram negative organism, 1 Enterobacter cloacae, 1 Streptococcus pneumoniae, 2 Gram positive cocci. Out of the 514 patients, 212 (41.2%) were treated with intravenous antibiotics. 3 patients with positive blood cultures (2 with E. Coli and 1 with Gram positive cocci) were not treated with antibiotics, all survived. On the other hand, 70 (13.6%) patients were treated with two or more antimicrobials without microbiology investigations performed, and 57 were treated with 2 or more antimicrobials with negative blood culture results.

CONCLUSIONS. Despite ongoing quality improvement initiatives, blood culture attainment in sepsis is low. This could partially explain the 3% bacteraemia rate observed in our study. There is evidence that one in seven patients with sepsis are treated with two or more antimicrobials, without attempts to establish causative organism, which could lead to spread of antimicrobial resistance.

Sepsis is a multifactorial disease, it is estimated that there are more than 30 million cases each year, of which 6 million die (1), there is little information on low and middle income countries, where 87% of the population lives world (2). In Mexico, it was estimated that close to 50% to 60% of emergency admissions were related to sepsis, of which 10% were admitted with septic shock (3).

OBJECTIVES. To determine the risk factors of patients with sepsis to develop septic shock.

METHODS. A single-day multicenter study was conducted (September 13, 2017), where all patients diagnosed with sepsis or septic shock were admitted, according to the Sepsis criteria -3 (4) admitted to the Emergency Department during the 24 hours a day, they were recorded on a digital platform (www.sepsismexico.org) and followed up for 30 days. The data analysis was performed in SPSS v.21.

RESULTS. 68 hospitals participated, 307 patients were included (56% women), who presented sepsis 86.6% and septic shock 13.4%. The common odds ratio was estimated by the Mantel-Haenzel method for a background list as shown in the tables. Medical risk fa... Chronic organic... Environmental r...

CONCLUSIONS. The preexisting organic faults such as respiratory, cardiac, renal and hepatic failure preexisting, most of them exacerbated by the infectious process; the reason why arrhythmias, cerebral vascular events, and gastrointestinal tract hemorrhages increase the risk in an important way is not known, this had not been previously described. Among the environmental factors, it is important to live in a nursing home or geriatric institution and recent hospitalization, this can be explained by exposure to microorganisms and other factors.

INTRODUCTION. The definition of sepsis was revised in 2016 for early recognition of sepsis. The definition captures a wide variation, from patients who require only intravenous antibiotics to critically-ill patients who require intensive care such as intubation and continuous renal replacement therapy which are associated with high mortality.

OBJECTIVES. To predict critically-ill sepsis patients using the National Early Warning Score (NEWS) and some variables measured easily on admission.

METHODS. This was a single-center retrospective cohort study. Of all patients who admitted to our emergency room and intensive care unit, we reviewed 80 patients who were diagnosed as sepsis between January 2014 and December 2017. Age, gender, vital signs (heart rate, body temperature, and respiratory rate), consciousness level, and serum lactate level were measured on admission. Primary outcome measure was in-hospital mortality. We calculated the NEWS with the variables measured on admission. Then, we created a prediction model using NEWS, age, gender and serum lactate level and performed receiver operating characteristic (ROC) analysis with estimation of the corresponding areas under the curve (AUC).

RESULTS. Among the eligible 80 patients, the median age was 75 years old (interquartile range [IQR]: 64-83) and 54 (67.5%) was male. Median lactate level was 4.4mmol/l (IQR: 2.3-8.0) on admission. About the NEWS on arrival at hospital, low clinical risk patients, middle clinical risk patients and high clinical risk patients were 7 (8.8%), 9(11.3%) and 64 (80.0%), respectively. The all-cause mortality rate was 43.8%. Continuous hemodiafiltration was performed for 32 patients (40%). ROC curves showed that NEWS had an AUC 0.45 (95% confidential interval [CI], 0.32-0.58); however, the combination of NEWS, age over 65 years, gender and serum lactate lever yielded an AUC 0.74 (95% CI, 0.63-0.85).

CONCLUSIONS. Among sepsis patients, combined use of NEWS, age, gender and serum lactate levels may be better predictor to detect critically-ill patients who were associated with high mortality.

INTRODUCTION. Fluid resuscitation is, along with prompt empiric antibiotic therapy the mainstay treatment in septic shock. Despite recomendation of agressive fluid therapy[1] there is no consensus about a safe threshold of amount of fluid administered or fluid balance not to increase mortality or pulmonary complications[2,3].

OBJECTIVES. To determine the influence of positive fluid balance during the initial resuscitation of septic shock on mortality and duration of mechanical ventilation.

METHODS. Retrospective cohort study in a medical/surgical ICU, adult patients with septic shock admitted to the unit from January 2013 to June 2017 were selected. Demographic, prognostic variables, origin of sepsis, fluid administration, fluid balance, need and duration of mechanical ventilation (MV), ICU and hospital mortality were recorded.

RESULTS. 159 patients were studied (67% men, 32% women) with an age of 71 ± 12 years. The source of sepsis was abdominal (51%), followed by respiratory (20%) and genitourinary (17%). The intra-ICU mortality was 29% and the in-hospital mortality was 39%. 73% of patients required MV, the duration of it was 7 ± 11 days. The fluid balance accumulated in the first 48 hours was lower in the survivors: -1113 ml (95% CI -2169 ml, -56 ml, p = 0.039). The amont of fluid administered was similar in both groups (24 hours: 4751 ± 2173 ml, 65 ± 33 ml / kg VS 4685 ± 2198 ml, 68 ± 32 ml / kg, 48 hours: 4744 ± 1547 ml, 64 ± 25 ml / kg VS 4553 ± 2712 ml, 66 ± 39 ml / kg). The fluid balance influenced the duration of MV (Spearman correlation 0.314, p < 0.01). Patients with a cumulative fluid balance in the first 48 hours greater than 6 liters showed an increase in mortality, RR = 1.52 (95% CI 1.02-2.25, p = 0.038); they also required longer MV time: +5.2 days (95% CI 1.1-9.3 days, p = 0.013). In the logistic regression

analysis, the need for MV, the APACHE II score> 21 and the BMI> 26 kg/m^2 appear as variables associated with mortality.

CONCLUSIONS. Fluid administration is an indispensable part of the treatment of septic shock, although a very positive fluid balance during the first 48 hours can increase the mortality and duration of mechanical ventilation.

The outcomes of inoperable critical ill cancer patients in medical ICU (MICU) is better than expected by prognostic scores

O. Obukhova, G. Yunaev, I. Kurmukov, S. Kashiya
N. N. Blokhin NMRC of Oncology, Moscow, Russian Federation
Correspondence: O. Obukhova

INTRODUCTION. Anticancer therapy (ACT) and tumor burden can cause conditions that require intensive care. The question of advisability and efficacy of intensive care escalation in critical ill patients (CIP) with end-stage cancer is still undetermined.

OBJECTIVES. We evaluated treatment results and predictors of adverse outcome CIP with end-stage cancer receiving ACT.

METHODS. The prospective observational cohort study included 169 adult patients with cancer III-IV stages who had been admitted to MICU since 01 Jan 2016 to 01 Jan 2017. APACHE II and MPMII0 scales calculated prognosis of outcome. Statistical analysis of predictors of adverse outcome was done by odds ratio and χ^2 calculation. The utility of prognostic scales was assessed by the area under ROC curves.

RESULTS. Median of age was 58 years (18-87), male - 93. The main reasons for ICU admission were respiratory failure (62%), arterial hypotension or cardiac failure (46%), deep cytopenia (36%) or impairment of consciousness (23%) which were often combined with each other. Etiologically, the causes of the critical illness were complications of cancer (35%), adverse events of ACT (27%), decompensation of concurrent conditions (20%) and severe infections (18%). Median of APACHE II score was 16 (10-38). Mortality in MICU was 9.5%, 30-day mortality was 17%. Medians of predicted 30-day mortality by MPMII$_0$ and APACHE II were 27% and 39% respectively. There was no statistically significant correlation between 30-day mortality and neither main reason of MICU admission nor etiological factor of critical illness. Comparative ROC-analysis of utility of analyzed prognostic scales revealed some advantage of MPMII$_0$: AUC (MPMII$_0$) 0,781 (95% CI: 0,671- 0,891), AUC (APACHE II) 0,660 (95% CI: 0,528-0,792).

CONCLUSIONS. Inoperable malignant tumor is not a reason of intensive care refusal in MICU in case of reversible critical ill. Evaluation of novel predictors of adverse outcome is warranted.

Assessment by MPMII$_0$ and APACHE II scales did not demonstrate satisfactory agreement with actual 30-day mortality.

Correspondence: N. Kessemeier

INTRODUCTION. With a clinical pharmacists' (CP) participation on an intensive care unit (ICU) previous international studies have shown a reduction of medication errors, drug costs and improvements of clinical outcomes such as ICU length of stay. CPs' influence on these outcomes on German ICUs has not been investigated yet. This controlled interventional study was designed to investigate a CPs' impact on medication errors (ME) on a German surgical ICU.

OBJECTIVES. The investigation aimed to determine if the medication review by a CP results in a significant reduction of ME related to a control period. Secondary outcomes were the reduction of potentially severe medication errors, the number of days without systemic anti-infective therapy and the length of stay.

METHODS. The study was divided in three phases. One control phase P_0 and two intervention phases P_1 and P_2. Throughout the control phase P_0 the data were collected without the CPs' intervention. In the following intervention periods P_1 and P_2, two CPs screened the medical records for drug related problems (DRP) and discussed them with the senior physician. During P_2 CPs attended ward rounds additionally. DRP detected by the CPs according to defined criteria, were taken into account as ME if a consensus with the physician was achieved.

RESULTS. The medication orders of 336 patients were reviewed. The number of ME was significantly reduced from 1660 to 622 respectively 401 (P_0 vs. P_1/P_2; both P < 0.05; Fisher's Exact Test) in total, respective 14.1% in P_0 vs. 5.1% in P_1 respectively 3.3% in P_2 related to the monitored medications (P_0 11755;P_1 12134; P_2 12329).

CONCLUSIONS. CPs' interventions led to a significant reduction of ME in a German ICU, contributing to a safer medication process. We strongly recommend a broad implementation of CPs on German ICUs.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1258

INTRODUCTION. Proper management of human resources is critical in providing a high quality of health care. The staff's perception of good high-commitment human resource practices and organizational management affects directly to their job and satisfaction.

OBJECTIVES. To evaluate the relationship between the assessment of management team's commitment towards the high-commitment human resource practices and ICU healthcare personnel's satisfaction and the commitment of the management team for the implementation of a quality management in the organization.

METHODS. Information was collected from August to November 2017 through a survey adapted to each professional category. The questionnaire included a 7-score Likert scale including 24 items aimed at assesing different aspects related to high-commitment human resources management.

As a previous step, a Confirmatory Factorial Analysis (CFA) was performed to corroborate the theoretical dimensions traditionally published in the literature on high-commitment human resource practices and the unidimensionality of the scales used to measure the personal satisfaction and the organizational commitment of the management team. In spite of the statistical significance of the model [χ^2=201.34, p=0.000], results showed that othat other adjustment indicators were within the value ranges recommended in the literature (CFI=0.97, NFI=0.92, RMSEA=0.08). Regarding internal consistency measurements of every dimesion composite reliability (CR) reached values over 0.70 and average variance extracted (AVE) reached values over 0.50. The Cronbach's alpha values verifies those observed in composite reliability. These results indicated that the measurement model was valid and reliable.

RESULTS. In order to analyze the relationship between HPWPs and the constructs of personal satisfaction and organizational commitment, a correlation test was performed using the Pearson correlation coefficient. Results are shown in the following table.

CONCLUSIONS. There is a statistically significant positive association between the organizational commitment and all the dimensions that make up the high-commitment human resource practices, which indicated that the greater the organizational commitment, the better HPWPs. Internal promotion is the dimension with the stronger relationship.

ICU healthcare personnel's perception of a high level of organizational commitment by the hospital management is related to better HPWPs, which improves the well-being, attitude and commitment of the staff.

On the other hand, good high-commitment human resource practices are associated to greater personal satisfaction on the part of ICU healthcare personnel.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1259

INTRODUCTION. Intensive care unit (ICU) patiënts are mostly surrounded by life saving equipment that contribute to noise levels exceeding the WHO recommended noise levels of max 35 A-weighted decibel (dBA) by far. Although many noise studies have been performed, it is unknown what the contributing effect is of equipment alarms to the noise levels in the ICU.

OBJECTIVES. The aim of our study is therefore to explore noise levels and frequency of equipment alarms and to determine the association between alarms and noise levels in the ICU.

METHODS. A multiple single center cross-sectional observational study was performed between February 17th and March 17th 2015 in a university hospital on 4 ICUs with 36 beds. During 29 days, alarms were recorded with use of the alarm tracking software. We distinguished the following categories: red alarms (life threatening alarms), yellow alarms (alarms exceeding limits) and blue alarms (technical alarms). Noise levels were quantified in dBA and continuously measured at the nurses' station located in the middle of the unit, and at the bedside during 2 randomly chosen days. Noise and alarm datasets were time synchronized to determine the association between alarms and noise levels using linear regression analysis.

RESULTS. At the nurses' station mean noise levels were 51.1dBA (±5.7) and bedside 46.7 dBA (±6.5).

During daytime, noise levels were significantly higher than during evening-time, on both locations; nurses' station: 52.2 vs 50.8, p< .01, and bedside: 48.7 vs 46.0, p< 0.01. Mean noise levels during evening-time were significantly higher than during nighttime on both locations; nurses' station: 50.8 vs 48.9, p< 0.01, bedside: 46.0 vs 42.8, p< 0.01.

In 29 days a total of 175,996 alarms were recorded of which 149,764 (85%) were exceeding limits (yellow), 18,080 (10%) were red alarms and 8,152 (5%) were technical alarms. All alarms on the 2 days were statistically significant associated with the nurses' station noise levels: RED (b=0.2; 95% CI, 0.06-0.32; p< .0001) YELLOW (b=-0.96; 95% CI, -0.98- -0.94; p< .001) and BLUE (b=0.13; 95% CI, 0.07-0.19; p< .001). Bedside, this was significantly associated for YELLOW (b=-0.97; 95% CI, 0.87- 1.075; p< .001) and BLUE (b=0.54; 95% CI, 0.73-0.7; p< .001), but not for RED alarms (b=0.28; 95% CI, -0.09 -0.65; p=0.14). The R Square of the model at the nurses' station was: 0.015 (standard error of estimate, 5.7; p< .001) and bedside: 0.001 (standard error of estimate, 7.0; p< .001).

CONCLUSIONS. In the ICU, during all time periods, noise levels exceed the maximum WHO recommended mean level of 35 dBA of which daytime is the noisiest. Although all type of alarms were statistically significantly associated with the noise levels, the contributing effect to the decibel level is only minimal. Alarms are meaningful but not in the sense of mean noise level.

INTRODUCTION. Use of social media (SoMe) is increasing and might represent an alternative way to share information on intensive care unit (ICU) related subjects to improve standards of care.
OBJECTIVES. To explore the use of SoMe among ICU staff and their opinion regarding the use of Facebook (FB) as a platform for sharing information on ICU related subjects.
METHODS. An observational cross-sectional, web-based survey. ICU physicians and nurses at four ICUs participated via an email-campaign. Questions were adapted from a Norwegian survey of SoMe use in general, supplemented by additional specific questions regarding nurses' and physicians' view on the use of existing closed FB groups to share information on ICU related subjects. The scores were rated on a Numeric Rating Scale (NRS) ranging from 0 (not at all) to 10 (very much). The questionnaire was pilot-tested and modified. Descriptive statistics are presented with frequencies, percentages, median and interquartile range (IQR). Chi-square test and $p < 0,05$ are used for comparison.
RESULTS. Of 394 eligible recipients, 253 (64%) responded, of whom 43 (17%) were physician, 210 (83%) nurses, 188 (74%) female and 154 (61%) >40 years old.
Overall, 234 (93%) had a SoMe profile, with 176 (70%) reporting contact with family/friends as one of three most important reasons for using SoMe, whereas 34 (13%) reported professional development as one of the top three reasons. FB was the most frequently used SoMe: 221 (87%) had a registered profile; among those 172 (78%) used FB daily (see Figure 1). FB-profiles were evenly distributed among men and women (82 vs 89% (p=0,102)), and physicians and nurses (81 vs. 89% (p=0,197)). However, having a FB-profile was less common among those >40 years than those < 40 years (81 vs 97% (p< 0,001)). Daily FB use differed between gender (68 vs. 81% (p=0,047)) and profession (60 vs. 81% (p=0,006)), but was similar in both age groups (76 vs. 80% (p=0,455)).
Overall, 193 (76%) were members in their ICUs existing closed FB group; 182 (87%) nurses and 11 (26%) physicians. When asking whether they would accept to receive information on ICU related subjects vs. other social work-related information through FB (n=193), median NRS score was 6 (6) vs. 8 (3), respectively. Not being annoyed by receiving information on ICU related subjects vs. other work-related social information through FB, was reported with median 2 (6) vs. 2 (5), respectively. Overall, the respondents were positive about being members of closed FB-groups dedicated to the exchange of information on ICU related subjects (median NRS-score = 9 (4)).
CONCLUSIONS. The majority of the ICU staff were active users on FB. They reported a positive attitude to receive information about ICU related subjects in closed FB groups. A prospective study using closed FB groups to optimize critical care is now being carried out in Oslo University Hospital.

Visiting polices in critical care area - liberal or restricted
K. Zirpe, S.K. Yadav, S. Gurav, A. Deshmukh, R.N. Yellapu
Hall Clinic, Neurotrauma Unit, Pune, India
Correspondence: K. Zirpe
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1261

INTRODUCTION. The Intensive Care Unit (ICU) is a highly stressful environment for patients and their families. Measurement of family satisfaction has, hence, been proposed as one of the several quality indicators of ICU care. In general, the time period of an ICU visit is described as restrictive (RVP) or open/liberal(OVP).
OBJECTIVES. To understand perception of-1] Nurses about restricted (RVP) and liberal / open visiting policies (OVP) in critical care area.
2] Visitors about restricted (RVP) and liberal visiting polices (OVP) in critical care area.
3] To suggest improve measures to address the needs of patients, relatives & staff.
METHODS. A cross sectional observational study.Statistical analysis performed by using SPSS (Statistical Package for social sciences) version 20:0 we have used Chi-square test to compare the Open vs Restricted in 2 different groups.
RESULTS. Our study suggest that majority of nurse in RVP compared to OVP think that 24hrs visiting policy will hinder the patient rest (P Value-0.006), their work will suffer much more interruption because of 24hrs visiting policy (P value-0.004) and also believe that a 24hrs visiting policy will lead to delay in examining and performing procedures on patients (P value-0.001). All these were found statistically significant (P value- < 0.005).Our study suggest, majority of nurses in both group think that increasing visiting hours may be decrease patient´s anxiety and stress. But there was no significant difference in two policies regarding patient recovery. Also, Majority of the Visitors in both groups (64% in OVP and 68.4% in RVP) believe that increasing the visiting hours may decrease patient's anxiety and stress. And it not was found any statistically significant difference in two policies. Our study found that majority of the Visitors in both groups (70% in OVP and 71.4% in RVP) believe that open visiting policy will force the patients relative to stay with the patient. Another interesting finding is that Majority of nurses in both policies think that ICU visitation policy may be adapted in cases of conflict or by patients request and there was no significant difference in both policies about their opinion that ICU policy visitation should be adapted in cases of conflict or by patients request.
CONCLUSIONS. Policy makers should be aware of staff nurse's beliefs and attitudes about their visiting policies and educate them about the rationale for visiting policies. A visiting policy should be balanced covering concerns of nursing staff and relatives and consider program development to assist nurses to work with patient's relatives.

Correspondence: A.C. Jorge
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1262

INTRODUCTION. Functional status is highly variable in post-ICU patients.
OBJECTIVE. To compare the functional status of patients with TBI in the ICU and three months after discharge, in an outpatient clinic.
METHODS. Retrospective study from January to December, 2014, conducted in an adult intensive care unit (ICU) and in the post-ICU outpatient clinic of a University Hospital. Functional Independence Measure (FIM), Functional Status Score (FSS) and Barthel score were used to assess functional capacity. Glasgow coma score (GCS) and Richmond Agitation-Sedation Scale (RASS) were used to assess the level of consciousness. All patients were adults, with TBI (traffic accidents, falls or violence) and were evaluated twice: (1)on ICU discharge day, and (2)after three months. In the statistical analysis, the data were described by mean and standard deviation, and the Wilcoxon test was used, using $p < 0.05$.
RESULTS. A total of 34 patients with TBI were included in the study, with a mean age 34.0 years, most male (85%), mean APACHE II 19.2 and 1st day SOFA 14.1. Mean duration of MV and sedation were 207.9 and 127.7 hours, respectively. ICU and hospital length of stay were 12.6 days and 25.4 days. In the assessment of the level of consciousness, mean GCS and RASS in the ICU and at the ouapatient clinic were [12.1 and -0.5], and [14.4 and -0.2], respectively. FIM, FSS and Barthel scale were reduced at ICU discharge; however, there was significant improvement after three months ($p < 0.05$) (Figure 1).
CONCLUSION. TBI patients showed reduction in functional status at ICU discharge, but with significant improvement after three months.

Development of a critical care rehabilitation clinic at a district general hospital

E. Morino, L. Ma
Hospital NHS Foundation Trust, Critical Care, Kingston-upon-Thames, United Kingdom
Correspondence: E. Morino
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1263

INTRODUCTION. The National Institute for Health and Clinical Excellence (NICE) recommended in 2009 (Clinical Guidance 83)[1] that patients should be reviewed by appropriately-skilled healthcare professionals 2-3 months following discharge from critical care. Based on functional assessment, patients should be referred to appropriate rehabilitation or specialist services. Patients should be reviewed for symptoms of anxiety, depression, and/or Post-traumatic stress disorder (PTSD).
OBJECTIVES. At Kingston Hospital, we identified the need for improved aftercare of critical care patients, specifically to address the physical, psychological, social and economic effects of critical illness. Our primary objectives were to develop a multi-disciplinary critical care rehabilitation clinic to co-ordinate aftercare by liaising with primary and secondary care providers. Our secondary objectives were to improve future patient care by collecting data on patient experience and satisfaction and providing feedback to staff for learning and development.
METHODS. The critical care rehabilitation clinic commenced in October 2017. The consultant-led team consists of doctors, nurses, physiotherapists and a clinical psychologist. A retrospective review looked at the number of patients seen over a 6-month period, mean length of stay (LOS), and referrals to different services. We looked at patient satisfaction via a feedback questionnaire.
RESULTS. 26 patients were seen in the first 6 months at our monthly clinic. Mean length of stay (LOS) in critical care was 17.3 days. Mean LOS in hospital was 37.8 days. Secondary care referrals for ongoing or new morbidity was made in 9/26 (34%) of patients. Referral to physiotherapy was made in 8/26 (31%) of patients. Referral to specialist psychology services for anxiety/low mood and/or symptoms of PTSD were made in 13/26 (50%) of patients. 16 patients completed the feedback questionnaire. 16/16 (100%) of patients agreed or strongly agreed that the events during their stay was explained at clinic, and that physical, emotional, and psychological issues were appropriately addressed. 16/16 (100%) of patients felt they benefited from attending. 5/16 (31%) felt they would benefit from a patient support group. We listened to the positive and negative experiences of intensive care and we used these to feedback to staff to improve care and enlighten practice.
CONCLUSIONS. Our review of our clinic outcomes in the first stages of its development showed that a significant number of critical care survivors require ongoing multi-disciplinary support, and that there is a need for engagement with primary and secondary care providers to ensure safety-netting of interventions. Patients overwhelmingly regarded the clinic visit as a positive experience.

Critical care drug pouch a case to avoid mistakes

F. Rubulotta
College London, London, United Kingdom
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1264

INTRODUCTION. Drugs errors are common and their incidence may vary depending on the clinical setting. Human factors remain a major contributor to these.
OBJECTIVES. The concept of a "drug grab pouch" is an established and essential part of military and paramedic equipment.
The project designed at Charing Cross Hospital, London, UK, proposes the use of a pre-set Critical Care Drug Pouch (CCDP) for the following uses in critical care (critical care drug pouch):

- Emergency intubation
- Interdepartmental and inter-hospital transfer of patients
- Safe transfer and sedation of critically unwell patients

METHODS. A modified Delphi method was used to gather consensus on an initial pilot CCDP by sending an online questionnaire. The results of this questionnaire were analysed and consensus agreed by an expert panel thereafter before introduction to the end-user.

RESULTS. 88% response rate was achieved among doctors (consultant and registers) and nurses. There was global agreement that drawing of drugs for emergency rapid sequence induction and transfer was subject to errors and delays, the available drugs were insufficient. 100% of respondents agreed that always or sometimes, patient care was compromised due to delays in drawing up of medications and 96% of respondents felt a CCDP would improve this experience. The questionnaire allowed respondents to express drugs they felt would be of use in such a project. A second round of consultation of departmental consultants and senior registrars permitted consensus of the bag form, contents (drugs and adjuncts) that would be essential based on the above results. Consensus was obtained that the pouch should be minimalistic in size and contents, to permit easy use, daily check and reduction of waste. It was agreed that it should be in keeping with infection control guidelines and have clinical governance procedures in place to ensure sustained quality and safety. The pouch should also contain all necessary syringes akin to routine anaesthetic practice and drawing up needles. It was agreed that colour coded syringe labels would be contained in harmony with UK regulations and common anaesthetic practice as per Royal College of Anaesthesia guidelines to prevent "wrong drug" administration. To facilitate standardisation, two small bags (20cm x 20cm x 7cm) with elasticated vial and mini-jet compartments, were introduced across the 25 bed unit. The bag also contained an fixed inventory and audit form permitting accountability and ease of daily check.

CONCLUSIONS. "To err is human" but instituting basic measures such as provision of essential drugs, standardised syringes and colour-coded labels in a single, compact and portable device, the CCP, is a solution to many preventable errors in critical care environments.

Non-pharmacological interventions to prevent or mitigate long-term consequences among ICU survivors: a systematic review
W. Geense[1], M. van den Boogaard[1], J. van der Hoeven[1], H. Vermeulen[2], M. Zegers[1]
[1]Radboud University Medical Center/ Radboud Institute for Health Science, Intensive Care Medicine, Nijmegen, Netherlands; [2]Radboud University Medical Center/ Radboud Institute for Health Science, IQ Healthcare, Nijmegen, Netherlands

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1265

INTRODUCTION. Long-lasting impairments in physical, cognitive and mental health, also called Post Intensive Care Syndrome (PICS), are common after hospitalization for critical illness. In recent years, many interventions emerged to prevent or mitigate PICS. However, an overall view of the effectiveness of these interventions is lacking.

OBJECTIVE. To systematically review non-pharmacological interventions aimed at preventing or mitigating long-term consequences among ICU survivors.

METHODS. PubMed, CINAHL, PsycInfo, EMBASE, and the Cochrane Library were searched for studies published from inception till September 2017. The EPOC study design criteria were used to include studies evaluating interventions conducted before, during, or after ICU aiming to prevent or mitigate long-term consequences. Studies including adult ICU patients, admitted ≥12 hours and reporting quantitative outcome measures after ICU discharge, were included. Two reviewers independently selected studies, extracted data and assessed the study quality using the Cochrane risk of bias tool.

RESULTS. From 11,080 publications, 42 studies with 5,723 patients were included. Eight intervention categories were identified in 40 RCTs and 2 N-RCTs: exercise and physical rehabilitation programs (n=21), neuromuscular electrical stimulation (NMES) (n=4), nurse led follow-up care (n=3), diaries (n=3), information or education programs (n=3), psychosocial programs (n=3), changes in care organization (n=2) and other interventions (n=3). Twenty interventions started in the ICU, 11 after ICU discharge, 10 after hospital discharge and one intervention before ICU admission.

Between the studies, heterogeneity was present regarding study participants, interventions, follow-up time points, measured outcomes and instruments. We found 95 unique outcomes, of which 50 physical, 12 mental, 10 cognitive, 7 quality of life and 16 other outcomes, such as activities of daily living. The maximum follow-up time was 12 months. Sample sizes were relatively small (median 136; minimum 20, maximum 386 participants).

None of the studies showed strong evidence for effectiveness of the interventions. Exercise and physical rehabilitation programs seems to improve physical functioning and quality of life among ICU survivors. NMES might increase muscles strength and the use of diaries might reduce symptoms of post traumatic stress, anxiety and depression. No clear overall effect was found for nurse led follow-up care, information or education program or psychosocial programs. We will present the outcomes of the meta-analysis at the congress.

CONCLUSIONS. There is a lack of evidence for interventions to prevent or mitigate long-term consequences among ICU survivors. Most of the studies had small samples sizes and measured short-term outcomes using different instruments. There is an urgent need for larger RCTs, measuring longer-term outcomes with uniform instruments.

Psychocognitive sequelae of ICU care, barriers to recovery, and correlation of post-ICU assessment with 3 months follow up
J. Schultz, M. Clark, P. Schulte, K. Philbrick, L. Karnatovskaia
Clinic, Rochester, United States
Correspondence: J. Schultz
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1266

INTRODUCTION. Over a third of critical illness survivors manifest significant psychocognitive impairments following discharge from the ICU. Yet little is known about which patient populations are at highest risk or whether performing assessment at ICU discharge can help plan outpatient treatment strategy.

OBJECTIVES. This single center study assessed the prevalence of psychocognitive morbidity among patients across six adult ICUs. The study also examined correlations between initial assessment and 3 months follow up. To understand the patient experience, patients provided feedback on perceived barriers to recovery and beneficial recovery strategies.

METHODS. Within 96 hours of dismissal from the ICU, patients with>48 hour stay completed Hospital Anxiety and Depression Scale (HADS; scores≥8 indicating significant symptoms of anxiety or depression), Impact of Events Scale-Revised (IES-R; scores≥1.6 indicating significant posttraumatic stress disorder symptoms), and Montreal Cognitive Assessment-Blind (MoCA-blind; scores< 18 indicating cognitive impairment). Patients were contacted 3 months following the initial evaluation; repeat assessments were completed by phone. Linear regression assessed the association of baseline characteristics with initial and 3-month assessments of HADS-D/A and MoCA-Blind, while logistic regression assessed associations with IES-R≥1.6. Variable selection using a backward stepwise procedure selected variables with the strongest associations.

RESULTS. 299 patients completed the initial assessment and 174 completed 3 month follow up. ICU length of stay averaged 4.2 (sd=3.3) days and did not significantly differ across ICU settings (p= 0.089). MoCA-Blind (mean=16.7 (sd=3.09)), HADS-D (mean=6.3 (4.1)) and HADS-A (mean=7.2 (4.1)) were similar across ICU settings (p>0.1

for each). Most common problem was cognitive with 58% of patients having MoCA-BLIND< 18 followed by anxiety with 45% having HADS-A≥8. 39% had IES-R≥1.6, and 37% had HADS-D>8. See Tables 1 and 2 for multivariable associations between baseline and ICU stay characteristics and psychocognitive scores post-ICU and at 3 months. There were moderate correlations between baseline and follow up psychocognitive outcomes, from ρ=0.35 for IES-R Avoidance to ρ=0.58 for HADS-D. Physical therapy in ICU was associated with lower HADS-D/A at 3 months (p< 0.001 and p=0.022, respectively). See Figure 1 for barriers to recovery and strategies patients found helpful.

CONCLUSIONS. While the prevalence of psychocognitive morbidity was high, there was no significant difference by the ICU type. There is a moderate correlation between the initial assessment and follow up scores suggesting that early screening of high risk patients may help facilitate timely follow up. Barriers to post-discharge recovery were generally rated as minimal. Successful strategies for recovery were reported for family, medical visits, exercise, and relaxation.

Sarcopenia and adverse outcomes in critically ill surgical patients

G.B. Fleming[1], D.A.J. Smith[2], L. Hogg[1]
[1]NHS Fife, Intensive Care Unit, Kirkcaldy, United Kingdom; [2]NHS Fife, Department of Radiology, Kirkcaldy, United Kingdom
Correspondence: G.B. Fleming
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1267

INTRODUCTION. Sarcopenia is the loss of skeletal muscle mass and function, a recognised component of the clinical syndrome of frailty, and is associated with increased mortality and morbidity in emergency and elective surgical patients [1,2]. We hypothesised that sarcopenia, demonstrated by morphometric measurements of the psoas muscles on pre-operative computed tomography (CT), would predict mortality and morbidity in critically ill patients undergoing laparotomy.

METHODS. A retrospective review was conducted of all patients admitted to the Intensive Care Unit, Victoria Hospital, Kirkcaldy, following emergency or elective laparotomy between Jan 2015 - Dec 2016. Clinical data was recorded from the electronic Wardwatcher system. For sarcopenia evaluation, psoas muscle area and density at the L4 level were measured on pre-operative CTs and the Hounsfield Unit Average Calculation (HUAC), a validated marker of muscle density and fatty infiltration [2], was derived. Patients were stratified into quartiles and defined as being sarcopenic if they fell below the 25th percentile.

RESULTS. 89 patients met the inclusion criteria for analysis. 53% were male and the median age was 66 years (IQR 50-75 years). Overall 30-day and 1-year mortality were 16% and 21% respectively. Patients were stratified into quartiles with the lowest quartile defined as sarcopenic (HUAC < 25). 23 patients met the defined criteria for sarcopenia. As expected, these patients were significantly older. Sarcopenia was associated with significantly increased 30-day and 1-year mortality, higher APACHE scores and

significantly increased ventilator days (Table 1). Although non-significant, there was also a trend towards increased renal replacement therapy in sarcopenic patients. The 1 year survival of sarcopenic vs non-sarcopenic patients is seen in the Kaplan Meier curve (Figure 1).

DISCUSSION. We demonstrated that sarcopenia in surgical patients, reflected by low psoas muscle HUAC, is associated with increased 30-day and 1-year mortality, and increased morbidity. We propose that psoas muscle measurement via CT is an objective and effective measurement which can be readily used in the pre-operative evaluation and counselling of patients and clinical teams. Early identification of sarcopenic patients via CT measurement may also have a further role of identifying patients likely to benefit from intensive multidisciplinary team input within ICU to optimise nutrition and mobilisation.

Right Data, Right Now: developing a big data machine-learning based prediction model to prevent ICU readmission

P.J. Thoral[1], M. Fornasa[2], H. Hovenkamp[2], R. Driessen[1], A.R.J. Girbes[1], P.W.G. Elbers[1]
[1]VU University Medical Center Amsterdam, Department of Intensive Care Medicine, Research VUmc Intensive Care (REVIVE), Amsterdam Cardiovascular Sciences (ACS), Amsterdam Infection and Immunity Institute (AI&II), Amsterdam, Netherlands; [2]Pacmed B.V., Amsterdam, Netherlands
Correspondence: P.J. Thoral

INTRODUCTION. ICU readmission after critical illness is associated with longer length of stay and increased mortality.[1,2] Unexpected readmissions may be prevented by delaying discharge from the ICU, though optimal timing is subject of debate. Especially in tertiary teaching hospitals where ICU capacity is often strained, unnecessarily long ICU stays may prevent timely admission of other patients requiring ICU treatment[3]. Decision-making supported by a prediction model may prevent readmission and mortality and allows optimizing ICU capacity. Given the large amount of data gathered routinely in the ICU and the complexity of the task, machine learning is particularly suited for the development and clinical implementation of said prediction model.

OBJECTIVES. The aim of the first phase of our study was to develop a machine-learning-based algorithm that ranks patients based on their chance of readmission or mortality after ICU discharge. In particular the algorithm should identify patients with a high/low risk of readmission/mortality when discharge from the ICU is being considered.

METHODS. Anonymized data was extracted from the Patient Data Management System (MetaVision, iMDsoft) at our 24-bed mixed surgical-medical ICU at VU University Medical Center, Amsterdam, The Netherlands. Data from adult patients admitted to our ICU between 2004 and 2016 were included in the analysis. Patient characteristics, clinical observations, (automated) physiological measurements and laboratory studies were considered as possible features for the model. The change over time of these features was captured by building aggregated model features. Different supervised learning algorithms (including neural networks and boosted decision trees) were trained to predict readmission or death within 7 days from ICU discharge on 75% of the patients and the final score was computed on the remaining 25%. Model development was performed in collaboration with Pacmed B.V., Amsterdam, The Netherlands using Python and the scikit-learn package.

RESULTS. After excluding patients that that did not survive their first ICU admission and ICU admissions longer than 7 days, our data set contained approximately 13.000 cases, with a readmission/mortality rate of approximately 4%. Preliminary results show high performances, with areas under the ROC curve consistently higher than 0.8, better than other prediction models available in the literature.

CONCLUSIONS. Our findings showed that the vast amount of ICU PDMS data can be used to develop a model that accurately predicts readmission and mortality after ICU discharge. The final optimization of the algorithm will also take into account its implementability into a decision-support tool that is transparent and integrates well with the PDMS and the workflow of intensivists.

Pessimism in the ICU: do long stays reduce survival?

D.C. Marshall, R. Hatch, D. Young, P. Watkinson
University of Oxford, Critical Care Research Group - Kadoorie Centre for Critical Care Research & Education, Oxford, United Kingdom
Correspondence: D.C. Marshall
Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1269

INTRODUCTION. Although a prolonged period of critical illness might plausibly be associated with a poor outcome it is unclear if the future probability of survival on any given day is dependent on the ICU stay up to that point. Large clinical databases provide sufficient patient numbers to investigate this question.

OBJECTIVES. Assess the relationship between day of ICU admission and future hospital survival, and examine the effect of age on this relationship.

METHODS. Retrospective cohort study of the Post Intensive Care Risk-Adjusted Alerting and Monitoring (PICRAM) database. PICRAM is an intensive care database generated from admissions between 2008 and 2016 to two English ICUs, a tertiary referral centre and district general hospital. Cohorts were generated for index admissions to ICU with subgroups generated initially for all patients, then > 1 day in ICU, > 2 days in ICU until cohort < 50 patients. Survival to hospital discharge was then calculated by cohort. Exploratory analyses assessing impact of age were performed with data dichotomised by < 75 and ≥ 75 years of age (≥ 75 years representing upper quartile of population). These methods were then replicated in the North American MIMIC-3 and eICU databases (1).

RESULTS. 7,057 index admissions were included in the initial cohort reducing to 44 patients who were admitted for longer than 40 days (Table 1). In all patients survival declined over the initial 4 days but then plateaued with no observable changes in survival as length of stay increased (Figure 1). When patients were dichotomised into < 75 years of age and ≥ 75 there was a steeper increase in mortality in the older age group (Figure 2). The probability of future survival continued to decrease up to 15 days in the older cohort with 40-45% survival contrasted with a plateau after 4 days and survival of ~75% in the younger cohort. Similar findings were identified in the MIMIC-3 database and the eICU database. In these cohorts of 38,532 (MIMIC-3) and 166,756 (eICU) patient survival also decreased after a length of stay of > 6 and > 8 days for MIMIC and eICU respectively with a more profound reduced survival in patients ≥ 75 years of age.

CONCLUSIONS. Overall after 4-8 days the future probability of hospital survival does not appear to decrease with length of stay in all patients admitted to ICU. There appears to be reduced survival with increasing length of stay in patients ≥ 75 years of age.

INTRODUCTION. Long-term cognitive impairment is a common complication in critical illness survivors [1-4] but its natural history and the temporal profile of cognitive recovery in individual patients remain unknown. Understanding these features is critical for identifying optimal therapeutic windows and selecting patient subgroups most likely to benefit from targeted interventions.

OBJECTIVES. The objective of this study was to assess the feasibility of using a widely validated, web-based neurocognitive test battery (Cambridge Brain Sciences, CBS) in a cohort of critical illness survivors.

METHODS. We conducted a prospective observational study in two intensive care units (ICUs) at two tertiary care hospitals. Twenty non-delirious ICU patients who were mechanically ventilated for a minimum of 24 hours underwent cognitive testing using the CBS battery while still in the ICU or shortly after discharge to ward. The CBS consists of 12 cognitive tests that assess a broad range of cognitive abilities, such as reasoning skills, short-term memory, and verbal processing. Twenty patients underwent cognitive assessment while still in the ICU or shortly after discharge to ward. Cognitive impairment on each test was defined as a raw score that was 1.5 or more standard deviations below age- and sex-matched norms.

RESULTS. We found that all patients were impaired on at least two tests and 18 patients were impaired on at least three tests. ICU patients had poorer performance on all three cognitive domains relative to healthy controls. We identified two feasibility issues with administration of the CBS test battery: patient fatigue due to battery length and patient inexperience with use of a computer mouse.

CONCLUSIONS. Use of a web-based patient-administered cognitive test battery is feasible and can be used in large-scale studies to identify domain-specific cognitive impairment in critical illness survivors and the temporal course of recovery over time.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1271

INTRODUCTION. Cytomegalovirus (CMV) DNA detection in severely ill adult patients has been associated with important adverse clinical outcomes, including duration of mechanical ventilation (MV), longer length of stay (LOS) and mortality. Despite the fact that there are several reasonable mechanisms that could link the presence of this virus with worse clinical outcomes, it remains unclear whether CMV acts as a true pathogen or if it is a surrogate for more severe illness.

OBJECTIVES. We aim to explore the comorbidities, clinical interventions and clinical outcomes associated with CMV DNA detection in critically ill adult patients.

METHODS. We conducted a retrospective observational study in the Intensive Care Unit of a single university hospital. All the patients who underwent testing for CMV DNA detection over a 3-year period were enrolled. Testing was implemented according to the standard of care, drawing the samples from the most suitable source in each case (blood, respiratory tract or gastrointestinal tract). CMV DNA extraction was accomplished with an automatic system (EasyMag® bioMérieux, Marcy-l'Étoile, France), and amplification was performed with real-time polymerase chain reaction (rtPCR) (RealStar CMV®, Altona, Hamburg, Germany), using thermocycler Smartcycler® (Cepheid, Sunnyvale, California, USA). This PCR includes a heterologous amplification (internal control) to identify a possible inhibition of the rtPCR and to guarantee the reliability of all the reactives. Clinical variables were compared between the groups with positive and negative CMV DNA detection, respectively. Multiple logistic regression analysis was used to jointly examine the influence of the comorbidities. Student's T, Chi-square (χ^2) and Fisher's exact tests were applied as appropriate.

RESULTS. 69 patients were tested for CMV DNA detection, 31.9% of them with a positive result. Frequencies of comorbidities in the groups with positive and negative tests for CMV DNA were, respectively: hematologic disorders 31.8% vs 23.4%, p=0.45; diabetes mellitus 27.3% vs 12.8%, p=0.14; tumors 22.7% vs 21.3%, p=0.89; immunosuppression 13.6% vs 40.4%, p=0.03; human immunodeficiency virus 13.6% vs 4.3%, p=0.16; chronic obstructive pulmonary disease 13.6% vs 8.5%, p=0.51; autoimmune disorders 9.1% vs 19.2%, p=0.29; and chronic kidney disease 9.1% vs 8.5%, p=0.94. Multiple logistic regression analysis of the comorbidities, clinical interventions and outcomes observed are summarized in the Tables.

CONCLUSIONS. In our series, HIV, COPD, hematological disorders and diabetes mellitus were found to be higher risk comorbidities to obtain a positive test for CMV DNA. Patients requiring HFNC, NIV or prolonged MV were more likely to have a positive result. CMV DNA detection was associated with longer LOS and higher frequency of ARDS and mortality, suggesting that CMV might act as a true pathogen rather than as an innocent bystander. Further research is required to confirm this hypothesis.

Left ventricular systolic functions in intensive care, ejection fraction vs aortic velocity time integral

K. Ahmad, Z. Alrais, M. Hamed
Rashid Hospital Dubai Health Authority, Intensive Care Medicine, Dubai, United Arab Emirates
Correspondence: K. Ahmad
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1272

INTRODUCTION. Ejection Fraction (EF) & Aortic Velocity Time Integral (VTI) are the two main parameters to measure left ventricular systolic functions. But in the Intensive Care settings, sometimes VTI has has more accuracy than EF in depicting systolic functions.

OBJECTIVE. To compare left ventricular systolic functions by Ejection Fraction Vs Velocity Time Integral.

STUDY DESIGN. Prospective descriptive analysis

METHODS. A cohort of 50 patients admitted to Intensive Care Unit from July 2017 to December 2017, hemodynamically unstable (MAP < 65 mmHg) were examined by Transthoracic Echocardiography (TTE). Ejection Fraction (EF) was measured by M-Mode in Left Parasternal Long Axis view and Modified Simpson method. Stroke Volume (SV) was calculated by measuring Aortic Velocity Time Integral (VTI) in Left Ventricular Outflow Tract (LVOT) in Apical 5-Chamber view. An average of 3 readings was recorded, and respiratory variation of VTI was also calculated in each individual. The data was collected on Microsft Excel. Quantitative data was analyzed by my mean, medium & mode. Qualitative data was analyzed by frequencies & percentages. Linear Regression analysis was done to see relationship between EF & VTI.

RESULTS. The mean age was 59.82 (Range 26-80) years. Majority belongs to > 50 years of age-group *(27/50)*. Males were 41(82%) Vs 9 (18%) females. 22 (44%) patients were on ionotropes, and 28(56%) without. Mean Ejection Fraction was calculated as 55.8 % (Range 26-87) Table-1. Majority of patients had EF > 60% *(21/50)*. Only two patients were found with EF < 30%, rest all *(27/50)* were between 30-60%. Mean VTI was found to be 15.4 (Range 7-21). Most patients were found with near normal *(16/50)* or moderately reduced VTI *(15/50)*. Ten patients were found with significant low VTI, < 10 cm (Table-2). Significant Respiratory variation of VTI (>12%) was found in 16 patients. While in 34 patients respiratory variation of VTI was < 12%. In 4 patients VTI was near normal $\geq$ 17 cm but their EF was found < 50%, and on other hand in 7 patients EF was above 60% but their VTI was found below 12 cm. Linear Regression analysis revealed a weak correlation between EF & VTI, Correlation Coefficient (R^2) of 0.2186 (Graph-1).

CONCLUSION. Aortic Velocity Time Integral (VTI) has better prediction to determine Left Ventricular systolic function as compared to Ejection Fraction alone in the intensive care. There is a weak correlation between EF & VTI to determine LV systolic functions.

KEY WORDS. Systolic functions, Velocity Time Integral, Ejection Fraction.

INTRODUCTION. Fluid responsiveness (FR) is defined as the ability of the heart to increase its stroke volume after fluid administration(1). Mini fluid challenge is one of the most robust methods for preload challenge(2), but it needs real time monitoring of cardiac output (CO)(3), to track instantaneous change of stroke volume (SV) with fluid loading. Recently $PvaCO_2$ gap (4)have been used to detect FR after passive leg raising test with high sensitivity and specificity. Venous-arterial carbon dioxide gap ($PvaCO_2$ gap) and which is defined by the difference between central venous and arterial CO_2 and the ratio between the gap and arterial-venous oxygen difference are

emerging tool to guide resuscitation in critically ill patients(3). However, to the best of our knowledge, no previous study investigated the validity of this method to detect FR in post liver transplant patient.
OBJECTIVES. Investigate the ability of VA-CO_2 gap to predict the hemodynamic response to fluid challenge in liver transplant patient.
METHODS. 40 patients post liver transplantation with hemodynamic instability, elevated lactate and normal scvo2. Pvaco2 gap calculated to detect FR .Fluid responders were defined as patients with increased stroke volume 15 %(measured by icon cardiometry device) after fluid bolus. arterial and central venous blood gases were obtained before and after fluid bolus. The predictive ability of the change in Pvaco2 gap with fluid bolus to predict FR was obtained with area under receiver operating characteristic (ROC) cu
RESULTS. Fluid responders were 26 patients (65%), AUC of Pvaco2 for prediction of FR;after fluid bolus showed sensitivity70.8% and specificity62.5%, AUC 0.65, 95%CI (0.48-0.79), P value 0.08. Scvo2 couldn't predict fluid responder patients post liver transplantation after fluid bolus with sensitivity 20%and specificity 45%, AUC 0.55,95% CI (-.007, 0.15).
CONCLUSIONS. Interpretation of Pvaco2 changes (or of absence of changes) must be particularly cautious. The changes in Pvaco2 gap should not be used as guiding tools for fluid challenge in patients with end stage liver disease post liver transplantation.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1274

INTRODUCTION. The resuscitation of the critically ill patient requires a goal-directed fluid therapy based on an accurate assessment of intravascular fluid volume and fluid responsiveness (FR). In the past years, respiratory variation in inferior vena cava diameter (ΔIVC) assessed by bedside ultrasonography is increasingly used as predictor of FR. However, published studies show conflicting results about the predictive value of ΔIVC.
OBJECTIVE. To review the current evidence for of ΔIVC in predicting fluid responsiveness.
METHODS. A meta-analysis was performed to assess the diagnostic accuracy of ΔIVC in predicting fluid responsiveness. Subgroup analyses were performed for patients on mechanical ventilation and spontaneously breathing patients. A total of 13 eligible studies (four

with spontaneously breathing patients and 9 studies with patients under mechanical ventilation) with a total of 1025 patients were included.

RESULTS. In spontaneously breathing patients (n = 230, 122 fluid responders (53.0%)), the pooled sensitivity and specificity were 78.2% (95% CI 66.7-87.8%) and 91.8 % (95% CI 82.7-97.7 %), respectively. Reported best cutoff was 35.5 ± 16.0 %. Pooled studies were characterized by moderate heterogeneity (I2=52.77%, p=0.09). For patients under mechanical ventilation (n= 795, 365 fluid responders (45.9%), pooled sensitivity and specificity were 67.1 % (95% CI 54.6-78.4%) and 78.6 % (95% CI 67.3-87.9%), respectively. Mean cut-off was 18.6 ± 11.0%. Pooled studies were characterized by substantial heterogeneity (I^2=73.82%).

CONCLUSION. The present study suggests that ΔIVC assessed by echocardiography might represent a reliable predictor of FR in critically ill patients. However, included studies are limited by small sample size, different populations and a significant heterogeneity. In addition, cutoff values of ΔIVC varied significantly across studies.

Assessment of stroke volume after cardiac surgery: comparison of transesophageal echocardiography and thermodilution with pulmonary artery catheter

K. Pilarczyk[1], J. Lubarski[2], J. Franke[2], F. Dusse[3], D. Dohle[4], H. Jakob[2]
[1]imland Klinik Rendsburg, managed by Sana Kliniken AG, Department of Intensive Care Medicine, Rendsburg, Germany; [2]West German Heart and Vascular Center Essen, University Hospital Essen, Department of Thoracic and Cardiovascular Surgery, Essen, Germany; [3]University Witten/ Herdecke, Hospital Cologne-Merheim, Department of Anesthesiology and Intensive Care Medicine, Cologne, Germany; [4]University of Mainz, Department of Cardiothoracic and Vascular Surgery, Mainz, Germany
Correspondence: K. Pilarczyk

INTRODUCTION. Echocardiography is increasingly used for hemodynamic evaluation and monitoring in critically ill patients. However, recent studies enhanced concerns about the interchangeability of stroke volume (SV) measurement using echocardiography and pulmonary artery catheter (PAC) thermodilution (TD) technique.

OBJECTIVE. The aim of this study was to compare these SV measurement techniques in respect of precision, accuracy, and trending ability.

METHODS. We performed a comparison of SV measurements obtained with transesophageal echocardiography (TEE) assessing the velocity time integral in the LVOT and PAC-TD. 40 consecutive hemodynamically stable patients undergoing cardiac surgery were enrolled in this study. SV was measured with PAC and TEE at 6 different time points: 1. Baseline (PEEP = 5-10cm H_2O), 2. PEEP challenge (PEEP + 10 cm H_2O for 5 minutes), 3. Baseline II (PEEP = initial value), 4. After passive leg raising 5. Baseline III (PEEP = initial value). 6. after a crystalloid fluid challenge of 6ml/kgBW. Measurements of stroke volume obtained by both techniques were compared using t-tests, correlation analyses and a Bland-Altman plot. A mean percentage error ≤30% for SV assessment by TEE was defined to indicate clinical reliability.

RESULTS. Mean stroke volume assessed by PAC was 64.4 ± 19.1 ml vs. 60.7 ± 15.4 ml in TEE (p = 0.01). Both measurements showed a correlation coefficient of 0.69 (95%CI 0.62-0.75, p< 0.001). Bland-Altmann-analyses revealed a mean difference (bias) of 3.7 ± 14.0 ml and limits of agreement were 23.8 ml and 31.5 ml. The percentage error of TEE was 45.7 %. After exclusion of small SV changes < 15% as grey zone, TEE correctly tracked the direction of stroke volume changes in 85% of measurements.

CONCLUSION. SV measurements with TEE had wide limits of agreement and a large percentage error. Thus, TEE seems not to be suitable to replace SV measurements performed by PAC TD. However, an acceptable trending ability was found and therefore, TEE could be a valuable tool in guiding therapy in mechanically ventilated patients after cardiac surgery.

Perioperative continuous cardiac monitoring for cardiac surgery

R. Barnett
Holy Spirit Northside Private Hospital, Intensive Care Unit, Brisbane, Australia

INTRODUCTION. Cardiac surgery has a quoted mortality rate of 3-5%. However as more cases are being performed for prognostic rather than symptom alleviation reasons it is important that mortality rates are forced closer to nil. The principle driver of morbidity and mortality is haemodynamic instability. Clinical evaluation of haemodynamic state is notoriously difficult without the measurement of cardiac output. Fortunately there are now a number of continuous cardiac output (CCO) monitors available for clinical use throughout the entire perioperative period.

OBJECTIVES. As part of a Quality Assurance Program our institution decided to implement CCO on all cardiac surgical cases for a six-month period, July 2017-December 2017 then compare the outcomes with a preceding period (Jan-Dec 2016) to determine if an improvement to patient outcomes could be achieved.

METHODS. A selection of CCO monitors (CCO Swan-Ganz, Volume View, Flotrac, PICCO, CardioQ) were evaluated against performance criteria of accuracy, simplicity, risk and cost. The Edwards Lifesciences Flotrac monitor was selected and haemodynamic profile specific management protocols were developed. CCO monitoring was performed on all cardiac surgical cases from July-December 2017. Data was then compared with the data routinely collected on all cardiac surgical cases for the 2016 calendar year, where CCO monitoring was not available. The predetermined points of comparison where ICU LOS, Hospital mortality and Standardized Mortality Ratio using Australian and New Zealand Risk of Death predictive Model (ANZROD).

RESULTS. Between time periods, there were no statistical differences in patient characteristics, with respect to age, gender, ethnicity, type of cardiac surgery and ANZROD.
In total 942 patients data was analysed 626 vs 316. ICU LOS 67 +/-98hrs vs 78+/-114, Hosp Mortality 1.92% vs0.95% were not significantly different. Standardised Mortality Rate 1.13 vs 0.7 (p-0.045) was significantly different.
The increase in LOS was entirely attributable to the fall in deaths, with deaths occurring early, and decreasing LOS.

CONCLUSIONS. Our data confirms that cardiac surgical mortality is falling. The introduction of CCO monitoring and haemodynamic profile specific management algorithms significantly reduced risk adjusted mortality rate while not significantly altering LOS. We would encourage all ICU's to consider CCO monitoring as being part of minimum monitoring for post-operative cardiac surgical cases.

1277

Continuous monitoring of dynamic arterial elastance by pulse pressure contour analysis during the early phase of septic shock

P. Revuelta
Hospital Universitario de Guadalajara, Intensive Care Unit, Guadalajara, Spain

INTRODUCTION. The relation of pulse pressure variation to stroke volume variation (PPV/SVV) is referred as dynamica arterial eastance

(Eadyn), and was originally conceived to answer a direct clinical question: in the setting of arterial hypotension, will increases in cardiac outpout (CO) also increase arterial pressure?(1). Eadyn has therefore been considered as a functional measure of the arterial load. Contrary to the static nature of any component of arterial load, Eadyn has therefore been considered as a functional measure of the arterial load, Since Eadyn is measured of asingle breth,increases in left ventricular contractility may cause Eadyn to increase even though actual arterial elastance (EaZ) remains unaltered, because if the rate of ventricular ejection , and aotric blood accelerates (as occurs with increase ventricular initropy) the arterial pulse pressure will increase for a given SV. Therefore changes in arterial load or in he pattern of blood flow should affect Eadyn (2), similarly to changes in oreload or cardiac function thay affect the preload-responsiveness parameters. Consequenty, Eadyn should be considered as a functional of rterail load in the same terms that preload-responsiveness relate to cardiac preload.

OBJECTIVES. To assess the stability or the variation range, of continuous monitoring of Eadyn under "steady-state" conditions (normotensive, and no changes in volume infusion nor in vasopressor doses), during he early phase of septic shock, after initial resuscitation.

METHODS AND RESULTS. Five male patients admitted to the ICU with septic shock after early resuscitation. All in sinus rythm receiving volume controlled ventilation. None of them fullfilled criteria for ARDS. Preload depence was evaluated by. SVV >15% with a positive leg raising test. Initial volume expansion and noradrenaline infusion rates at phycisian decision, to achieve a mean arterial pressure (MAP) ≥ 70 mmHg. Pulse pressure contour analysis monitoring was used with the FloTrac System 4.0, integrated algoritms. Data were continiuosly registered every 12 seconds and saved after15 minutes at least, of steady-state condition exported and processed by data depuration and processing with a generated command algorithm with Stata 15/C statistical package, Statistical parametric descriptive tests and graphics were performed.

CONCLUSIONS. Eadyn contimuous monitoring in septic chock patients during steady state conditions, may b a useful tool for clinical decision but our results show that its value is not stable and ranges between 0.6 to 1,3.

Correlation between peripheral and central venous blood partial pressure of carbon dioxide in critically ill patients with shock

C. Karnjanarachata[1], T. Pravitharangul[1], S. Morakul[1], P. Theerawit[2]
[1]Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Department of Anesthesiology, Bangkok, Thailand; [2]Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Department of Internal Medicine, Bangkok, Thailand
Correspondence: T. Pravitharangul

INTRODUCTION. Adequacy of tissue perfusion during shock resuscitation is crucial. Central venous-to-arterial carbon dioxide gap (CO_2 gap, P(cv-a) CO_2) is widely used to assess adequacy of tissue perfusion to guide resuscitation, however; central venous catheter is needed for central venous carbon dioxide tension ($PcvCO_2$). Central venous catheter insertion is not without risk while the benefit became less apparent. Since, superior vena cava receives venous drainage from

Fig. 1 (abstract 1277). SSV_PPV

upper part of the body, upper extremity peripheral venous blood may be considered to be less invasive alternative for $PcvCO_2$.

OBJECTIVES. To determine correlation and relationship between peripheral and central venous blood partial pressure of carbon dioxide in critically ill patients with shock.

METHODS. Single center, observational study. Paired sample of 1 ml upper extremity peripheral and 1 ml central venous blood was taken simultaneously from intensive care unit adult patients receiving vasopressor or inotropic drug who already had central venous catheter in place. Only one paired sample per day and maximum of 3 paired samples were allowed for one patient. All samples underwent blood gas analysis. Data on carbon dioxide tension was then analyzed using intraclass correlation coefficient (ICC) and Bland-Altman plot.

RESULTS. 30 paired samples were obtained from 12 patients (2 medical and 1 surgical intensive care units) aged between 53-90 years who receiving norepinephrine infusion ranged from 0.01 to 0.95 mcg/kg/min actual body weight. The intraclass correlation revealed that peripheral venous carbon dioxide tension ($PpvCO_2$) was significantly associated with $PcvCO_2$ [ICC 0.98 (95% confidence interval 0.96-0.99); P< 0.001]. A The Bland-Altman plot demonstrated mean bias of 0.2 with the limits of agreement of -5.3 to 5.8.

CONCLUSIONS. The study revealed excellent correlation between $PpvCO_2$ and $PcvCO_2$ in critically ill patients with shock.

Reassessment of the accuracy of cardiac Doppler pulmonary artery pressures measurements in ventilated ICU patients: a simultaneous Doppler-catheterization study

Y. Zerbib[1], P. Mercado[2], J. Maizel[1], C. Beyls[1], L. Kontar[1], S. Orde[3], S. Huang[3], A. McLean[3], C. Tribouilloy[4], M. Slama[1]

INTRODUCTION. Doppler echocardiography (DE) is a well-recognized technique for the non-invasive evaluation of pulmonary artery pressure (PAP) but little information is available concerning patients under mechanical ventilation (MV). Furthermore, recent studies have reported reservation regarding the relevance of this technique to assess PAP.

The aim was to reassess the accuracy of DE to evaluate PAP and to predict pulmonary hypertension (PH).

METHODS. Prospective observational study in Amiens ICU, France. In 40 patients under MV we simultaneously recorded DE parameters (from tricuspid (TR) and pulmonary (PR) regurgitations) and invasive central venous pressure (CVP), systolic (SPAP), diastolic and mean (MPAP) PAP.

RESULTS. SPAP assessed from the TR derived maximal pressure gradient added to the CVP demonstrated the best correlation with the invasive SPAP (r=0.87) with a small bias (-3 mmHg) and a precision of 9 mmHg. A DE SPAP>39 mmHg predicted a PH (MPAP≥25 mmHg) with 100% sensitivity and specificity. TR maximal velocity >2.82 m/s as well as TR pressure gradient >32 mmHg predicted the presence of PH well. PR was recorded in 10 patients (25%). No correlation was found between PR velocities and PAP. Pulmonary acceleration time< 57ms and isovolumic relaxation time < 40ms respectively predicted pulmonary hypertension in 100% of time and had 100% of negative predictive value

CONCLUSIONS. When present, TR maximal velocity pressure gradient added, or not, to invasive CVP seems to assess accurately systolic and mean PAP in ICU MV patients and may predict PH.

INTRODUCTION. Cardiac output is the most frequent advanced monitoring in critical care units given its utility to guide resuscitation in septic shock. Recently there's a preference of less invasive techniques for cardiac output measurement in order to reduce the implicit risks of invasive techniques. Echocardiography has been postulated has the gold standard for non-invasive cardiac output measurement, however this technique is operator-dependent and should be performed by an expert. Other techniques such as bioreactance and Doppler monitoring by semiautomatic USCOM system are a 100% non-invasive techniques, also these measurements are not operator or expert dependent.

OBJECTIVE. To analyze the agreement of cardiac output by echocardiography vs Bioreactance and semiautomatic Doppler of the USCOM system.

METHODS. Prospective observational study in which 26 patients diagnosed with septic shock admitted to the intensive care unit were cardiac output was measured by echocardiography, bioreactance and USCOM system. Bland Altman method was performed to analyze the agreement between the different techniques: Echocardiography Vs USCOM and Echocardiography Vs Bioreactance. Also Linn coefficient was calculated in the same groups of measurements.

RESULTS. Bioreactance vs echocardiography reported a bias (mean of the differences) of -0.08 with a standard deviation (precision) of 0.85 and a 95% confidence interval of 1.59 to -1.75, finally an error of 24% and Linn coefficient of 0.78.

USCOM vs echocardiography reported a bias (mean of the differences) of 1.11 with a standard deviation (precision) of 0.95 and a 95% confidence interval of 2.98 to -0.75, finally an error of 41% and Linn coefficient of 0.6.

CONCLUSIONS. Bioreactance is a promising technique for cardiac output measurement given its good agreement with echocardiography, in the other hand USCOM did not showed a satisfactory agreement with echocardiography, more studies are needed to verify the clinical usefulness of these different techniques.

INTRODUCTION. Mixed venous-to-arterial carbon dioxide tension difference ($P_{(v-a)}CO_2$) is an easily derived parameter which is inversely related to cardiac index (CI). Bolus fluid treatment (BFT) is a tool for critically ill patients with hypovolemia where changes in CI and oxygen consumption (VO_2) are expected.

OBJECTIVES. This study aimed to investigate the changes of $P_{(v-a)}CO_2$ after BFT.

METHODS. Prospective observational study in adult critically ill patients. CI was measured either by echocardiography or by thermodilutional method. Haemodynamic measurements and blood gas analysis were obtained before and after fluid challenge with either 1000 ml crystalloid or 500 ml colloid . Arterial and central venous blood gas samples were taken simultaneously. VO_2 was calculated according to Fick formula. $P_{(v-a)}CO_2$ was calculated before and after BFT. Patients were divided into responders and non-responders according to their change in CI (> 15%). Changes in $VO2 \geq 15\%$ were considered significant.

RESULTS. We assessed 68 patients (69 ± 16 years, APACHE II score 22.7 ± 8) that received BFT. Twenty-five patients were responders to BFT (36%). We found no correlation of changes in $P_{(v-a)}CO_2$ and changes in CI after BFT ($r^2 = 0.01$, $p = 0.26$). No change in $P_{(v-a)}CO_2$ was observed in non-responders (7.9 ± 0.6 vs. 7.7 ± 0.6 mmHg, $p = 0.87$). A significant decrease in $P_{(v-a)}CO_2$ was observed in responders to BFT (7.9 ± 4 vs. 6.1 ± 3 mmHg, $p = 0.01$). However, a decrease in $P_{(v-a)}CO_2$ was unable to differentiate responders from non-responders (AUC: 0.65, 95%CI 0.46-0.74, $p = 0.15$). Thirty-five patients did not have any significant change in VO_2 after BFT. In these patients, we did not observe any statistical significant change in $P_{(v-a)}CO_2$ (6.5 ± 0.5 vs. 7.4 ± 0.7 mmHg, $p = 0.21$), and in mixed central venous saturation ($S_{cv}O_2$) ($66 \pm 2\%$ vs. 66 ± 2 %, $p = 0.69$). The change in CI in this group of patients was $7.9 \pm 2\%$. Ten patients had a significant decrease in VO_2 after BFT. $P_{(v-a)}CO_2$ significantly decreased in these patients (9.8 ± 0.9 vs. 6.6 ± 0.7 mmHg, $p = 0.01$). However, an important increase in $S_{cv}O_2$ was observed ($62 \pm 4\%$ vs. $67 \pm 3\%$, $p = 0.03$) in these patients despite no significant change in CI ($3 \pm 4\%$). Twenty-two patients had a significant increase in VO_2. We observed a statistically significant decrease in $P_{(v-a)}CO_2$ (9.4 ± 1 vs. 6.9 ± 0.7 mmHg, $p < 0.01$) and in $S_{cv}O_2$ (68% vs. 65% $p < 0.01$). Also, a significant increase in CI was detected in these patients ($32 \pm 6\%$).

CONCLUSIONS. Significant changes in $P_{(v-a)}CO_2$ can be observed after BFT. A decrease in $P_{(v-a)}CO_2$ was mostly observed in responders. However, in several patients with a decrease in VO_2, likely to reflect a spontaneous decrease in metabolism, we observe a decrease in $P_{(v-a)}CO_2$ combined with an increase in $S_{cv}O_2$. The combination of changes in $P_{(v-a)}CO_2$ and $S_{cv}O_2$ might be useful to differentiate changes in VO_2 related to spontaneous changes and changes in response to BFT in order to further guide therapy.

Prediction of fluid responsiveness in the immediate post-operative period of cardiac surgery

B.B. Albano, L.M. Habana
Philippine Heart Center, Adult Cardiology, Division of Critical Care, Quezon City, Philippines
Correspondence: B.B. Albano
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1282

INTRODUCTION. Fluid replacement is most important therapeutic intervention in critically-ill patients including those in the post-operative period of cardiac surgery [1]. However, giving fluids does not always improve hemodynamics as one expects [2]. In fact, only 50% of these patients will benefit from fluid loading while the rest will suffer from the danger of over hydration [3]. Prediction of fluid responsiveness can identify patients who will benefit from fluid loading. Several hemodynamic parameters may help identify those who will benefit from hydration.

OBJECTIVES. This study aimed to determine and compare the parameters that predict fluid responsiveness in post-cardiac surgery patients; and to identify which tool is most accurate to guide initiation of fluid therapy in this clinical setting.

METHODS. This prospective cohort study included 101 post-cardiac surgery patients. Hemodynamic parameters were recorded at baseline and after an 8 mL/kg IV fluid challenge. Fluid responders were those with an increase in stroke volume of $\geq 15\%$. Multivariate analysis was used to identify independent predictors of fluid responder status. Sensitivity and

specificity analyses were done to determine the predictive accuracy of each parameter.

RESULTS. The rate of fluid responsiveness in this study was 54.5%. Independent predictors of fluid responsiveness were: central venous pressure (CVP) ≤ 6 mmHg (p=0.001), pulmonary artery occlusion pressure (PAOP) ≤ 12 mmHg (p=0.016), PAOP increase by ≥ 7 mmHg (p=0.002), pulse pressure variability (PPV) >12% (p< 0.001), PPV decrease by >5% (p=0.049) and weight (p=0.04). PPV>12% was the most sensitive (92%), while PPV decrease by >5% was the most specific (79%); while PAOP was the least sensitive (70%) and CVP the least specific (51%). PPV had the highest ability to discriminate fluid responders (AUC 0.83) compared to PAOP (AUC 0.21) and CVP (AUC 0.40) (p< 0.0001).

CONCLUSIONS. PPV (a dynamic index) is superior to CVP and PAOP (static indices) in discriminating fluid responders in adult patients who underwent cardiac surgery. PPV is the favored tool to guide initiation of fluid therapy in this clinical setting. However, in the absence of PPV monitoring, relying on CVP and PAOP may still be considered, although these have lower accuracy compared to PPV.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1283

INTRODUCTION. Patients undergoing cardiac surgery often have vasoplegia, defined by low systemic vascular resistance and high cardiac output, due to cardiopulmonary bypass. Postoperative fluid management can be difficult in this population. Peripheral Intravenous Analysis (PIVA) has been shown to detect blood loss prior to arterial and pulmonary artery pressure in human subjects and in a porcine animal model of hemorrhage (1,2). We hypothesize that PIVA will detect volume responsiveness in post-cardiac surgery subjects with vasoplegia.

OBJECTIVES.

1. Determine the utility of PIVA in post cardiac surgery patients with vasoplegia.
2. Determine the correlation between PIVA and change in cardiac output with fluid administration.

METHODS. Thirty post cardiac surgery subjects were enrolled in the intensive care unit at Vanderbilt University Medical Center. All subjects were intubated, mechanically ventilated, with a right internal jugular and pulmonary artery catheter (Edwards Lifesciences, CA, USA) in place. All subjects required norepinephrine (between 1-10 mcg/min) to maintain a mean arterial pressure>60mmHg. A TruWave pressure transducer (Edwards Lifesciences, CA, USA) was connected directly to a dedicated arm peripheral IV, 18g or 20g. Subjects received 500mL

Plasmalyte (Baxter International, USA) bolus over 5 minutes. Thermodilution cardiac output was obtained before and after the fluid bolus. Data was stored on a desktop computer and analyzed using automated software to determine PIVA Score using an algorithm based on the Fourier transformation of the peripheral venous waveform (Figure 1).

RESULTS. Twenty-nine post-cardiac surgery subjects were successfully enrolled and initial hemodynamic parameters were used to predict fluid responsiveness. All subjects had a systemic vascular resistance < 1000 dynes·sec·cm^{-5}.There was significantly significant correlation ($p< 0.05$, $r=-0.44$) between baseline PIVA score and change in cardiac output with fluid administration (Figure 2). Central venous pressure did not have a significant correlation with percent change in cardiac output ($p=0.242$, $r=0.24$). Diastolic pulmonary artery pressure had a non-significant correlation with percent change in cardiac output ($p=0.063$, $r=0.36$).

CONCLUSIONS. PIVA predicts fluid responsiveness in postoperative cardiac surgery patients with vasoplegia. These results warrant further investigation in patients with distributive shock including sepsis and burn injuries.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1284

INTRODUCTION. The venous-arterial CO2 to arterial-venous O2 content difference ratio (DvaCO2/ΔCavO2) has been correlated with anaerobic metabolism during tissular hypoxia in shock[1], and different studies have used it to guide resuscitation and have demonstrated impact in mortality and prognosis[2].

OBJECTIVES. The aim of this study was to evaluate the statistical value of the DvaCO2/ΔCavO2 in critically ill patients with septic shock diagnosis after fulfilled resuscitation. As secondary outcome, DvaCO2/ΔCavO2 was compared with a simplified formula with venous gasometrical parameters.

METHODS. We retrospectively studied 110 septic shock patients with available data of arterial and venous gasometrical parameters at admission, and at the time of concluding resuscitation according with intensivist criteria, between 24-48 hours from ICU admission. DvaCO2/ΔCavO2 was calculated derived from oxygen content of blood formulas. All variables showed a normal distribution so were reported as mean and standard deviation, considering statistically significant p values < 0.05, evaluated through OpenEpi software version 2013. Student's T-test was used to compare survivors and non-survivors groups. A simplified empirical formula was proposed based only in venous gasometrical values $((100-SvO2)/(100-PvCO2))$. According with previous studies, a cut-off value of DvaCO2/ΔCavO2 $>1,4$ was set for mortality analysis[3], and for our proposed formula the cut-off value was 0.6. Sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were determined, by calculating Cohen's kappa coefficient. Afterwards, a Bayesian analysis was tested to determine the prognostic value for both formulas.

RESULTS. Demographic characteristics between both groups were similar. Mortality was 35%, similar to previous reports for septic shock. Cardiac output showed greater values in survivors group (5.9 ±1.4 vs 5.1±2.5 L/min, $p< 0.001$), while the same group reported smaller values for DvaCO2 (3.9±1.3 vs 9.2±1.9 mmHg, $p< 0.05$), lactate (1.4±0.7 vs 4.6±3.1 mmol/L, $p< 0.05$) and DvaCO2/ΔCavO2 (1.1±0.4 vs 1.6±0.8, $p< 0.0001$). DvaCO2/ΔCavO2 sensibility was 53.8% and specificity was 87.3%. For the simplified formula sensibility was 94.8% and specificity was 83.1%. Bayesian analysis for DvaCO2/ΔCavO2 founded a positive likelihood ratio (LR) of 4.2 and a negative LR 0.5, values that improved with the simplified formula to +LR 5.6 and -LR 0.06.
CONCLUSIONS. A simplified formula with venous gasometrical parameters shows favorable results to be implement as a subrogate of DvaCO2/ΔCavO2. Prospective studies are required to obtain better statistical power, as well as an external validation to establish its usefulness in critically ill patients without needing arterial blood samples.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1285

INTRODUCTION. The Photoplethysmography (PPG) signal is a critical vital sign in the Intensive Care Unit (ICU). Due to limitations in sensor technology, current approaches in PPG signal collection are easily affected by artifacts, generating numerous false alerts and impeding successful integration of PPG for the purpose of developing robust predictive analytics.
OBJECTIVES. We propose a beat-to-beat (B2B) real-time PPG signal artifacts removal approach using machine learning.

METHODS. We extracted PPG signals from patients included in the Medical Information Mart for Intensive Care (MIMIC) III Waveform Database [1]. The PPG signal was split into 60-second non-overlapping data frames. In this study, a Hilbert-Huang transformation [2] was applied to detect the signature. The signature of clean, artifact free signals is characterized by low power in the low frequency domain (0-0.8Hz) of its spectrum. If deviations from this normal signature were detected in a data frame, a beat-to-beat artifact detection algorithm (B2BA) was applied to each beat. B2BA was developed as follows: A sample of PPG waveforms were classified manually as acceptable (A) or unacceptable (U) as per visual quality. After waveform rescaling, twelve distance metrics to a common ideal waveform template were generated. A logistic regression model was constructed to produce a probability of acceptability for each beat.

RESULTS. 2286 PPG waveforms (30 data frames) were used for model development and testing, where 1039 PPG waveforms (13 data frames) were detected as artifact-free by HH and did not need B2BA. In B2BA development, 1247 PPG waveforms (623 training set, 624 test set) were used. All twelve distance metrics were significantly different between A and U in univariate analysis. The B2BA discriminated well between the A and U with receiver operating characteristic (ROC) area under the curve performance of 0.908 in the test set. To evaluate real-time potential, the model was deployed to waveform data from 986 ICU admissions (865 monitoring hours). A typical example of artifact removal is shown in Fig.1. Total computation time for a 30-minute PPG waveform was 15.84 seconds in a conventional workstation (Intel Xeon E5520, 76GB).

CONCLUSIONS. We proposed a real-time artifact removal system for PPG signal. This machine learning based approach achieves both efficiency and accuracy in artifact removal.

INTRODUCTION. Pulmonary artery occlusion pressure (PAOP) is a valuable tool for the management of critically ill patients. In ventilated critically ill patients, few studies have evaluated transthoracic echocardiography (TTE) to predict PAOP and conflicting data are available. The objective of the present study was to evaluate the predictive value of TTE to predict PAOP in this population.

METHODS. In 53 mechanically ventilated patients PAOP was measured using a pulmonary arterial catheter (PAC). TTE was used to estimate PAOP based on mitral flow and tissue Doppler Imaging (TDI) of mitral annulus.

RESULTS. Seventy nine TTE measurements were recorded, of them 10 were excluded by monophasic mitral flux. There was a weak correlation between the PAOP measurements and lateral E/E' (r=0.31; p< 0.0094), E/A (r=0.37; p< 0.0018) and TDE (r=-0.29; p< 0.02). The area under the ROC curve [95%CI] for the ability of lateral E/E' for detecting a PAOP≥18 mmHg was 0.59 [0.46-0.71] and an E/E'>15 could detect a PAOP≥18 mmHg with a sensitivity of 33% and specificity of 98%. The area under the ROC curve [95%CI] for the ability of E/A for detecting a PAOP≥18 mmHg was 0.73 [0.61-0.83] and an E/A > 1.75 could detect a PAOP≥18 mmHg with a sensitivity of 56% and specificity of 94%. When using both echocardiographic cutoff obtained with the ROC curves we found that by measuring lateral E/E' of more than 15 and an E/A of more than 1.75 a PAOP≥18 mmHg could be detected with a 18% of sensibility and 98% of specificity.

CONCLUSION. In critically ill mechanically ventilated patients, E/E' ratio>15 and or E/A ratio>1.75 predicted PAOP>18 mmHg with high specificity. However, a majority of patients were in the grey zone preventing any estimation of PAOP using Doppler technique.

Assessing the accuracy of focused intensive care echocardiography (FICE)

J. McLoughlin, T. Samuels, R. Kumar
Surrey and Sussex Healthcare NHS Trust, Critical Care, Redhill, United Kingdom
Correspondence: J. McLoughlin
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1287

INTRODUCTION. Focused Intensive Care Echocardiography (FICE) scans are undertaken in critically ill patients, contributing to overall assessment and aiding decisions regarding treatment.

OBJECTIVES. The aim of the study was to compare the qualitative results from patients who had undergone FICE scans to the quantitative measurements of their formal echocardiogram.

METHODS. Over a period of 3 months we recorded 28 patients, from which 15 had also received a subsequent formal echocardiogram. We compared the ability of FICE scans to correctly identify both left and right ventricular significant impairment and dilatation. On the formal echocardiogram, we used the left ventricular ejection fraction (LVEF) of < 35% as significant impairment, left ventricular internal diameter (diastole) (LVIDd) > 6.2 cm for female patients and > 6.9 cm

for male patients for significant dilatation, right ventricle (RV) basal diameter > 4.2 cm for dilatation and tricuspid annular plane systolic excursion (TAPSE) < 1.6 cm for significant impairment.[1]

RESULTS. The results are collated and shown in Table 1.

CONCLUSIONS. FICE is a useful tool in detecting gross abnormalities in patients in the critical care setting. Our results suggest that at our institution FICE is more accurate at assessing the left ventricle than the right. None of our FICE scans undertaken fully contradicted the formal echo report. Further research is required to assess the impact of FICE scanning in critical care and its accuracy when compared to formal echo.

INTRODUCTION. Traumatic brain injury (TBI) is often associated with acute subdural hematoma (ASDH), which has been reported to be a major determinant of post-TBI outcome[1], in a particular in the elderly and/or cardiovascular co-morbid patient[2]. The guidelines for the management of TBI include control of intracranial pressure (ICP) and maintenance of cerebral perfusion pressure (CPP) as well as prevention of hypoxia by measurement of partial pressure of oxygen (PtcO$_2$) in brain tissue[3].

OBJECTIVE. We established a long-term, resuscitated porcine model of TBI to study the effects of unilateral ASDH on parameters of brain multimodal monitoring.

METHODS. Anesthetized, mechanically ventilated and surgically instrumented pigs (n=9, bodyweight 57-71kg) with human-like co-agulation[4] underwent TBI induced by trepanation above the left parietal cortex and subdural injection of 20mL of blood[5]. After induction of unilateral ASDH, animals underwent intensive care therapy according to the guidelines of TBI management[3] for up to 54 hours. Multimodal brain monitoring included measurement of ICP, CPP, brain temperature and PtcO$_2$ of both the injured (ipsilateral) and non-

injured (contralateral) side together with systemic hemodynamics, gas exchange, acid-base status, and metabolism. Resuscitation comprised fluid infusion and continuous i.v. norepinephrine to maintain mean arterial pressure (MAP) at pre-ASDH levels and CPP>75mmHg. Data is presented as median and interquartile range.

RESULTS. ICP after surgical instrumentation was similar at the ipsilateral and the contralateral side (2 [-2;16] and 2 [-2;8] mmHg, p=0.87). Subdural blood injection caused a transitory increase in ICP (individual peak values up to 50mmHg). The time course of the parameters of multimodal brain monitoring did not differ between the ipsi- and contra-lateral brain hemisphere: ICP 18 (12;23) vs. 14 (12;18) mmHg, p=0.19; CPP 112 (92;118) vs. 103 (77;117) mmHg, p=0.73; brain temperature 38.2 (38.1;38.3) vs. 38.2 (38.0;38.6) °C, p=0.96; PtcO$_2$ 20 (11;25) vs. 25 (10;37) mmHg, p=0.65 at the end of the experiment. Nevertheless, upon necropsy the ipsilateral hemisphere showed major macroscopic and microscopic morphological damage.

CONCLUSION. Our long-term, resuscitated porcine model of unilateral ASDH-induced TBI did not show any differences with respect to multimodal brain monitoring despite major morphological damage of the injured brain hemisphere.

Critical care follow up organisation with technology support: a feasibility survey to explore the utility of an "app" based post-critical illness support

J. McKenna[1], T. Price[2], M. Shyamsundar[1]
[1]Queen's University Belfast, Centre for Experimental Medicine, Belfast, United Kingdom; [2]Royal Victoria Hospital, Regional Intensive Care Unit, Belfast, United Kingdom
Correspondence: J. McKenna
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1289

INTRODUCTION. Technology is permeating every-day life and health-care apps can be leveraged to study outcomes post critical illness (1). Post-intensive care syndrome (PICS) is increasingly recognised as a significant contributor to post critical illness morbidity. Despite the importance of identifying PICS various interventions such as follow up clinics have failed to show impact. A web based or "app" based follow up could have advantages in being cost effective, ability to have longer and closer follow up, identification of trends in physical and psychological recovery, personalised approach by identifying only the patients showing deterioration or lack of improvement. Critical care population is following the trend in other specialities with patients being of older age group and could have significant co-morbidities which might limit their interaction with technology. This survey was conducted to identify the attitude and perceptions of patients admitted to critical care regarding the use of technology for follow up after critical illness.

OBJECTIVES. Understand the use of communication devices, pattern of interaction and attitude of patients admitted to critical care.

METHODS. A questionnaire survey of patients admitted to the Regional Intensive Care Unit (RICU), Royal Victoria Hospital, Belfast over an 8 week period. RICU is a tertiary trauma centre and a mixed medical surgical ICU. 35 patients completed the survey. Data was collected on demographics, use of communication devices, educational status, interaction with the technological device, use of internet, duration of device use per day. Their attitude towards technology based follow up was explored.

RESULTS. Thirty-five patients completed the questionnaire, 51.4% were > 60 years of age and 48.6% were female. 89% of patients had access to at least one internet enabled device and 91.4% of patients engaged in complex interactions such as completing surveys. 94% patients

surveyed would be receptive to a technology based follow up would support their next of kin submitting responses on their behalf.

CONCLUSIONS. This survey demonstrates the increasing age of patients surviving critical illness. Despite their age, they have significant knowledge and use of communication devices and engage in complex online interactions and are receptive to the use of technology supported follow up care. A technology supported follow up service has the potential to be cost effective, allow closer and longer monitoring of patients. This approach could enable us identify patients in need of face to face follow up and personalise our approach to follow up and improve PICS outcomes.

Arterial pressure and vasopressor dose as predictors of mortality in patients with distributive shock

N.D. Nielsen[1], J.-L. Vincent[2], N.I. Shapiro[3], M.E. Gerbasi[4], A. Grossman[4], R. Doroff[4], G. Oster[4], F. Zeng[5], P. Young[6], J.A. Russell[7]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1290

INTRODUCTION. Distributive shock (DS) is a disease with high mortality rate. The management of DS calls for a careful balance between catecholamine dose and maintenance of sufficient blood pressure. The association of norepinephrine-equivalent dose (NED) and hypotension and their interaction with mortality in a real-world setting is not fully defined.

OBJECTIVES. The Medical Information Mart for Intensive Care (MIMIC-III) database was used to examine the predictors of mortality in patients with DS in a real-world setting. We were particularly interested in the association of hypotension time and maximum NED on intensive care unit (ICU) mortality, as well as their combined interaction with mortality.

METHODS. We identified patients with DS in the MIMIC-III database which contains information for 61,532 admissions to ICU at Beth Israel Deaconess Medical Center (BIDMC) in Boston between 2001 and 2012. Inclusion criteria: 1) ≥18 years, 2) treated with vasopressors for ≥6 hours, and 3) no indications of other conditions for which vasopressors are standard treatment, such as cardiogenic, hypovolemic, or obstructive shock. Patient baseline MAP was categorized as above or below 65 mmHg at initiation of vasopressors. Patient hypotension time was categorized as greater than or less than 2 hours spent continuously below 65 mmHg during the ICU stay. Maximum catecholamine dose was represented by categorical variables based on NED: < 0.2, ≥0.2-0.5, ≥0.5-1, ≥1-1.5, ≥1.5-2, ≥2-2.5, and ≥2.5 µg/kg/min. We performed a logistic regression with ICU mortality as the primary outcome. Control variables: age, gender, source of sepsis and sequential organ failure assessment (SOFA) scores at ICU admission.

RESULTS. Of 5347 patients with DS, 4995 had MAP recorded at initiation of vasopressors. Among these patients, 53% had MAP ≥65 mmHg at vasopressor initiation; 62% of patients stayed below 65 mmHg continuously for at least 2 hours. 40%, 31%, 16%, 7%, 2%, 1% and 3% of patients had a maximum NED of < 0.2, ≥0.2-0.5, ≥0.5-1, ≥1-1.5, ≥1.5-2, ≥2-2.5, and ≥2.5 µg/kg/min, respectively. The logistic regression results show that baseline MAP < 65 mmHg (odds ratio [OR]=1.27, p=0.0007) and MAP below 65 mmHg continuously for ≥2 hours (OR=1.78, p< 0.0001) were associated with higher mortality. When compared to patients with a max NED of 0.0-0.2, patients with max NED ≥0.2 all had significantly higher mortality, and mortality generally increased with NED: ≥0.2-0.5, OR = 2.43; ≥0.5-1.0, OR=5.33; ≥1.0-1.5, OR=7.78; ≥1.5-2.0, OR=10.41; ≥2.0-2.5, OR=13.76; ≥2.5, OR=7.84. Interaction terms between hypotension time and maximum NED were not significant.

CONCLUSIONS. We found that longer hypotension time and higher maximum NED were individually associated with higher ICU mortality rates in regression analysis. However, we did not find an interaction of hypotension time and maximum NED with mortality.

Clinical, biochemical and haemodynamic variables as independent predictors of 90-day mortality: the Simple Intensive Care Studies-I

B. Hiemstra, G. Koster, F. Keus, I.C.C. van der Horst, SICS Study Group
University of Groningen, University Medical Center of Groningen, Department of Critical Care, Groningen, Netherlands
Correspondence: B. Hiemstra
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1291

INTRODUCTION. Clinical, biochemical and haemodynamic variables are used to diagnose circulatory shock and guide treatment in the critically ill. Literature is inconsistent which clinical signs have the best prognostic value on top of well-validated prognostic scores such as the simplified acute physiology score (SAPS II).

OBJECTIVES. The objective of the Simple Intensive Care Studies-I (SICS-I: NCT02912624) was to evaluate the association of clinical, biochemical and haemodynamic variables with 90-day mortality in a large, consecutive, cohort of critically ill patients [1].

METHODS. This prospective cohort study included all consecutive adults who were acutely admitted with an intensive care unit (ICU) stay expected to last beyond 24 hours. We conducted a protocolised clinical examination and critical care ultrasonography (CCUS) within 24 hours of ICU admission. Our primary outcome was 90-day mortality. Our secondary outcomes were 7- and 30-day mortality, and 90-day mortality by type of circulatory shock and clinical subgroups. We used multivariable Cox regression analyses to identify independent predictors of mortality.

RESULTS. From 27 March 2015 until 22 July 2017, 1104 patients were included. A total of 298 patients (28%) died at 90-day follow-up. Patients who died were older, more often ventilated, unconscious and dependent on noradrenalin, had lower blood pressures and urine output, and more often had an impaired microcirculation (tables 1 - 3). Multivariable Cox regression adjusted for age and SAPS-II score showed that respiratory rate (HR 1.02; 95% CI 1.00 - 1.04), unresponsiveness (HR 1.53; 95% CI 1.08 - 2.16) and serum lactate (HR 1.08; 95% CI 1.03 - 1.13) were independently associated with 90-day mortality. In patients with septic shock independent predictors were mottling rate (HR 1.27; 95% CI 1.02 - 1.58) and serum lactate (HR 1.11; 95% CI 1.02 - 1.22), whereas diuresis < 0.5 ml/kg/h (HR 2.27; 95% CI 1.00 - 5.15) and a mean arterial pressure < 70 mmHg despite vasopressor treatment (HR 5.08; 95% CI 2.00 - 12.9) were independent predictors in patients with heart failure.

CONCLUSIONS. Simple clinical variables as respiratory rate, consciousness, and serum lactate are independently associated with 90-day mortality in a large, unselected cohort of critically ill patients. The predictive value of clinical signs changed in clinical subgroups. Skin mottling and lactate showed the strongest associations in

patients with septic shock and impaired diuresis and low mean arterial pressures were independently associated with 90-day mortality in patients with heart failure.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1292

INTRODUCTION. Elderly patients admitted to the intensive care unit (ICU) is increasing. Comorbidity in this population supposed an important issue that may have an impact on outcomes.
OBJECTIVES. To study the influence of baseline comorbidities on the evolution of elderly patients admitted to ICU.
METHODS. We performed a retrospective analysis of a prospective database including patients admitted to our polivalent ICU in last 7 years. We studied data related to the presence of prior comorbidities, severity scores at admission, supportive organ therapies and clinical outcomes. We compared patients younger from older than 80 years and studied the impact of different factors in both populations. For statistical analysis we used Chi-square, Fisher or T-Student tests as appropriate.
RESULTS. During the study period 3026 patients were admitted, 421 over 80 years old.
APACHE II, SAPS II and Glasgow scale at admission were significantly higher in elderly patients group.
Patients older than 80 had higher rates of chronic kidney disease (CKD) (18 vs 9.9 %, p < .001), COPD (17.6 vs 9.8, p < .001) and diabetes (41.2 vs 27.2, p< 0.001) and lower rates of inmunodeppression (2.6 vs 10.2, p < .001) and cirrhosis (0.3 vs 3.4, p .002) No differences were observed in terms of malignancy.
Mechanical ventilation was used less frequently in older than 80 group (49.7 vs 42.5 %, p.006) and during shorter period of time (5.46 (CI 95 % 4.2-6.7) vs 8.12 (7.4-8.9) days, p .012. Less reintubation (1.9 vs 4.4 %, p.015) and less performance of tracheostomy (3.6 vs 7.8, p.002) were observed in older than 80.
Significantly shorter ICU and hospital length of stay was observed in older than 80 group. ICU and hospital mortality were higher in older than 80 group (24.9 vs 14.2 %, p< .001 and 39.2 vs 20.8 %, p< .001 respectively)
We analyzed both groups of patients separately and focused on factors associated with mortality. Higher severity scores were significantly associated with mortality in both groups. Medical condition for admission had higher mortality in younger than 80 patients (15.6 vs 10.2 %, p< .001), with no differences in the older one. Trauma admission (compared with non-traumatic) carried higher ICU mortality (58.3 vs 24 %, p .007) in older than 80 and lower mortality in younger than 80 group.
In older than 80 group, no differences in mortality were observed according to the presence of any comorbidity. Conversely, in younger than 80, higher mortality was observed in presence of inmunodepression (23.7 vs 13.1, p< .001), CKD (19.6 vs 13.9, p .031) or cirrhosis (35.8 vs 13.7, p< .001)
CONCLUSIONS. Our results suggest that the weight of comorbidity may have less importance in the evolution of older than 80 years patients admitted to ICU. The inherent triage to admission of this old population may have limit patients with more severe comorbidities to be admitted to ICU and mask our findings.

1293

Mobile ICU response team (MIRT), a novel solution to expand undelayed critical care beyond the ICU doors; outcome on mortality and length of stay

A. Omranian[1], B. Mankidy[1], C.K. Morgan[1], C.M. Howard[1], M.A. Siddique[1], Y. Ababio[2], J. Herlihy[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1293

INTRODUCTION. The exponential damages of delay in providing intensive care to critically ill patients from the ED are well described.[1]

OBJECTIVES. To determine the effect on mortality and length of stay by the introduction of MIRT which provides immediate and comprehensive intensive care to critically ill patients anywhere in the hospital.

METHODS. This is a retrospective study in an 850 bed quaternary academic hospital. All ICUs admissions from the ED, patient care units, PACU (2012 to 2017) were included and divided into 2 groups. The intervention group after the implementation of MIRT and the control group prior to that. Primary end point was determined as all-cause mortality rate in all ICUs. Secondary outcome was determined as all-cause mortality rate and hospital length of stay (LOS) in Medical-Neuro ICU. Case mixed index (CMI) as a severity of illness value was compared.

RESULTS. 128,493 patients were discharged out of the hospital from January 2012 to December 2017, out of which 7775 patients were from the ICUs. All-cause mortality rate of all ICUs was reduced from $31.6\%\pm3.1$ to $28.4\%\pm7.7$ (p-value 0.17) in the control versus intervention group respectively, with mean CMI of 3.6 ± 0.3 versus 3.7 ± 0.2; (p-value 0.008). All-cause mortality rate in Medical-Neuro ICU was reduced from $37.3\%\pm6.4$ to $34.2\%\pm8.9$ (p-value 0.34) with mean CMI also reducing from 3.1 ± 0.4 to 2.9 ± 0.4 (Graph 1-2). Hospital length of stay for the patients admitted to Medical-Neuro ICUs was reduced from 12.3 ± 1.5 to 11.0 ± 2.1 days (p-value 0.12). Patients who died in these ICUs had a significant reduction in LOS from 9.1 ± 1.2 to 7.4 ± 1.4 (p-value 0.004) between control and intervention group.
Conclusion. Implementation of rapid response team (RRT) has been dramatically improving the hospital outcome[2]. In a recent study, other colleagues identified a reduction in hospital-wide code blues from 2.1 to 1.6 codes per 1000 patient days (p-value = 0.007) after introduction of RRT however lack of adequate intensivist coverage outside the ICU has been observed.

We introduced MIRT in late 2014. The team included a critical care attending physician, critical care fellow, and a mid-level provider in addition to 2 or 3 specially trained RRT nurses, equipped with portable ultrasound, videoscopic airway equipment and i-STAT lab devices. Difficult airway and procedure cars were parked in multiple locations in the hospital for their use.

In our study there was an increase in the proportion of ICU patients which could imply a higher tendency towards moving more patients to the ICU. Decrease in LOS of those who died in the ICU could be explained by more goals of care discussions. There was a trend toward better outcomes but not statistically significant. More detailed and possibly prospective studies is needed to validate this assertion.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1294

INTRODUCTION. Consensus clinical guidelines recommend maintaining mean arterial pressure (MAP) ≥65 mmHg for patients with distributive shock (DS). Catecholamines are recommended as first-line vasopressor, but are associated with significant toxicities at high doses. Vasopressin and other vasopressors are often added to therapeutic regimens as they increase and maintain MAP while reducing the need for high doses of catecholamines. Little research has been done on the impact of vasopressin on MAP among patients with DS in a real-world setting.
OBJECTIVES. This study uses the Medical Information Mart for Intensive Care (MIMIC-III) database to examine MAP response and catecholamine-sparing effects of vasopressin in patients with DS in a real-world setting.
METHODS. We identified patients with DS in the MIMIC-III database which contains information for 61,532 admissions to intensive care units (ICU) at Beth Israel Deaconess Medical Center (BIDMC) in Boston, Massachusetts between 2001 and 2012. Inclusion criteria: 1) ≥18 years, 2) treated with vasopressors for ≥6 hours, 3) no indications of other conditions for which vasopressors are standard treatment, such as cardiogenic shock or vasoplegia, and 4) receipt of vasopressin and at least one catecholamine (norepinephrine, epinephrine, phenylephrine, or dopamine) at vasopressin initiation.
RESULTS. Of 5347 patients with DS, 1053 patients received vasopressin and at least one catecholamine at vasopressin initiation. Of the 641 patients with MAP ≥65 mmHg at vasopressin initiation, 84% remained at this level after 3 hours, while MAP decreased to below 65 mmHg in 15% and 1% were no longer in ICU; at 3 hours, of the 634 patients who remained in ICU, 11% and 8% had achieved 25% and 50% reduction in norepinephrine equivalent dose (NED) of catecholamines, respectively. Of 171 patients with MAP ≥60 but < 65 mmHg at vasopressin initiation, 18% remained at this level after 3 hours, while MAP increased to ≥65 mmHg in 68%, decreased to < 60 mmHg in 14%, and 1% were no longer in ICU; at 3 hours, 15% and 7% of 170 patients remaining in ICU had achieved 25% and 50% reduction in NED, respectively. Of 241 patients with MAP < 60 mmHg at vasopressin initiation, 27% remained at this level 3 hours after vasopressin initiation, while MAP increased to ≥65 mmHg in 49% and ≥60 but < 65 mmHg in 18%, and 6% were no longer in ICU; at 3 hours, 21% and 15% of the 227 patients remaining in ICU had achieved 25% and 50% reduction in NED, respectively.
CONCLUSIONS. Of patients with DS treated with vasopressin in this real-world setting, subsets of patients either failed to maintain their current MAP or were unable to raise MAP to the recommended target of 65 mmHg. In addition, a majority of patients did not achieve 25% reduction in NED 3 hours after initiation of vasopressin. This suggests a need for adjunctive therapies that can help maintain and increase MAP while sparing the use of catecholamines to reduce toxicity.

Lactate clearance in the burned patient, does it really clarify something?

M. Aviles Garcia[1], K. Nanwani Nanwani[1], J.M. Cantero Escribano[2], E. Herrero de Lucas[1], M. Sanchez Sanchez[1], A. García de Lorenzo Mateos[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1295

INTRODUCTION. The alteration of the permeability and the important displacements of liquids in thermal trauma are responsible for the formation of edema and massive loss of fluid. The objective of resuscitation is restore the oxygen supply to tissues and lactate is a parameter that reflects perfusion in absolute values and as a clearance. Lactate clearance is calculated as quotient between the initial lactate and second lactate divided by the initial lactate. Numerous studies postulated that clearance of lactate in the first hours of resuscitation influence the prognosis of burned patients and indicate in some way the efficacy of resuscitation.
OBJECTIVES. Assess how early lactate clearance influences the prognosis and mortality of critically burned patients, using initial lactate levels before initiation of treatment.
METHODS. Retrospective study in a ICU university hospital CESUR for the assistance of burned patient. All burned patients with or without associated inhalation syndrome who were transferred by an emergency service and who required admission to Critical Burns Unit for 2 years (January 2014 - December 2015).
We studied demographic, clinical variables, analytical values, transfer times, burned body surface, volume of resuscitation, need for orotracheal intubation and early/late mortality.
RESULTS. 55 patients transferred to our hospital, 28 patients admitted to ICU. The mean age was 55 ± 22.5, flame was the most frequent mechanism.
The resuscitation time from the initial notification until the patient arrived at hospital was 65.59 ± 26.4 m. Mortality in the first 24 hours was 7%, and the ABSI score had a median of 5 ± 3, an average of 536.67 ± 429.5 ml of Saline 0.9% was administered; The extra-hospital lactate levels showed a median of 3.7 ± 5.23 mmol/L while the hospital levels were 1.9 ± 2.1 mmol/L, with an early lactate clearing a mean of +49, 26 ± 36%. Only one patient died in the first 24 hours with negative lactate clearance.
No statistically significant correlation was found between the clearance lactate and the volume of fluid infused, nor between the clearance of lactate and the time of resuscitation, nor between the clearance lactate and the body surface burned.
CONCLUSIONS. Although it has been postulated that the clearance of lactate in the first hours of resuscitation can influence the prognosis of burned patients, in our study the clearance of lactate extrahospital with an average time of transfer of 1 hour did not correlate with the volume of fluid infused neither with the resuscitation time nor with the burned body surface. Although 93% of the patients who presented positive values of lactate clearance survived, the only patient with negative lactate clearance values died in the first 24 h, suggesting in some way that the negative clearance of lactate could be related to the poor prognosis in these patients, however, more studies are needed to discern the use of lactate clearance in resuscitation of burned patient.

Thriving or surviving, national targets verses regional needs: outcomes for out of hospital cardiac arrests (OHCA) from intensive care in a geographically, architecturally and economically challenged region

INTRODUCTION. The chain of survival is a tool implemented to highlight various stages following out of hospital cardiac arrest. Early cardiac intervention protocols were designed using trials for ST Elevation Myocardial Infarction (STEMI), in patients who maintain cardiac output, but are being applied to OHCA patients without ongoing return of spontaneous circulation.

Our hospital has a unique set of circumstances; we are one of the most socioeconomically deprived and geographically challenged regions in the UK. In addition we have a split hospital site meaning that all ongoing cardiac arrests are transferred to an intensive care via the emergency department (ED) on a site without percutaneous coronary intervention (PCI) abilities and a resident cardiologist unless a STEMI is demonstrated.

OBJECTIVES. To determine if national guidance and targets in combination with our unique set of circumstances are having an adverse effect on the outcomes of OHCA patients in our region.

METHODS. 94 OHCA were identified via ICNARC between January 2012 and June 2017 and appraised for a set of predetermined parameters, with telephone interviews, using the EQ-5D tool, for those whom survived.

RESULTS. Results were applied to the Myocardial Ischemia National Audit Project 2016. We achieved direct transfer to a PCI centre in 26%, call to balloon in 31% and hospital to balloon time in 19% of patients. However we achieved a survival to hospital discharge of 43%.

With respect to our split site, transfer from ED to the PCI centre adds on average 173 minutes to call-balloon time yet there was no mortality difference between direct or indirect admissions. An increase in mortality was evident in the cohort whom remained on the non-cardiac site.

We found that patients whom survived had by comparison to the general population an overall reduction in quality of life (QOL) by 7%. However despite the life-changing event, 20% of those whom survived had a very good-excellent quality of life, well above the national average.

CONCLUSIONS. Overall and quality of survival from OHCA is reduced in socioeconomically deprived areas.

We have demonstrated that despite significantly underperforming against the national targets, we almost achieve the national average of survival to hospital discharge.

The demonstrated modifiable domains in our region propose that we refocus priorities, concentrate on quality of care and outcomes rather than targets.

In particular addressing the incorporation of cardiac interventions into good evidence based post resuscitation protocols on all of our intensive care unit across the city and standardizing OHCA guidance including prognostication and appropriate transfer, regardless of the patient's route of admission to our hospital and the immediate presence of a cardiologist The need for fast turn around to meet inappropriate national targets puts a vulnerable cohort at risk, particularly if they are not transferred for PCI at all.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1297

INTRODUCTION. Patients admitted to intensive care units (ICUs) have an especially high risk of acquiring healthcare-associated infections (HAI), and many of these are caused by multidrug-resistant organisms (MRDO). The HAIs caused by MDRO are emerging and spreading in ICUs globally. Little is known about the difference of attributed cost and length of stay (LOS) of patients with HAI caused by MRDO or caused by non-MRDO in ICU settings after propensity-score matching.

OBJECTIVES. We aimed to determine the case fatality rate, LOS, and healthcare cost of ICU patients with HAIs caused by MDROs (case group) and ICU patients with HAIs caused by non-MDROs (control group).

METHODS. A propensity-score matched case-control study was performed with patients aged 18 years or older who were admitted to Kaohsiung Chung Gang Memorial Hospital with 15 ICUs (a total of 200 beds) for adults from January 2010 to December 2017. Patients were followed and data were collected until death or discharge from the hospital. Patients in case group were matched with controls under a ratio of 1:2 by age, gender, APACHE-2, ICU specialty, underlying diseases, and the length of stay before transfer to ICUs. Main outcome measures are overall mortality, LOS of ICU, LOS of hospital, antimicrobial duration and healthcare costs.

RESULTS. During the study period, 46,237 patients were admitted to ICUs, 690 patients were selected (1:2) after propensity score matching. Urinary tract infection was the most frequently detected infection (45.6%), followed by bloodstream infections (34.5%). The most common isolate organism was *Escherichia coli* (21.1%). After propensity-score matching, there were no significantly difference on treatment cost (median [(inter-quartile range, IQR) €2313 (IQR 535-3050) vs. €950 (IQR 731-2683); P=0.30), and LOS of ICU (20.1±13.6 days vs.18.9±12.8 days; P=0.36), LOS of hospital (41.8±27.5 days vs. 39.2±23.5 days; P=0.35)] and duration of antimicrobial therapy (17.3 ±14.0 days vs.17.4±13.8 days; P=0.80) between ICU patients with HAIs caused by MDROs and ICU patients with HAIs caused by non-MDROs. The overall mortality rate was also not statistically difference (36.0% vs. 38.5%; P=0.52) between these two groups.

CONCLUSIONS. HAIs are a common adverse health event with substantial health and economic burden in ICU setting with or without MDRO.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1299

INTRODUCTION. Data from our tertiary hospital ICU demonstrated an unmet psychological need in former critical care patients (Kieron et al., 2014). In response a psychological wellbeing service has recently been set-up which provides structured interventions to patients at the bedside. A lack of empirical research findings in this area means that such interventions are based on best practice from more general evidence-base (e.g. Richards and Whyte, 2011) rather than robust ICU evidence. Psychological interventions for depression, anxiety, and stress were developed. To assess the effectiveness of these interventions distress specific Subjective Units of Distress (SUDS) on a scale of 1 - 10 are collected before and after each intervention with each patient.

OBJECTIVES. To investigate whether a significant difference in SUDS level can be detected:
(a) within and between individual sessions overall;
(b) within and between distress specific sessions overall;
(c) within areas of intervention (cognitive, behavioural or mindfulness); and (d) between different interventions for each area of distress.

METHODS. A series of 2-tailed paired-sample t-tests and Welch's t-tests were undertaken to measure whether statistically significant differences exist between the SUDS ratings specified within the objectives session.

RESULTS. Please see the tables below.

CONCLUSIONS. A strong statically significant difference between all within (at the start and at the finish) session SUDS analysed, and the reduced mean averages, suggesting that the psychological interventions undertaken are effective at reducing distress in each area at the time of the respective sessions. Similarly, the within interventions findings suggest that cognitive, behavioural and mindfulness approaches are all effective at reducing distress during a session.

However, whilst a similar difference is shown between the first and last sessions for all sessions and for anxiety, there was a signal for similar change which did not reach statistical significance between sessions for the treatment of depression or stress. This may either reflect inadequate sample size or that the interventions for depression and stress might not have as lasting or cumulative distress reducing affect as that for anxiety.

No statistically significant difference was found between treatment options for specific areas of distress, suggesting that no intervention compared within this small sample is more effective at reducing SUDS than any other.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1300

INTRODUCTION. The physical disability experienced by survivors of critical illness is well documented[1], and improving the quality of survival is a fundamental aspect of care[2]. Many measures have reported the recovery of patients and despite the variety of measures used significant burdens are consistently identified[1]. However, measures commonly report on function at isolated time points post discharge, not relating to previous levels of function. Baseline limitations in function will alter the ability to achieve higher scores in various domains and confound measurements of function. The World Health Organisation Disability Assessment Schedule 2.0 (WHODAS 2.0) measures multiple health domains and has been used to assess disability at follow up for ICU survivors[3].

OBJECTIVES. To report the feasibility of assessing the pre-admission functional status of ICU patients using the WHODAS 2.0, with repeat assessment at six months post ICU discharge.

METHODS. A prospective longitudinal observational cohort design recruited consecutive adult major trauma admissions to a UK general ICU, between 1st November 2016 and 1st November 2017. The ICU physiotherapy team underwent pre-study training. The 12-item WHODAS 2.0 was completed with the patient or using a consultee to assess pre-admission functional status as soon as possible after ICU admission. The measure was repeated at six months post ICU discharge, through ICU follow-up clinic or by post. Final attempts at follow up were made by telephone.

RESULTS. The ICU physiotherapy team were trained in the use of the WHODAS 2.0 in 2.5 hours. Of the 73 eligible patients 57 were recruited and completed initial assessments. The mean time from ICU admission to assessment was 38 hours, with the assessment taking an average of three minutes to complete. At the time of analysis there were follow up attempts made for 47 participants, with 22 completed (47%). The median six months WHODAS 2.0 score was 27, increasing from baseline assessment by a median of 14 points. Of the responses received 12 were via post, 5 via ICU follow-up clinic, and 2 by telephone.

CONCLUSIONS. With minimal resources standardised assessment of pre-admission functional status was feasible to collect. Follow up was challenging although deterioration in function was evident. Future research should investigate the clinical relevance of scores, and the validity of the WHODAS 2.0 in ICU patients.

Comparison of lung ultrasound (US) based weaning indices with RSBI: are they helpful?

A. Banerjee, G. Mehrotra
Tata Main Hospital, Dept of Anesthesiology and Critical Care, Jamshedpur, India
Correspondence: A. Banerjee
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1301

INTRODUCTION AND OBJECTIVES. The diaphragm is considered the main respiratory muscle and difficulty in weaning can occur because of impaired diaphragmatic function. Hence, monitoring diaphragmatic function is important. The aim of this study is to assess the ability of various lung US indices and rapid shallow breathing index (RSBI) to predict the outcome of weaning process and compare them with RSBI.

METHODS. This was a prospective study conducted on patients admitted in critical care unit at a tertiary care hospital in north India from February 2017 to June 2017. Patients were put to Spontaneous breathing trial (SBT) when they met the weaning criterias. Initial US were done immediately after putting the patient on SBT to check anatomy of diaphragm and rule out patients according to exclusion criteria. This was followed by complete lung US after 20 minutes of SBT.

RESULTS. The RSBI performed better than all other parameters, with an area under curve (AUC) of 0.996.The sensitivity and specificity is 100 %. Only comparable to RSBI is speed of diaphragmic contraction (DC) which has AUC of 0.93. All other parameters had an AUC less than 0.8. Moreover the DC and (Lung ultrasound score) LUS are strongly positively correlated with RSBI whereas diaphragmic excursion (DE) and Diaphragmic thickness fraction (DTF %) are weakly correlated.

CONCLUSIONS. In ICU, RSBI is the best clinical tool for weaning and DC is found to be the best parameter for weaning among the ultrasound based weaning parameters. It can even be a substitute of RSBI, in today's world of real time monitoring methods.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1302

INTRODUCTION. Right heart failure is increasingly being recognized as an independent predictor of adverse outcome in the critically ill. Right ventricular (RV) - pulmonary artery (PA) coupling quantifies right heart efficiency and performance. Mechanical ventilation, pulmonary pathology,

and cardiovascular support affect RV-PA coupling. Therefore, assessment of RV-PA coupling in ICU patients may yield important guidance for diagnosis and treatment [1,2]. Theoretically, bedside determination of RV-PA coupling is possible using ultrasound (US), circumventing the need of MRI and/or right heart catheterization (RHC).

OBJECTIVES. To determine feasibility and validity of measuring RV-PA coupling using US.

METHODS. Right heart US examination was performed before and during passive leg raising (PLR) in patients with known or presumed pulmonary hypertension undergoing RHC and/or MRI. Using 2D, Continuous Waved and Pulsed Waved Doppler US, fractional area change, tricuspid regurgitation velocity and PA flow were determined. These measurements serve as derivatives of RV ejection fraction (EF), pressure (RVP) and stroke volume (SV), respectively. US measurements were compared to RHC and MRI measurements.

RESULTS. Preliminary results (n=4) of RHC and MRI measurements compared to US measurements are shown in Table 1. These measurements are the basis of RV-PA coupling values. Using US measurements the systolic part of a pressure-volume (PV) loop was constructed (Figure 1).

CONCLUSIONS. It is feasible to construct the systolic part of a PV loop from US measurements. Thereof US RV-PA coupling can be determined. Despite discrepancy between gold standard and US measurements, the US method may provide patient specific guidance during ICU treatment and may be therefore of additional value.

INTRODUCTION. It has been shown that the presence of a pharmacist in the Intensive Care Units in the Netherlands prevents medication errors (1). This is recognized in the Dutch 'quality standard of the Intensive Care (2016)'. This quality standard says: 'It is likely that the daily presence of an IC-committed pharmacist will positively influence the outcome of the patients. In addition, the pharmacist contributes to a more rational medication policy and cost effectiveness. ´ To our knowledge the presence of an IC-committed pharmacist has not been described as a daily practice among Dutch top-clinical hospitals.

OBJECTIVES. The objective of the study was to investigate the added value of a daily pharmacist within the ICU of the Elisabeth-Tweesteden hospital (ETZ) in Tilburg, the Netherlands.

METHODS. The pilot study was carried out at the ICU of the ETZ from 10-07-2017 till 11-08-2017. During workdays from 8:00h till 12:00h a pharmacist was present in the ICU and was stationed at a dedicated workspace. Figure 1 shows the workflow. The ETZ is a top-clinical hospital located in Tilburg, the Netherlands. The ICU is a level 3 accredited IC and is a regional trauma center. The IC has 34 beds divided over 4 units.

RESULTS. A total of 122 pharmacotherapeutic and pharmacological interventions were proposed. 112 (92%) of the proposed interventions were implemented by the physicians. Interventions were divided into the following categories: dose, intoxication, feeding tube, start, stop, switch, therapeutic drug monitoring (TDM), drug interaction, consultation and other (see figure 2).

CONCLUSIONS. During one month, 122 pharmacotherapeutic and pharmacological interventions were proposed, of which 112 were implemented by the physicians. Therefore an added value was shown when a pharmacist was present on a daily basis in the ICU of a Dutch top-clinical hospital.

Comparing intravenous unfractionated heparin and subcutaneous low molecular weight heparin as therapeutic anticoagulation on intensive care

S. Case, R. Gayner, N. Weston-Smith, A. Clarke
Bristol Royal Infirmary, Intensive Care, Bristol, United Kingdom
Correspondence: R. Gayner
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1304

INTRODUCTION. Intravenous unfractionated heparin (UH) and subcutaneous low molecular weight heparin (LMWH) are used as therapeutic anticoagulants on intensive care units (ICUs) for a variety of indications. In the treatment of venous thromboembolism (VTE) a recent Cochrane review has shown LMWH is associated with fewer major haemorrhagic episodes, lower mortality and reduced incidence of recurrence compared to intravenous UH[1]. There is limited evidence comparing their use in non-VTE indications or in the ICU setting.

OBJECTIVES.
· Compare prescribing practices for UH and LMWH as therapeutic anticoagulants in ICU and the frequency of complications
· Assess ICU monitoring of UH using activated partial thromboplastin time ratios (APTRs)

METHODS. Retrospective audit of admissions to a 21-bed mixed medical/surgical ICU in Bristol, UK. The electronic clinical record was interrogated over a 12 month period to return a dataset of prescriptions for therapeutic anticoagulation. From the UH group, we defined a subgroup (n=20) to identify the frequency of APTR monitoring, duration of therapeutic APTR results and compliance with hospital infusion protocol.

RESULTS. We identified 45 prescriptions for UH and 31 prescriptions for LMWH. Of the 65 patients involved, 11 received both UH and LMWH (separately) during the audit period. The commonest indication for anticoagulation was new VTE (34 prescriptions, 45%; 18 UH vs 16 LMWH) and second commonest indication was for a pre-existing condition (23 prescriptions, 30%; 11 UH vs 12 LMWH). Other indications included new atrial fibrillation, acute coronary syndrome and arterial thrombosis. 10 patients received UH for haemofiltration. In the UH group 58% of APTR measurements were done within 6 hours of the last measurement. 40% of APTR measurements were not in the therapeutic range and appropriate dose adjustments were made in 82% of occurrences. 11 (24%) patients in the UH group had bleeding complications; 2 were life-threatening: one had a fatal subarachnoid haemorrhage despite sub-therapeutic anticoagulation; another had a massive intra-abdominal haemorrhage and survived. The LMWH group had no bleeding complications although 2 patients had procedures delayed due to anticoagulation.

CONCLUSIONS. UH and LMWH are used for a variety of indications on ICU, with crossover between conditions. UH was associated with minor and major bleeding complications, whilst no complications were seen with LMWH. Given the higher rates of complications and difficulties maintaining UH in the therapeutic range it may be worth considering using LMWH more frequently as a therapeutic anticoagulant. Therapeutic anticoagulation may expose patients to higher bleeding risk than necessary, particularly for non-acute indications.

INTRODUCTION. Delirium is the most frequent psychiatric syndrome in the Intensive Care Unit (ICU). This form of acute brain dysfunction predicts higher mortality rates and is associated with worse global cognition after ICU discharge [1]; [2]. Therefore, delirium prevention bundles have become an integral part of guideline recommendations. Clinical trials investigating pharmacological strategies have failed to demonstrate consistent results in terms of patient outcomes. Hence, focus has moved towards non-pharmacological approaches.

OBJECTIVES. Within an interdisciplinary project, we developed a new ICU room concept . In 2013 we finished the renovation of 2 double ICU rooms (Fig. 1 and 1). Beside interventions aimed at noise reduction, workflow optimisation and infection control, we developed a new light ceiling that enables clinicians to apply patient individualised light therapy [3]; [4]. We hypothesised that the delirium incidence for patients treated in the modified rooms is significantly lower when compared to patients treated in the standard rooms.

METHODS. After sample size calculation, 74 mechanically ventilated patients with an expected ICU length of stay >48 hours were included in this prospective cohort study (NCT02143661). Amongst other reasons, patients with a substantial recent ICU exposure [2], patients who were unlikely to survive for 24 hours and patients who could not be reliably assessed for delirium were excluded from study participation. Delirium was assessed every 8 hours by research physicians with the Confusion Assessment Method for the ICU (CAM-ICU).

RESULTS. The incidence of ICU delirium was significantly lower among patients treated in the modified rooms (46%) compared to patients treated in the standard rooms (76%, $p = 0.017$) (Table 1). The association between the modification of ICU environment and

the delirium incidence was statistically significant (odds ratio, 0.15; 95% confidence interval, 0.04 - 0.66; p = 0.012) after adjusting for covariates.

CONCLUSIONS. This study is the first to show that a modification in ICU environment is significantly associated with a reduced delirium incidence. Further analysis is needed to investigate which of the room interventions may contributed to this clinical effect.

INTRODUCTION. Elevated levels of lactate are associated to poor outcomes in patients undergoing cardiac surgery, since they may represent anaerobic metabolism consequent of imbalanced cellular oxygen consumption and supply. However, whether a lactate-guided resuscitation in the postoperative of cardiac surgery improves outcomes is still unknown.

OBJECTIVES. We aimed to determine whether a postoperative hemodynamic therapy based on lactate levels reduces postoperative complications in patients undergoing cardiac surgery, when compared to a postoperative hemodynamic therapy which lactate levels were not disclosed to clinicians.

METHODS. We performed a single centre, randomized, double-blind, controlled-parallel trial between October 2016 to December 2017 at the Heart Institute of the University of Sao Paulo, Brazil. Patients undergoing cardiac surgery were randomly assigned to either receive fluids, vasopressors or inotropes by physicians who were aware of lactate levels of patients, or to a group which physicians were not informed about patient's lactate levels during the first 8 hours after ICU admission. Lactate levels were measured every 2h and the aim of the treatment in the lactate group was to reduce lactate levels at least in 20% if lactate levels were higher than 3 mmol/L. Primary outcome was defined as acute kidney failure, defined as Acute Kidney Failure Network (AKIN) score $\geq$1, at postoperative day 7. Secondary outcomes were the incidence of myocardial ischemia, AKI, requirement of renal replacement therapy, length of stay in the ICU and in the hospital, and mortality rate at 28 days.

RESULTS. A total of 280 patients were included. During the first 8 hours after a ICU admission, patients of the lactate group received more fluid than patients of control group, 797 mL (standard deviation[SD] ±789) vs 583 mL (SD ±554), P=0.009. There was no difference regarding lactate levels between groups. At 7 days, 66 of 141 patients (46.8%) in the lactate group and 82 of 139 patients (59.4%) in the control group

presented acute kidney injury (P=0.035). No significant differences in secondary outcomes were observed between groups.

CONCLUSIONS. Postoperative lactate-guided therapy during the first 8 hours after ICU admission reduces the incidence of acute kidney injury 7 days after surgery in patients undergoing cardiac surgery.

The relationship of endothelial glycocalix with hemodynamic and metabolic parameters during perioperative period of valve surgery

M. Kirov, Y. Ilyina, N. Izotova, M. Sokolova, D. Volkov, E. Yakovenko, V. Kuzkov
Northern State Medical University, Department of Anesthesiology and Intensive Care, Arkhangelsk, Russian Federation

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1307

INTRODUCTION. The endothelial glycocalix (EG) plays an important role in regulation of vascular integrity, permeability, and endothelial activation. The perioperative EG shedding can be associated with capillary leak, hemodynamic disturbances, and increased morbidity.

OBJECTIVE. To assess the response of EG to valve surgery requiring cardiopulmonary bypass.

METHODS. Twenty-six adult patients scheduled for elective on-pump valvular interventions were enrolled into a single-centre prospective observational study. The components of EG including Heparan Sulfate Proteoglycan (HSPG) and Syndecan-1 (S1) were measured after the induction of anaesthesia, and at 6 and 24 hrs postoperatively using ELISA Kits SEA565Hu and SEB966Hu (Cloud-Clone Corp., USA). The hemodynamics, blood gases, pro-B-type natriuretic peptide (NT-proBNP), and biochemical parameters were determined perioperatively. The statistical analysis was performed using Mann-Whitney U-test, ANOVA, Spearman's rho, and ROC-analysis. Data are presented as median (25th-75th percentiles). p values < 0.05 were regarded as statistically significant.

RESULTS. At 6 hrs after surgery, we observed a decrease in HSPG concentration from 6.13 (4.20-9.04) ng/ml to 5.08 (4.18-7.21) ng/ml (p < 0.01), while S1 increased from 0.80 (0.56-1.13) ng/ml to 1.25 (1.04-1.41) ng/ml (p < 0.001). At 24 hrs, HSPG and S1 returned to values close to baseline. The baseline HSPG correlated with systemic vascular resistance index (rho = -0.55, p = 0.004), postoperative cardiac index (rho = 0.43-0.46, p = 0.03), pulse pressure variations (rho = -0.76, p = 0.003), and glucose concentration (rho = -0.50, p = 0.02). In addition, the baseline HSPG concentrations above 5.1 ng/mL predicted postoperative hyperlactatemia (> 2 mmol/l) with AUC 0.75, sensitivity 100% and specificity 58% (p = 0.02). The baseline NT-proBNP demonstrated weak correlation with HSPG concentration at 6 hrs after surgery (rho = 0.42, p = 0.04). The values of HSPG at all stages and the baseline S1 concentration correlated with duration of mechanical ventilation (rho = 0.46-0.49, p < 0.02).

CONCLUSIONS. During perioperative period of valve surgery, the EG system demonstrates relatively minor shedding and moderate associations with hemodynamics, metabolic response, and duration of respiratory support.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1309

INTRODUCTION. Cardiopulmonary bypass (CPB) is often associated with degrees of complex inflammatory response. This inflammatory reaction, sometimes referred to as "post-pump syndrome", is characterized by activation of numerous inflammation pathways leading, in severe cases to systemic hypotension and organ dysfunction [1, 2]. Cytokine Hemoadsorption (HA) might therefore improve outcomes of patients undergoing cardiac surgery.

OBJECTIVES. In this randomized control trial (NCT02775123), we aim to evaluate the safety and efficacy of a cytokine HA on post-CPB inflammatory response in patients undergoing elective cardiac surgery and at risk of post-operative complications.

METHODS. 30 patients undergoing elective cardiac surgery were randomly assigned either to standard CPB (control group) or to CPB plus Cytosorb® (Cytosorbents, New Jersey, USA) (Cytosorb group). Our primary outcome was levels of inflammatory cytokines (IL-1a, IL-1b, IL-2, IL-4, IL-5, IL-6, IL-10, TNF-alpha, IFN-gamma, MCP-1) were measured at T0 (after induction of anaesthesia), T2 (end of CPB), T3 (6 hours after CPB initiation) and T4 (24 hours after CPB initiation).

Values are presented as median (IQR). Comparisons were made using chi-square and Wilcoxon signed-rank test. A p value < 0.05 was considered statistically significant.

RESULTS. Baseline demographics, peri-operative characteristics and procedures are detailed in Table 1 and 2. There was no difference between the two groups in terms of need for any vasoconstrictor (p=1.0), mean noradrenaline dose on the first post-operative day (p=0.87), need for any inotrope (p=0.682), duration of mechanical ventilation (p=0.305), incidence of AKI (p=1.0), ICU length of stay (p=1.0), ICU and hospital mortality (both p=1.0). Cytokine levels are still pending.

CONCLUSIONS. There was no difference in baseline demographics, peri-operative characteristics nor post-operative outcomes between the two sets of patients. Our primary outcome remains yet to be determined as cytokine levels are still pending.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):1310**

INTRODUCTION. Pulmonary resection surgery is associated with high morbidity [1]. Enhanced recovery pathway (ERP) has been proved to influence post-operative course after colorectal surgery but data on thoracic surgery are scarce[2].
OBJECTIVES. To evaluate the factors associated with post-operative complications occurrence within a thoracic surgery enhanced recovery pathway.
METHODS. A monocentric observational study was conducted after approval of our local institutional board. All consecutive patients candidates to a lobectomy or segmentectomy entered to the study protocol. Demographic data, clinical data as well as data related to ERP procedures (smoking cessation, pre-operative carbohydrate intake, setting up of a patient controlled regional analgesia, prescription of non-steroidal anti-inflammatory drugs (NSAIDs), chest tube removal at day 2) were prospectively collected.
RESULTS. Over a 1 year period, 206 patients, 51% male (n=105), benefited from the ERP in our institution. They had an average of 66 ± 10 years, a median BMI of 25Kg/m^2[23-28] and most of them were ASA 2 (n=171, 83%). The majority had lobectomy (n=151, 73%). One-third of patients had post-smoking COPD (n = 67), 41% (n = 84) had hypertension, 11% (n = 23) had diabetes, and 10% (n = 20) had coronary artery disease. Among the procedures associated with the ERP, 65% (n = 100) of smokers stopped tobacco before their intervention, 71% (n = 146) of patients had carbohydrates preoperatively, 44% (n = 91) had a patient controlled loco-regional anesthesia pump, 52% (n = 107) had NSAIDs and 54% (n = 111) had their chest tube removed on D2 postoperatively. The overall complication rate was 32% (N = 66), of which 18% (n = 37) was respiratory (pneumonia (n=17; 46%); hemothorax (n=6; 16%)), the median hospital stay was 7 days [6-9], and 83% (n = 172) patients have returned home. The results of univariate analysis found that the presence of COPD (p < 0.0001), hospitalization in the intermediate care unit (p = 0.002), active smoking (p=0.02), the lack of prescription of NSAIDs (p = 0.03) and the presence of chest tube at day 2 (p = 0.01), were associated with a higher postoperative complications rate. The multivariate analyzes showed that the hospitalization in the intermediate care unit (p=0.02; OR=3.53 [1.22-10.22]) and the presence of chest tube at day 2 were independent factors associated with complications (p< 0.0001; OR=4.69 [2.17-10.17]).
CONCLUSIONS. Within a thoracic surgery enhanced recovery pathway, less than one in five patients suffered from respiratory complications. Hospitalization in an intermediate care unit and the presence of chest tube at day 2 are associated with the occurence of post-operative complications.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):1311**

INTRODUCTION. There are 10-20 million vascular procedures performed worldwide each year. Patients undergoing vascular surgeries are at high risk of perioperative cardiac complications. It was recently proven that preoperative abnormalities in coagulation and fibrinolysis are associated with higher incidence of myocardial injury after noncardiac surgery.[1]
OBJECTIVES. The aim of our study was to compare concentrations of coagulation (Factor VIII, von Willebrand Factor: Ag) and fibrinolysis (D-Dimer) markers between control group, patients undergoing surgeries for abdominal aortic aneurysm (AAA) and those undergoing procedures for peripheral artery disease (PAD).
METHODS. We enrolled 131 patients ≥ 45 years old undergoing surgery for abdominal aortic aneurysm (54 cases) or peripheral artery disease (77 cases) under general or regional anesthesia, hospitalized at least one night after the procedure. Patients undergoing carotid artery surgery and those who had bypass graft thrombosis, cancer, renal failure defined as eGFR < 30 ml/min/1.73 m^2, venous thromboembolism 3 months prior to surgery or acute infection were excluded from the study. Additionally, we enrolled a control group comprising of 40 volunteers. In patients undergoing vascular procedures blood samples were obtained within 24 hours before surgery.
RESULTS. The mean age of study group was 66.4 (9.2) years. Control group comprised of significantly younger individuals, however the difference between AAA and PAD groups was not significant. Clinical characteristics of study group are presented in Table 1. We have

observed significant differences between control group, patients undergoing surgery for AAA and those undergoing procedure for PAD in serum concentrations of Factor VIII (89.6 vs. 141.9 vs. 176.9 %, p< 0.001), von Willebrand Factor: Ag (116.7 vs. 198.0 vs. 314.5 %, p< 0.001) and D-Dimer (265.0 vs. 2590.5 vs. 808.0 ng/ml, p< 0.001).

CONCLUSIONS. We believe that presented results suggest that activity of both coagulation and fibrinolytic systems is higher in patients undergoing vascular surgery compared to general population. Among them patients undergoing surgery for PAD seem to be at the highest risk of perioperative complications due to particularly pronounced hypercoagulation and lower activity of fibrinolysis.

INTRODUCTION. Patients with chronic thromboembolic pulmonary hypertension undergoing pulmonary endarterectomy (PEA) may develop respiratory failure due to reperfusion edema with or without right ventricular (RV) failure, being occasionally, refractory to all standard therapeutic measures. These patients could benefit from mechanical respiratory and circulatory support.

OBJECTIVES. To describe the results of a case series following PEA with refractory respiratory failure needing the assistance of extracorporeal membrane oxygenation (ECMO).

METHODS. A retrospective observational study based on a prospectively collected database was made. All patients with the previous characteristics admitted to the Intensive Care Unit (ICU) from January 2010 to April 2018 were included. We analyzed variables such as demographic, hemodynamic, length of stay in ICU and hospital, hours of mechanical ventilation and ECMO assistance, complications and mortality. The quantitative variables are presented as median and 25th-75th percentile range and the qualitative ones, as percentage.

RESULTS. Among all of the 225 PEA during this period, 16 patients (7,1%) required ECMO support. The median age was 49 years (IQR 41-68), 50% women. A veno-venous ECMO (VV) was implanted in 56%, while 44% had, besides, RV failure and/or prominent pulmonary hypertension, needing the veno-arterial (VA) configuration. However, 3 conversions from ECMO VA to VV were required (due to 2 Harlequin syndromes and 1 large arterial cannula bleeding) and 1 conversion from VV to VA due to RV failure, making a total of 20 ECMO devices. Peripheral access was chosen in 95% of the cases. Seven were femoral-femoral, 12 femoral-jugular and the central one, was right atrium-aortic. The underlying pathology was respiratory failure due to reperfusion edema, adding RV failure in 44% and diffuse alveolar hemorrhage in 12%. A median ECMO support of 180 hours was recorded (ICR 144-291). Eleven patients (69%) presented complications associated with the device, each of which, 2 cardiac tamponade requiring surgical reintervention, 1 hemorrhagic stroke, 3 cannula bleedings (1 required change of ECMO), 4 minor bleedings that did not require blood transfusion, 1 lower extremity ischemia and 1 thrombosis. Regarding the patients, the median time of mechanical ventilation were 461 hours (IQR 268-588), the length of stay at the ICU was 25 days (IQR 17-31) and at the hospital of 33 (IQR 19-41). The overall ICU mortality was 56%.

CONCLUSIONS. Occasionally, PEA may present a postoperative course with refractory severe respiratory complications, such as reperfusion pulmonary edema, with or without RV failure, requiring mechanical support. The ECMO assistance has shown to be helpful in this group of patients. The results are comparable to those published in this context.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1313

INTRODUCTION. Postoperative diaphragmatic dysfunction has been described after cardiac and abdominal surgery. However, there is a lack of data regarding thoracic surgery. Echography is a non-invasive procedure allowing repeated assessment of diaphragmatic excursion and thickening fraction at the bedside.

OBJECTIVES. Our goal was to describe the time course of, both, diaphragmatic excursion and thickening fraction following elective thoracic surgery.

METHODS. We conducted a prospective, single-center observational study in consecutive patients undergoing thoracic surgery between January 8th and March 11th 2018. Patients were recruited after providing informed consent and the study was approved by an ethical committee. Diaphragmatic excursion and thickening fraction of both hemi-diaphragms were measured by two observers blinded to each other at 3 different time-points : prior to surgery (D-1), immediately after extubation (D0), and at postoperative day 3 (D3). The time-course of excursion (cm) and thickening fraction (%) were compared according to the side (operated or non-operated) using a two-way ANOVA. In case of significant interaction, multiple comparisons were performed using a Student-Newman-Keuls test.

RESULTS. 50 patients aged 60 +/- 15 years have been included. Sixty percent were males, 30 patients underwent lobectomy, 17 tumorectomy and 3 pneumonectomy. We observed a significant decrease in diaphragmatic excursion (Figure 1) and thickening fraction (Figure 2) of the diaphragm on the operated side at D0 and D3 with respect to D-1. These values remained unchanged over the study period on the non-operated side.

CONCLUSIONS. Thoracic surgery is responsible for a diaphragmatic dysfunction on the operated side, which is noted immediately after extubation and persists at least up to the third postoperative day. No alteration of diaphragmatic excursion or thickening fraction was observed on the non-operated side.

Table 1 (abstract 1314). Rhabdomyolysis related factors

INTRODUCTION. Rhabdomyolysis syndrome characterized by dissolution of skeletal muscles and release of myoglobulin into the bloodstream.

OBJECTIVES. To investigate perioperative factors correlated with Rhabdomyolysis following elective cardiac surgery with use of cardiopulmonary bypass in Cardiothoracic Department G.Papanikolaou Hospital Thessaloniki Greece.

METHODS. Patients who underwent elective cardiac surgery from June 2012 to February 2018 and had postop Creatine kinase (CK) value > 2,000 U/l were included. We have exluded from the study: 179 urgent/emergent operations, 22 off pump procedures and 6 perioperative myocardial infarction patients.

The following prospectively collected data were analyzed: Age, Gender, Euro-score II, Smoking habit, REDO operations, Cardio Pulmonary Bypass(CPB) time >120 min, Acute Kidney Injury-AKI(defined by RIFLE criteria), renal replacement therapy(RRT) because of AKI, use of Intra-aortic balloon(IABP), Multiple Organ Dysfunction Syndrome(MODS) and Mortality.

Chi square test was used for the statistical analysis.

RESULTS. In total 2495 patients were included. Rhabdomyolysis was present in 73(2.9%)pts(25 females), consisting Group A, mean aged 65.7 ±10.1 vs 64.5 ±10.6, Euroscore II 4.5±5.7 vs 1.95±2.1 of the rest of the cohort. No relationship was found with smoking (p=0.114) and REDO procedures(p=0.171). Factors with statistical significant relationship are shown in table 1.

CONCLUSIONS. Postoperative rhabdomyolysis after elective cardiac surgery has statistical significant correlation with prolonged CPB time, IABP use, postoperative AKI, AKI-RRT, MODS and higher mortality.

Intensive Care Medicine Experimental 2018, **6(Suppl 2):**1315

INTRODUCTION. The European Lung Cancer Working Group and others studies suggested that a high preoperative neutrophil / lymphocyte ratio (NLR) might be a convenient biomarker to identify patients with a poor prognosis after resection for non-small cell lung cancer (NSCLC) (2). Although there are variations in ERP among the institutions, the evidence suggests that implementation of Enhanced Recovery After Surgery (ERAS) in major surgery significantly reduces postoperative complications and length of hospital stay. (3).

OBJECTIVE. This study aimed to investigate the effect of ERAS fluid protocol on platelet count and neutrophil-lymphocyte ratio (COP-NLR), mortality and morbidity in lung resectable cancer cases.

METHODS. Patients' clinical characteristics and laboratory test data at initial diagnosis were collected at our institute. The COP-NLR was calculated on the basis of data obtained. Patients with both an increased platelet count ($>275 \times10^3$ mm^{-3}) and an elevated NLR (>2.5) were assigned a score of 2, and patients with on or neither were assigned as a score of 1 or 0, respectively.

RESULTS. A total of 97 NSCLC patients were enrolled in this analysis between 2012 and 2017. ERAS fluid protocol was applied in 42 patients. There were no differences in terms of age, sex and duration of operation between two groups. Postoperative COP-NLR values were lower in the ERAS group but mortality rates were not different. Duration of the stay in intensive care unit, intraoperative hypotension, inotropic requirement, and cardiac complication development risk were also less in ERAS group.

CONCLUSION. A lower detection of COP-NLR on postoperative day 1 in cases of pulmonary resection with ERAS protocol may be used as a marker for lower complication rates.

Relationship between hemoglobin level at admision and renal injury during hospital stay and after in patients undergoing cardiac surgery

M.R. Diaz Contreras, R. De la Chica Ruiz-Ruano, F. Villagran Ramirez
Hospital Universitario Virgen de las Nieves, Intensive Care Unit, Granada, Spain
Correspondence: F. Villagran Ramirez
Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1316

INTRODUCTION. Renal injury is a frequent and serious complication in cardiac surgery patients. Although it can usually recover completely in many patients, a significant number can can maintain altered renal function over time after hospital discharge. In previous studies we found that age, COPD presence and the NYHA grade were prognostic factors in the development of permanent kidney injury in post-operative cardiac surgery patients.

OBJECTIVES. Our target is to analyze whether hemoglobin levels at admission in patients who are going to be subjected to cardiac surgery in our hospital can influence the development of permanent kidney injury.

MATERIAL and METHODS. We used the data from the base of the Andalusian registry of cardiac surgery within the plan of integral attention to heart diseases, referring to the patients operated in our hospital and admitted to our Intensive Care Unit of the Hospital Virgen de las Nieves de Granada, in a period of five years.

RESULTS: 2,443 patients underwent cardiac surgery and were discharged from the hospital alive. Of these, 1,497 had normal renal function prior to surgery (defined by plasma creatinine $\leq$ 1.2 mg). A total of 149 were discharged with a plasma creatinine that exceeded 0.3 mg basal values and / or an increase of 50% of these values, regardless of what happened during their hospital stay. The most relevant baseline characteristics of patients with and without kidney injury were:

To the previous data we have added the study of preoperative hemoglobin and the maximum peak of creatinine during the hospital stay of each patient. Using Pearson´s correlation, we compared two quantitative varibles of an independent group finding an association between maximum creatinine and preoperative hemoglobin levels with a significance level of 0.01. This level of significance has also been found when comparing the variables of creatinine levels at discharge and preoperative hemoglobin.

CONCLUSIONS. Preoperative hemoglobin levels are associated with the development of renal injury (maximum creatinine during hospital stay and after discharge) in patients undergoing cardiac surgery. Therefore they should be taken into account especially in the preoperative study and be optimized pre-intervention.

INTRODUCTION. Physical activity has been suggested to influence perioperative outcome after lung transplantation.

OBJECTIVES. We aimed to investigate the association between improvement of physical activity and early postoperative outcomes in lung transplant recipients who received early mobilization physical therapy initiated in intensive care unit (ICU).

METHODS. We retrospectively evaluated a total of 22 patients who received pulmonary rehabilitation initiated in ICU within 2 weeks after lung transplantation at Severance Hospital Yonsei University from March 2015 to February 2016. Physical activity levels were graded according to our institutional pulmonary rehabilitation program: grade 1, bedside (G1); grade 2, dangling (G2); grade 3, standing (G3); grade IV, gait (G4), and then weekly graded throughout pulmonary rehabilitation.

RESULTS. Fourteen (64%) patients were male: median age, 57 years (range, 25-73). Initial physical activity levels were G1 in 9 patients, G2 in 7, G3 in 4, and G4 in 2. According to final physical activity levels, patients were dichotomized as responders with G4 (n = 14) or non-responders who never achieved G4 or down-graded to a lower level (n = 8). The mMRC dyspnea scale and the NYHA functional class were significantly lower in responders compared to non-responders (p=0.074; p=0.022). Durations of propofol and remifentanyl infusion were also significantly lower in responders (p=0.021; p=0.006). The 6-months mortality was significantly lower in responders (21.4% *vs.* 87.5%, p=0.006). After a median follow-up of 13.4 months (range, 7.0-16.0) after lung transplantation, cumulative survival outcomes were 61.2% in responders and 12.5% in non-responders (p< 0.001).

CONCLUSIONS. This study, we showed that patients who achieved and maintained an improved physical activity (ambulatory) had increased survival after lung transplantation.

INTRODUCTION. ECMO post-cardiac surgery has emerged as a supportive therapy in Postcardiotomy cardiogenic shock refractory to inotropic and intra-aortic balloon pump support.

OBJECTIVES. The aim of our study was to show outcomes in a post-cardiac surgery specialized unit but new ECMO referral center.

METHODS. Prospective, observational study at our institution from November 2016 to March 2018 at our institution. We included those patients who needed ECMO due to postcardiotomy cardiogenic shock during the study period. Baseline characteristics, intraoperative variables and outcomes were analyzed, together with laboratory data.

RESULTS. 16 patients were included; age 61.1±10.3 years; 62.5%(10) were male; BMI:27.6±4.1Kg•m^{-2}; APACHE II:18±8; SOFA: 9.3±3.4. 56.25%(9) were bypass and 31.25%(5) were valvular surgeries. In-hospital mortality was 37.5%(6) and 1-year mortality 43%(7). ECMO was performed during the first 72h in our patients with a mean ECMO support of 6±3.2 days. During ECMO, 37.5%(6) suffer bleeding complications, 31.25%(5) re-exploration, 50%(8) sepsis and none thrombosis. We did not find differences in terms of preoperative, intraoperative and outcomes between survivors and non-survivors sub-groups but there was a trend towards more need for Platelet (units) during ECMO in non-survivors (2.0±1.95 vs.5.17±2.13;*P=0.01*). We also showed higher arterial lactate on day 3 (1.80±0.66vs.7.2±7.38 mmol·L^{-1};P=0.03) in those who died.

CONCLUSIONS. In our short experience, haemodynamic support with ECMO may provide a survival benefit with reasonable intermediate and long-term outcomes. Perfusion laboratory values and bleeding related variables seemed to be associated with worst prognosis in our small population.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1319

INTRODUCTION. The patient´s self-report is the gold standard measure of pain; however, it is not possible to obtain it in all patients in the intensive care unit (ICU) due to inability to communicate. In such situations, behavioral scales are alternative measures as no physiologic methods are available.[1] Indeed, single physiologic parameters (e.g., heart rate, blood pressure) are not valid for ICU pain assessment.[2] The newly developed Nociception Level (NOL) index (Medasense, Israel) incorporates several physiologic parameters to estimate the pain level.[3] It has been validated in anesthesia,[3-4] but its use in the ICU is new.

OBJECTIVES. This study explored the ability of the NOL index to detect pain during mediastinal tube removal (MTR) in cardiac surgery ICU patients.

METHODS. A prospective cohort study design was conducted in an ICU in Montreal, Canada. Adult patients admitted for elective cardiac surgery and able to self-report postoperatively were eligible. Patients were asked to self-report their pain intensity with the 0-10 Numeric Rating Scale (NRS). The NOL index is a single number from 0 to 100 obtained through a non-invasive finger probe, and for patients under general anesthesia values >25 are indicative of pain. It incorporates heart rate, heart rate variability, plethysmograph wave amplitude, skin conductance level, number of skin conductance fluctuations, and their time derivatives, using a non-linear regression algorithm to estimate the pain level.[3] Data was collected at rest pre-procedure (T1), during MTR procedure (T2), and 15 minutes post-procedure (T3). The sample and study variables were described, and ROC curve analysis of the NOL index for the detection of the patient´s pain intensity at T2 was performed.

RESULTS. Fifty-four cardiac surgery ICU participants (72% males, mean age=66) were included. Descriptive findings (median, percentiles 25%-75%) were the following at T1 [pain intensity (2.00, 0.00-5.00), NOL (19.11, 7.64-26.16)], at T2 [pain intensity (6.00, 3.00-9.00), NOL (28.90, 23.23-35.74)], and at T3 [pain intensity (3.00, 0.00-5.00), NOL (8.62, 2.76-15.82)]. At T2, the NOL (>34) showed a sensitivity of 80% and a specificity of 70% to classify participants with no or mild pain (0-4) to those with significant pain (5-10) with an area under the curve (AUC) of 0.79 (95% CI:0.63-0.94).

CONCLUSIONS. Pain intensity and NOL values were higher during MTR compared to rest pre/post. The NOL's ability to detect pain during MTR in this ICU group was good. Some factors (e.g., anxiety, stress) in awake patients may be reflected in the study results. Research on the NOL's validity for ICU pain assessment is on-going.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1320

INTRODUCTION. Systemic vasculitis may cause life threatening complications requiring admission to the intensive care unit (ICU).

OBJECTIVES. The aim of this study was to evaluate general characteristics and outcome of patients with systemic vasculitis admitted to a medical ICU.

METHODS. We retrospectively reviewed the medical records of 1496 patients diagnosed with vasculitis and followed in the Hacettepe University Faculty of Medicine Vasculitis Centre between January 2014 and January 2018 and selected those admitted to the medical ICU.

RESULTS. In 4 years, 18 patients (1.2%) were admitted to the medical ICU with 23 ICU admissions (5 repeated admissions). Ten (55.6%) of them were male and mean (±SD) age was 54.9±20.0 years. The most common vasculitis was ANCA associated vasculitis (n=11). Others were temporal arteritis (n=2), Goodpasture (n=1), Behcet's disease (n=1), Polyarteritis nodosa (n=1), *Cryoglobulinemic vasculitis* (n=1) and Cerebral vasculitis (n=1). The reasons for ICU admission were pneumonia (n=7), alveolar hemorrhage (n=6), pulmonary edema (n=6), acute kidney injury (n=1), ARDS (n=1), pulmonary thromboembolism (n=1) and gastrointestinal bleeding (n=1). Mean APACHE II and SOFA scores were 19.4±10.1 and 7.2±5.4, respectively. Invasive mechanical ventilation was applied in 18 admissions. Pulse steroid treatment was given in 9 admissions. Plasmapheresis was applied in 8 admissions (5 alveolar hemorrhage and 3 pulmonary edema) during the ICU stay. Mean ICU length of stay was 15.2±12.8 days. Five (31.3%) patients (4 ANCA associated, 1 cerebral vasculitis) died in the ICU due to pneumonia (n=3) and alveolar hemorrhage (n=2).

CONCLUSIONS. ANCA associated vasculitis was the most common vasculitis with high mortality rate, pneumonia and alveolar hemorrhage being the most common causes of admission in our ICU.

Small-vessel vasculitides patients have the highest mortality among systemic autoimmune diseases patients in intensive care unit: a retrospective study with 5-year follow-up

A. Włudarczyk[1], K. Polok[1], J. Górka[1], G. Biedroń[2], J. Musiał[2], W. Szczeklik[1]

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1321

INTRODUCTION. Systemic autoimmune diseases are a heterogeneous group of disorders associated with dysfunction of multiple organs and unpredictable course. Complicated management and treatment becomes even more challenging for patients requiring critical care.
OBJECTIVES. This study aims to compare outcomes of small-vessel vasculitides (SSV) and other systemic autoimmune diseases (SAD) patients admitted to the intensive care unit (ICU).
METHODS. Retrospective, observational study conducted in the ICU of Allergy and Immunology Department at the University Hospital in Krakow, Poland, between years 2001-2014, and with 5-years follow-up after ICU discharge and no lost to follow-up patients.
RESULTS. 74 patients with autoimmune diseases were enrolled in the study. 23 with SSV and 51 with other SAD. Patients in the SVV group achieved higher scores in APACHE II (28 vs 21.5 points, p=0.02) and III (94 vs 72 points, p=0.04), SAPS II (58 vs 36 point, p< 0.001) and SOFA at ICU admission. The SVV patients required renal replacement techniques, blood products transfusion and immunosuppressive treatment more often. SVV patients had higher ICU mortality (60,9% vs. 35,3%, p=0.04), however after discharge from ICU, in long term follow-up (1-year and 5 years) mortality was similar in both studied groups.
CONCLUSIONS. Among systemic autoimmune diseases small vessel vasculitides appear to be associated with the highest ICU mortality, higher requirement for advanced procedures and aggressive immunosuppressive therapy.

Intensive Care Medicine Experimental 2018, **6**(Suppl 2):1323

INTRODUCTION. Multiple serious adverse events may occur during intrahospital transport. Physiological monitoring (e.g. ECG, SpO2… etc…) is a fundamental and the accuracy/ergonomy of transport monitoring systems are of utmost importance.
OBJECTIVES. The aims of this study were to provide a comprehensive evaluation of recent transport monitors, taking into account their « *time to operate* », error rate and psycocognitive evaluation.
METHODS. The study was performed in a university healthcare simulation center, affiliated to the LATIM INSERM UMR 1101, that has developed a global evaluation model [1]. Two devices were compared, Philips Companion X3 (P) and GE Carescape One (GE).
After a pre-run phase, we standardized the scenarios (1- intubated patient in the OR; 2- transport of the patient; 3- arrival in the ICU) and immersive environments. Recorded parameters were video acquisition from 9 cameras and psycho-cognitive scales (Likert, NASA TLX - for mental workload, SUS and USX - for usability, NPS - for promotion). All videos were identified, qualified, and synchronized for timing. Different tasks' steps were identified and a precise evaluation of duration by video-tagging was performed.
RESULTS. 25 nurses were included (Age=41±8 yrs; Site of daily practice: OR [n=14]; ICU [n=6]; ED [n=5]). Most of them were not familiar with the tested devices (64%). Readiness for transport (366±113 vs. 242±77 sec; p=0.0001) and overall transport time (694±196 vs. 514±156 sec; p=0.003) were shorter with GE, the main determinant being cables plugging. Failure rate was lower with GE (4 vs. 10% ; p=0.017). Usability was higher (65±16 vs. 70±17) and mental workload lower (50±21 vs. 41±19) with GE, without statistical significance. Clinicians were more likely to recommend the GE device (NPS=7.5±1.4 vs. 6.8 ±1.7; p=0.14).
CONCLUSIONS. GE Carescape One improves readiness for transport (i.e. improving OR use), decreases global time for transport (i.e. improving staff workflow) and decreases failure rate, as compared to Philips X3. It tends to be easier to perform tasks with GE and it is the only device to get a SUS value higher than the reference (SUS=68).
