### Abstract

**Background**—The mechanism of Atrial Fibrillation (AF) that emerges spontaneously during acute oxidative stress is poorly defined and its drug therapy remains suboptimal. We hypothesized that oxidative activation of Ca-calmodulin dependent protein kinase (CaMKII) promotes Early Afterdepolarization-(EAD)-mediated triggered AF in aged fibrotic atria that is sensitive to late Na current ( $I_{Na-L}$ ) blockade.

**Method and Results**—High-resolution voltage optical mapping of the Left and Right Atrial (LA & RA) epicardial surfaces along with microelectrode recordings were performed in isolated-perfused male Fisher 344 rat hearts in Langendorff setting. Aged atria (23–24 months) manifested 10-fold increase in atrial tissue fibrosis compared to young/adult (2–4 months) atria ( $P < 0.001$ ). Spontaneous AF arose in 39 out of 41 of the aged atria but in 0 out of 12 young/adult hearts ( $P < 0.001$ ) during arterial perfusion of with 0.1 mm of hydrogen peroxide ( $H_2O_2$ ). Optical Action Potential (AP) activation maps showed that the AF was initiated by a focal mechanism in the LA suggestive of EAD-mediated triggered activity. Cellular AP recordings with glass microelectrodes from the LA epicardial sites showing focal activity confirmed optical AP recordings that the spontaneous AF was initiated by late phase 3 EAD-mediated triggered activity. Inhibition of CaMKII activity with KN-93 (1  $\mu M$ ) ( $N=6$ ) or its downstream target, the enhanced  $I_{Na-L}$  with GS-967 (1  $\mu M$ ), a specific blocker of  $I_{Na-L}$  ( $N=6$ ), potently suppressed the AF and prevented its initiation when perfused 15 min prior to  $H_2O_2$  ( $n=6$ ).

**Conclusions**—Increased atrial tissue fibrosis combined with acute oxidative activation of CaMK II Initiate AF by EAD-mediated triggered activity. Specific block of the  $I_{Na-L}$  with GS-967 effectively suppresses the AF. Drug therapy of oxidative AF in humans with traditional antiarrhythmic drugs remains suboptimal; suppressing  $I_{Na-L}$  offers a potential new strategy for effective suppression of oxidative human AF that remains suboptimal.

### Keywords

Atrial fibrillation; CaMKII; Fibrosis; Early afterdepolarizations; Optical activation map; Hydrogen Peroxide; GS-967; Late inward sodium current

## Introduction

Oxidative stress has been shown to increase the susceptibility of the heart to ventricular and atrial fibrillation (VF and AF respectively) in animal models that manifest increased cardiac fibrosis [1,2]. Increased systemic and atrial myocardial oxidative stress is often observed in post-operative patients with new onset (acute) paroxysmal AF (POAF) [3,4] with an incidence of up to 50% [5]. Diverse etiological factors such as fibrosis [6,7] and increased  $Ca^{2+}$ /calmodulin-dependent protein kinase II (CaMKII) activity [8,9] among others, are thought to play a key role in the initiation of oxidative AF [4,10]. While the causative and signaling factors of oxidative AF are reasonably well identified, the mechanism of spontaneous initiation (i.e., not induced by electrical stimulation) of acute oxidative AF in experimental and human studies, remains undefined [10]. The lack of mechanistic cellular insight into the genesis of oxidative AF hampered the development of effective pharmacological therapy to suppress and/or prevent the oxidative AF [11]. For example, beta-blockers [12] and Amiodarone, [13] considered first line preventive drugs against POAF, are only partially effective. Interestingly, both human and animal studies have shown increased atrial CaMKII activity as the molecular signal that couples oxidative stress with AF [10]. Activated CaMKII phosphorylates cardiac Na and Ca channels enhancing the highly arrhythmogenic late Na ( $I_{Na-L}$ ) [14] and the late L-type Ca ( $I_{Ca-L}$ ) [15] currents. Isolated myocytes and dynamic-clamp experiments have shown that an isolated increase of either of these two late inward currents promotes cellular early and delayed afterdepolarizations (EADs and DADs respectively) causing rapid triggered activity [16,17]. Indeed inhibition of the  $I_{Na-L}$  with the highly potent ( $IC_{50}=0.143 \mu M$ ) and selective inhibitor GS-967 [18] suppresses EADs in isolated atrial myocytes [18,19]. The purpose of this study is to test the following two hypotheses; 1) oxidative stress-mediated activation of CaMKII signaling with hydrogen peroxide ( $H_2O_2$ ) in structurally remodeled atria characterized with increased atrial tissue fibrosis promotes AF by the mechanism of EAD and DAD-mediated triggered activity; and 2) selective inhibition of the enzymatic activity of CaMKII or its distal target, the  $I_{Na-L}$  with the specific  $I_{Na-L}$  blocker, GS-967, [18] suppresses the oxidative AF.

## Methods

Our study protocol conforms to the Guide for the Care and Use of Laboratory Animals and is approved by our Institutional Animal Use and Care Committee.

## Langendorff preparation

**Optical mapping and microelectrode recording**—We used male Fisher 344 rats. The isolated hearts were arterially perfused with oxygenated normal Tyrode's solution. The hearts were stained with the voltage-sensitive fluorescent dye, RH-237 for optical activation mapping of the epicardial surfaces of both the LA and the RA appendages. We use a CMOS camera (MiCAM Ultima, Brain Vision, Tokyo, Japan) at 1 ms/frame and  $100 \times 100$  pixels with a spatial resolution of  $0.35 \times 0.35 \text{ mm}^2/\text{pixel}$ . Cytochalasin D ( $5 \text{ } \mu\text{mol/l}$ ) was added to the perfusate to eliminate motion artifacts during optical recordings [20,21]. Sites of frequent atrial epicardial focal activity arising at the onset of AF detected with the optical mapping were subsequently probed with single cell glass microelectrode recordings to determine the cellular mechanism of the underlying focal activity.

**Histological analyses of atrial tissue fibrosis**—The hearts of the young and the old rats were fixed in 4% buffered formalin for 1 hour and then placed in 70% alcohol. Longitudinal and transverse sections ( $5 \text{ } \mu\text{m}$  thickness) were made in the LA appendage and the free wall and stained with trichrome that stain collagen fibers blue. Percent LA fibrosis was determined as we previously described [7,20].

**Statistical analyses**—Significant differences in the incidence of AF (dichotomous comparisons) were determined using Fisher's exact test. The APDs were determined using repeated-measures ANOVA. We consider  $P$  value of  $<0.05$  as significant. Data are presented as means  $\pm$  SD.

## Results

### Increased fibrosis in atria from aged versus young/adult atria

A significant and highly heterogeneous increase in the LA and RA interstitial and replacement tissue fibrosis was observed in atria of aged (22–24 months) as compared to young/adult (2–4 months) rats ( $12.7 \pm 10.6$  vs.  $1.4 \pm 0.6$ ,  $P < 0.001$ ) (Figure 1). These findings are consistent with our previous findings in aged rats and rabbits atria [1,7,20,22] as well as in aged human atria [23].

### Spontaneous AF initiation in aged rat hearts during acute oxidative stress caused by arterial perfusion of $\text{H}_2\text{O}_2$ : The role of CaMKII signaling

Because oxidative stress with  $\text{H}_2\text{O}_2$  also promotes VF in aged hearts [1] we determined the mechanism(s) of spontaneous AF initiation of AF only when the AF preceded the VF or when the AF was not associated with VF as shown in figure 2. Under these conditions the AF emerged after a mean of  $12 \pm 7$  min exposure to  $\text{H}_2\text{O}_2$  and was often preceded by a transient period of monomorphic atrial tachycardia or flutter (AT/AFI) at a mean cycle length (CL) of  $80 \pm 46$  ms (Figure 2). The transient AT then suddenly degenerates to a very rapid (CL of  $45 \pm 12$  ms) and irregular atrial electrogram activity indicating the transition of AT/AFI to AF (Figure 2). We then determined the role of atrial CaMKII activity on  $\text{H}_2\text{O}_2$ -mediated AF. For this purpose, we first perfused the hearts of aged rats ( $N=6$ ) with the specific CaMKII inhibitor KN-93 ( $1 \text{ } \mu\text{M}$ ) for 15 min and then added  $0.1 \text{ mM}$   $\text{H}_2\text{O}_2$  to the perfusate in the continuous presence of KN-93. No AF emerged for one hour of observation

in any of the six aged hearts studied (Figure 3). At this point, we replaced the KN-93 with its inactive form KN-92 (1  $\mu$ M) in the continuous presence of H<sub>2</sub>O<sub>2</sub> to determine if off target effects of KN-92 played any role in the AF suppression. The switch caused the emergence of AT/AF in all six hearts after  $8 \pm 4$  mins (Figure 3). In six additional hearts, KN-93 (1  $\mu$ M) was added after the onset of H<sub>2</sub>O<sub>2</sub>-induced AF. KN-93 terminated AF in all six hearts after a mean exposure time of  $14 \pm 7$  mins (Figure 3). These findings indicate that activation of atrial CaMKII signaling pathway plays a key role in the initiation H<sub>2</sub>O<sub>2</sub>-mediated AF in aged rat hearts characterized by increased atrial tissue fibrosis.

### **H<sub>2</sub>O<sub>2</sub> fails to induce atrial arrhythmias in hearts of young/adult rats**

In contrast to the susceptibility of aged atria to oxidative AF, arterial perfusion of 0.1 mM H<sub>2</sub>O<sub>2</sub> in young/adult hearts for up to 90 mins failed to induce AF in all 6 hearts studied. Furthermore, elevation of the H<sub>2</sub>O<sub>2</sub> concentration for up to 2 mM (N=5) in the young/adult hearts still failed to promote EADs and/or atrial ectopic activity consistent with our previous findings [1,7,22] and by Lin CS et al. [24]. The discrepancy between the ease of oxidative EAD formation at the single myocyte level isolated from young/adult atria [18,25] and the resistance to EAD formation at the atrial tissue level in young/adult hearts, suggests that atrial tissue factor(s) must have been responsible in the aged tissue to readily promote EAD and EAD-mediated triggered activity. These findings suggest that increased atrial tissue fibrosis observed in the aged atria may indeed be a key factor in facilitating the formation EADs and EAD-mediated AF.

### **Optical activation map and single cell microelectrode recordings during the onset of spontaneous AF**

We successfully captured atrial epicardial activation pattern at the onset of spontaneous oxidative AF in three hearts. Optical action potentials (Figure 4A) manifest a progressive emergence of late phase EAD-like activity on the LA epicardial appendage (Figure 4B). These sub thresholds EADs subsequently triggered rapid repetitive activity causing rapid focal activity on the LA as observed on the optical activation map (Figures 4B and 4C). The focal activity then propagated as a target wave over the LA epicardial surface eventually degenerating to disorganized wavefront activity that signaled the sudden onset of AF (Figures 4B and 4C). Figure 4D shows the isolated rat heart with locations of the right and left atrial appendages (RA and LA respectively as well as the right and the left ventricles (RV and LV). Panel D shows optical action potential map with and adjacent color bar showing depolarization and repolarization respectively. In additional five aged hearts continuous single cell glass microelectrode recordings from the LA epicardial appendages showing focal activity at the onset of AF initiation determined with optical activation maps, confirmed that the focal activity was indeed initiated by cellular late phase 3 EAD-mediated triggered activity as shown in figures 5A–C. After the onset of EAD-mediated AF continuous microelectrode recordings showed the emergence of DADs which then in turn initiated DAD-mediated triggered activity contributing to the maintenance of AF as shown in figure 5. Synergistic interaction between the EADs and the DADs (EAD promoting DAD and DAD promoting EADs) was convincingly demonstrated in ventricular myocytes and simulated ventricular myocytes [26]. The present result extends this phenomenon to atrial tissue as well. Interestingly the emergence of DADs in the atrial tissue (Figure 5) caused

only single premature atrial complexes (PAC) but failed to initiate triggered activity and AF. DAD-mediated triggered activity required priming by a prior EAD-mediated triggered activity, a phenomenon help maintain the AF.

### **Suppressive and preventive effects of GS967 against oxidative AF in aged atria**

The addition of GS-967 in the perfusate 15 min prior to exposure to H<sub>2</sub>O<sub>2</sub> prevented AF initiation in 6 out of 6 hearts studied for up to one hour of observation. However, upon washout of GS-967, AT/AF emerged in all six hearts after a mean of 16 ± 4 mins. GS-967 also suppressed the AF after it was initiated with H<sub>2</sub>O<sub>2</sub> in six out six aged hearts after a mean perfusion time of 14 ± 6 mins (Figure 6C). The effect if GS-967 was reversible as AF reemerged after a mean of 21 ± 7 mins of GS-967 washout (Figure 6D).

### **Effects of H<sub>2</sub>O<sub>2</sub> and GS-967 on atrial action potential duration (APD) in young/adult and aged rat atria**

There were no significant differences ( $P>0.3$ ) in the APD to 90 percent repolarization (APD<sub>90</sub>) between the young/adult and aged left atrial appendages at baseline (54 ± 6 ms vs. 55 ± 10 ms) (Table 1). Arterial perfusion with 0.1 mM H<sub>2</sub>O<sub>2</sub> significantly prolonged ( $P<0.01$ ) atrial APD<sub>90</sub> in both age groups, 100 ± 8 ms vs. 105 ± 12 respectively. (N=6 in each group, PCL=400 ms) (Table 1). The addition of GS-967 normalized the APD<sub>90</sub> in both age groups exposed to H<sub>2</sub>O<sub>2</sub> (56 ± 8 ms and 56 ± 10 ms) in the young/adult and the aged group respectively) (Table 1).

## **Discussion**

### **Novel findings**

The major findings of this study are as follows: 1) acute oxidative stress with H<sub>2</sub>O<sub>2</sub> in isolated-perfused aged atria readily promotes spontaneous AF *via* the activation of CaMKII signaling pathway; 2) oxidative stress with similar or even 10 time higher levels of H<sub>2</sub>O<sub>2</sub> fail to promote AF in the young/adult atria; 3) left atrial epicardial transmembrane APD<sub>90</sub> was not significantly different between the two age groups both before and after arterial perfusion of H<sub>2</sub>O<sub>2</sub> or after the combined perfusion of H<sub>2</sub>O<sub>2</sub>+GS-967; 4) the mechanism of oxidative AF initiation is caused by cellular EAD-mediated triggered activity; 5) oxidative AF is prevented and suppressed by either direct enzymatic inhibition of CaMKII activity (proximal target) or by downstream inhibition of CaMKII-mediated enhanced I<sub>Na-L</sub> by GS-967. These results provide a novel cellular insight into the mechanism of spontaneous initiation (not electrically-induced) of oxidative AF that was not reported previously.

### **Oxidative AF: substrate, mechanisms and signaling**

Our results highlight that the combined presence of both atrial tissue fibrosis and acute oxidative stress are necessary for the initiation of spontaneous AF. Neither fibrosis alone (aged atria perfused with normal Tyrode's solution) nor acute oxidative stress alone (peroxide perfusion in non-fibrotic young/adult atria) is sufficient to promote AF. This suggests a synergistic interaction between oxidative stress and increased atrial tissue fibrosis in the promotion of spontaneous AF [27]. Indeed young/adult isolated atrial myocytes readily manifest EADs and TA at the isolated atrial myocyte level [18,28] however, not at

tissue level as shown in this study. Simulation studies [29] have convincingly demonstrated the importance of electrotonic repolarizing “sink” effect caused by well-coupled cells that prevents initiation of EAD-mediated arrhythmias in normal well-coupled atrial tissue. Increased interstitial fibrosis diminishes repolarizing “sink” effect by decreased cellular coupling [30] allowing the EADs to emerge and propagate in the tissue [29]. Indeed in the present study we found no difference in the APD between the two age groups, suggesting no major role played by electrical remodeling in the enhanced sensitivity to AF in the aged atria. This finding further strengthens the major role played by increased atrial tissue fibrosis as a substrate and trigger in the promotion of oxidative EAD-mediated AF.

The potent suppressive effect of GS-967 against oxidative AF provides a novel class of antiarrhythmic drug action not considered in previous drug action classification [11]. Interestingly, recent studies demonstrated, consistent with the results of the present study, that increased  $I_{Na-L}$  plays a key role in the induction of rapid pacing-induced AF in mice and its suppression by GS-967 [31]. The importance of  $I_{Na-L}$  blockade in the suppression of AF with the novel specific  $I_{Na-L}$  blocker, eleclazine was also demonstrated in larger animals (pigs) [32] indicating the potential antiarrhythmic efficacy of this new class of drug action in humans [11].

### Clinical implications

The demonstration of cellular EAD-mediated new onset AF during acute oxidative stress provides an important clinical translational value. It is quite difficult, if not impossible, to obtain reliable recordings of cellular events in intact human hearts at the onset of AF [33]. Human clinical studies demonstrated the occurrence of new onset acute oxidative AF by showing that inhalation of pro-oxidant particulate matters promotes acute AF in patients with cardiac disease [34] and that such effects can be minimized by antioxidant therapy [35]. Genomic analyses showed that genes that were uniquely up regulated in patients with no POAF were mostly supported by reduction reactions suggesting that the overall redox balance favors anti-oxidant state in these patients resistant to POAF [3]. Indeed, mice lacking critical oxidation sites in CaMKII or mice over expressing methionine sulfoxide reductase A, an enzyme that reduces oxidized CaMKII, are resistant to oxidative AF evaluated by programmed electrical stimulation [10]. Recent clinical studies showed that POAF originated from the LA and not from the pulmonary veins (PVs) [36,37] as in the present study. Furthermore it was shown in post-surgical patients manifesting increased atrial tissue fibrosis (confirmed by biopsies) facilitated the emergence LA foci (“sources”) leading to AF [6,25]. That indeed the EAD-mediated triggered activity is the final path to AF initiation is emphasized by suppressing the AF by the selective block of the  $I_{Na-L}$  with GS-967 a powerful and selective inhibitor of EADs. Finally, the additional activation of the CaMKII signaling [38] secondary to the elevation of cytosolic  $Ca^{2+}$  during the AF further promotes EADs by increasing enhanced  $I_{Na-L}$  in a positive feedback loop [38].

### Limitations

Although reduction of electrical load caused by fibrosis provides a plausible explanation for the increased susceptibility of aged hearts to oxidative EAD formation and EAD-mediated AT/AF, we cannot exclude the possibility that other aspects of aging-related remodeling

(e.g., altered  $Ca_i^{2+}$  cycling) may also make important contributions. Indeed, human atrial myocytes isolated from patients with AF show increased CaMKII-dependent phosphorylation of RyR2 leading to increased SR  $Ca^{2+}$  leak and elevated cytosolic  $Ca^{2+}$  levels [39]. These altered subcellular calcium dynamics promotes EADs and DADs formation [26] in a positive feedback loop [38] promoting AF. Finally, the validity of  $H_2O_2$  as clinically relevant oxidative stress may be questioned. However as stressed previously [40] levels 100–150  $\mu M$  concentrations of  $H_2O_2$  have been suggested to be clinically relevant to mimic reversible pro-oxidant pathological states [41]. Indeed  $H_2O_2$  has been used successfully to assess the influence of oxidative stress in AF in diverse animal models [23,25,42,43].

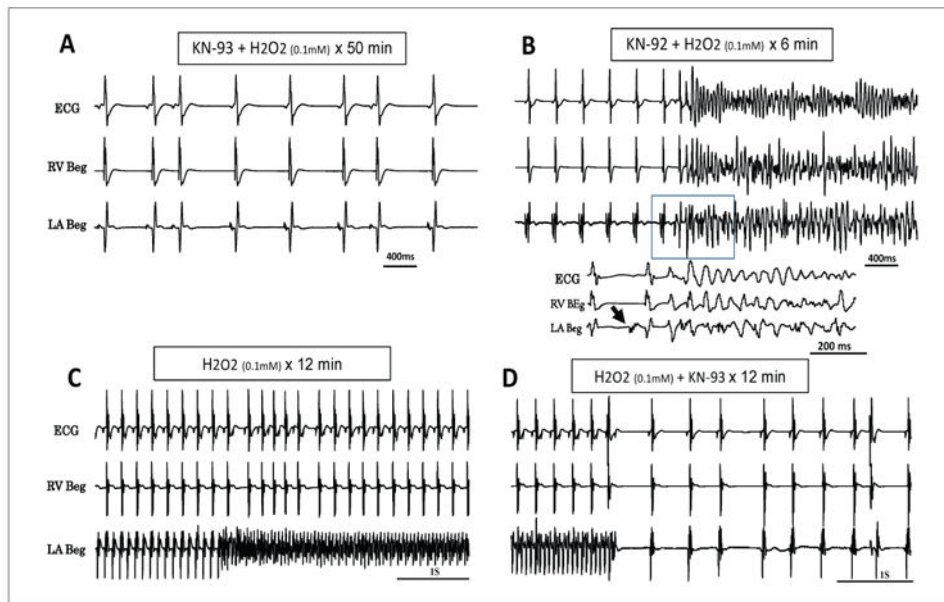

**Figure 1.** Histological sections of trichrome staining of LA epicardial appendages in a young/adult (A) *versus* an old (B) rat heart. Note the increased interstitial fibrosis (blue stain) in the old rat myocardium, causing separation of myocardial bundles (stained red).

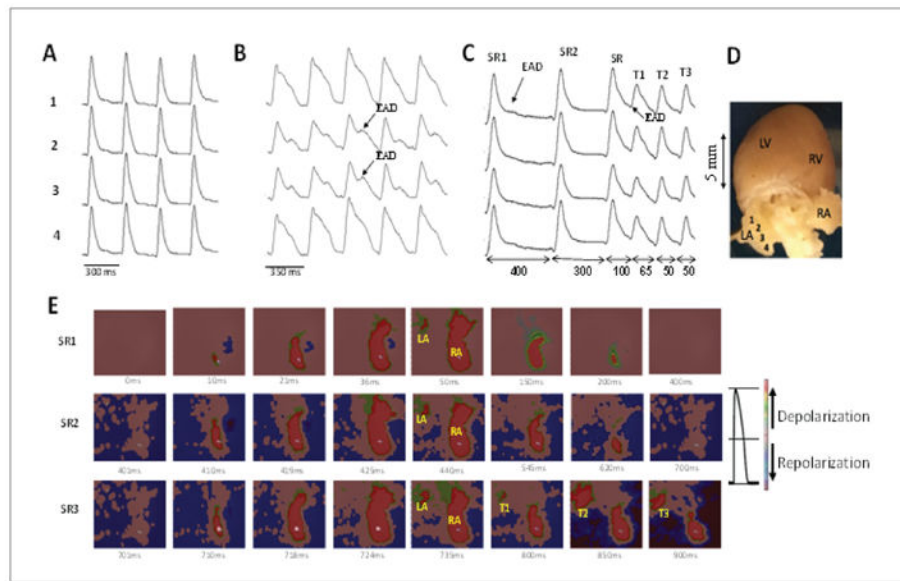

**Figure 2.**

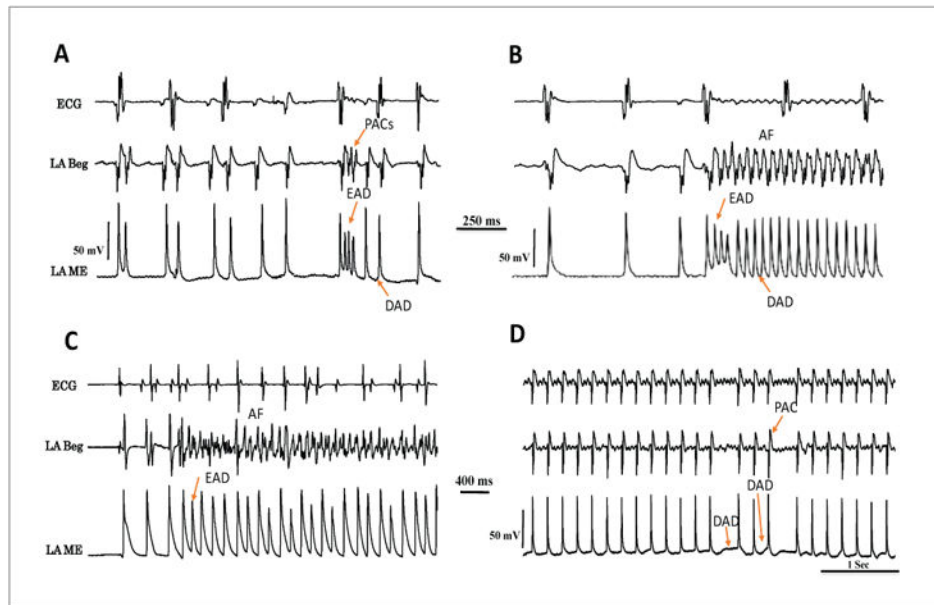

Patterns of spontaneous initiation of AF in isolated-perfused aged hearts exposed to  $H_2O_2$  (hydrogen peroxide) (0.1 mM) in three different aged hearts. Panel A shows sudden onset of AF arising during sinus rhythm. In panel B, AF starts after a prior transient period of AT at a CL of 120 ms and panel C shows the sudden emergence of AT at a cycle length of 116 ms that last more than 30 sec before degenerating to AF.

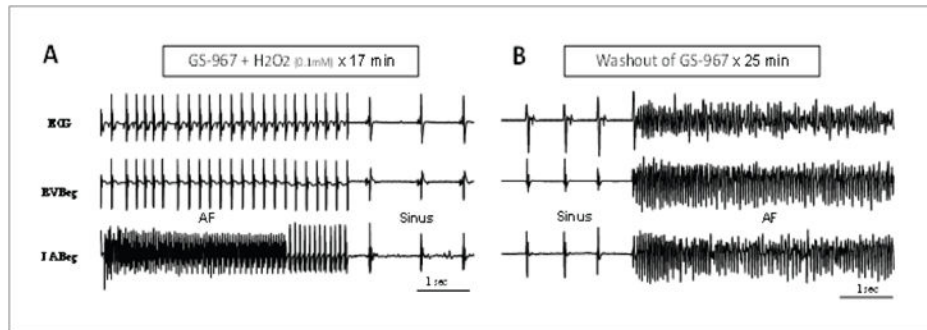

**Figure 3.** Prevention and suppression of acute oxidative AF with the CaMKII inhibitor KN-93 (1  $\mu$ M). Pretreatment with KN-93 prevents emergence of H<sub>2</sub>O<sub>2</sub>-induced AF over a 50 min of observation (panel A). However, subsequent replacement of KN-93 with its inactive form, KN-92 (1  $\mu$ M) causes AF to emerge within 6 minutes of the switch (panel B). Note below the panel B a faster sweep recording showing the onset of AF (arrow) followed immediately by VF. Panel C shows another aged heart in which the AF was initiated with H<sub>2</sub>O<sub>2</sub> (0.1 mM) and was effectively suppressed by the addition of KN-93(1  $\mu$ M) in the continuous presence of H<sub>2</sub>O<sub>2</sub>

**Figure 4.** Optical APs (OAPs) and voltage snapshots of epicardial LA and RA activation during sinus rhythm and at the onset of oxidative AF in an aged rat heart. Panel A shows four rows of OAPs recorded from the LA epicardial surface from sites shown in panel D during perfusion with normal Tyrode's. Panel B shows the influence of 8 min of perfusion with  $H_2O_2$  (0.1 mM) on these OAPs with the emergence of subthreshold EADs. Panel C shows the last three sinus beats just before the onset of EAD-mediated triggered activity (T1–T3). Note that the EAD amplitude during the sinus beat#1 and #2 manifest subthreshold EAD (arrows). However, the 3<sup>rd</sup> sinus beat initiates triggered activity (T1–T3). Double-headed arrows indicate the CL of the specified intervals. Panel E shows the snap shots of the six beats SR1, SR2, SR3, T1, T2, and T3, with the origination of the sinus beats from the RA and triggered beats arising from the LA. Adjoining the maps is a color bar showing depolarization and repolarization respectively.

**Figure 5.** Glass microelectrode recordings of LA epicardial APs showing Premature Atrial Complexes (PAC) in panel A; atrial tachycardia (panel B) and AF (panel C) initiated with  $H_2O_2$  (0.1 mM). Notice the onset of these arrhythmias by EAD-mediated triggered beats. While DADs also appear after a prior run of EAD-mediated triggered activity DAD-mediated causing triggered (Panels A and B), DADs cause only single triggered beats (PAC) as shown in panel D.

**Figure 6.**

Suppression of H<sub>2</sub>O<sub>2</sub>-mediated AF with 1 μM GS-967 Notice an initial transition from AF to rapid AT before converting to sinus rhythm (panel A). Panels B demonstrates that the anti-AF effect of the GS-967 is reversible as AF re-emerges upon the washout of the drug. Also notice the simultaneous emergence of oxidative VF upon the washout of the GS-967 (panel B).

**Table 1**Effects of GS-967 on APD<sub>90</sub> during baseline and after H<sub>2</sub>O<sub>2</sub>

	Young	Aged	<i>p</i> -value
	APD 90%	APD 90%	
Baseline	55 ± 10 ms	54 ± 6	0.67
GS-967	28 ± 8 ms *	31 ± 4 *	0.1
H <sub>2</sub> O <sub>2</sub>	105 ± 12 ms <sup>×</sup>	100 ± 8 ms <sup>×</sup>	0.08
H <sub>2</sub> O <sub>2</sub> +GS-967	56 ± 10 ms *	58 ± 8 *	0.38

\*  
p<0.05<sup>×</sup>  
p<0.01

All values are determined during Pacing Cycle Length (PCL) of 400 ms. The symbols \* and <sup>×</sup> indicate the level of significance. H<sub>2</sub>O<sub>2</sub> and GS-967 concentrations are 0.1 MM and 1 μM respectively. All values are mean ± SD. N=6 in each group.
