Abstract

Multifunctional yolk/shell-structured hybrid nanomaterials have attracted increasing interest as theranostic nanoplatforms for cancer imaging and therapy. However, because of the lack of suitable surface engineering and tumor targeting strategies, previous research has focused mainly on nanostructure design and synthesis with few successful examples showing active tumor targeting after systemic administration. In this study, we report the general synthetic strategy of chelator-free zirconium-89 (⁸⁹Zr)-radiolabeled, TRC105 antibody-conjugated, silica-based yolk/ shell hybrid nanoparticles for *in vivo* tumor vasculature targeting. Three types of inorganic nanoparticles with varying morphologies and sizes were selected as the internal cores, which were encapsulated into single hollow mesoporous silica nanoshells to form the yolk/shell-structured hybrid nanoparticles. As a proof-of-concept, we demonstrated successful surface functionalization of the nanoparticles with polyethylene glycol, TRC105 antibody (specific forCD105/endoglin), and ⁸⁹Zr (a positron-emitting radioisotope), and enhanced *in vivo* tumor vasculature-targeted positron emission tomography imaging in 4T1murine breast tumor-bearing mice. This strategy could be applied to the synthesis of other types of yolk/shell theranostic nanoparticles for tumor-targeted imaging and drug delivery.

Electronic Supplementary Material: Supplementary material (TEM images and quantitative data of 89 Zr-labeling, PET, and biodistribution studies) is available in the online version of this article at https://doi.org/10.1007/s12274-2078-9.

We report the general synthetic strategy of chelator-free zirconium-89 (⁸⁹Zr)-radiolabeled, TRC105 antibody-conjugated, silica-based yolk/shell hybrid nanoparticles for *in vivo* tumor vasculature targeting. This strategy could be applied to the synthesis of other types of yolk/shell theranostic nanoparticles for tumor-targeted imaging and drug delivery.

Keywords

yolk/shell; intrinsic radiolabeling; vasculature targeting; positron emission tomography; zirconium-89

1 Introduction

Despite great challenges in the clinical translation of nanomedicine [1-3], scientists worldwide are devoting great efforts in searching for various types of multifunctional nanomaterials to improve future cancer management. The last decade has witnessed an unprecedented expansion in the design, synthesis, and preclinical applications of various kinds of nanomaterials [4, 5]. Among them, silica-based hybrid nanoparticles have shown immense potential in targeted cancer diagnosis and therapy [6, 7]. Silica, or silicon dioxide, is "generally recognized as safe" by the U.S. Food and Drug Administration (ID Code: 14808-60-7) [8]. To date, the silica-shell-coating strategy remains one of the most used, economical, and practical techniques for the design and synthesis of hybrid nanomaterials [9]. Ultra-small dye-encapsulated fluorescent silica nanoparticles, known as C dots (or "Cornell dots"), entered clinical trials in January 2011 (NCT01266096, NCT02106598) [10, 11]. These "target-or-clear" hybrid silica nanostructures (< 10 nm) are encapsulated with near-infrared (NIR) dyes (e.g. Cy5), tumor-homing peptides (e.g. cRGDY), and radioisotopes (e.g. iodine-124 (124 I, $t_{1/2} = 100.8$ h) and zirconium-89 (89 Zr, $t_{1/2} = 78.4$ h)), allowing for positron emission tomography (PET)-/optical dual-modality-targeted imaging of cancer [10, 12–14]. Besides its high clinical translational potential, silica is also known as a versatile nanoplatform for intrinsic radiolabeling [15, 16]. Recently, we and others have successfully developed a silica-based intrinsic radiolabeling technique for isotopes of ⁸⁹Zr [15, 16], copper-64 (⁶⁴Cu, $t_{1/2}$ = 12.7 h) [17], arsenic-72 (⁷²As, $t_{1/2}$ = 26 h) [18], and titanium-45 (⁴⁵Ti, $t_{1/2} = 3.1$ h) [19], to name a few.

Biocompatible porous silica nanoparticles, such as mesoporous silica nanoparticles (MSNs), with a relatively larger particle size (> 50 nm) than that of C dots (< 10 nm) have been attractive drug delivery systems because of their high specific surface area and pore volume [20–24]. By introducing a large cavity inside each original MSN, hollow mesoporous silica nanoparticles (HMSNs) have attracted increasing interest as a new drug delivery system with greatly enhanced drug loading capacity [25, 26]. To further integrate other optical or magnetic functionalities, a new type of hybrid nanomaterial, named yolk/shell-structured nanoparticles, has also been developed [27–33]. Each hybrid nanoparticle possesses an inorganic functional core for imaging or therapy, a large cavity for the storage of chemotherapeutic drugs, and a thin mesoporous silica shell with tunable pore size for facilitating the loading and release of the pre-loaded drugs [34].

Efficient targeting of these silica-based hybrid nanomaterials to the tumor site is critical. The focus of previous research on yolk/shell-structured nanoparticles was mainly on the nanoparticle design and synthesis [8, 35, 36]. However, because of the lack of suitable surface engineering and tumor targeting strategies, very few of them showed the capability of *in vivo* whole-body biodistribution and active tumor-targeted imaging. Tumor vessels are known to have high vascular permeability and lack functional lymphatics because of the uncontrolled growth rate and changes in endothelial cell shape, resulting in the accumulation of various nanoparticles (typically smaller than 300 nm) in tumor tissues based on the enhanced permeability and retention (EPR) effect [37]. Tumor vasculature targeting (i.e. targeting receptors overexpressed on tumor vascular endothelial cells) is a generally applicable targeting strategy for a wide variety of nanoparticles regardless of tumor type [38]. By targeting CD105 (also known as endoglin, which is an ideal marker that is almost exclusively overexpressed on proliferating endothelial cells [39]), we have demonstrated the broad potential of CD105-targeted nanomaterials in cancer-targeted imaging and therapy using TRC105, a human/murine chimeric IgG1 monoclonal antibody that binds to both human and murine CD105 [40], or its fragments as the targeting moieties [23, 25, 41–43].

In this work, we report the general synthesis strategy of chelator-free ⁸⁹Zr-radiolabeled, TRC105-conjugated, silica-based yolk/shell hybrid nanoparticle for *in vivo* tumor vasculature targeting. Three types of inorganic nanoparticles with varying morphologies and sizes were selected as the internal cores, which were encapsulated into single HMSNs to form the yolk/shell-structured hybrid nanoparticles. As a proof-of-concept, we showed the successful post-surface functionalization of the nanoparticles with polyethylene glycol (PEG), TRC105, and ⁸⁹Zr, and demonstrated the *in vivo* tumor vasculature-targeted PET imaging in 4T1 murine breast tumor-bearing mice. This strategy could be applicable to the synthesis of other types of yolk/shell nanoparticles, creating an attractive multifunctional nanoplatform for tumor-targeted imaging and drug delivery.

2 Results and discussion

2.1 General synthesis of multi-functional yolk/ shell-structured hybrid nanomaterials

As shown in Scheme 1, the general synthesis of yolk/shell-structured tumor vasculaturetargeted silica-based hybrid nanoparticles started with a surfactant-stabilized (e.g. oleic acid) inorganic functional nanoparticle (e.g. upconversion nanoparticle (UCNP),

superparamagnetic iron oxide nanoparticle (SPION), or quantum dot (QD)) as the internal core. Subsequently, an oil-in-water reverse micro-emulsion silica coating approach was introduced to uniformly coat each hydrophobic nanoparticle core with a thickness-controllable and biocompatible non-porous silica interlayer. This step will facilitate the coating of the third porous silica outer layer with the presence of template surfactants (e.g. cetyltrimethylammonium chloride solution, or CTAC). A selective silica etching protocol was then adopted to carefully etch out the non-porous silica interlayer, leaving a cavity inside each ~ 100-nm yolk/shell nanoparticle. Afterwards, a silica-based chelator-free ⁸⁹Zr labeling strategy was employed to stably radiolabel the nanoparticle with ⁸⁹Zr for *in vivo* whole-body PET imaging. The radiolabeled nanoparticles were then surface-PEGylated and functionalized with TRC105 to improve stability in the bloodstream and specific targeting of CD105 in the tumor vasculature.

2.2 Synthesis of UCNP@HMSN hybrid nanoparticles

UCNPs have gained growing interest owing to their unique upconversion luminescence features that are highly suitable for multimodal imaging in living subjects [44]. After excitation using a 980-nm laser, UCNPs exhibited attractive optical features, such as sharp emission lines [45], long lifetimes (~ ms) [46], large anti-Stokes shift [45], superior photostability [47], high detection sensitivity [48], non-blinking and non-bleaching [47, 49], deeper tissue penetration depth [50], minimal photo-damage [51], and extremely low autofluorescence [52]. In this study, we synthesized uniform ~ 25-nm UCNPs of β -NaYF₄:Tm/Yb (2/20 mol.%) (Fig. 1(a)) using a modified procedure that has been reported previously [53, 54]. The inset in Fig. 1(a) shows a digital photo of β -NaYF₄:Tm/Yb (suspended in cyclohexane) emitting ultraviolet (UV), blue, and NIR light after excitation with a 980-nm laser (only the blue light was captured by a digital single-lens reflex (DSLR) camera). As-synthesized UCNPs were then coated with a dense silica (dSiO₂) shell in an oilin-water reverse micro-emulsion system [55]. Figure 2(a) shows the transmission electron microscopy (TEM) image of ~ 78-nm UCNP@dSiO₂. The thickness of the dSiO₂ layer was estimated to be ~ 14 nm. The delivery rate of tetraethyl orthosilicate (TEOS) during the synthesis of UCNP@dSiO₂ was found to have significant impact on the yield of UCNP@dSiO₂, which was carefully controlled at 100 µL·h⁻¹ using a syringe pump to avoid aggregation and homogeneous nucleation of silica [55].

The introduction of the dSiO₂ layer is critical for the successful formation of the yolk/shell nanostructure. It not only facilities the growth of the third porous silica layer, but also serves as a hard template that will later be selectively etched out to form the cavity. To grow the third porous silica layer, as-synthesized UCNP@dSiO₂ suspended in deionized water were mixed with CTAC, triethanolamine (TEA), and TEOS. A slow and controllable TEOS delivery procedure (rate: 40 μ L·min⁻¹) was again used in this case with a syringe pump. Figure 1(c) shows the TEM image of ~ 100-nm UCNP@dSiO₂@MSN. The inset is a single UCNP@dSiO₂@MSN showing the UCNP core (the inner dark dot), the first dSiO₂ layer (middle layer with a lighter color), and the second MSN layer (the outermost layer with the lightest color). The thickness of the third porous silica layer was found to be ~ 11 nm.

Before performing any nanoparticle purification procedures, the reaction system was cooled down to 50 °C, followed by the addition of sodium carbonate (Na₂CO₃), and kept under constant stirring for 30–70 min to selectively etch out the dSiO₂ interlayer, forming yolk/ shell-structured UCNP@HMSN, as shown in Fig. 1(d). The final average size of UCNP@HMSN was measured to be ~ 115 nm. The surfactant CTAC was later removed via an extraction process by stirring the nanoparticles in a 1 wt.% solution of NaCl in methanol [56]. The pore size of the nanoparticle porous silica layer was 2–3 nm, similar to that of previously reported MSNs [23].

2.3 Optimization of the selective silica etching procedure

Cationic surfactants (in our case, CTAC) play vital roles in the formation of the yolk/shell nanostructure. It is important to note that CTAC needs to stay in the MSN network to ensure successful selective etching of dSiO₂. During the etching process, positively charged free cetyltrimethylammonium cations (CTA⁺) will first adsorb to the surface of UCNP@dSiO₂@MSN(CTAC) via electronic attraction. Subsequently, with the presence of Na₂CO₃ in the solution and CTAC in the MSN shell, selective etching of silica from the dSiO₂ core starts and will be accelerated by the surrounding free CTAC, forming uniform UCNP@HMSN(CTAC) after the re-deposition process [57]. The effective etching of the dSiO₂ interlayer was demonstrated to be highly dependent on the free CTAC concentration, etching temperature, and etching time, as we reported previously [25]. To avoid overetching, the optimal etching temperature was fixed to be 50 °C. Figures 2(a) and 2(b) show the representative TEM images of UCNP@HMSN with nearly half of the dSiO₂ being etched out. The UCNP core was still in the center of the nanoparticle, supported by the dSiO₂ network. Prolonging the etching time to 70 min while keeping the same etching temperature could lead to complete etching of the dSiO₂ interlayer, causing the inner UCNP to move to the wall of the MSN layer because of the lack of dSiO₂ support, as shown in Figs. 2(c) and 2(d).

2.4 Synthesis of other types of yolk/shell hybrid nanomaterials with irregularly shaped cores

To demonstrate the general applicability of the above-mentioned strategy, we extended the uniform 25-nm UCNP cores to other nanoparticles with irregular shapes and smaller sizes. Oleic acid-capped SPIONs with an average particle size of 8–10 nm were synthesized based on a previously reported thermal decomposition approach [55, 58]. As shown in Fig. 3(a), as-synthesized SPIONs had a relatively broad size distribution and non-spherical morphology. The inset in Fig. 3(a) shows the clear superparamagnetism of SPIONs suspended in cyclohexane at room temperature. The third functional nanocrystal core we selected was the commercially available organic QD705 (1 μ M in decane, purchased from Life Technology). A representative TEM image of QD705 (Fig. 3(d)) revealed a rod-shaped QD705 with dimensions of ~ 6.5 nm × ~ 13 nm. The inset in Fig. 3(d) is a photo showing the optical imaging (*E*m = 700 nm) of QD705 under blue light excitation (*E*x = 465 nm) using an IVIS Spectrum imaging system. Successful formation of monodispersed yolk/shell-structured SPION@HMSN and QD705@HMSN was found to be highly dependent on the dSiO₂ coating step (Figs. 3(b) and 3(e)), where severe nanoparticle aggregation should be avoided to improve the yield and stability of the final hybrid nanoparticles (Fig. S1 in the

Electronic Supplementary Material (ESM)). The final sizes of SPION@HMSN and QD705@HMSN measured by TEM were ~ 77 and ~ 67 nm, respectively, which were significantly smaller than the ~ 115-nm UCNP@HMSN. Because of the smaller core size and greater difficulties in achieving monodispersed core@dSiO₂ nanoparticles, higher yields of twins and triplets (Figs. 3(c) and 3(f)) were observed in these two cases when compared with UCNP@HMSN (as shown in Fig. 1(d)). Taken together, we demonstrated the successful extension of the yolk/shell hybrid nanoparticle synthesis to other functional (magnetic and optical) nanoparticles with varying sizes and morphologies.

2.5 Surface functionalization of UCNP@HMSN for in vitro CD105 targeting

To demonstrate the active targeting of a representative yolk/shell hybrid nanomaterial, assynthesized uniform UCNP@HMSN were selected and subjected to post-surface functionalization, which included amination, PEGylation, and antibody conjugation based on previously reported procedures [23, 25, 43]. Without suitable PEGylation, the highly negatively charged UCNP@HMSN could form severe aggregation in phosphate-buffered saline (PBS) within minutes. The stability was significantly improved after surface PEGylation. The hydrodynamic diameter (HD) of the final UCNP@HMSN-PEG_{5k}-TRC105 was measured to be 171.9 \pm 1.2 nm by dynamic light scattering (DLS), as shown in Fig. 4(a).

Before *in vivo* investigation, human umbilical vein endothelial cells (HUVECs, CD105positive) were subjected to flow cytometry to confirm the *in vitro* CD105 targeting efficiency of the non-radioactive UCNP@HMSN-PEG_{5k}-TRC105. Because of the lack of a 980-nm excitation light source in the BD FACSCalibur four-color analysis cytometer, which was equipped with 488-nm and 633-nm lasers, NHS-fluorescein was conjugated to the surface of the nanoparticles to facilitate the flow cytometry study. The results from Fig. 4(b) indicated that incubation with fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 (50 nM, targeted group) could significantly enhance the mean fluorescence intensity of HUVECs, while treatment with fluorescein-conjugated UCNP@HMSN-PEG_{5k} (50 nM, non-targeted group) or fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 with a blocking dose of TRC105 (500 μ g·mL⁻¹, blocking group) only yielded minimal fluorescence enhancement via non-specific binding.

2.6 Chelator-free ⁸⁹Zr labeling and in vivo CD105-targeted PET imaging

 Zr^{4+} is a hard Lewis acid and thus prefers hard Lewis bases as donor groups. Previously, we demonstrated that the deprotonated silanol groups ($-Si-O^-$), which originated from the hydrolysis and condensation of TEOS [59], could function as hard Lewis bases for stable chelator-free ⁸⁹Zr labeling of silica-based nanoparticles [15]. Approximately 2–3 million – Si–OH groups in each 150-nm MSN was estimated based on our previous research [15]. For typical chelator-free radiolabeling, aminated UCNP@HMSN (or UCNP@HMSN-NH₂, concentration: ~ 1 mg·mL⁻¹) were suspended in 4-(2-hydroxyethyl)-1- piperazineethanesulfonic acid (HEPES) buffer (pH 7.5, 0.1 M) and mixed with 3 mCi (or 111 MBq) of ⁸⁹Zr-oxalate at 75 °C for 3 h. The final pH of the mixture was carefully readjusted to 7–8 with 2 M Na₂CO₃. The labeling yield was found to be greater than 80% after labeling at 75 °C for 3 h. The yield continued to increase over time and reached > 90% after

22 h of incubation (Fig. 4(c) and Table S1 in the ESM). Such ⁸⁹Zr labeling was also found to be concentration-and temperature-dependent, with higher concentration and incubation temperature giving higher labeling yield, similar to what we have observed previously [15]. For example, slightly reduced labeling yield over time was achieved by lowering the labeling temperature to 37 °C, as shown in Table S2 in the ESM. To further demonstrate the role of deprotonated silanol groups in chelator-free ⁸⁹Zr labeling, the pH of the labeling solution was adjusted to near the isoelectric point of silica, which is approximately 2, to ensure protonation of the silanol groups as -Si-OH. As expected, the ⁸⁹Zr labeling yield was almost completely inhibited, with the maximal labeling yield found to be lower than 2%, as shown in Table S1 in the ESM. As-synthesized UCNP@[89Zr]HMSN-NH2 was easily collected by centrifugation and readily PEGylated by reacting with SCM-PEG_{5k}-Mal (SCM denotes succinimidyl carboxy methyl ester; Mal denotes maleimide) (5 mg) at pH 7 for 2 h, forming UCNP@ [89Zr]HMSN-PEG5k-Mal. UCNP@[89Zr]HMSN-PEG5k-TRC105 was finally obtained by reacting UCNP@ [89Zr]HMSN-PEG5k-Mal with TRC105-SH in PBS at room temperature, as reported previously [23, 41]. Figure 4(d) shows the representative PD-10 elution profile of UCNP@[89Zr]HMSN-PEG5k-TRC105 (PBS was used as the mobile phase), with the products eluted from 2.5 mL to 4.0 fractions. These fractions were collected for further in vivo tumor-targeted PET imaging and ex vivo biodistribution experiments.

In vivo tumor-targeted PET imaging was then carried out in 4T1 murine breast tumorbearing mice, which express high levels of CD105 in the tumor neovasculature [60]. Each mouse was injected with 5-10 MBq of 89Zr-labeled yolk/shell nanoparticles, and time points of 0.5, 6, 24, and 48 h post-injection (p.i.) were chosen for serial PET scans to show the *in* vivo biodistribution patterns of tumor-bearing mice from targeted, non-targeted, and blocking groups (Fig. 5). Quantitative data obtained from region-of-interest (ROI) analysis of these PET images are also shown in Fig. 5 and Tables S3-S5 in the ESM. The circulation of the ⁸⁹Zr-labeled nanoparticles in all three groups was indicated by the dominant radioactivity signal in mouse heart (or blood) at 0.5 h p.i., with the radioactivity signal in the heart ranging from 22.6 % ID·g⁻¹ (percentage of the injected dose per gram) to 30.5 % ID·g⁻¹ (Tables S3–S5 in the ESM). The clearance of the nanoparticles from blood to the liver and spleen was also observed among these groups, with a clear decrease in radioactive signal in the bloodstream and rapid accumulation of nanoparticles in the mouse reticuloendothelial system (RES) (Fig. 5). The blood circulation half-life of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 in 4T1 tumor-bearing mice was estimated to be approximately 4.5 h based on the PET data.

The accumulation of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 in the 4T1 tumor was found to be $2.4 \pm 0.3 \%$ ID·g⁻¹ at 0.5 h p.i., and peaked at $10.0 \pm 0.9 \%$ ID·g⁻¹ at 6 h p.i., as shown in Figs. 5(a), 6(a), and Table S3 in the ESM (*n* = 3). In contrast, without the conjugation of TRC105 (i.e. passive targeting alone), the 4T1 tumor uptake of UCNP@[⁸⁹Zr]HMSN-PEG_{5k} was found to be only about half that of the targeted group at all time points examined (*n* = 3, Figs. 5(b), 6(b), and Table S4 in the ESM), indicating that TRC105 conjugation could be the controlling factor for enhanced tumor accumulation of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105. To further confirm the CD105 targeting specificity for UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 *in vivo*, blocking studies were performed. Administration of a blocking

dose (1 mg/mouse) of free TRC105 at 1 h before UCNP@[89Zr]HMSN-PEG_{5k}-TRC105 injection significantly reduced the tumor uptake to 4.3 ± 0.7 %ID·g⁻¹ at 6 h p.i. (n = 3, Figs. 5(c), 6(c), and Table S5 in the ESM), clearly demonstrating the specificity of CD105 toward UCNP@[89Zr]HMSN-PEG5k-TRC105 in vivo. Figure 6(d) also summarizes the comparison of 4T1 tumor uptake in the three groups at different time points, where UCNP@[89Zr]HMSN-PEG_{5k}-TRC105 shows the highest tumor uptake throughout the study period (**p < 0.005). Similar to what we have observed previously with TRC105conjugated nanoparticles with similar HDs (50-200 nm) [23, 25, 41], besides tumor accumulation, most of the ⁸⁹Zr-labeled nanoparticles were taken up by the RES with liver uptake found to be 20.7 ± 0.7 %ID·g⁻¹ at 0.5 h p.i., and further increased to 32.3 ± 4.9 %ID·g⁻¹ at 48 h p.i. for the targeted group (n = 3, Fig. 6(a) and Table S3 in the ESM). The maximal liver uptake was found to be even higher for the non-targeted (54.9 \pm 2.7 %ID·g⁻¹ at 48 h p.i., Fig. 6(b) and Table S4 in the ESM) and blocking group (46.9 \pm 3.6 %ID·g⁻¹ at 48 h p.i., Fig. 6(c) and Table S5 in the ESM). Figure 6(e) and Table S6 (in the ESM) summarize the biodistribution data of the ⁸⁹Zr-labeled nanoparticles at 48 h after the last PET scans. Overall, the quantitative results matched well with PET ROI analysis except that of 4T1 tumors due to the significantly enlarged tumor volume at 48 h p.i. High RES uptake and potential toxicity are two of the major issues for the different types of nanoparticles with HDs of > 10 nm during clinical translation. The current design of the UCNP@[89Zr]HMSN-PEG_{5k}-TRC105 has a HD of ~ 200 nm and was expected to have high non-specific RES uptake, as shown in Figs. 5 and 6. Although no systematic and longterm toxicity studies were performed here, both the core (UCNPs, Fe₃O₄, and QDs) and the mesoporous silica shell were considered relatively safe, as demonstrated repeatedly in other research work [61-66].

3 Conclusion

In conclusion, to address the challenges in the synthesis, whole-body biodistribution, and *in vivo* active tumor targeting of silica-based hybrid nanoparticles, we report the general synthesis of three types of uniform yolk/ shell-structured nanoparticles and present the chelator-free radiolabeling and *in vivo* tumor vasculature-targeted PET imaging of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 in 4T1 tumor-bearing mice. Vascular targeting led to > 2-fold enhancement in tumor uptake compared to that of passive targeting alone based on the EPR effect (~ 10 %ID·g⁻¹ vs. ~ 5 %ID·g⁻¹). Despite great challenges in the clinical translation of nanomedicine, we believe that the reported strategy might provide a highly valuable tool for scientists to create other attractive yolk/shell-structured multifunctional nanoplatforms for future tumor-targeted imaging and image-guided drug delivery.

4 Methods

4.1 Materials

TRC105 was provided by TRACON Pharmaceuticals Inc. (San Diego, CA). Chelex 100 resin (50–100 mesh), tetraethyl orthosilicate (TEOS), triethanolamine (TEA), (3- aminopropyl)triethoxysilane (APTES), cetyltrime-thylammonium chloride solution (CTAC, 25 wt.%), absolute ethanol, sodium chloride (NaCl), sodium hydroxide (99.99%), oleic acid,

1-octadecene (technical grade, 90%), ammonia, yttrium(III) chloride hexahydrate, ytterbium(III) chloride hexahydrate, thulium(III) chloride, Igepal CO-520, and ammonium fluoride were obtained from Sigma-Aldrich and used without further purification. Iron chloride hexahydrate (FeCl₃·6H₂O, > 99%) was purchased from Acros. PD-10 columns were purchased from GE Healthcare (Piscataway, NJ). SCM-PEG_{5k}-Mal was obtained from Creative PEGworks. QD705 (1 μ M in decane) was purchased from Life Technology. Water and all buffers were of Millipore grade and pretreated with Chelex 100 resin to ensure that the aqueous solution was free of heavy metals.

4.2 Synthesis of oleic acid-capped upconversion nanoparticles (NaYF₄:Tm/Yb)

Uniform-sized NaYF₄:Tm/Yb UCNPs were synthesized via a modified procedure that was reported previously [53, 54]. In a typical synthesis of 25-nm β -NaYF₄:Tm/Yb (2/20 mol%), YCl₃·6H₂O (473.24 mg, 1.56 mmol), YbCl₃· 6H₂O (155 mg, 0.4 mmol), and TmCl₃·6H₂O (11 mg, 0.04 mmol) in deionized water were added to a 100-mL flask containing 15 mL of oleic acid and 30 mL of 1-octadecene. The solution was then stirred at room temperature for 1 h. Afterwards, the mixture was slowly heated to 120 °C to remove water under an argon atmosphere. The solution was maintained at 156 °C for approximately 30 min until a homogeneous transparent yellow solution was obtained. The system was then cooled down to room temperature in argon. Subsequently, 10 mL of methanol solution of NH₄F (296.3 mg, 8 mmol) and NaOH (200 mg, 5 mmol) was added, and the solution was stirred at room temperature for another 2 h. After methanol was evaporated, the solution was heated to 290 °C and kept for 2 h before it was cooled down to room temperature. The resulting nanoparticles were precipitated by the addition of 20 mL of ethanol and collected by centrifugation at 10000 rpm for 10 min. The product was re-dispersed with 5 mL of cyclohexane and precipitated again by adding 15 mL of ethanol, then collected by centrifugation at 10,000 rpm for 10 min. After four washes, the final product was well dispersed in 20 mL of cyclohexane.

4.3 Synthesis of oleic acid-capped SPIONs

A previously reported two-step synthetic approach [55, 58] was used in this work for the synthesis of SPIONs.

4.3.1 Step 1: synthesis of iron-oleate complex—Iron-oleate complex was used as the precursor for the synthesis of SPIONs. $FeCl_3 \cdot 6H_2O$ (3.243 g, 12 mmol) and NaOH (1.44 g, 36 mmol) were dissolved in methanol (40 mL) under magnetic stirring. Oleic acid (12 mL, 36 mmol) was added to the $FeCl_3$ -methanol solution, followed by addition of NaOH-methanol solution using a separatory funnel. The mixture was stirred overnight at room temperature. A reddish-brown product was found at the bottom of the mixture the next morning. The product was washed twice with methanol and twice with deionized water before it was dried at room temperature for 48 h. The final iron-oleate complex was obtained in a waxy solid form.

4.3.2 Step 2: synthesis of SPIONs—In a typical synthesis of 8-10 nm SPIONs, preprepared iron-oleate (2.9 g, ~ 3 mmol) was dissolved in 1-octadece (40 mL). The mixture was first heated to 80 °C to accelerate the dissolution of solid iron-oleate. It was then heated

to 120 °C and maintained at this temperature for 2 h to remove air and water in the system. The reaction mixture was then directly heated to 300 °C and kept for 30 min. No extra oleic acid was used during the synthesis process. The black-brown mixture was cooled down to room temperature, washed with hexane and ethanol, and separated by magnetic separation. The final product was well dispersed in cyclohexane.

4.4 Synthesis of UCNP@HMSN

A three-step synthetic procedure was employed for the synthesis of UCNP@HMSN (or SPION@HMSN, QD@HMSN).

4.4.1 Step 1: synthesis of UCNP@dSiO₂—To synthesize dense silica-coated UCNP (UCNP@dSiO₂) with a ~ 14-nm silica shell, Igepal CO-520 (NP-5, 2 mL) was dispersed in cyclohexane (40 mL) in a 100-mL three-necked flask and stirred for 5 min. Subsequently, oleic acid-capped UCNPs in cyclohexane solution (1 mL) was added into the cyclohexane/NP-5 mixture and stirred for 2 h at room temperature. Further, ammonia (280 µL, 30%) was added, and the system was sealed and stirred for another 2 h. TEOS (400 µL) was then delivered into the system at a rate of 100 µL·h⁻¹ using a syringe pump. The mixture was sealed and kept under magnetic stirring for 48 h at room temperature before adding methanol to collect the nanoparticles. The product was precipitated with excess hexane and collected by centrifugation. The nanoparticles were re-dispersed in ethanol under ultrasonic treatment, precipitated with excess hexane, and collected by centrifugation. The process was repeated at least three times to completely remove the excess NP-5. The as-obtained UCNP@dSiO₂ were well-dispersed in ethanol or deionized water.

4.4.2 Step 2: synthesis of UCNP@dSiO₂@MSN—CTAC (2 g) and TEA (20 mg) were dissolved in 20 mL of high Q water and stirred at room temperature for 1 h. Subsequently, 10 mL of as-synthesized UCNP@dSiO₂ solution in water was added and stirred at room temperature for 1 h before the addition of 0.2 mL of TEOS using a syringe pump at 40 μ L·min⁻¹. The mixture was stirred for 1 h at 80 °C in a water bath to form UCNP@dSiO₂@MSN.

4.4.3 Step 3: selective etching of the dSiO₂ interlayer to form UCNP@HMSN— The reaction system was cooled down to 50 °C followed by the addition of 636 mg of Na₂CO₃ and kept under constant stirring for 30–70 min to selectively etch out the dense silica layer, forming UCNP@HMSN. To remove the CTAC, the product was extracted for 24 h with a 1 wt.% solution of NaCl in methanol at room temperature. This process was carried out at least three times to ensure complete removal of CTAC. A similar three-step procedure was used for the synthesis of SPION@HMSN and QD@HMSN.

4.5⁸⁹Zr production

⁸⁹Zr-oxalate was produced according to previous procedures by the University of Wisconsin-Madison cyclotron group [67]. Briefly, natural yttrium-89 (⁸⁹Y) foil (250 μm, 99.9%) was irradiated with a proton beam to create ⁸⁹Zr via the ⁸⁹Y(p,n)⁸⁹Zr reaction using a 16-MeV GE PETtrace cyclotron (the actual proton beam energy used was ~ 13.8 MeV).

After isotope separation and purification, ⁸⁹Zr-oxalate was obtained with a specific activity of > 20 GBq·µmol⁻¹ of Zr.

4.6 Intrinsic ⁸⁹Zr labeling of UCNP@HMSN

The intrinsic radiolabeling of UCNP@HMSN with ⁸⁹Zr was based on the strong interaction between ⁸⁹Zr⁴⁺ and the abundant deprotonated silanol groups ($-Si-O^-$) from the HMSN shell [15]. For typical labeling, 250 µL of UCNP@HMSN at ~ 1 mg·mL⁻¹ were suspended in HEPES buffer (pH 7.5, 0.1 M) and mixed with 3 mCi (or 111 MBq) of ⁸⁹Zr-oxalate at 75 °C for 3 h. The final pH of the mixture was carefully re-adjusted to 7–8 using 2 M Na₂CO₃. The labeling yield was found to be greater than 80% after labeling at 75 °C for 3 h. As-synthesized UCNP@[⁸⁹Zr]HMSN could be easily collected by centrifugation at 21,000*g* for 10 min. After washing three times with water, the final radioactive nanoparticles were well suspended in deionized water.

4.7 Synthesis of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 for tumor vasculature targeting

To prepare UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105, as-synthesized UCNP@HMSN were first functionalized with $-NH_2$ groups using APTES, as reported previously [25]. Briefly, UCNP@HMSN were dispersed in 20 mL of absolute ethanol, followed by addition of 1 mL of APTES. The system was sealed and kept at 86–90 °C in a water bath for 24 h. Afterwards, the mixture was centrifuged and washed several times with ethanol to remove the residual APTES. As-synthesized UCNP@HMSN-NH₂ was well dispersed in water, and the concentration of $-NH_2$ groups (nmol·mL⁻¹) was measured using a Kaiser test kit. Subsequently, 250 µL of UCNP@HMSN-NH₂ at ~1 mg·mL⁻¹ in HEPES buffer (pH 7.5, 0.1 M) was mixed with 3 mCi (or 111 MBq) of ⁸⁹Zr-oxalate at 75 °C for 2–3 h at pH 7–8. Assynthesized UCNP@[⁸⁹Zr]HMSN-NH₂ were easily collected by centrifugation at 21,000*g* for 10 min. Subsequently, a PEGylation step was introduced by reacting UCNP@[⁸⁹Zr]HMSN-NH₂ with SCM-PEG_{5k}-Mal (5 mg) at pH 7 for 2 h, forming UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-Mal. UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 was obtained by reacting UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-Mal with TRC105-SH in PBS at room temperature, as reported previously [23, 41].

4.8 Flow cytometry study

Cells were first harvested and suspended in cold PBS with 2% bovine serum albumin at 5×10^{6} cells·mL⁻¹ and incubated with fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 (targeted group) or fluorescein-conjugated UCNP@HMSN-PEG_{5k} (non-targeted group) for 30 min at room temperature. The same fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 (targeted group) and fluorescein-conjugated UCNP@HMSN-PEG_{5k} (non-targeted group) in order to maintain the exact same fluorescein/nanoparticle ratio during the flow cytometry studies. The cells were washed three times with cold PBS and centrifuged for 5 min. Subsequently, the cells were washed and analyzed using a BD FACSCalibur four-color analysis cytometer, which is equipped with 488-nm and 633-nm lasers (Becton-Dickinson, San Jose, CA) and FlowJo analysis software (Tree Star, Ashland, OR). "Blocking" experiment was also performed in cells incubated with the same amount of fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 was added to

evaluate the specificity of fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 toward CD105. The cells were also examined under a Nikon Eclipse Ti microscope to validate the results.

4.9 4T1 tumor model

All animal studies were conducted following a protocol approved by the University of Wisconsin Institutional Animal Care and Use Committee. To generate the 4T1 tumor model, 4- to 5-week-old female BALB/c mice were purchased from Envigo (Indianapolis, IN, USA), and tumors were established by subcutaneously injecting 2×10^6 cells, suspended in 100 µL of 1:1 mixture of RPMI 1640 and Matrigel (BD Biosciences, Franklin Lakes, NJ, USA), into the front flank of the mice. The tumor sizes were monitored every other day, and the animals were subjected to *in vivo* experiments when the tumor diameter reached 5–8 mm.

4.10 In vivo tumor vasculature-targeted PET imaging and biodistribution studies

PET scans at various time points post-injection were performed using a microPET/microCT Inveon rodent model scanner (Siemens Medical Solutions USA, Inc.) Image reconstruction and region-of-interest analysis of the PET data were performed similar to previously described protocols [41, 68–71]. Quantitative PET data were presented as $\% ID \cdot g^{-1}$. Tumorbearing mice were each injected with 5–10 MBq of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 (targeted group, ~ 32 µg of nanoparticles) or UCNP@[⁸⁹Zr]HMSN-PEG_{5k} (non-targeted group, ~ 32 µg of nanoparticles) via the tail. Another group of three 4T1 tumor-bearing mice were each injected with 1 mg of unlabeled TRC105 at 1 h before UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 administration to evaluate the CD105-targeting specificity of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 *in vivo* (blocking group). After the last PET scans at 48 h p.i., biodistribution studies were carried out. The mice were euthanized, and the blood, 4T1 tumor, and major organs/tissues were collected and wet-weighed. The radioactivity in the tissue was measured using a gamma-counter (Perkin-Elmer) and presented as %ID·g⁻¹ (mean ± SD).

Figure 1.

Synthesis of UCNP@HMSN hybrid nanoparticles. (a) Schematic illustration and TEM image of ~ 25-nm Tm/Yb co-doped UCNP (NaYF₄:Tm/Yb). Inset is a digital photo showing the blue light emission of NaYF₄:Tm/Yb under the excitation of a 980-nm laser (captured by a DSLR camera). (b) Schematic illustration and TEM image of ~ 78-nm UCNP@dSiO₂. The thickness of the dSiO₂ layer was estimated to be ~ 14 nm. (c) Schematic illustration and TEM image of ~ 100-nm UCNP@dSiO₂@MSN. Inset is a single nanoparticle clearly showing the core (the inner dark dot), the first dSiO₂ layer (middle layer with a lighter color), and the second MSN layer (the outermost layer with the lightest color). The thickness of the MSN layer was estimated to be ~ 11 nm. (d) Schematic illustration and TEM image of ~ 115-nm UCNP@HMSN.

Page 18

UCNP core in the center (dSiO₂ half-etched)

UCNP core off the center (dSiO₂ fully-etched)

Figure 2.

Optimization of the etching protocol. (a) TEM image of UCNP@HMSN synthesized by etching at 50 °C for 30 min. (b) TEM image of a single UCNP@HMSN with half-etched $dSiO_2$ (left) and its corresponding scheme (right). (c) TEM image of UCNP@HMSN synthesized by etching at 50 °C for 70 min. (d) TEM image of a single UCNP@HMSN with fully etched $dSiO_2$ (left) and its corresponding scheme (right). The UCNP cores are indicated by red arrows in both (b) and (d).

Figure 3.

Synthesis of SPION@HMSN and QD@HMSN. (a) TEM image of oleic acid-capped SPIONs. Inset is a photo showing the ferrofluidic behavior of SPIONs in cyclohexane at room temperature. (b) TEM image of SPION@dSiO₂. (c) TEM image of SPION@HMSN. Inset shows a single SPION@HMSN, where the SPION core is indicated by a red arrow. (d) TEM image of organic QD705 purchased from Life Technology. Inset is a photo showing the optical imaging of QD705 using an IVIS Spectrum system (Ex = 465 nm, Em = 700nm). (e) TEM image of QD705@dSiO₂. (f) TEM image of QD705@HMSN. Inset shows a single QD705@HMSN, where the QD705 core is indicated by a red arrow.

Chen et al.

Figure 4.

DLS measurement, *in vitro* CD105 targeting, chelator-free ⁸⁹Zr labeling, and elution profile of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105. (a) Size distribution of UCNP@HMSN-PEG_{5k}-TRC105 measured by DLS. (b) Flow cytometry analysis of fluorescein-conjugated UCNP@HMSN-PEG_{5k}-TRC105 (50 nM, 30 min incubation) in HUVECs (CD105positive). (c) ⁸⁹Zr labeling yields of UCNP@HMSN at varying temperatures in solutions of different pH values. (d) A PD-10 elution profile of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105. PBS was used as the mobile phase.

Chen et al.

Figure 5.

In vivo CD105-targeted PET imaging. Serial coronal PET images of UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 ((a), targeted group), UCNP@[⁸⁹Zr]HMSN-PEG_{5k} ((b), non-targeted group), and UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 with 1 mg of free TRC105 ((c), blocking group) in 4T1 murine breast tumor-bearing mice at different time points (0.5, 6, 24, and 48 h p.i.) n = 3 for all these groups.

Chen et al.

Figure 6.

Quantitative ROI analysis of the PET imaging data and *ex vivo* biodistribution studies. Time–activity curves of the liver, blood, 4T1 tumor, and muscle upon intravenous injection of (a) UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105, (b) UCNP@[⁸⁹Zr]HMSN-PEG_{5k}, or (c) UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 after a blocking dose (1 mg per mouse) of TRC105. (d) Comparison of 4T1 tumor uptake among the three groups. The difference in 4T1 uptake between UCNP@[⁸⁹Zr]HMSN-PEG_{5k}-TRC105 and the two control groups was statistically significant (**p < 0.005). (e) Biodistribution comparison in 4T1 tumor-bearing mice at 48 h p.i. All data represent three mice per group.

Chen et al.

Scheme 1.

General synthesis of multi-functional yolk/shell-structured hybrid nanomaterials. Preprepared inorganic functional nanocrystal (1, such as UCNP, SPION, or QD) was selected as the core and coated with dense silica to form core@dSiO₂ (2). The nanoparticle was further coated with another layer of mesoporous silica nanoshell, forming core@dSiO₂@MSN (3). A selective etching strategy was then introduced to selectively etch the dSiO₂ layer while leaving the MSN layer intact, forming core@HMSN (4, where HMSN stands for hollow mesoporous silica nanoshell). Because of the presence of abundant silanol groups (–Si–OH) on the surface and inside the meso-channels of core@HMSN, ⁸⁹Zr could be labeled to the nanoparticles without using any extra chelators, forming core@[⁸⁹Zr]HMSN (5). The nanoparticle was finally modified with PEG and tumor vasculature-targeted antibody (e.g. TRC105) to form core@[⁸⁹Zr]HMSN-PEG-TRC105 (6).
