ABSTRACT

Background

Current management of preterm prelabour rupture of the membranes (PPROM) involves either initiating birth soon after PPRM or, alternatively, adopting a 'wait and see' approach (expectant management). It is unclear which strategy is most beneficial for mothers and their babies. This is an update of a Cochrane review published in 2010 (Buchanan 2010).

Objectives

To assess the effect of planned early birth versus expectant management for women with preterm prelabour rupture of the membranes between 24 and 37 weeks' gestation for fetal, infant and maternal well being.

Search methods

We searched Cochrane Pregnancy and Childbirth's Trials Register (30 September 2016), and reference lists of retrieved studies.

Selection criteria

Randomised controlled trials comparing planned early birth with expectant management for women with PPRM prior to 37 weeks' gestation. We excluded quasi-randomised trials.

Data collection and analysis

Two review authors independently evaluated trials for inclusion into the review and for methodological quality. Two review authors independently extracted data. We checked data for accuracy. We assessed the quality of evidence using the GRADE approach.

Main results

We included 12 trials in the review (3617 women and 3628 babies). For primary outcomes, we identified no clear differences between early birth and expectant management in neonatal sepsis (risk ratio (RR) 0.93, 95% confidence interval (CI) 0.66 to 1.30, 12 trials, 3628 babies, evidence graded moderate), or proven neonatal infection with positive blood culture (RR 1.24, 95% CI 0.70 to 2.21, seven trials, 2925 babies). However, early birth increased the incidence of respiratory distress syndrome (RDS) (RR 1.26, 95% CI 1.05 to 1.53, 12 trials, 3622 babies, evidence graded high). Early birth was also associated with an increased rate of caesarean section (RR 1.26, 95% CI 1.11 to 1.44, 12 trials, 3620 women, evidence graded high).

Assessment of secondary perinatal outcomes showed no clear differences in overall perinatal mortality (RR 1.76, 95% CI 0.89 to 3.50, 11 trials, 3319 babies), or intrauterine deaths (RR 0.45, 95% CI 0.13 to 1.57, 11 trials, 3321 babies) when comparing early birth with expectant management. However, early birth was associated with a higher rate of neonatal death (RR 2.55, 95% CI 1.17 to 5.56, 11 trials, 3316 babies) and need for ventilation (RR 1.27, 95% CI 1.02 to 1.58, seven trials, 2895 babies, evidence graded high). Babies of women randomised to early birth were delivered at a gestational age lower than those randomised to expectant management (mean difference (MD) -0.48 weeks, 95% CI -0.57 to -0.39, eight trials, 3139 babies). Admission to neonatal intensive care was more likely for those babies randomised to early birth (RR 1.16, 95% CI 1.08 to 1.24, four trials, 2691 babies, evidence graded moderate).

In assessing secondary maternal outcomes, we found that early birth was associated with a decreased rate of chorioamnionitis (RR 0.50, 95% CI 0.26 to 0.95, eight trials, 1358 women, evidence graded moderate), and an increased rate of endometritis (RR 1.61, 95% CI 1.00 to 2.59, seven trials, 2980 women). As expected due to the intervention, women randomised to early birth had a higher chance of having an induction of labour (RR 2.18, 95% CI 2.01 to 2.36, four trials, 2691 women). Women randomised to early birth had a decreased total length of hospitalisation (MD -1.75 days, 95% CI -2.45 to -1.05, six trials, 2848 women, evidence graded moderate).

Subgroup analyses indicated improved maternal and infant outcomes in expectant management in pregnancies greater than 34 weeks' gestation, specifically relating to RDS and maternal infections. The use of prophylactic antibiotics were shown to be effective in reducing maternal infections in women randomised to expectant management.

Overall, we assessed all 12 studies as being at low or unclear risk of bias. Some studies lacked an adequate description of methods and the risk of bias could only be assessed as unclear. In five of the studies there were one and/or two domains where the risk of bias was judged as high. GRADE profiling showed the quality of evidence across all critical outcomes to be moderate to high.

Authors' conclusions

With the addition of five randomised controlled trials (2927 women) to this updated review, we found no clinically important difference in the incidence of neonatal sepsis between women who birth immediately and those managed expectantly in PPRM prior to 37 weeks' gestation. Early planned birth was associated with an increase in the incidence of neonatal RDS, need for ventilation, neonatal mortality, endometritis, admission to neonatal intensive care, and the likelihood of birth by caesarean section, but a decreased incidence of chorioamnionitis. Women randomised to early birth also had an increased risk of labour induction, but a decreased length of hospital stay. Babies of women randomised to early birth were more likely to be born at a lower gestational age.

In women with PPRM before 37 weeks' gestation with no contraindications to continuing the pregnancy, a policy of expectant management with careful monitoring was associated with better outcomes for the mother and baby.

The direction of future research should be aimed at determining which groups of women with PPRM would not benefit from expectant management. This could be determined by analysing subgroups according to gestational age at presentation, corticosteroid usage, and abnormal vaginal microbiological colonisation. Research should also evaluate long-term neurodevelopmental outcomes of infants.

PLAIN LANGUAGE SUMMARY

Is it better for the baby to be born immediately or wait for labour to start if the waters break without contractions before 37 weeks of pregnancy?

What is the issue?

If a pregnant woman's waters break without contractions before 37 weeks of pregnancy there are two options: for the baby to be born as soon as possible, or to wait for labour to start naturally. We need to carefully look at the risks and benefits of both options.

Why is this important?

Being born too early can increase the chance of problems linked to prematurity, such as breathing difficulties and longer stays in the neonatal intensive care unit. However, staying in the womb may cause infections for both mother and baby that can lead to serious health problems and even death. This review aims to find out which is the best option.

What evidence did we find?

We included 12 trials that involved 3617 women with preterm prelabour rupture of the membranes. Women were randomly selected to either early birth or expectant management (wait for birth). The women were between 25 to 37 weeks of pregnancy. The studies happened in 16 countries between 1977 and 2013. Overall, the 12 studies were assessed as being at low or unclear risk of bias and the evidence was of moderate to high quality.

We found no difference in the rate of infant infection or infant death before birth between the two groups. However, early birth increased the risk of infant death after birth, as well as breathing problems, with the newborn needing extra help to breathe. The babies of women who had a planned early birth were more likely to be admitted to neonatal intensive care, and were born earlier than babies of women who waited to give birth. Early birth also increased the rate of caesarean section, induction of labour and the risk of infection of the lining of the womb but decreased the risk of infection in the membranes. Women had a longer hospital stay if they were randomised to waiting.

What does this mean?

In women whose waters break before 37 weeks of pregnancy, waiting for labour to begin naturally is the best option for healthier outcomes, as long as there are no other reasons why the baby should be born immediately.

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Planned early birth compared to expectant management for preterm prelabour rupture of membranes prior to 37 weeks' gestation

Planned early birth compared to expectant management for preterm prelabour rupture of membranes prior to 37 weeks' gestation

Patient or population: women with preterm prelabour rupture of membranes prior to 37 weeks' gestation

Settings: USA, the Netherlands, Mexico, Albania, Australia, New Zealand, Argentina, South Africa, Brazil, UK, Norway, Egypt, Uruguay, Poland, and Romania

Intervention: planned early birth

Comparison: expectant management

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Expectant management	Planned early birth

	103 per 1000	51 per 1000 (27 to 98)			
Length of hospital stay (maternal)	The mean length of hospital stay (maternal) in the expectant group was 7.6 days	The mean length of hospital stay (maternal) in the early birth group was 1.75 days lower (2.45 to 1.05 lower)	MD -1.75 (-2.45 to -1.05)	2848 (6 studies)	⊕⊕⊕⊖ moderate ³

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio;

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹Wide confidence interval crossing the line of no effect, and the lines of appreciable benefit and harm.

²Some statistical heterogeneity ($I^2 = 48\%$).

³Statistical heterogeneity: $I^2 = 63\%$, likely due to differences in women's management.

BACKGROUND

Description of the condition

Preterm prelabour rupture of the membranes (PPROM) occurs when there is rupture of the membranes prior to term and prior to the onset of labour. PPRM complicates pregnancy for 1% to 2% of all women and is associated with 30% to 40% of preterm births (less than 37 weeks) (Arias 1982; Lee 2001; Mercer 2000; Mercer 2005).

Description of the intervention

The purpose of this review is to determine the optimal management for women and their babies with pregnancies complicated by PPRM. This could either be planned delivery soon after rupture of the membranes or expectant management. Planned early birth involves the birth of the baby near to the time of rupture of the membranes and may be by induction of labour or caesarean section. Expectant management involves observation of the mother and baby and awaiting the spontaneous onset of labour in the absence of any complications that may necessitate delivery. Women with PPRM who are managed expectantly may then have the delivery of their baby planned for term if labour has not ensued.

How the intervention might work

The management of PPRM is dependent upon the gestation at which rupture of the membranes occurs. The health benefits for the fetus in continuing a pregnancy after PPRM may be considerable, particularly in the late second and early third trimesters. However, there is currently no consensus as to the optimal management of PPRM in women in whom the fetus is relatively mature, at gestations near to term such as in the late second trimester and third trimester of pregnancy. The aim of care for women with PPRM is to maximise the benefits of further fetal maturity while avoiding the potential harms of remaining in utero.

There are treatments such as antibiotics and antenatal corticosteroids that can reduce associated complications for the mother and baby in pregnancies complicated by PPRM. The use of antibiotics in PPRM significantly improves neonatal and maternal morbidity including prolongation of pregnancy, reduction in neonatal infection, reduced need for oxygen therapy and less risk of abnormal cerebral ultrasound (Kenyon 2001; Kenyon 2003). In addition, antenatal corticosteroids have been shown to reduce the risk of neonatal respiratory distress, intraventricular haemorrhage (bleeding within the ventricles of the baby's brain) and neonatal death in the preterm neonate (Roberts 2006). These beneficial effects of corticosteroids also apply to women with PPRM (Harding 2001).

Why it is important to do this review

There are recognised maternal and fetal risks associated with PPRM. These complications decrease the nearer to term that PPRM occurs. The recognised complications include ascending infection, cord prolapse (prolapsing of the umbilical cord through the cervix), intrapartum fetal distress and abruption (premature detachment of the placenta from the uterine wall) (Gonen 1989; Major 1995; Mercer 2003). It may be that managing PPRM expectantly by awaiting the spontaneous onset of labour increases the risk to the fetus of these complications. In particular prolonged exposure to intrauterine infection is of major concern for the neonate. In fact it has been demonstrated that neonatal sepsis is

twice as common in the setting of PPRM compared with preterm birth after preterm labour with intact membranes (Seo 1992).

There are potential risks associated with planned early delivery in pregnancies complicated by PPRM between 30 and 37 weeks' gestation. In particular the attendant risks of iatrogenic prematurity associated with birth before term but greater than 30 weeks' gestation are significant. These complications may include respiratory distress (Jones 2000; Lewis 1996), sepsis, necrotising enterocolitis (injury to the bowel of newborn babies), intraventricular haemorrhage, prolonged stays in the neonatal nursery, difficulty with thermoregulation and difficulty with breastfeeding (Engle 2008; Robertson 1992). These complications are less common when delivery occurs after 32 weeks' gestation (Mercer 2003). A number of retrospective studies have similarly found a decrease in neonatal morbidity associated with birth at 34 weeks' gestation (Lewis 1996; Neerhof 1999). The incidence of respiratory distress syndrome, hyperbilirubinaemia (high bilirubin within in the babies' blood which results in a yellow discolouration of the neonates' skin referred to as jaundice) and duration of stay in the neonatal nursery was significantly reduced in infants born after 34 weeks' gestation compared with those born before 34 weeks (Lewis 1996; Neerhof 1999). Infants born beyond 34 weeks' gestation do have better outcomes than those born prior to 34 weeks, however those babies born between 34 and 37 weeks' gestation are still physiologically immature and as such do have significantly increased morbidity and mortality as compared with those infants born at term (Engle 2007; Engle 2008).

The previous version of this review (Buchanan 2010), which included seven trials and 690 women, found there was insufficient evidence available at that time to guide clinical practice and that all included trials had methodological weaknesses.

There is consensus on the management of term pregnancies with PROM (prelabour rupture of the membranes) (Middleton 2017). This Cochrane review found that fewer women in the planned compared with the expectant management groups had chorioamnionitis (inflammation of the fetal membranes) and/or endometritis (a postpartum infection of the lining of the womb) (average risk ratio (RR) 0.49, 95% confidence interval (CI) 0.33 to 0.72, eight trials, 6864 women). Additionally, early birth appeared to reduce the likelihood of definite or probable early-onset neonatal sepsis (RR 0.73, 95% CI 0.58 to 0.92, sixteen trials, 7314 infants). There was no clear difference in the mode of birth between the groups.

It is evident that there is an increased incidence of chorioamnionitis associated with expectant management in women with PROM (Hannah 1996). Histological evidence of chorioamnionitis is present in up to 50% of women who deliver preterm and is often not associated with clinical symptoms or signs. Chorioamnionitis is a known significant risk factor for the development of both cystic periventricular leukomalacia (cystic changes around the ventricles of the babies brain) and cerebral palsy (Gaudet 2001; Wu 2000). Therefore, the question remains as to whether there is an increased chance of an adverse neurological outcome in those infants whose mothers are managed expectantly with PPRM by increasing their duration of exposure to often subclinical chorioamnionitis.

The objective of this review is to assess and further define the optimal management for women with PPRM prior to 37 weeks' gestation.

OBJECTIVES

To assess the effect of planned early birth versus expectant management for women with preterm prelabour rupture of the membranes between 24 and 37 weeks' gestation for fetal, infant and maternal well being.

METHODS

Criteria for considering studies for this review

Types of studies

We considered for inclusion all identified randomised controlled trials (RCTs) comparing planned early birth versus expectant management for women with preterm prelabour rupture of the membranes (PPROM) prior to 37 weeks' gestation. We did not consider quasi-randomised studies for inclusion in the review. We also assessed for inclusion studies that were presented in abstract form only.

In studies in which gestational ages overlapped the less-than-37-week gestation inclusion criteria, we attempted to extract gestational age-specific data from the studies. We also attempted to contact researchers to provide further information.

Types of participants

Women with PPRM before 37 weeks' gestation with no specific maternal or fetal contraindications to expectant management.

Types of interventions

Planned early birth compared with expectant management.

Planned early birth is planned birth soon after PPRM. The mode of birth may either be via induction of labour by any means and a vaginal birth, or by caesarean section.

Expectant management involves planning to wait for birth until the baby is at term.

Types of outcome measures

Primary outcomes

Neonatal infection/sepsis:

- proven neonatal infection with positive blood culture within 48 hours of birth;
- proven neonatal infection with positive blood culture 48 hours or more after birth.

Respiratory distress syndrome
 Caesarean section

Secondary outcomes

Fetal/perinatal outcomes

Perinatal death
 Intrauterine death
 Cord prolapse
 Gestational age at birth

Neonatal outcomes

Neonatal death

Suspected neonatal infection
 Treatment with antibiotics
 Treatment with surfactant
 Need for ventilation
 Days of neonatal ventilation
 Duration of oxygen therapy
 Oxygen therapy at 36 weeks' postmenstrual age
 Cord arterial pH
 Birthweight
 Apgar score less than 7 at five minutes
 Abnormality on cerebral ultrasound:

- cystic periventricular leukomalacia;
- cerebroventricular haemorrhage (including grade of intraventricular haemorrhage).

Necrotising enterocolitis
 Admission to neonatal intensive care unit
 Admission to neonatal intensive care unit after 24 hours
 Length of stay in neonatal intensive care unit
 Days from birth to discharge home from hospital
 Disability at time of childhood follow-up

Maternal outcomes

Chorioamnionitis
 Endometritis
 Postpartum fever
 Placental abruption
 Induction of labour
 Mode of induction of labour
 Use of epidural anaesthesia
 Vaginal birth
 Operative vaginal birth
 Caesarean section for fetal distress
 Duration of hospitalisation:

- days of antenatal hospitalisation;
- days of postnatal hospitalisation.

Maternal satisfaction:

- views of care;
- preferences of care;
- presence of postnatal depression.

Breastfeeding:

- whether breastfeeding established;
- time after birth breastfeeding established.

Search methods for identification of studies

The following methods section of this review is based on a standard template used by Cochrane Pregnancy and Childbirth.

Electronic searches

We searched Cochrane Pregnancy and Childbirth's Trials Register by contacting their Information Specialist (30 September 2016).

The Register is a database containing over 22,000 reports of controlled trials in the field of pregnancy and childbirth. For full search methods used to populate Pregnancy and Childbirth's Trials Register including the detailed search strategies for CENTRAL,

MEDLINE, Embase and CINAHL; the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service, please follow this link to the editorial information about the [Cochrane Pregnancy and Childbirth](#) in the Cochrane Library and select the '**Specialized Register**' section from the options on the left side of the screen.

Briefly, Cochrane Pregnancy and Childbirth's Trials Register is maintained by their Information Specialist and contains trials identified from:

1. monthly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
2. weekly searches of MEDLINE (Ovid);
3. weekly searches of Embase (Ovid);
4. monthly searches of CINAHL (EBSCO);
5. handsearches of 30 journals and the proceedings of major conferences;
6. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Two people screen search results and review the full text of all relevant trial reports identified through the searching activities described above. Based on the intervention described, each trial report is assigned a number that corresponds to a specific Pregnancy and Childbirth review topic (or topics), and is then added to the Register. The Information Specialist searches the Register for each review using this topic number rather than keywords. This results in a more specific search set which has been fully accounted for in the relevant review sections ([Included studies](#); [Excluded studies](#); [Ongoing studies](#)).

For the 2010 update ([Buchanan 2010](#)), we carried out additional author searching. See [Appendix 1](#) for details.

Searching other resources

We searched reference lists of trials and other review articles. We contacted researchers to provide further information as required. We did not apply any language or date restrictions.

Data collection and analysis

For the methods used when assessing the trials identified in the previous version of this review, see [Buchanan 2010](#).

For this update, we used the following methods for assessing the 11 additional reports that were identified as a result of the updated search.

The following methods section of this review is based on a standard template used by Cochrane Pregnancy and Childbirth.

Selection of studies

Two review authors independently assessed for inclusion all the potential studies identified as a result of the search strategy. We resolved any disagreement through discussion or, if required, we consulted a third review author.

Data extraction and management

We designed a form to extract data based on Cochrane Pregnancy and Childbirth recommendations. For eligible studies, two review authors (DB and JM) extracted the data using the agreed form.

We resolved discrepancies through discussion or, if required, we consulted the third review author (KL). One author (DB) entered data into Review Manager 5 (RevMan) software ([RevMan 2014](#)) and two others checked for accuracy (JM, KL).

David P van der Ham was Chief Investigator and first author of the PPROMEXIL trials and so JM and DB were responsible for data extraction and assessment of all trial reports relating to this study. Jonathan Morris was the Chief Investigator and first author for the NHMRC- (National Health and Medical Research Council) funded PPROMT trial and so data was assessed and extracted independently by PM.

When information regarding any of the above was unclear, we contacted authors of the original reports to provide further details.

Assessment of risk of bias in included studies

Two review authors (DB and KL) independently assessed risk of bias for each study using the criteria outlined in the Cochrane Handbook for Systematic Reviews of Interventions ([Higgins 2011](#)). We resolved any disagreement by discussion or by involving a third assessor.

(1) Random sequence generation (checking for possible selection bias)

We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We have assessed the method as:

- low risk of bias (any truly random process, e.g. random number table; computer random number generator);
- high risk of bias (any non-random process, e.g. odd or even date of birth; hospital or clinic record number);
- unclear risk of bias.

(2) Allocation concealment (checking for possible selection bias)

We described for each included study the method used to conceal allocation to interventions prior to assignment and assessed whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We have assessed the methods as:

- low risk of bias (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk of bias (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear risk of bias.

(3.1) Blinding of participants and personnel (checking for possible performance bias)

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judged that the lack of blinding was unlikely to affect results. We assessed blinding separately for different outcomes or classes of outcomes.

We have assessed the methods as:

- low, high or unclear risk of bias for participants;
- low, high or unclear risk of bias for personnel.

(3.2) Blinding of outcome assessment (checking for possible detection bias)

We described for each included study the methods used, if any, to blind outcome assessors from knowledge of which intervention a participant received. We assessed blinding separately for different outcomes or classes of outcomes.

We have assessed methods used to blind outcome assessment as:

- low, high or unclear risk of bias.

(4) Incomplete outcome data (checking for possible attrition bias due to the amount, nature and handling of incomplete outcome data)

We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported and the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or could be supplied by the trial authors, we planned to re-include missing data in the analyses that we undertook.

We have assessed methods as:

- low risk of bias (e.g. no missing outcome data; missing outcome data balanced across groups);
- high risk of bias (e.g. numbers or reasons for missing data imbalanced across groups; 'as treated' analysis done with substantial departure of intervention received from that assigned at randomisation);
- unclear risk of bias.

(5) Selective reporting (checking for reporting bias)

We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found.

We have assessed the methods as:

- low risk of bias (where it was clear that all of the study's pre-specified outcomes and all expected outcomes of interest to the review were reported);
- high risk of bias (where not all the study's pre-specified outcomes were reported; one or more reported primary outcomes were not pre-specified; outcomes of interest were reported incompletely and so could not be used; study failed to include results of a key outcome that would have been expected to have been reported);
- unclear risk of bias.

(6) Other bias (checking for bias due to problems not covered by (1) to (5) above)

We described for each included study any important concerns we had about other possible sources of bias.

(7) Overall risk of bias

We made explicit judgements about whether studies were at high risk of bias, according to the criteria given in the Handbook for Systematic Reviews of Interventions (Higgins 2011). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it likely to impact on the findings. In future updates, we will explore the impact of the level of bias through undertaking sensitivity analyses - see [Sensitivity analysis](#).

Assessment of the quality of evidence using the GRADE approach

For this update we assessed the quality of the evidence using the GRADE approach as outlined in the [GRADE handbook](#) in order to assess the quality of the body of evidence relating to the following outcomes for the main comparisons.

- Neonatal infection/sepsis
- Neonatal respiratory distress syndrome
- Need for ventilation
- Admission to neonatal intensive care
- Caesarean section
- Chorioamnionitis
- Length of hospital stay (maternal)

We used the [GRADEproGDT](#) (GRADEpro Guideline Development Tool) to import data from RevMan 5.3 (RevMan 2014) to create 'Summary of findings' tables. We produced a summary of the intervention effect and a measure of quality for each of the above outcomes using the GRADE approach. The GRADE approach uses five considerations (study limitations, consistency of effect, imprecision, indirectness and publication bias) to assess the quality of the body of evidence for each outcome. The evidence can be downgraded from 'high quality' by one level for serious (or by two levels for very serious) limitations, depending on assessments for risk of bias, indirectness of evidence, serious inconsistency, imprecision of effect estimates or potential publication bias.

Measures of treatment effect

Dichotomous data

For dichotomous data, we presented results as summary risk ratio (RR) with 95% confidence intervals (CI).

Continuous data

We used the mean difference (MD) if outcomes were measured in the same way between trials. In future updates if appropriate, we will use the standardised mean difference to combine trials that measure the same outcome, but use different methods.

Unit of analysis issues

We considered trials including twin pregnancies for inclusion in the review. For trials that included twin pregnancies, for fetal outcomes the denominator used for analysis was the number of pregnancies. However, for neonatal outcomes the denominator used for analysis was the number of individual babies randomised.

Cluster-randomised trials

Cluster-randomised trials were not eligible for inclusion in this review.

Cross-over trials

Cross-over trials were not eligible for inclusion in this review.

Dealing with missing data

For included studies, we noted levels of attrition. In future updates, if more eligible studies are included, we will explore the impact of including studies with high levels of missing data in the overall assessment of treatment effect by using sensitivity analysis.

For all outcomes, we carried out analyses, as far as possible, on an intention-to-treat basis, that is, we attempted to include all participants randomised to each group in the analyses. The denominator for each outcome in each trial was the number randomised minus any participants whose outcomes were known to be missing.

Assessment of heterogeneity

We assessed statistical heterogeneity in each meta-analysis using the Tau^2 , I^2 (Higgins 2003) and Chi^2 statistics. We regarded heterogeneity as substantial if I^2 was greater than 30% and either Tau^2 was greater than zero, or there was a low P value (less than 0.10) in the Chi^2 test for heterogeneity. If we identified substantial heterogeneity (above 50%), we planned to explore it by pre-specified subgroup analysis (Deeks 2011).

Assessment of reporting biases

In this update, if there were 10 or more studies in the meta-analysis, we investigated reporting biases (such as publication bias) using funnel plots. We assessed funnel plot asymmetry visually. If asymmetry was suggested by a visual assessment, we planned to perform an exploratory analyses to investigate it (Sterne 2011).

Data synthesis

We carried out statistical analysis using the RevMan software (RevMan 2014). We used fixed-effect meta-analysis for combining data where it was reasonable to assume that studies were estimating the same underlying treatment effect: that is, where trials were examining the same intervention, and the trials' populations and methods were judged sufficiently similar.

If there was clinical heterogeneity sufficient to expect that the underlying treatment effects differed between trials, or if substantial statistical heterogeneity was detected, we used random-effects meta-analysis to produce an overall summary if an average treatment effect across trials was considered clinically meaningful. We treated the random-effects summary as the average range of possible treatment effects and we discussed the clinical implications of treatment effects differing between trials. If the average treatment effect was not clinically meaningful, we did not combine trials. If we used random-effects analyses, we presented the results as the average treatment effect with 95% confidence intervals, and the estimates of Tau^2 and I^2 tests.

Subgroup analysis and investigation of heterogeneity

If we identified substantial heterogeneity, we investigated it using subgroup analyses and sensitivity analyses. We considered whether an overall summary was meaningful, and if it was, we used random-effects analysis to produce it.

We carried out the following subgroup analyses.

- Corticosteroid usage versus no corticosteroid usage
- Gestational age at randomisation with stratification into:
 - * less than 30 weeks' gestation
 - * 30 to 33 plus 6 weeks' gestation
 - * 34 to 37 weeks' gestation
- Antibiotic usage versus no antibiotic usage
- Time from randomisation to early birth: less than 24 hours versus greater than 24 hours

We used the following outcomes in subgroup analyses.

Fetal/neonatal outcomes

Neonatal infection
 Neonatal infection confirmed with positive blood culture
 Respiratory distress syndrome

Maternal outcomes

Caesarean section
 Chorioamnionitis
 Endometritis

We assessed subgroup differences by interaction tests available within RevMan (RevMan 2014). We reported the results of subgroup analyses quoting the Chi^2 statistic and P value, and the interaction test I^2 value.

Sensitivity analysis

We included all eligible trials in the initial analysis and planned to carry out sensitivity analyses to evaluate the effect of trial quality. We also planned to perform a sensitivity analysis based on the randomisation process, assessing the presence of blinding of assessors to the primary outcome, assessing the quality of treatment allocation and assessing the presence of losses to follow-up.

RESULTS

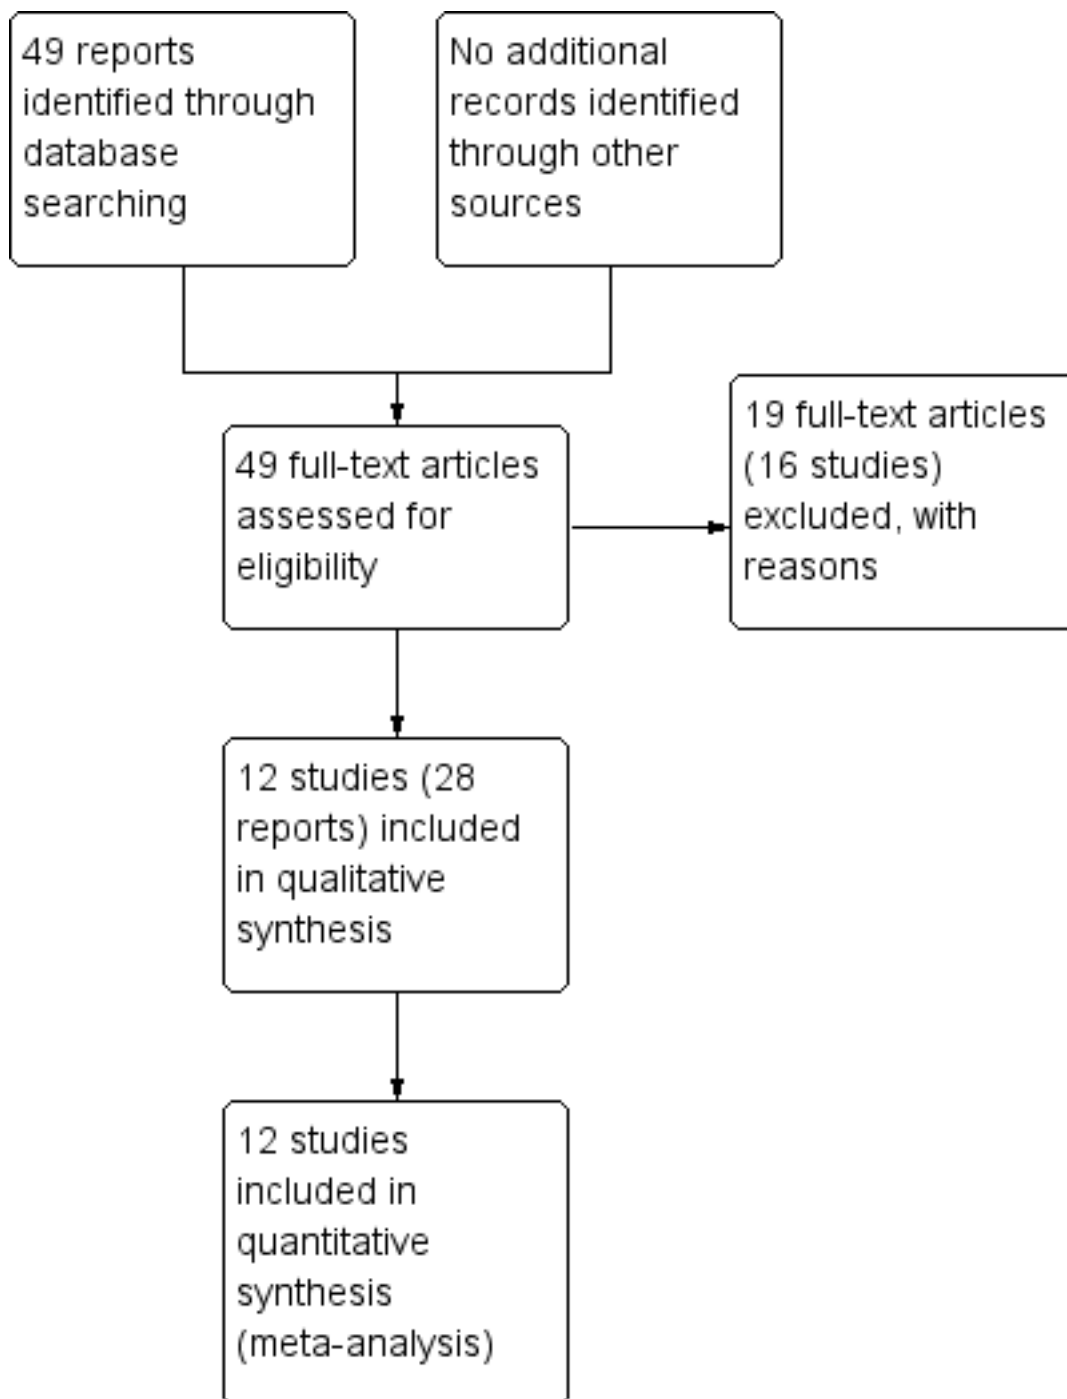

Description of studies

Refer to the [Characteristics of included studies](#) and [Characteristics of excluded studies](#) tables for further detailed information on individual studies.

Results of the search

The search of the Cochrane Pregnancy and Childbirth's Trials Register retrieved 14 additional reports for consideration in this updated review, which contributed four additional studies to the review. Five of the reports were based on one study (Morris 2016), six on another (Van der Ham 2012a), four on the third (Van der Ham 2012b) and one on the fourth (Korovesi 2013). We moved one study from 'excluded studies' in the first review to 'included studies' (Eroiz-Hernandez 1997) in this update as the authors felt the study fitted the inclusion criteria after translation into English. We moved another study from 'ongoing' to 'excluded' as the trial was terminated prematurely due to poor recruitment (Lacaze 2006). One study remained ongoing as we were unable to ascertain the current status (Pasquier 2006). See [Figure 1](#).

Figure 1. Study flow diagram

Included studies

We have included 12 randomised controlled trials in this review, which comprise 3617 women and 3628 babies (Cox 1995; Eroiz-Hernandez 1997; Garite 1981; Iams 1985; Koroveshi 2013; Mercer 1993; Morris 2016; Naef 1998; Nelson 1985; Spinnato 1987; Van der Ham 2012a; Van der Ham 2012b). One study was performed in Albania (Koroveshi 2013), one in Mexico (Eroiz-Hernandez 1997), two in the Netherlands (Van der Ham 2012a; Van der Ham 2012b), and one, though based in Australia, included a total of 11 countries: Australia, Argentina, Brazil, Egypt, New Zealand, Norway, Poland,

Romania, South Africa, UK and Uruguay (Morris 2016). The other seven studies were performed in the USA. All but one of the included studies were reported in English, but we were able to translate the Mexican study (Eroiz-Hernandez 1997) from Spanish to English. Five studies recruited women from multiple sites (Garite 1981; Iams 1985; Morris 2016; Van der Ham 2012a; Van der Ham 2012b), while the remainder recruited from a single centre only (Cox 1995; Eroiz-Hernandez 1997; Koroveshi 2013; Mercer 1993; Nelson 1985; Naef 1998; Spinnato 1987). The studies were performed between 1977 and 2016. As Koroveshi 2013 was a

published abstract only, this study provided limited information for this review and as a result has been excluded from most of the following discussion about participants, interventions and outcomes. Outcomes were included in the analysis only.

A summary of the trials is provided (Table 1).

Participants

The studies included women with pregnancies complicated by preterm prelabour rupture of the membranes (PPROM) of differing gestational ages. Eroiz-Hernandez 1997, Garite 1981, Iams 1985 and Nelson 1985 included women with PPRM between 28 and 34 weeks' gestation, while Spinnato 1987 included women from 25 to 36 weeks' gestation. Cox 1995 included women with PPRM at 30 to 34 weeks' gestation. Mercer 1993 included women from 32 to 36 weeks' gestation, while Korovesi 2013, Morris 2016, Naef 1998; Van der Ham 2012a and Van der Ham 2012b included women from 34 weeks' gestation to 36 weeks' plus six days' gestation. Three trials (Cox 1995; Van der Ham 2012a; Van der Ham 2012b) included twin pregnancies for a total of three pairs of twins randomised to early birth and eight pairs randomised to expectant management. One study (Eroiz-Hernandez 1997), although inclusion criteria specified singleton pregnancies only, reported outcomes for two sets of twins in each group in the analysis.

Importantly, the entry criteria also differed between the studies. Eroiz-Hernandez 1997, Garite 1981, Iams 1985, Mercer 1993 and Spinnato 1987 required amniotic fluid sampling to assess fetal pulmonary maturity prior to study entry. Garite 1981 and Iams 1985 used a mature lecithin-sphingomyelin (L/S) as an exclusion criteria and then treated the early birth group with corticosteroids, while in contrast Mercer 1993 and Spinnato 1987 used a mature L/S as an inclusion criteria and did not use antenatal corticosteroids. Eroiz-Hernandez 1997 excluded women with 'positive' fetal lung maturity tests based on "tap*, clements* and 650 nm spectrophotometry" (*we were unsure of the definition of these tests, which may have been an error in translation) and used a different fetal lung maturity protocol of intravenous aminophylline for each arm of the trial. They also required an amniotic fluid index of greater than 5 cm for trial inclusion. Cox 1995, Morris 2016, Nelson 1985, Naef 1998, Van der Ham 2012a and Van der Ham 2012b did not require documented pulmonary maturity prior to study entry. Exclusion criteria included active labour, chorioamnionitis or non-reassuring fetal status as assessed at the time of randomisation in all the studies. Morris 2016 included an additional broadly defined exclusion as being any other contraindications to continuing the pregnancy, while Van der Ham 2012a and Van der Ham 2012b more specifically included additional exclusion criteria as being: monochorionic multiple pregnancy; major fetal anomalies; haemolysis; elevated liver enzymes and low platelets (HELLP) syndrome; and severe pre-eclampsia (see Table 1).

All of the studies defined determination of gestational age for inclusion by menstrual history or early ultrasound examination to give the most accurate clinical estimate. In the absence of an accurate clinical estimate, seven of the studies used ultrasound at the time of presentation to hospital to date the pregnancy (Garite 1981; Morris 2016; Naef 1998; Nelson 1985; Spinnato 1987; Van der Ham 2012a; Van der Ham 2012b).

All of the trials defined ruptured membranes by clinical assessment with a sterile speculum examination and visualising amniotic fluid passing through the cervical os and pooling in the posterior fornix of the vagina. Six of the trials (Garite 1981; Iams 1985; Mercer 1993; Naef 1998; Nelson 1985; Spinnato 1987) also confirmed the presence of PPRM with a Nitrazine test to demonstrate an alkaline pH and or ferning of a specimen of vaginal fluid on microscopy. Eroiz-Hernandez 1997 used 'cristallography' or the 'flame test' as an additional diagnosis.

Six of the included trials (Cox 1995; Garite 1981; Iams 1985; Mercer 1993; Naef 1998; Spinnato 1987) did not allow digital cervical examinations to be performed in the absence of labour.

Intervention

The intervention assessed by these studies was the effect of early birth on maternal and fetal well being. The timing of intervention for early birth differed between the studies. The mean latency from PROM to birth in four studies (Cox 1995; Mercer 1993; Naef 1998; Spinnato 1987) indicated that birth was planned as soon as practicable from randomisation and less than 24 hours, although this was not explicitly stated in all the trials. One study (Eroiz-Hernandez 1997) did not indicate when birth was intended but results indicated a median latency of three days. Nelson 1985 planned for early birth between 24 and 48 hours after initial rupture of membranes and 24 hours after initiation of steroid therapy, while Garite 1981 defined planned early birth as 48 hours after treatment with corticosteroids. Iams 1985 had an even longer delay in the early birth group and planned for early birth 48 to 72 hours after PPRM and initiation of steroid treatment. Morris 2016 defined timing of birth as birth scheduled as close to randomisation as possible and preferably within 24 hours. In both Van der Ham 2012a and Van der Ham 2012b women were randomised if not spontaneously delivered within 24 hours after initial rupture of membranes and women randomised to early birth were induced within 24 hours after randomisation.

The only study with a control arm of early birth for PPRM was Eroiz-Hernandez 1997. As a result, for the discussion and analysis, we flipped the definition and results for the 'treatment' group and the 'control' group in this study to be consistent with the rest of the studies, which all defined the control arm as being expectant management. The intention of expectant management was defined in the majority of studies as waiting until spontaneous labour or until there was medical indication to facilitate birth, such as infection or fetal distress. The exceptions were Eroiz-Hernandez 1997, Korovesi 2013 and Nelson 1985, which did not specify the intent of expectant management, although Eroiz-Hernandez 1997 did indicate in an outcomes table that the reasons for delivery in the expectant management group were onset of labour, infection, oligohydramnios and fetal distress. Iams 1985, Morris 2016, Spinnato 1987, Van der Ham 2012a and Van der Ham 2012b allowed women to be discharged home at the discretion of the attending physician or according to local protocol, while the remainder of the studies required the women in the trial to be hospitalised until birth.

The co-interventions also differed between the included studies. Cox 1995, Mercer 1993, Naef 1998 and Spinnato 1987 did not treat the women with corticosteroids or tocolysis. Garite 1981 and Iams 1985 treated women in the early birth groups with corticosteroids and tocolysis as required. Nelson 1985 randomised women to

steroids or no steroid therapy in the early birth group. These women in the early birth group were also treated with tocolytics. [Morris 2016](#) used tocolytics, antibiotics and corticosteroids according to local protocol, whereas [Van der Ham 2012a](#) and [Van der Ham 2012b](#) only used tocolytics and antibiotics according to local protocol, but gave corticosteroids to women with PPRM less than 34 weeks' gestation. [Eroiz-Hernandez 1997](#) used tocolytics as well as a fetal lung maturity protocol of intravenous aminophylline in the early birth arm, which was repeated weekly in the women randomised to expectant management. Antibiotics were not used unless there were signs of chorioamnionitis, in which case birth was indicated. [Naef 1998](#) was the only trial in which prophylactic antibiotics were used for all women. In this trial all women were treated with ampicillin.

Outcomes

Neonatal infection was variably defined in the studies. [Cox 1995](#), [Garite 1981](#) and [Spinnato 1987](#) did not document their criteria required for documenting neonatal infection while [Eroiz-Hernandez 1997](#), [Iams 1985](#), [Mercer 1993](#), [Morris 2016](#), [Naef 1998](#), [Nelson 1985](#), [Van der Ham 2012a](#) and [Van der Ham 2012b](#) required a positive culture of blood, cerebrospinal fluid or urine in addition to clinical features of sepsis for diagnosis.

Chorioamnionitis was defined in all of the studies as maternal temperature associated with uterine tenderness, maternal or fetal tachycardia, or both, and/or foul smelling amniotic fluid in the absence of any other cause of identifiable infection. None of the studies confirmed the presence of clinical chorioamnionitis pathologically with a histological examination of the placenta and fetal membranes. [Eroiz-Hernandez 1997](#) additionally included in their diagnosis a leucocyte count of 15,000 in maternal blood at the start of the study or a 50% increase from the baseline reading.

Excluded studies

We excluded 16 studies from the review (see [Characteristics of excluded studies](#)). [Fayez 1978](#) used a quasi-randomisation schema in which women were randomised to either early birth or expectant management based on odd or even hospital record numbers. We also excluded [Parsons 1989](#) and [Bergstrom 1991](#) as these were prospective but not randomised trials.

We excluded six trials ([Cararach 1994](#); [Gloeb 1989](#); [Griffith-Jones 1990](#); [Ladfors 1996](#); [Mateos 1998](#); [Van Heerden 1996](#)) because the gestational age criteria for trial entry included women both prior to term and at term. We attempted to obtain information of the subgroup of women with PPRM prior to term in these trials; however, this was not successful.

We excluded another five studies because they assessed interventions other than the effect of birth on maternal and fetal well-being in women with PPRM ([Decavalas 1995](#); [El-Qarmalawi 1990](#); [Haghighi 2006](#); [Miodovnik 1988](#); [Perez 1992](#)).

We excluded one study because it was available in abstract form only and did not quantify outcomes that we could include in a meta-analysis ([Makhlouf 1997](#)).

[Lacaze 2006](#) was moved from 'ongoing' in the previous review to 'excluded' in this review as the trial had been terminated due to poor recruitment and there were no outcome data available.

Risk of bias in included studies

Please see [Figure 2](#) and [Figure 3](#) for summary of risk of bias assessments.

Figure 2. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies

Figure 3. Risk of bias summary: review authors' judgements about each risk of bias item for each included study

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias
Cox 1995	+	?	+	?	+	?	+
Eroiz-Hernandez 1997	+	?	+	?	-	-	+
Garite 1981	?	?	+	?	-	?	+
Iams 1985	+	?	+	?	-	?	+
Korovesi 2013	?	?	?	?	?	-	?
Mercer 1993	+	?	+	?	+	?	+
Morris 2016	+	+	+	+	+	+	+
Naef 1998	+	?	+	?	+	+	+
Nelson 1985	+	?	+	?	+	+	+
Spinnato 1987	+	?	+	?	-	?	+
Van der Ham 2012a	+	+	+	+	+	+	+
Van der Ham 2012b	+	+	+	+	+	+	+

The trials were of variable methodological quality but overall of low to unclear risk of bias.

We assessed publication bias using funnel plots (Sterne 2011). We noted no visual asymmetry (Figure 4; Figure 5; Figure 6; Figure 7; Figure 8; Figure 9; Figure 10; Figure 11).

Figure 4. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.1 Neonatal infection/sepsis

Figure 5. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.3 Respiratory distress syndrome

Figure 6. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.4 Caesarean section

Figure 7. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.5 Perinatal mortality

Figure 8. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.6 Intrauterine death

Figure 9. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.9 Neonatal death

Figure 10. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.15 Birthweight (g)

Figure 11. Funnel plot of comparison: 1 Any planned birth versus expectant management: by type, outcome: 1.31 Vaginal birth

Sensitivity analysis

We did not perform sensitivity analyses for this version of the review, due to very small differences in the potential risk of bias between the included studies. We assessed heterogeneity with subgroup analyses of outcomes.

Allocation

Random sequence generation

Ten of the 12 included trials discussed the method of randomisation (Cox 1995; Eroiz-Hernandez 1997; Iams 1985; Mercer 1993; Morris 2016; Naef 1998; Nelson 1985; Spinnato 1987; Van der Ham 2012a; Van der Ham 2012b). This involved computer-generated randomisation sequences, randomisation cards and random number tables. Garite 1981 and Koroveshi 2013 did not report on the method of randomisation.

Allocation concealment

Allocation concealment was unclear in all of the studies except Morris 2016, Van der Ham 2012a and Van der Ham 2012b each of which were considered low risk of bias.

Blinding

Blinding of participants and personnel (performance bias)

Blinding was not possible due to the intervention, however this is likely low risk of bias due to objective and specific assessment

criteria for outcomes, where lack of blinding would not affect treatment decisions or other aspects of care. However, for one trial (Koroveshi 2013), the risk was unclear as the assessment criteria for outcomes was not mentioned.

Blinding of outcome assessment (detection bias)

Blinding of outcome assessors was only performed in three of the included trials (Morris 2016; Van der Ham 2012a; Van der Ham 2012b). In one trial (Garite 1981), only radiologists for reviewing X-rays prior to diagnosis of hyaline membrane disease were blinded as to treatment allocation. It is not clear in the other trials whether outcome assessors were blinded to treatment allocation.

Incomplete outcome data

All of the trials reported on short-term outcomes. The only trials that assessed any maternal or neonatal outcomes after discharge from hospital were Van der Ham 2012a, which reported on neurodevelopmental outcomes at two years of age, and Morris 2016, which reported on maternal satisfaction and breastfeeding duration greater than 12 weeks. There was incomplete outcome data in four of the studies (Eroiz-Hernandez 1997; Garite 1981; Iams 1985; Spinnato 1987). Eroiz-Hernandez 1997 showed results inconsistent with the number randomised. There was no explanation to account for the inconsistencies and incomplete data. Garite 1981 removed a fetal death that occurred in the expectant management group from the denominator of neonatal outcomes. Iams 1985 excluded five women from analysis after

randomisation. Three of these women were randomised to the expectant management group and were discharged home and they subsequently delivered their babies in another hospital and were excluded from analysis. Another mother and baby were excluded (also in this trial) due to failure to complete steroid therapy, and an additional neonate was excluded post-randomisation due to the presence of congenital abnormalities. [Spinnato 1987](#) excluded 15 women on case review after randomisation. Seven of these women were excluded for preterm labour, four for protocol violation and four others for unspecified reasons. In addition, two perinatal deaths resulting from lethal congenital anomalies were excluded in this trial after randomisation.

Selective reporting

Selective reporting bias was considered high in two of the trials. Although [Koroveshi 2013](#) was a published abstract only, in which three outcomes as well as secondary unspecified outcomes were reported, the full paper has not yet been published despite completion of the trial in 2011. In [Eroiz-Hernandez 1997](#), outcomes were only reported in results, and not pre-specified. Although the inclusion criteria was singleton pregnancy only, results for caesarean section indicate there were two sets of twins in each group, which was not reported.

Other potential sources of bias

As [Koroveshi 2013](#) was a published abstract only, it was unclear as to whether or not there were other sources of bias. We did not identify other potential sources of bias in any of the other included studies.

Effects of interventions

See: [Summary of findings for the main comparison Planned early birth compared to expectant management for preterm prelabour rupture of membranes prior to 37 weeks' gestation](#)

We included 12 randomised controlled trials in this review. This included 3617 women and 3628 babies with preterm premature rupture of the membranes randomised to either planned early birth or expectant management.

Primary outcomes

Fetal/neonatal outcomes

Infection

We identified no clear differences in the primary outcomes of probable or definite neonatal sepsis, or both (risk ratio (RR) 0.93, 95% confidence interval (CI) 0.66 to 1.30, 12 trials, 3628 babies, evidence graded moderate, [Analysis 1.1](#)), or proven neonatal infection with positive blood culture (RR 1.24, 95% CI 0.70 to 2.21, seven trials, 2925 babies, [Analysis 1.2](#)). No separate data were available for proven neonatal infection with a positive blood culture specifically within 48 hours of birth or after 48 hours of birth. Therefore, we further categorised neonatal sepsis into subgroups of: neonatal sepsis proven with positive blood culture (and included those trials that specified their sepsis outcome was defined by a positive culture); presumed sepsis; and neonatal treatment with antibiotics.

Three trials ([Mercer 1993](#); [Van der Ham 2012a](#); [Van der Ham 2012b](#)) reported on suspected neonatal sepsis and found a reduction

associated with early birth (RR 0.56, 95% CI 0.36 to 0.88, 829 babies, [Analysis 1.10](#)).

Respiratory distress syndrome

Early birth increased the incidence of respiratory distress syndrome (RDS) (RR 1.26, 95% CI 1.05 to 1.53, 12 trials, 3622 babies, evidence graded high, [Analysis 1.3](#)). Included in this outcome is [Spinnato 1987](#) who included RDS in the definition of "transient pulmonary insufficiency" along with respiratory insufficiency of prematurity and transient tachypnoea of the newborn. Three trials included a sub-category of severe respiratory distress, which showed no difference between the two groups (RR 1.54, 95% CI 0.80 to 2.97, three trials, 321 babies, [Analysis 1.21](#)). However, the definition of severe respiratory distress differed between the trials, and the numbers were too small to adequately assess this outcome.

Maternal outcomes

Caesarean section

Early birth was associated with an increased rate of caesarean section (RR 1.26, 95% CI 1.11 to 1.44, 12 trials, 3620 women, evidence graded high, [Analysis 1.4](#)).

Secondary outcomes

Fetal outcomes

There was no clear difference in the overall perinatal mortality (RR 1.76, 95% CI 0.89 to 3.50, 11 trials, 3319 babies, [Analysis 1.5](#)), or intrauterine deaths (RR 0.45, 95% CI 0.13 to 1.55, 11 trials, 3321 babies, [Analysis 1.6](#)) when comparing early birth with expectant management. There was no difference in incidence of cord prolapse (RR 1.24, 95% CI 0.33 to 4.61, four trials, 2722 babies, [Analysis 1.7](#)). Babies of women randomised to early birth tended to be born at a gestational age lower than those randomised to expectant management (mean difference (MD) -0.48 weeks, 95% CI -0.57 to -0.39, eight trials, 3139 babies, [Analysis 1.8](#)).

Neonatal outcomes

Neonatal mortality

Early birth was associated with a higher rate of neonatal death (RR 2.55, 95% CI 1.17 to 5.56, 11 trials, 3316 babies, [Analysis 1.9](#)). There was a disproportionate increased number of deaths in the planned early delivery arm of one trial ([Eroiz-Hernandez 1997](#)). This was the only trial comparing a fetal lung maturity protocol using intravenous aminophylline every eight hours in the early-birth arm and weekly in the expectant-management arm.

Neonatal morbidity

Early birth was associated with an increased need for neonatal ventilation (RR 1.27, 95% CI 1.02 to 1.58, seven trials, 2895 babies, evidence graded high, [Analysis 1.12](#)) and increased the arterial pH in the umbilical cord to above the normal range (MD 0.09, 95% CI 0.07 to 0.11, one trial, 120 babies, [Analysis 1.14](#)).

There were no clear differences between the groups in other measures of neonatal morbidities, including neonatal treatment with antibiotics (average RR 0.86, 95% CI 0.63 to 1.19, four trials, 2638 babies, $\text{Tau}^2 = 0.08$, $I^2 = 80\%$, [Analysis 1.11](#)), days of oxygen therapy (RR -3.05, 95% CI -6.92 to 0.82, one trial, 73 babies, [Analysis 1.13](#)), birthweight (MD -47.10 g, 95% CI -96.00 to 1.80), 10 trials, 3263 babies, $\text{Tau}^2 = 2260.76$, $I^2 = 44\%$, [Analysis 1.15](#)), Apgar score less

than seven at five minutes (RR 0.96, 95% CI 0.54 to 1.69, five trials, 2700 babies, [Analysis 1.16](#)), abnormality on cerebral ultrasound (RR 1.90, 95% CI 0.52 to 6.92, three trials, 271 babies, [Analysis 1.17](#)), periventricular leukomalacia (RR 1.00, 95% CI 0.14 to 6.99, two trials, 707 babies, [Analysis 1.18](#)), cerebroventricular haemorrhage (RR 1.19, 95% CI 0.40 to 3.52, six trials, 1095 babies, [Analysis 1.19](#)), and necrotising enterocolitis (RR 0.81, 95% CI 0.25 to 2.62, six trials, 2842 babies, [Analysis 1.20](#)).

There was substantial heterogeneity between the trials in assessing neonatal treatment with antibiotics as demonstrated by an I^2 of 80%. This was likely due to the differences in clinical practice guidelines between sites regarding antibiotic use. There was also high heterogeneity for birthweight which was likely due to the differences in gestational age at randomisation between trials.

Neonatal hospitalisation

Admission to neonatal intensive care (RR 1.16, 95% CI 1.08 to 1.24, four trials, 2691 babies, evidence graded moderate, [Analysis 1.22](#)) was higher for those babies randomised to early birth. However, the length of stay in neonatal intensive care for those babies who were admitted to the neonatal intensive care unit (NICU) was no different between the two groups (MD -0.17 days, 95% CI -1.62 to 1.27, four trials, 2121 babies, $Tau^2 = 1.65$, $I^2 = 85%$, [Analysis 1.23](#)). This may suggest that although fewer babies in the expectant management arm were admitted to NICU, their length of stay in NICU was longer. Furthermore, the duration of days in NICU for one trial ([Iams 1985](#)) was considerably longer than the other three trials that assessed this outcome. This may be attributed to the earlier gestation at randomisation (28 to 34 weeks as compared to 34 to 36 + 6 weeks) as well as being the oldest of the four trials (1985). Changes in clinical practice over time may have influenced time spent in NICU. Two trials ([Van der Ham 2012a](#); [Van der Ham 2012b](#)) were excluded from this outcome on the advice of the study author as there was uncertainty regarding the denominator used for the analysis. Overall duration of neonatal hospitalisation (MD 0.67 days, 95% CI -0.28 to 1.61, six trials, 2832 babies, $Tau^2 = 0.80$, $I^2 = 71%$, [Analysis 1.24](#)) was also no different between those babies in the early birth group compared to the expectant management group.

Heterogeneity for all these outcomes was high. This was likely due to the differences in clinical practice as evidenced by the large number of countries and sites represented in this review. Many hospitals routinely admit babies where the pregnancy is complicated by PPRM to NICU for observation for a specified period of time, whereas others do not.

Long-term disability

There were no clear differences in neurodevelopmental outcomes at two years of age between children in the early birth group compared to children in the expectant when assessed by the Child Behaviour Checklist (CBCL) (RR 0.64, 95% CI 0.26 to 1.59, one trial, 199 babies, [Analysis 1.38](#)) or the Ages and Stages Questionnaire (ASQ) (RR 0.61, 95% CI 0.35 to 1.05, one trial, 228 babies, [Analysis 1.39](#)). However, the trial was not powered for this outcome and with a 45% follow-up rate, the numbers may be insufficient for an overall effect.

Maternal outcomes

Infection

In assessing maternal outcomes, we found that early birth was associated with a decreased rate of chorioamnionitis (average RR 0.50, 95% CI 0.26 to 0.95, eight trials, 1358 women, evidence graded moderate, $Tau^2 = 0.36$, $I^2 = 48%$, [Analysis 1.25](#)). However, early birth was associated with an increased rate of endometritis (RR 1.61, 95% CI 1.00 to 2.59, seven trials, 2980 women, [Analysis 1.26](#)). There was no difference between early planned birth and expectant management in the risk of postpartum fever (RR 0.52, 95% CI 0.26 to 1.03, one trial, 1835 women, [Analysis 1.27](#)).

There was substantial heterogeneity between the trials in assessing chorioamnionitis as demonstrated by an I^2 of 48%. To analyse the source of heterogeneity we performed a number of subgroup analyses. The subgroup analysis comparing those trials in which early birth occurred less than 24 hours after randomisation reduced chorioamnionitis (RR 0.22, 95% CI 0.17 to 0.55, three trials, 342 women), while no difference was seen when planned birth was 24 hours or more from randomisation (RR 1.10, 95% CI 0.62 to 1.95, five trials, 1016 women). An interaction test for this difference between subgroups was significant in assessing the subgroup of early birth on chorioamnionitis: $Chi^2 = 6.02$, $df = 1$ ($P = 0.01$), $I^2 = 83.4%$, [Analysis 5.5](#)). Likewise, the subgroup analysis for gestational age at randomisation showed a reduction in chorioamnionitis in women greater than 34 weeks' gestation (RR 0.26, 95% CI 0.12 to 0.57, three trials, 847 women) compared to women less than 34 weeks' gestation (RR 0.77, 95% CI 0.45 to 1.30, four trials, 418 women). However, the interaction test for subgroup differences was not significant, [Analysis 3.5](#).

Other complications

There were no clear differences in rates of placental abruption between the two groups (RR 1.19, 95% CI 0.36 to 3.87, one trial, 1835 women, [Analysis 1.28](#)).

Mode of birth

As expected due to the intervention, women randomised to early birth had a higher chance of having an induction of labour as compared to women randomised to expectant management (RR 2.18, 95% CI 2.01 to 2.36, four trials, 2691 women, [Analysis 1.29](#)). In [Analysis 1.30](#), the results were probably in favour of the expectant management group, with more women in the planned early birth group using spinal/epidural anaesthesia (average RR 1.28, 95% CI 0.99 to 1.65, three trials, 2562 women, $Tau^2 = 0.03$, $I^2 = 57%$, [Analysis 1.30](#)). The high heterogeneity for this outcome was likely due to the differences in clinical practice between sites regarding the availability and use of epidural/spinal anaesthesia. The chances of a vaginal birth were lower in women randomised to early birth (RR 0.94, 95% CI 0.91 to 0.97, 12 trials, 3618 women, [Analysis 1.31](#)), although the rate of operative vaginal birth showed no difference (RR 0.85, 95% CI 0.67 to 1.10, four trials, 2685 women, [Analysis 1.32](#)). Although caesarean section rates were higher in the early birth group, if the reason for the caesarean section was fetal distress, the difference between the early birth group and the expectant management group was not apparent (RR 0.89, 95% CI 0.66 to 1.20, seven trials, 2918 women, [Analysis 1.33](#)).

Duration of maternal hospital stay

Women randomised to early birth showed a decrease in the total length of hospitalisation (MD -1.75 days, 95% CI -2.45 to -1.05, six trials, 2848 women, $Tau^2 = 0.41$, $I^2 = 63\%$, [Analysis 1.34](#)), including the length of antenatal hospitalisation (MD -6.30 days, 95% CI -9.67 to -2.93, one trial, 73 women, [Analysis 1.33](#)). This result remained consistent in trials which allowed for antenatal discharge between randomisation and birth (MD -1.64 days, 95% CI -3.06 to -0.23, two trials, 213 women, $Tau^2 = 0.65$, $I^2 = 58\%$, [Analysis 1.36](#)). The differences in patient admission management between different sites and countries likely accounted for the high heterogeneity regarding duration of maternal hospital stay.

Time from randomisation to birth

As expected, the time from randomisation to birth was shorter for those randomised to early birth (MD -79.48 hours, 95% CI -88.27 to -70.69, three trials, 2571 women, [Analysis 1.37](#)).

Satisfaction and breastfeeding

There was no difference in overall maternal satisfaction relating to their birth experience when comparing early birth with expectant management (RR 0.99, 95% CI 0.86 to 1.13, one trial, 493 women, [Analysis 1.40](#)). Likewise there was no difference between the two groups in the number of women who continued to breast feed for longer than 12 weeks following birth (RR 0.95, 95% CI 0.80 to 1.12, one trial, 415 women, [Analysis 1.41](#)).

Subgroup analyses

Antenatal corticosteroids

The trials differed in their use of antenatal corticosteroids in randomised women. Five trials ([Cox 1995](#); [Eroiz-Hernandez 1997](#); [Mercer 1993](#); [Naef 1998](#); [Spinnato 1987](#)) did not give antenatal corticosteroids to any of their randomised participants. Two trials ([Garite 1981](#); [Iams 1985](#)) gave corticosteroids to the women randomised to early birth and not to women randomised to expectant management. One trial ([Nelson 1985](#)) gave corticosteroids only to one group of women randomised to early birth and not to the second group or to the expectant management group. One trial ([Morris 2016](#)) used corticosteroids according to local protocol, and two trials ([Van der Ham 2012a](#); [Van der Ham 2012b](#)) gave corticosteroids to women who ruptured their membranes prior to 34 weeks' gestation. No trials gave antenatal corticosteroids to all their randomised participants. [Koroveshi 2013](#) did not stipulate corticosteroid usage.

There was no evidence of a difference between subgroups for corticosteroid use for the following outcomes: neonatal infection, [Analysis 2.1](#), neonatal infection confirmed with positive culture, [Analysis 2.2](#), RDS, [Analysis 2.3](#), caesarean section, [Analysis 2.4](#), chorioamnionitis, [Analysis 2.5](#), and endometritis, [Analysis 2.6](#), between trials in which no antenatal corticosteroids were used and trials where some antenatal corticosteroids were used.

Gestational age

Five trials ([Koroveshi 2013](#); [Morris 2016](#); [Naef 1998](#); [Van der Ham 2012a](#); [Van der Ham 2012b](#)) randomised women greater than 34 weeks' gestation, and five trials ([Cox 1995](#); [Eroiz-Hernandez 1997](#); [Garite 1981](#); [Iams 1985](#); [Nelson 1985](#)) randomised women less than 34 weeks' gestation. Two trials ([Mercer 1993](#); [Spinnato 1987](#)) included women before and after 34 weeks' gestation.

The test for subgroup differences were not significant for neonatal infection ([Analysis 3.1](#)), neonatal infection confirmed with positive culture ([Analysis 3.2](#)), RDS ([Analysis 3.3](#)), caesarean section, ([Analysis 3.4](#)), and chorioamnionitis ([Analysis 3.5](#)) between trials that randomised women after 34 weeks' gestation compared to before 34 weeks' gestation. There was a decrease in endometritis in women randomised to early delivery in trials greater than 34 weeks' gestation (RR 0.37, 95% CI 0.10 to 1.40, three trials, 2562 women) compared to women randomised in trials less than 34 weeks' gestation (RR 2.23, 95% CI 1.29 to 3.84, four trials, 418 women). The test for subgroup differences showed: $Chi^2 = 5.99$, $df = 1$ ($P = 0.01$), $I^2 = 83.3\%$, [Analysis 3.6](#). There were overall effect differences in RDS and chorioamnionitis showing an increase in RDS in early delivery in trials that recruited women greater than 34 weeks' gestation (RR 1.45, 95% CI 1.10 to 1.90, five trials, 2992 babies), and a decrease in chorioamnionitis in expectant management in trials that recruited women greater than 34 weeks' gestation (RR 0.26, 95% CI 0.12 to 0.57, three trials, 847 women). This may suggest better infant and maternal outcomes related to expectant management after 34 weeks' gestation. However, these results must be interpreted with caution as there were considerably fewer women in the subgroup less than 34 weeks' gestation compared to more than 34 weeks' gestation.

Prophylactic antibiotics

One trial ([Naef 1998](#)) gave prophylactic antibiotics to all women randomised to the trial. Seven trials ([Cox 1995](#); [Eroiz-Hernandez 1997](#); [Garite 1981](#); [Iams 1985](#); [Mercer 1993](#); [Nelson 1985](#); [Spinnato 1987](#)) did not use prophylactic antibiotics. Three trials ([Morris 2016](#); [Van der Ham 2012a](#); [Van der Ham 2012b](#)) used prophylactic antibiotics according to local protocol which differed between sites. [Morris 2016](#) provided individual participant data regarding the use of antibiotics for the outcome of neonatal sepsis. [Koroveshi 2013](#) did not mention whether they used prophylactic antibiotics.

The test for subgroup differences were not significant for neonatal infection ([Analysis 4.1](#)), neonatal infection confirmed with positive blood culture ([Analysis 4.2](#)), RDS ([Analysis 4.3](#)), caesarean section ([Analysis 4.4](#)), or chorioamnionitis ([Analysis 4.5](#)), between trials whether all, none or some women received prophylactic antibiotics. However, there was an increase in endometritis in women randomised to early birth in trials that did not use prophylactic antibiotics (RR 2.23, 95% CI 1.29 to 3.84, four trials, 418 women) as compared to trials where some women received prophylactic antibiotics (RR 0.37, 95% CI 0.10 to 1.40, three trials, 2562 women). The test for subgroup differences showed: $Chi^2 = 5.99$, $df = 1$ ($P = 0.01$), $I^2 = 83.3\%$, [Analysis 4.6](#). Overall effect differences showed a decrease in chorioamnionitis in expectant management when all or some prophylactic antibiotics were used, suggesting that antibiotics were effective in reducing maternal infections. Again, the results for this subgroup analysis must be interpreted with caution due to the considerably increased number of women in the 'some antibiotics' category compared to those who did not receive antibiotics. Independent participant data analysis would be useful to assess this more comprehensively.

Timing of birth

The timing of intervention for early birth differed between the studies. The mean latency from PROM to birth in four studies ([Cox 1995](#); [Mercer 1993](#); [Naef 1998](#); [Spinnato 1987](#)) indicated that early birth was planned for less than 24 hours, even though this was

not explicitly stated. One study (Eroiz-Hernandez 1997) did not indicate when birth was intended but results indicated a median latency of three days. Three studies (Garite 1981; Iams 1985; Nelson 1985) planned for women in the early birth arm to give birth more than 24 hours after randomisation. Three studies (Morris 2016; Van der Ham 2012a; Van der Ham 2012b) intended for women randomised to early birth to have labour initiated within 24 hours. However, the mean latency from randomisation to birth in these trials ranged from 33.9 to 39 hours. Korovesi 2013 did not indicate or provide data to support timing of early birth. Because of the lack of information related to 'intention' of timing of delivery in four of the trials, we based subgroup analysis on mean latency results rather than intended timing of early birth.

Subgroup analysis by timing of birth showed the tests for subgroup differences were not significant for neonatal sepsis (Analysis 5.1), neonatal infection confirmed with positive blood culture (Analysis 5.2), RDS (Analysis 5.3), caesarean section (Analysis 5.4), and endometritis (Analysis 5.6) between trials where early birth occurred less than 24 hours after randomisation as compared to trials where early birth occurred more than 24 hours after randomisation. However, chorioamnionitis was reduced in women randomised to early birth when planned birth occurred within 24 hours (RR 0.25, 95% CI 0.10 to 0.61, three trials, 342 women) as compared to when planned birth occurred more than 24 hours from randomisation (RR 0.76, 95% CI 0.41 to 1.42, five trials, 1016 women). The test for subgroup differences showed: $\text{Chi}^2 = 4.06$, $\text{df} = 1$ ($P = 0.04$), $I^2 = 75.4\%$, Analysis 5.5.

Outcomes not able to be assessed

There were no data related to secondary neonatal outcomes of treatment with surfactant, days of neonatal ventilation, oxygen therapy at 36 weeks' postmenstrual age, or admission to NICU after 24 hours.

There were no data related to secondary maternal outcomes of mode of induction of labour and days of postnatal hospitalisation.

DISCUSSION

Summary of main results

The existing evidence arose from clinical trials in which the protocols differed in their management of women with preterm prelabour rupture of the membranes (PPROM), particularly the use of prophylactic antibiotics, use of corticosteroids, timing of early birth and gestational age at trial entry. However, subgroup analyses of these four factors did not alter the result of the primary outcome of sepsis, which indicated that there was no difference in the incidence of neonatal sepsis between women who gave birth immediately or were managed expectantly in PPRM prior to 37 weeks' gestation.

Planned early birth was associated with an increase in the incidence of neonatal RDS, neonatal mortality and the likelihood of birth by caesarean section. Babies in the early birth arm were more likely to be admitted to neonatal intensive care unit, and receive ventilatory support.

Maternal outcomes indicated early birth was associated with an increased likelihood of induction of labour and endometritis, which was reduced with the use of antenatal antibiotics, and a decreased incidence of chorioamnionitis. The clinical significance of the

decreased likelihood of chorioamnionitis following early planned birth but an increased risk of endometritis is difficult to interpret. Chorioamnionitis was defined clinically and by those not blinded to treatment allocation so there is a possibility of bias in reporting this outcome. Long term follow-up studies are necessary to ascertain whether there are any sequelae beyond the neonatal period that may result from these exposures. Chorioamnionitis was decreased when randomisation occurred greater than 34 weeks of gestation and if birth occurred within 24 hours of randomisation. However, not all trials assessed this outcome on women randomised to early birth as the presence of chorioamnionitis was an exclusion criteria. The length of time between randomisation and birth as well as overall length of maternal hospitalisation was longer in women randomised to expectant management. The three trials which reported on suspected neonatal infection showed an increase in babies who were managed expectantly, however the numbers were too small to be interpreted with confidence.

Overall completeness and applicability of evidence

The applicability of findings from the meta-analysis to other populations and settings is limited by several factors. Firstly, the gestational age for inclusion into the studies was often wide. As the perinatal complications associated with PPRM change with gestational age, the management of women with a pregnancy complicated by PPRM requires a stratified approach based largely on gestational age. However, the addition of four trials with inclusion criteria between 34 and 37 weeks' gestation provided some meaningful gestational age-based management for women at 34 or more weeks' gestation.

Secondly, a number of trials included co-interventions in addition to the timing of birth such as corticosteroids, tocolysis and antibiotics which may also limit the applicability of these findings. Since the publication of these earlier trials it has been clearly demonstrated that a number of these co-interventions are of benefit for the mother and baby in the setting of PPRM. There is a beneficial effect for both the mother and the baby in the use of prophylactic erythromycin in the setting of PPRM (Kenyon 2001; Kenyon 2003) similar to the demonstrated beneficial effects of antenatal corticosteroids for women with PPRM, particularly for the neonate at gestations less than 34 weeks (Harding 2001). Only one of these trials (Naef 1998) used prophylactic antibiotics for all women. However, Morris 2016 provided data for those women who did receive prophylactic antibiotics that contributed a substantial number towards the analysis. None of the trials used corticosteroids for both the early birth and expectant management groups. Using corticosteroids for both the early birth and expectant management groups in women at gestations less than 34 weeks would have provided clinically meaningful information and would have removed the confounder of steroids in assessing the effect of early birth on maternal and neonatal outcomes.

Quality of the evidence

Overall, all 12 studies were assessed as being at low or unclear risk of bias. Some of the studies lacked an adequate description of methods and the risk of bias could only be assessed as unclear. In five of the studies there were one or two domains where the we judged the risk of bias as high. However, this was unlikely to change the magnitude of effect. We used GRADE profiling to assess neonatal outcomes of infection/sepsis, RDS, need for ventilation, and admission to NICU: and maternal outcomes of caesarean

section, chorioamnionitis, and length of hospital stay. The results show the quality of evidence across all critical outcomes to be moderate to high. Downgrading was mainly due to imprecision where few events resulted in wide confidence intervals, and inconsistency as evidenced by heterogeneity.

Potential biases in the review process

The inclusion criteria for this review were intentionally broad, with the aim of being able to better examine all of the possible evidence available. These trials differed with respect to inclusion criteria, co-interventions and the timing of the early birth intervention. The results provided by the subgroup analysis should be interpreted with caution due to the large differences in numbers of women between the subgroups.

We acknowledge that there was the potential for bias at all stages in the reviewing process. We attempted to minimise bias in a number of ways; for example, two review authors independently carried out data extraction and assessed risk of bias. David P van der Ham was Chief Investigator and first author of the PPROMEXIL trials and so JM and DB were responsible for data extraction and assessment of all trial reports relating to this study. Jonathan Morris was the Chief Investigator and first author for the NHMRC- (National Health and Medical Research Council) funded PPROMT trial and so data was assessed and extracted independently by PM. However, we acknowledge that such assessments involve subjective judgments, and another review team may not have agreed with all of our decisions.

Agreements and disagreements with other studies or reviews

We are not aware of any other reviews addressing this question. Most of the studies included in this review concur with expectant management as not having an increased risk to neonatal outcomes. The exceptions are [Mercer 1993](#) and [Naef 1998](#) which concluded that early birth resulted in decreased infection for both mothers and infants. However, these trials were underpowered to adequately assess this outcome.

AUTHORS' CONCLUSIONS

Implications for practice

Current evidence does not demonstrate a difference in neonatal sepsis between women who give birth immediately or are managed expectantly in preterm prelabour rupture of the membranes (PPROM) prior to 37 weeks' gestation. Early planned birth is associated with an increase in the incidence of neonatal respiratory distress syndrome, neonatal mortality, endometritis, induction of labour, and the likelihood of birth by caesarean section, and a decreased incidence of chorioamnionitis. In pregnancies complicated by preterm premature rupture of the membranes a policy of expectant management with careful observation is associated with better outcomes for the mother and baby.

Implications for research

Future randomised trials should be adequately powered to evaluate the effect of the different management strategies on long-term childhood health, behaviour and cognitive outcomes. Also, future research should be aimed at identifying women with PPROM who would not benefit from expectant management by comparing gestational age at presentation, corticosteroid use and abnormal vaginal microbiological colonisation in both groups. An independent participant data analysis could be considered to address these differences.

ACKNOWLEDGEMENTS

As part of the pre-publication editorial process, this review was commented on by three peers (an editor and two referees who are external to the editorial team), a member of the Pregnancy and Childbirth Group's international panel of consumers and the Group's statistical adviser.

This project was supported by the National Institute for Health Research, via Cochrane Programme Grant funding to Cochrane Pregnancy and Childbirth. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Cox 1995

Methods	<p>RCT</p> <p>Duration of study: May 1991-30 April 1994</p>
Participants	<p>Setting: Parkland Hospital, Dallas, Texas, USA</p> <p>Participants: 129 women with confirmed premature rupture of the membranes between 30-34 weeks' gestation; 1 twin pair in each of early delivery and expectant management group resulting in a total of 131 babies:</p> <ul style="list-style-type: none"> • 61 women were randomised to early delivery • 68 women were randomised to expectant management <p>Inclusion criteria</p> <ul style="list-style-type: none"> • Preterm ruptured membranes at 30-34 weeks' gestation • Temperature less than 37.8°C • No labour • No maternal or fetal complications necessitating delivery <p>Exclusion criteria</p> <ul style="list-style-type: none"> • Active labour • Chorioamnionitis defined as a temperature greater than 37.9°C with either uterine tenderness or maternal tachycardia • Maternal hypertension
Interventions	<p>Intervention: oxytocin labour stimulation if the fetus was cephalic; caesarean section was performed for all other presentations</p> <p>Control: expectant management</p> <ul style="list-style-type: none"> • Maternal observations and fetal heart rate recorded every 8 h • Electronic fetal heart rate and uterine activity monitoring was performed for 1 h each d until delivery • Hospitalisation until delivery • Criteria for delivery included: <ul style="list-style-type: none"> * spontaneous labour; * fever; * abnormal fetal heart rate <p>Corticosteroids, tocolysis and antibiotics were not used</p> <p>Vaginal examinations were not performed in the absence of labour</p>
Outcomes	<p>Maternal</p> <ul style="list-style-type: none"> • Admission to delivery interval • Labour induction • Caesarean delivery • Chorioamnionitis <p>Fetal</p> <ul style="list-style-type: none"> • Gestational age at delivery

Cox 1995 (Continued)

- Respiratory distress:
 - * none
 - * halo
 - * ventilator
- Intracranial haemorrhage
- Necrotising enterocolitis
- Sepsis: did not specify whether positive culture required
- Duration of time spent in special care nursery
- Stillbirths
- Neonatal deaths

Notes	<ul style="list-style-type: none"> • Gestational age: determined by menstrual history, timing of first auscultation of fetal heart sounds, fundal height or ultrasound examination. • Ruptured membranes was diagnosed when amniotic fluid was visualised by sterile speculum examination draining from the cervical os.
-------	--

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table with group allocation pre-determined
Allocation concealment (selection bias)	Unclear risk	Sequentially numbered sealed envelopes. Not stated if envelopes were opaque or not
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses to follow-up reported No post-randomisation exclusions
Selective reporting (reporting bias)	Unclear risk	Outcomes only reported in results. Not pre-specified
Other bias	Low risk	None noted

Eroiz-Hernandez 1997

Methods	RCT Duration of study: November 1992-October 1993
Participants	Setting: Perinatology Department, Centro Medico Nacional, IMSS, Torreon, Coah, Mexico Participants: 58 women with PROM between 28-34 weeks of gestation <ul style="list-style-type: none"> • 30 women were randomised to early delivery • 28 women were randomised to expectant management

Planned early birth versus expectant management for women with preterm prelabour rupture of membranes prior to 37 weeks' gestation for improving pregnancy outcome (Review)

Eroiz-Hernandez 1997 (Continued)

Inclusion criteria

- Preterm ruptured membranes between 28-34 weeks' gestation
- Amniotic liquid index > 5 cm
- A negative culture of amniotic liquid obtained by amniocentesis

Exclusion criteria

- Women undergoing labour
- Positive fetal lung maturity tests (tap*, clements* and 650 nm spectrophotometry)

Interventions

Control: managed with short-term delivery with the application of a fetal lung maturity protocol of 6 doses of 250 mg of intravenous aminophylline every 8 h. Delivered according to obstetric characteristics of each woman

Treatment: managed with the same lung maturity protocol as the controls, but repeating weekly if possible

- All participants had leukocyte counts every 3 d and daily biophysical profile
- Antibiotics not given prophylactically
- Tocolytics used for management of uterine contractions
- Participant delivered if signs of chorioamnionitis

Outcomes

Maternal

- Chorioamnionitis, defined by 15,000 leukocytes in maternal blood at the start of the study or a 50% increase from baseline reading, body temperature > 37.5°C, abdominal pain or a fetal heart rate of > 160 beats/minute without apparent cause
- Caesarean section
- Days between randomisation and delivery
- Causes of caesarean section
- Causes of delivery

Fetal

- Hyaline membrane disease: diagnosed by prematurity, neonatal asphyxia, progressive onset of respiratory insufficiency, thorax X-rays with the presence of peripheral aerial bronchogram with reticulogranular infiltrates and gasometric respiratory acidosis followed by mixed acidosis
- Neonatal septicaemia diagnosed if the following were present: general poor condition, paleness, jaundice, petechia, equimosis, hypoactivity or irritability, seizure, hepatosplenomegaly, abnormal bleeding, vomit, diarrhoea, gastric residual and hypothermia or fever, leukocytosis (> 25,000), leucopenia (< 5000), total bands (> 500), neutropenia (< 1500), Shilling index of > 0.2 and thrombocytopenia (< 100,000), 1 of 3 lumbar puncture blood culture positive with: > 20 cells, hypoglycorrhaghia (< 40 mg/dL), hyperproteinrhachia (> 280 mg/dL). Sepsis also diagnosed if sepsis protocol started with clinical suspicion without positive culture and clinical improvement after antibiotics
- Birthweight
- Apgar scores at 1 min and 5 min
- Silverman score at 1 min and 5 min
- Perinatal death
- Musculoskeletal abnormalities
- Amniotic band syndrome

Notes

Gestational age calculated by date of last menstrual period or ultrasound PROM diagnosis performed by Tamiere* procedure (maneuver), cristallography, or the flame test

*The authors are unsure of what this procedure is, although this may be an error in translation.

Risk of bias

Eroiz-Hernandez 1997 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	High risk	Results inconsistent with number randomised. Incomplete data not recorded
Selective reporting (reporting bias)	High risk	Outcomes only reported in results. Not pre-specified. Although inclusion criteria was singleton pregnancy only, results for caesarean section indicate 2 sets of twins in each group. This was not reported.
Other bias	Low risk	None noted

Garite 1981

Methods	RCT Duration of study: May 1977-July 1980
Participants	<p>Setting: Obstetric services at the University of California Irvine Medical Center and Women's Hospital Memorial Medical Center of Long Beach, Orange County, California, USA</p> <p>Participants: 160 women; 80 women in early delivery group and 80 women in expectant management group</p> <p>Inclusion criteria</p> <ul style="list-style-type: none"> • Women with preterm premature rupture of the membranes • 28-34 weeks' gestation <p>Exclusion criteria</p> <ul style="list-style-type: none"> • Fetal distress • Chorioamnionitis • Mature L/S ratio • Advanced labour <p>Prior to randomisation all women</p> <ul style="list-style-type: none"> • Monitored with an external fetal heart rate monitor for a minimum of 30 min • Ultrasound examination performed where BPD determined. • Amniocentesis performed for L/S ratio, gram stain and culture • Management was delayed until results were known - "usually 3 to 4 hours"

Garite 1981 (Continued)

- If the L/S ratio was 1.8:1 or greater or if the gram stain demonstrated bacteria the fetus was not included in the study

Interventions

Intervention: 80 women were randomised to corticosteroids and delivery 48 h after treatment with steroids

- This included betamethasone 12 mg intramuscularly 2 doses 24 h apart
- Tocolysis used when contractions occurred
- Delivery was after 48 h by discontinuing the tocolytic and either induction of labour with oxytocin or caesarean section for obstetric indications

Control: 80 women were randomised to expectant management

- Delivered when labour, chorioamnionitis or fetal distress evident

Criteria for delivery for women in the expectant management group included:

- labour
- chorioamnionitis
- fetal distress

Corticosteroids and tocolysis used in early delivery group. Prophylactic antibiotics not used.

Vaginal examinations were not performed in the absence of labour.

Outcomes

Maternal

- Admission to delivery time
- Caesarean section
- Chorioamnionitis: fever $\geq 100.4^{\circ}\text{F}$ in the absence of other explanations
- Endometritis
- Wound infection
- Urinary tract infection
- Duration of postpartum hospital stay

Fetal

- Birthweight
- Gestational age
- Respiratory distress
 - * made when clinical signs and chest X-ray film were confirmatory
 - * infant required > 24 h/oxygen therapy
 - * severe RDS: requiring a ventilator
- Sepsis: not stated as to whether a positive culture required for diagnosis
- Meningitis
- Ophthalmitis
- Pneumonia
- Necrotising enterocolitis
- Fetal death
- Neonatal death

Notes

- Gestational age determined by menstrual history and examination, or by a BPD on presentation
- Rupture of the membranes was documented by sterile speculum examination visualising amniotic fluid pooling in the posterior vaginal vault, alkaline pH by Nitrazine paper and ferning on microscopic examination of fluid from the posterior vaginal fornix.

Risk of bias

Garite 1981 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation schema not defined
Allocation concealment (selection bias)	Unclear risk	Not defined
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Radiologists (for reviewing X-rays prior to diagnosis of hyaline membrane disease) were blinded as to treatment allocation. However it was not mentioned if all other analysts were blinded to treatment.
Incomplete outcome data (attrition bias) All outcomes	High risk	No losses to follow-up reported. However, 1 fetal death in expectant management group removed from denominator of neonatal outcomes
Selective reporting (reporting bias)	Unclear risk	Outcomes only reported in results. Not pre-specified
Other bias	Low risk	None noted

Iams 1985

Methods	RCT Duration of study: September 1979-November 1982
Participants	Setting: Ohio State University Hospitals, Ohio, USA Participants: 73 women; 38 early delivery, 35 expectant management Inclusion criteria <ul style="list-style-type: none"> • Preterm premature rupture of the membranes • 28-34 weeks' gestation Exclusion criteria <ul style="list-style-type: none"> • Women with mature L/S ratios (greater than 2:1 or more) were delivered • Active labour • Infection • Twin pregnancy
Interventions	Intervention: corticosteroids, tocolysis and delivery 48-72 hours after initiation of steroid treatment <ul style="list-style-type: none"> • Hydrocortisone 500 mg intravenously every 8 h for 4 doses • Tocolysis included either magnesium sulphate, terbutaline or ritodrine • Caesarean section for obstetric indications Control: expectant management. <ul style="list-style-type: none"> • Admission to hospital initially

lams 1985 (Continued)

- Serial observations including vital signs, abdominal examination, WBC counts
- Delivery after labour, chorioamnionitis or fetal distress occurred
- Outpatient management at discretion of managing clinician

Criteria for delivery of women in the expectant management group included

- labour
- chorioamnionitis
- fetal distress

Corticosteroids and tocolysis given to early delivery group. Prophylactic antibiotics not given.

Vaginal examinations were not performed in the absence of labour.

Outcomes	<p>Maternal</p> <ul style="list-style-type: none"> • Ruptured membranes to delivery time • Caesarean section • Chorioamnionitis • Endometritis: temp > 100.6°F on 2 readings 6 or more h apart > 24 h postpartum • Duration of hospitalisation <p>Fetal</p> <ul style="list-style-type: none"> • Birthweight • Duration of admission to delivery • Apgar score • Duration of total hospitalisation • Respiratory distress: required > 24 h oxygen therapy with compatible clinical and chest X-ray findings <ul style="list-style-type: none"> * duration of time on ventilator * duration of time requiring oxygen therapy • Sepsis: required a positive culture for diagnosis • Leukopenia • Jaundice • Perinatal mortality
Notes	<ul style="list-style-type: none"> • Gestational age defined by obstetric history and sonography • Ruptured membranes defined by visualisation of amniotic fluid pooled in the posterior vaginal fornix on sterile speculum examination or positive Nitrazine and ferning tests. • An L/S ratio is a ratio used to determine fetal pulmonary maturity and therefore, the risk of neonatal RDS if the fetus is delivered prematurely. It is found by testing the amniotic fluid and when the fetal lungs are mature, lecithin exceeds sphingomyelin by 2 to 1.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table
Allocation concealment (selection bias)	Unclear risk	Not defined
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.

Iams 1985 (Continued)

Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not defined
Incomplete outcome data (attrition bias) All outcomes	High risk	Losses to follow-up: 3 women in expectant management group delivered at another hospital and were excluded from analysis. Post-randomisation exclusions: 1 neonate with congenital anomalies was excluded post delivery, 1 mother and her baby were excluded for failure to complete steroid therapy.
Selective reporting (reporting bias)	Unclear risk	Outcomes only reported in results. Not pre-specified
Other bias	Low risk	None noted

Koroveshi 2013

Methods	Prospective RCT Duration of study: March 2008-October 2011
Participants	Setting: Albania Participants: 307 pregnant women, 157 in planned early birth group and 150 to expectant management group Inclusion criteria <ul style="list-style-type: none"> • Women with preterm premature rupture of the membranes • 34-37 weeks' gestation Exclusion criteria <ul style="list-style-type: none"> • Not defined
Interventions	Planned early birth versus expectant management - not defined
Outcomes	Maternal <ul style="list-style-type: none"> • Caesarean section Fetal <ul style="list-style-type: none"> • Neonatal sepsis • RDS
Notes	Abstract only. Limited data available

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method not specified

Koroveshi 2013 (Continued)

Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding not possible due to intervention. However the risk was unclear as assessment criteria for outcomes was not mentioned
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Not specified
Selective reporting (reporting bias)	High risk	Only 3 outcomes as well as secondary unspecified outcomes reported in abstract. Full paper not published
Other bias	Unclear risk	As this is an abstract publication only, cannot determine the overall risk of bias

Mercer 1993

Methods	RCT Duration of study: 1 March 1991-31 July 1992
Participants	Setting: University of Tennessee, Memphis, USA Participants: 93 women <ul style="list-style-type: none"> • 46 women were randomised to induction of labour • 47 women were randomised to expectant management Inclusion criteria <ul style="list-style-type: none"> • Confirmed premature rupture of the membranes at 32 weeks-36 weeks 6 days • Amniotic fluid testing suggestive of fetal pulmonary maturity Exclusion criteria <ul style="list-style-type: none"> • Cervical dilatation greater than 2 cm • Persistent regular contractions or progressive labour • Blood or meconium-stained amniotic fluid • Suspected chorioamnionitis • Any maternal or fetal contraindication to expectant management • Women with fetuses with intrauterine growth restriction • Women with fetuses with congenital malformations • A non-reassuring fetal heart rate tracing (defined as recurrent decelerations, heart rate greater than 160 beats per minute, or the absence of heart rate accelerations)
Interventions	Intervention: intravenous oxytocin infusion Control: expectant management <ul style="list-style-type: none"> • This included 12 h of continuous fetal heart rate monitoring • Observations performed every 8 h

Mercer 1993 (Continued)

- Women restricted to bed rest
- Criteria for delivery included
 - * progressive labour
 - * chorioamnionitis (defined as a temperature > 100.4°F plus any 2 of the following: fetal or maternal tachycardia, uterine contractions or tenderness, foul smelling amniotic fluid in the absence of other identifiable cause)
 - * non-reassuring fetal heart rate pattern including persistent fetal tachycardia or recurrent deceleration and positive cultures for *Neisseria gonorrhoeae* or GBS

Corticosteroids, tocolysis and prophylactic antibiotics not used

Vaginal examinations not performed in the absence of labour

Outcomes	Maternal
	<ul style="list-style-type: none"> • Latency from randomisation to labour • Latency from randomisation to delivery • Duration of maternal hospital stay • Chorioamnionitis: T > 100.4°F plus 2 of the following: <ul style="list-style-type: none"> * fetal or maternal tachycardia * uterine contractions or tenderness * foul-smelling amniotic fluid in the absence of other identifiable cause • Caesarean delivery • Postpartum infection requiring antibiotics
	<p>Fetal</p> <ul style="list-style-type: none"> • Neonatal sepsis: required a positive culture for diagnosis <ul style="list-style-type: none"> * subgrouped into suspected and confirmed sepsis: <ul style="list-style-type: none"> <input type="checkbox"/> suspected neonatal sepsis: clinical findings suggestive of neonatal infection or persistent leucopenia with a WBC count < 4000/mm³ or a C-reactive protein level elevated greater than 0.6; <input type="checkbox"/> confirmed neonatal sepsis: infants with symptoms of sepsis and positive blood cultures • Abnormal fetal heart rate pattern • Birthweight • Apgar scores • Respiratory distress: <ul style="list-style-type: none"> * required oxygen therapy (at least 40%) at least 24 h in absence of other identifiable cause • Pneumonia • Necrotising enterocolitis • Intraventricular haemorrhage • Duration of neonatal hospital stay • Mortality
Notes	<ul style="list-style-type: none"> • Gestational age: determined clinically on the basis of menstrual history, earliest ultrasound examination and first clinical assessment • Ruptured membranes diagnosed by: visualisation of amniotic fluid passing from the cervical os on sterile speculum examination or the presence of a pool of fluid in the posterior vaginal fornix that was positive to both Nitrazine paper and ferning tests • Fetal pulmonary maturity was determined on pooled vaginal fluid (foam stability index ≥ 47 considered mature), an amniocentesis was performed in the absence of adequate vaginal fluid.

Risk of bias

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

Mercer 1993 (Continued)

Random sequence generation (selection bias)	Low risk	Computer-generated random number tables
Allocation concealment (selection bias)	Unclear risk	Not clearly defined. Stated that "blinded" random number tables were used, but no further explanation was given as to what this entailed.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Neonatologists were not blinded to the perinatal clinical course. It was not specified whether the assessors of maternal outcomes were blinded to their clinical course.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses to follow-up or post-randomisation exclusions
Selective reporting (reporting bias)	Unclear risk	Outcomes only reported in results. Not pre-specified
Other bias	Low risk	None noted

Morris 2016

Methods	Multi-centre, international RCT Duration of study: May 2004-June 2013
Participants	Setting: 65 tertiary hospitals in 11 countries (Australia, Argentina, Brazil, Egypt, New Zealand, Norway, Poland, Romania, South Africa, UK, Uruguay) Participants: 1835 women <ul style="list-style-type: none"> • 923 women were randomised to induction of labour • 912 women were randomised to expectant management Inclusion criteria <ul style="list-style-type: none"> • Over 16 years of age • Singleton pregnancy • Clinically suspected ruptured membranes between 34 weeks-36 + 6 weeks' gestation Exclusion criteria <ul style="list-style-type: none"> • Established labour • Chorioamnionitis • Meconium staining • Any other contraindications to continuing the pregnancy
Interventions	Intervention <ul style="list-style-type: none"> • Delivery scheduled as close to randomisation as possible and preferably within 24 h • Mode of birth was determined by usual obstetric indications Control: expectant management

Morris 2016 (Continued)

- Inpatient or outpatient management according to local guidelines

Criteria for delivery included

- Spontaneous labour
- At term
- When the attending clinician felt that birth was mandated according to usual indications

Antibiotics were prescribed according to local protocols.

Laboratory testing and other management was per usual hospital practice.

Placental histology was encouraged but not uniformly requested.

Outcomes	Maternal
	<ul style="list-style-type: none"> • Antepartum or intrapartum haemorrhage • Antepartum or postpartum thrombosis • Cord prolapse • Postpartum treatment with antibiotics • Intrapartum fever (pyrexia $\geq 38.5^{\circ}\text{C}$) • Postpartum haemorrhage (> 1000 mL) • Mode of delivery • Onset of labour • Duration of hospitalisation (total days from randomisation to delivery, and from delivery to discharge or transfer) • Chorioamnionitis among the women with expectant management
	<p>Fetal</p> <ul style="list-style-type: none"> • Definite or probable neonatal sepsis <ul style="list-style-type: none"> * Definite: <ul style="list-style-type: none"> <input type="checkbox"/> positive culture of a known pathogen from blood or CSF <input type="checkbox"/> baby treated with antibiotics for 5 or more days (or died before 5 days) <input type="checkbox"/> presence of clinical signs of infection: respiratory distress (requiring ventilation, continuous positive airway pressure or supplemental oxygen for more than 1 h), apnoea, lethargy, abnormal level of consciousness, circulatory compromise (including hypotension, poor perfusion, need for inotropic support or volume expansion) and/or temperature instability (temperature $< 36^{\circ}\text{C}$ or $\geq 38^{\circ}\text{C}$); <input type="checkbox"/> for organisms of low virulence and/or high likelihood of skin contamination of the blood culture, both a positive blood culture and an abnormal full blood count (WCC $< 5 \times 10^9/\text{L}$ or $> 30 \times 10^9/\text{L}$, platelet count $< 100,000$, neutrophil count $< 1.5 \times 10^9/\text{L}$ or raised immature to total neutrophil ratio (I:T ratio > 0.2)) or abnormal C-reactive protein > 10 mg/L were required * Probable: <ul style="list-style-type: none"> <input type="checkbox"/> presence of clinical signs where the baby was treated with antibiotics for 5 or more days together with 1 or more of: an abnormal FBC; abnormal C-reactive protein; positive GBS antigen on bladder tap urine, blood or CSF; elevated CSF WCC⁵ (CSF WCC $> 100 \times 10^6/\text{L}$); growth of a known virulent pathogen (e.g. GBS, <i>E. coli</i>, <i>Listeria</i>) from surface swab; or a histologic diagnosis of pneumonia in an early neonatal death • Composite neonatal morbidity and mortality indicator (sepsis, mechanical ventilation > 24 h, stillbirth or neonatal death) • Respiratory distress • Perinatal mortality • Pneumonia • Mechanical ventilation (intermittent positive pressure ventilation, continuous positive airway pressure or high frequency ventilation) for greater than 24 h • Duration of stay in a neonatal intensive or special care unit • Duration of stay in hospital

Morris 2016 (Continued)

- Birthweight
- Apgar score ≤ 7 at 5 min
- Antibiotics in the first 48 h
- Lumbar puncture
- Circulatory compromise requiring arterial line
- Fluid bolus or inotropic support
- Receiving breast milk at discharge (exclusive or mixed feeding)

Notes

- Women who presented with ruptured membranes earlier in pregnancy became eligible on reaching 34 weeks' gestation.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	A computer-generated randomisation schedule was used in a 1:1 ratio in balanced blocks of variable size, stratified by centre.
Allocation concealment (selection bias)	Low risk	A central telephone service was used for randomisation allocation.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	The primary outcome was determined by comprehensive review of the neonatal data by a central adjudication committee masked to the treatment allocation.
Incomplete outcome data (attrition bias) All outcomes	Low risk	All analyses were by intention-to-treat. No participants were excluded from the primary intention-to-treat analysis due to protocol violations.
Selective reporting (reporting bias)	Low risk	All a-priori outcomes were reported on.
Other bias	Low risk	None noted

Naef 1998

Methods	RCT Duration of study: 1992-1994
Participants	Setting: University of Mississippi Medical Center, Jackson, Mississippi, USA Participants: 120 singleton pregnancies <ul style="list-style-type: none"> • 57 women were randomised to early delivery • 63 women were randomised to expectant management Inclusion criteria <ul style="list-style-type: none"> • Cephalic presentation • Singleton pregnancy

Naef 1998 (Continued)

- 34 weeks' gestation to 36 weeks 6 days gestation
- Preterm premature rupture of the membranes

Exclusion criteria

- Non-cephalic presentation
- Fetal distress
- Labour on admission
- Chorioamnionitis
- Maternal medical conditions including hypertension, diabetes, active genital herpes, placenta praevia
- Severe fetal anomalies
- Meconium-stained amniotic fluid

Interventions

Intervention: induction of labour with intravenous oxytocin

Control: expectant management

- Observations and a fetal heart rate assessment every 8 h
- Bed rest and hospitalised until delivery
- Treatment with ampicillin 2 g intravenously was carried out for all participants for GBS prophylaxis
- Criteria for delivery included:
 - * non-reassuring fetal status (recurrent decelerations or persistent tachycardia)
 - * initiation of labour
 - * signs of clinical chorioamnionitis (defined in the absence of other causes of pyrexia as a temperature > 100.4 °F with either uterine tenderness, leucocytosis, maternal or fetal tachycardia or a foul smelling vaginal discharge)

Corticosteroids and tocolysis not used. Routine antibiotic prophylaxis for all women

Vaginal examinations not performed in the absence of labour

Outcomes

Maternal

- Admission to delivery interval
- Chorioamnionitis: temperature > 100.4 °F with either uterine tenderness (or contractions), leukocytosis, maternal or fetal tachycardia, or a foul-smelling vaginal discharge
- Postpartum endometritis: temperature > 100.4 °F after the first 24 postpartum hours with associated uterine tenderness
- Duration of hospital stay
- Mode of delivery

Fetal

- Birthweight
- Apgar scores
- Cord pH
- Neonatal nursery admission
- Respiratory distress
- Mechanical ventilation
- Sepsis: positive culture required for diagnosis
- Intraventricular haemorrhage
- Patent ductus arteriosus
- Bronchopulmonary dysplasia
- Duration of hospital stay
- Stillbirth
- Neonatal death

Naef 1998 (Continued)

- Notes
- Gestational age was confirmed by a reliable last menstrual period, early ultrasound or first trimester pelvic examination
 - * In the absence of certain dates an ultrasound estimate of fetal weight ≥ 1800 g and ≤ 2500 g was used as an entry criteria.
 - Ruptured membranes was confirmed by visualisation of pooling of fluid in the posterior vaginal fornix on sterile speculum examination or ferning under microscopic review in addition to a positive Nitrazine test.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random number cards
Allocation concealment (selection bias)	Unclear risk	Opaque sealed envelopes but did not state if envelopes were sequentially numbered
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Neonatologists were not blinded to the perinatal clinical course. It was not specified whether the assessors of maternal outcomes were blinded to their clinical course.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses to follow-up No post-randomisation exclusions
Selective reporting (reporting bias)	Low risk	All a-priori outcomes were reported on
Other bias	Low risk	None noted

Nelson 1985

Methods	RCT Duration of study: not specified
Participants	Setting: Wake Forest University Medical Center, North Carolina, USA Participants: 68 women <ul style="list-style-type: none"> 22 women randomised to steroid and early delivery group 22 women randomised to no-steroid and early delivery group 24 women randomised to no-steroid and expectant group Inclusion criteria <ul style="list-style-type: none"> Women with preterm premature rupture of the membranes 28-34 weeks' gestation Exclusion criteria <ul style="list-style-type: none"> Evidence of fetal distress

Nelson 1985 (Continued)

- Active labour
- Cervix > 3 cm dilated
- Sensitivity to tocolysis
- History of preterm premature rupture of the membranes > 24 h
- Existing infection

Interventions

Intervention: included 2 groups

Group 1. Steroid group who received intramuscular betamethasone 6 mg or 12 mg on admission and another dose 12 h later

- Ritodrine or terbutaline tocolysis used for a minimum of 24 h after the first steroid dose
- Delivery between 24-48 h after initial PROM and after 24 h of steroid therapy
- Caesarean section performed for obstetric indications

Group 2. No-steroid group who received similar treatment to group 1 except no steroids were given

Control: expectant management

- 24 women randomised to expectant group
- Received no tocolytics or steroids
- Caesarean section for usual obstetric indications

Criteria for delivery in the expectant group not specified

Corticosteroids and tocolysis used for early delivery group. Prophylactic antibiotics not used.

Not specified as to whether digital vaginal examinations were performed

Outcomes

Maternal

- Duration of latency period
- Maximum temperature
- Maternal sepsis: T > 37.7°C on 2 occasions at least 6 h apart, uterine tenderness and a rising WBC
- Use of tocolysis
- Mode of delivery

Fetal

- Birthweight
- Duration of hospitalisation
- Respiratory distress:
 - * none
 - * mild
 - * moderate
 - * severe
- Neonatal sepsis: positive culture required for diagnosis
- Neonatal deaths

Notes

- Gestational age confirmed by ultrasound on admission
- Ruptured membranes diagnosed by ferning under microscopy, Nitrazine test and/or visualisation of pooling of amniotic fluid in the posterior fornix or the vagina at the time of sterile speculum examination

Risk of bias

Authors' judgement **Support for judgement**

Nelson 1985 (Continued)

Random sequence generation (selection bias)	Low risk	Randomised cards were used. Participants were randomly assigned by drawing a sealed envelope from a group of randomised cards, it did not state how the randomisation sequence was generated.
Allocation concealment (selection bias)	Unclear risk	Sealed envelopes but did not state if opaque or sequentially numbered
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses to follow-up No post-randomisation exclusions
Selective reporting (reporting bias)	Low risk	All a-priori outcomes were reported on
Other bias	Low risk	None noted

Spinnato 1987

Methods	RCT Duration of study: 1 June 1983-15 November 1984
Participants	Setting: E.H. Crump Women's Hospital and Perinatal Center, Memphis, Tennessee, USA Participants: 47 women <ul style="list-style-type: none"> • 26 women randomised to early delivery • 21 women randomised to expectant management Inclusion criteria <ul style="list-style-type: none"> • 25-36 weeks' gestation • Preterm premature rupture of the membranes • Fetal pulmonary maturity demonstrated on amniotic fluid (an L/S ratio of 2 or more or a Foam stability index of 47 or more) Exclusion criteria <ul style="list-style-type: none"> • Spontaneous labour at presentation • Chorioamnionitis
Interventions	Intervention: early delivery either by induction of labour with oxytocin or caesarean section for all non-vertex presentations Control: expectant management <ul style="list-style-type: none"> • External electronic fetal monitoring performed for 8-12 h • Bed rest for as long as amniotic fluid leakage continued • Hospital discharge permitted at the discretion of the attending physician

Spinnato 1987 (Continued)

- Monitored with serial temperature, pulse, fetal heart rate, WBC and differential counts

Criteria for delivery in the expectant group of women

- Labour
- Fetal distress
- Chorioamnionitis

Corticosteroids, tocolysis and prophylactic antibiotics not used

Vaginal examinations not performed in the absence of labour

Outcomes	<p>Maternal</p> <ul style="list-style-type: none"> • Time from rupture of membranes to labour • Time from rupture of membranes to delivery • Duration of labour • Delivery by caesarean section • Chorioamnionitis: maternal fever (38°C on 2 occasions or a single reading on 38.3°C) with foul-smelling vaginal discharge and uterine tenderness, or when no other source for maternal fever could be identified • Endometritis: fever (excluding during 1st 24 h postpartum) plus uterine tenderness or foul-smelling lochia <p>Fetal</p> <ul style="list-style-type: none"> • Birthweight • Apgar score < 7 at 5 min • Neonatal duration of hospitalisation • Hyaline membrane disease • Transient pulmonary insufficiency (includes respiratory insufficiency of prematurity, RDS, and transient tachypnoea of the newborn) • Need for mechanical ventilation > 24 h • Need for oxygen therapy > 3 d • Infection • Sepsis: not specified if positive culture required for diagnosis • Pneumonia • Meningitis • Necrotising enterocolitis • Intracranial haemorrhage • Seizures • Perinatal death
Notes	<ul style="list-style-type: none"> • Gestational age determined by "best clinical estimate" including ultrasound examination on admission • Ruptured membranes diagnosed by speculum examination demonstrating pooled amniotic fluid in the vaginal vault or alkaline pH by Nitrazine paper and microscopic ferning of air dried vaginal vault fluid • Fetal pulmonary maturity required

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Sequential sealed envelope odd-even random numbers

Spinnato 1987 (Continued)

Allocation concealment (selection bias)	Unclear risk	Sealed envelopes, did not specify if opaque or sequentially numbered
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	<ul style="list-style-type: none"> • Obstetricians not blinded to maternal allocation group • Neonatologists blinded to perinatal clinical course However, did not mention if outcome assessors were blinded
Incomplete outcome data (attrition bias) All outcomes	High risk	Losses to follow-up: no losses to follow-up Post-randomisation exclusions: 7 women for preterm labour, 4 women for "protocol violations", and 4 other women with unspecified reason
Selective reporting (reporting bias)	Unclear risk	Outcomes only reported in results. Not pre-specified
Other bias	Low risk	None noted

Van der Ham 2012a

Methods	Multi-centre, parallel, open-label RCT Duration of study: January 2007-September 2009
Participants	Setting: 8 academic and 52 non-academic hospitals in the Netherlands Participants: 532 women <ul style="list-style-type: none"> • 266 women randomised to early birth (included 268 babies) • 266 women randomised to expectant management (included 270 babies) Inclusion criteria <ul style="list-style-type: none"> • Singleton or twin pregnancy with PPROM between 34 and 36 + 6 weeks' gestation who were not in labour within 24 h of PPROM • PPROM had to be diagnosed after 26 + 0 weeks Exclusion criteria <ul style="list-style-type: none"> • Monochorionic multiple pregnancy • Abnormal (non-reassuring) cardiotocogram • Meconium-stained amniotic fluid • Signs of intrauterine infection • Major fetal anomalies • Haemolysis, elevated liver enzymes, and low platelets (HELLP syndrome) • Severe pre-eclampsia
Interventions	Intervention: induction of labour within 24 h after randomisation. Induction performed according to national guidelines. After vaginal examination, labour induced with either prostaglandin or oxytocin, or caesarean section performed as soon as feasible in case of planned caesarean Control: expectant management

Van der Ham 2012a (Continued)

- Monitored according to local protocol until spontaneous birth, which could be outpatient or inpatient
- Daily maternal temperature, monitoring and twice-weekly blood sampling for maternal leukocyte count and C-reactive protein measurement

Criteria for delivery in the expectant group of women

- Induced at 37 weeks according to national guidelines
- If planned caesarean section, caesarean section performed as soon as labour commenced
- Induction of labour < 37 weeks if clinical signs of infection or other fetal or maternal indication for birth

Tocolysis and prophylactic antibiotics used according to local protocols

Corticosteroids given in PPROM < 34 weeks' gestation

Vaginal examinations not performed in the absence of labour

Outcomes
Maternal

- Antepartum haemorrhage
- Uterine rupture
- Umbilical cord prolapse
- Signs of chorioamnionitis (defined as fever before or during labour and a temperature < 37.5°C on 2 occasions more than 1 h apart before or during labour, or a temperature > 38.0°C on 1 occasion with uterine tenderness)
- Leukocytosis
- Maternal or fetal tachycardia (or a foul-smelling vaginal discharge in absence of any other cause of hyperpyrexia)
- Maternal sepsis (defined as a temperature > 38.5°C and a positive blood culture or circulatory instability requiring intensive care monitoring)
- Thromboembolic complications
- Urinary tract infection treated with antibiotics
- Endometritis (defined as a temperature > 38.0°C on 2 occasions at least 1 h apart after the 1st 24 h postpartum with associated uterine tenderness)
- Pneumonia
- Anaphylactic shock
- HELLP syndrome
- Maternal death
- Other complications
- Total length of hospital stay
- Admission to the ICU
- Mode of birth
- Need for anaesthesia

Fetal

- Neonatal sepsis:
 - * positive blood culture at birth (excluding *Staph epidermidis*)
 - * 2 or more symptoms of infection (apnoea, temperature instability, lethargy, feeding intolerance, respiratory distress, haemodynamic instability) within 72 h after birth plus 1 of the following: positive blood culture, C-reactive protein > 20 mmol/L, positive surface cultures of a known virulent pathogen
- RDS
- Wet lung
- Meconium aspiration syndrome
- Pneumothorax/pneumomediastinum
- Asphyxia
- Late onset neonatal sepsis

Van der Ham 2012a (Continued)

- Hypoglycaemia
- Necrotizing enterocolitis
- Hyperbilirubinaemia
- Intraventricular haemorrhage
- Periventricular leucomalacia
- Convulsions
- Other neurological abnormalities
- Other complications
- Intrapartum death
- Total length of hospital stay and admission
- Length of stay on NICU

Notes	<ul style="list-style-type: none"> • Rupture of membranes was diagnosed based on history and clinical findings such as gross vaginal fluid loss in combination with other available diagnostic test methods. • Gestational age was based either on first trimester ultrasound scan or, in women with a regular cycle, on the first day of the last menstrual cycle if the expected date of birth differed less than 7 days from that estimated by ultrasound. In women with unknown EDD, gestational age was estimated by 2nd trimester ultrasound measurements.
-------	--

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	A computer-generated randomisation schedule was used in a 1:1 ratio using a block size of 4, stratified for centre and parity.
Allocation concealment (selection bias)	Low risk	Randomisation allocation was performed on a central password-protected web-based application.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Criteria for sepsis were entered in the database and the case was judged by an independent panel of paediatricians who were unaware of the allocation of randomisation.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Data analysed on intention-to-treat basis. 2 participants were excluded post randomisation from the primary intention-to-treat analysis due to ineligibility.
Selective reporting (reporting bias)	Low risk	All a-priori outcomes were reported on.
Other bias	Low risk	None noted

Van der Ham 2012b

Methods	Multi-centre, parallel, open-label RCT Duration of study: December 2009-January 2011
Participants	Setting: 8 academic and 52 non-academic hospitals in the Netherlands Participants: 195 women

Van der Ham 2012b (Continued)

- 100 women randomised to early birth (included 100 babies)
- 95 women randomised to expectant management (included 98 babies)

Inclusion criteria

- Singleton or twin pregnancy with PPROM between 34 and 36 + 6 weeks' gestation who were not in labour within 24 h of PPROM
- PPROM had to be diagnosed after 26 + 0 weeks

Exclusion criteria

- Monochorionic multiple pregnancy
- Abnormal (non-reassuring) cardiotocogram
- Meconium-stained amniotic fluid
- Signs of intrauterine infection
- Major fetal anomalies
- HELLP syndrome
- Severe pre-eclampsia

Interventions

Intervention: induction of labour with 24 h after randomisation. Induction performed according to national guidelines. After vaginal examination, labour induced with either prostaglandin or oxytocin, or caesarean section performed as soon as feasible in case of planned caesarean.

Control: expectant management

- Monitored according to local protocol until spontaneous birth which could be outpatient or inpatient
- Daily maternal temperature, monitoring and twice-weekly blood sampling for maternal leukocyte count and C-reactive protein measurement

Criteria for birth in the expectant group of women

- Induced at 37 weeks according to national guidelines
- If planned caesarean section, caesarean section performed as soon as labour commenced
- Induction of labour < 37 weeks if clinical signs of infection or other fetal or maternal indication for birth

Tocolysis and prophylactic antibiotics used according to local protocols

Corticosteroids given in PPROM < 34 weeks' gestation

Vaginal examinations not performed in the absence of labour

Outcomes

Maternal

- Antepartum haemorrhage
- Uterine rupture
- Umbilical cord prolapse
- Signs of chorioamnionitis (defined as fever before or during labour and a temperature < 37.5°C on 2 occasions more than 1 h apart before or during labour, or a temperature > 38.0°C on 1 occasion with uterine tenderness)
- Leukocytosis
- Maternal or fetal tachycardia (or a foul-smelling vaginal discharge in absence of any other cause of hyperpyrexia)
- Maternal sepsis (defined as a temperature > 38.5°C and a positive blood culture or circulatory instability requiring intensive care monitoring)
- Thromboembolic complications
- Urinary tract infection treated with antibiotics
- Endometritis (defined as a temperature > 38.0°C on 2 occasions at least 1 h apart after the 1st 24 h postpartum with associated uterine tenderness)
- Pneumonia

Van der Ham 2012b (Continued)

- Anaphylactic shock
- HELLP syndrome
- Maternal death
- Other complications
- Total length of hospital stay
- Admission to the ICU
- Mode of birth
- Need for anaesthesia

Fetal

- Neonatal sepsis:
 - * positive blood culture at birth (excluding *Staph epidermidis*);
 - * 2 or more symptoms of infection (apneas, temperature instability, lethargy, feeding intolerance, respiratory distress, haemodynamic instability) within 72 h after birth plus 1 of the following: positive blood culture, C-reactive protein > 20 mmol/L, positive surface cultures of a known virulent pathogen
- RDS
- Wet lung
- Meconium aspiration syndrome
- Pneumothorax/pneumomediastinum
- Asphyxia
- Late onset neonatal sepsis
- Hypoglycaemia
- Necrotizing enterocolitis
- Hyperbilirubinaemia
- Intraventricular haemorrhage
- Periventricular leucomalacia
- Convulsions
- Other neurological abnormalities
- Other complications
- Intrapartum death
- Total length of hospital stay and admission
- Length of stay on NICU

Notes

- Rupture of membranes was diagnosed based on history and clinical findings such as gross vaginal fluid loss in combination with other available diagnostic test methods.
- Gestational age was based either on first trimester ultrasound scan or, in women with a regular cycle, on the first day of the last menstrual cycle if the expected date of birth differed less than 7 days from the estimated by ultrasound. in women with unknown EDD, gestational age was estimated by 2nd trimester ultrasound measurements.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	A computer-generated randomisation schedule was used in a 1:1 ratio using a block size of 4, stratified for centre and parity.
Allocation concealment (selection bias)	Low risk	Randomisation allocation was performed on a central password-protected web-based application.
Blinding of participants and personnel (performance bias)	Low risk	Blinding not possible due to intervention. However this was likely low risk of bias due to objective and specific assessment criteria for outcomes, where lack of blinding did not affect treatment decisions or other aspects of care.

Van der Ham 2012b (Continued)

All outcomes

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Criteria for sepsis were entered in the database and the case was judged by an independent panel of paediatricians who were unaware of the allocation of randomisation.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Data analysed on intention-to-treat basis. No participants were excluded.
Selective reporting (reporting bias)	Low risk	All a-priori outcomes were reported on.
Other bias	Low risk	None noted

2 perinatal deaths resulting from lethal congenital abnormalities were excluded from analyses post-randomisation.

BPD: biparietal diameter of the fetal head

CSF: cerebrospinal fluid

EDD: estimated due date

GBS: Group B *Streptococcus*/Streptococcal

HELLP: haemolysis, elevated liver enzymes, and low platelets

L/S: Lecithin-sphingomyelin

NICU: neonatal intensive care unit

PPROM: preterm prelabour rupture of the membranes

RCT: randomised controlled trial

RDS: respiratory distress syndrome

WBC: white blood cells

WCC: white cell count

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Bergstrom 1991	Not a RCT
Cararach 1994	Unable to establish that all women were prior to 37 weeks' gestation. Included women at term
Decavalas 1995	Assessed effect of tocolysis in women with PPRM. Tocolysis was used for 24 h in 1 group and until birth in the other group of women. Primary outcome was efficacy of tocolysis - delivered if tocolysis failed or if complications occurred relating to tocolysis therapy. No expectant management arm of study included. Also women were excluded if tocolysis failed and they delivered within 24 h of randomisation.
El-Qarmalawi 1990	Assessed treatment with either prostaglandins or oxytocin for women with PPRM. In all women induction was commenced 3 h after PPRM. The study did not assess the intervention of early birth, rather the mode of induction of labour.
Fayez 1978	Quasi-randomised trial Allocation to treatment groups by odd or even hospital record number
Gloeb 1989	Included women from 34-41 completed weeks' gestation Unable to extract subgroup of women prior to term
Griffith-Jones 1990	Unable to establish that all women were prior to term Included women greater than 35 weeks' gestation

Study	Reason for exclusion
Haghighi 2006	Assessed intravaginal misoprostol for induction of labour in women with PPRM for pregnancy termination
Lacaze 2006	This study was terminated prematurely due to slow recruitment.
Ladfors 1996	Unable to establish that all women were prior to 37 weeks. Study included women from 34-42 weeks
Makhoulf 1997	Abstract available only Randomisation schema not available in abstract. Abstract did not quantify events in either early birth or expectant management groups
Mateos 1998	Included women at term and prior to term. Included women greater than 34 weeks' gestation but subgroup analysis of women prior to term not able to be performed
Miodovnik 1988	Did not assess intervention of early birth
Parsons 1989	Abstract only Not enough information to assess methodology for inclusion or obtain meaningful results States trial was prospective but it does not appear to have been a randomised trial
Perez 1992	Did not include a group of women with expectant management. Women with PPRM were randomised to either induction with prostaglandin or induction with oxytocin within 12 h of presenting to hospital with PPRM
Van Heerden 1996	Included women prior to term and at term Unable to extract data on subgroup of women who were prior to term

PPROM: preterm prelabour rupture of the membranes

RCT: randomised controlled trial

Characteristics of ongoing studies *[ordered by study ID]*

[Pasquier 2006](#)

Trial name or title	The MICADO study
Methods	A RCT in 23 hospitals to compare intentional birth with expectant management in women with preterm premature rupture of the membranes.
Participants	Women with preterm prelabour rupture of the membranes between 28 and 31 weeks' gestation. Randomised to intervention or control 24 h after the second dose of corticosteroids
Interventions	Early birth
Outcomes	
Starting date	2006
Contact information	Jean Charles Pasquier, Department of Obstetrics and Gynecology, Hospital Herriot, Lyon, France.
Notes	

DATA AND ANALYSES

Comparison 1. Any planned birth versus expectant management: by type

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Neonatal infection/sepsis	12	3628	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.66, 1.30]
2 Neonatal infection confirmed with positive blood culture	7	2925	Risk Ratio (M-H, Fixed, 95% CI)	1.24 [0.70, 2.21]
3 Respiratory distress syndrome	12	3622	Risk Ratio (M-H, Fixed, 95% CI)	1.26 [1.05, 1.53]
4 Caesarean section	12	3620	Risk Ratio (M-H, Fixed, 95% CI)	1.26 [1.11, 1.44]
5 Perinatal mortality	11	3319	Risk Ratio (M-H, Fixed, 95% CI)	1.76 [0.89, 3.50]
6 Intrauterine death	11	3321	Risk Ratio (M-H, Fixed, 95% CI)	0.45 [0.13, 1.55]
7 Cord prolapse	4	2722	Risk Ratio (M-H, Fixed, 95% CI)	1.24 [0.33, 4.61]
8 Gestational age at birth (weeks)	8	3139	Mean Difference (IV, Fixed, 95% CI)	-0.48 [-0.57, -0.39]
9 Neonatal death	11	3316	Risk Ratio (M-H, Fixed, 95% CI)	2.55 [1.17, 5.56]
10 Suspected neonatal infection	3	829	Risk Ratio (M-H, Fixed, 95% CI)	0.56 [0.36, 0.88]
11 Neonatal treatment with antibiotics	4	2638	Risk Ratio (M-H, Random, 95% CI)	0.86 [0.63, 1.19]
12 Need for ventilation	7	2895	Risk Ratio (M-H, Fixed, 95% CI)	1.27 [1.02, 1.58]
13 Duration of oxygen therapy (days)	1	73	Mean Difference (IV, Fixed, 95% CI)	-3.05 [-6.92, 0.82]
14 Umbilical cord arterial pH	1	120	Mean Difference (IV, Fixed, 95% CI)	0.09 [0.07, 0.11]
15 Birthweight (g)	10	3263	Mean Difference (IV, Random, 95% CI)	-47.10 [-96.00, 1.80]
16 Apgar score less than 7 at 5 minutes	5	2700	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.54, 1.69]
17 Abnormality on cerebral ultrasound	3	271	Risk Ratio (M-H, Fixed, 95% CI)	1.90 [0.52, 6.92]
18 Periventricular leukomalacia	2	707	Risk Ratio (M-H, Fixed, 95% CI)	1.00 [0.14, 6.99]
19 Cerebroventricular haemorrhage	6	1095	Risk Ratio (M-H, Fixed, 95% CI)	1.19 [0.40, 3.52]
20 Necrotising enterocolitis	6	2842	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.25, 2.62]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
21 Severe respiratory distress	3	321	Risk Ratio (M-H, Fixed, 95% CI)	1.54 [0.80, 2.97]
22 Admission to neonatal intensive care unit	4	2691	Risk Ratio (M-H, Fixed, 95% CI)	1.16 [1.08, 1.24]
23 Length of stay in neonatal intensive care unit (days)	4	2121	Mean Difference (IV, Random, 95% CI)	-0.17 [-1.62, 1.27]
24 Duration (days) from birth to neonatal hospital discharge	6	2832	Mean Difference (IV, Random, 95% CI)	0.67 [-0.28, 1.61]
25 Chorioamnionitis	8	1358	Risk Ratio (M-H, Random, 95% CI)	0.50 [0.26, 0.95]
26 Endometritis	7	2980	Risk Ratio (M-H, Fixed, 95% CI)	1.61 [1.00, 2.59]
27 Postpartum fever	1	1835	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.26, 1.03]
28 Placental abruption	1	1835	Risk Ratio (M-H, Fixed, 95% CI)	1.19 [0.36, 3.87]
29 Induction of labour	4	2691	Risk Ratio (M-H, Fixed, 95% CI)	2.18 [2.01, 2.36]
30 Use of epidural/spinal anaesthesia	3	2562	Risk Ratio (M-H, Random, 95% CI)	1.28 [0.99, 1.65]
31 Vaginal birth	12	3618	Risk Ratio (M-H, Fixed, 95% CI)	0.94 [0.91, 0.97]
32 Operative vaginal birth	4	2685	Risk Ratio (M-H, Fixed, 95% CI)	0.85 [0.67, 1.10]
33 Caesarean section for fetal distress	7	2918	Risk Ratio (M-H, Fixed, 95% CI)	0.89 [0.66, 1.20]
34 Duration (days) of maternal hospitalisation	6	2848	Mean Difference (IV, Random, 95% CI)	-1.75 [-2.45, -1.05]
35 Duration (days) of antenatal hospitalisation	1	73	Mean Difference (IV, Fixed, 95% CI)	-6.30 [-9.67, -2.93]
36 Duration (days) of maternal hospitalisation (excluding trials with antenatal discharge)	2	213	Mean Difference (IV, Random, 95% CI)	-1.64 [-3.06, -0.23]
37 Time (hours) from randomisation to birth	3	2571	Mean Difference (IV, Fixed, 95% CI)	-79.48 [-88.27, -70.69]
38 Disability at 2 years, abnormal CBCL	1	199	Risk Ratio (M-H, Fixed, 95% CI)	0.64 [0.26, 1.59]
39 Disability at 2 years, abnormal ASQ	1	228	Risk Ratio (M-H, Fixed, 95% CI)	0.61 [0.35, 1.05]
40 Maternal satisfaction	1	493	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.86, 1.13]
41 Breastfeeding > 12 weeks	1	415	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.80, 1.12]

Analysis 1.1. Comparison 1 Any planned birth versus expectant management: by type, Outcome 1 Neonatal infection/sepsis.

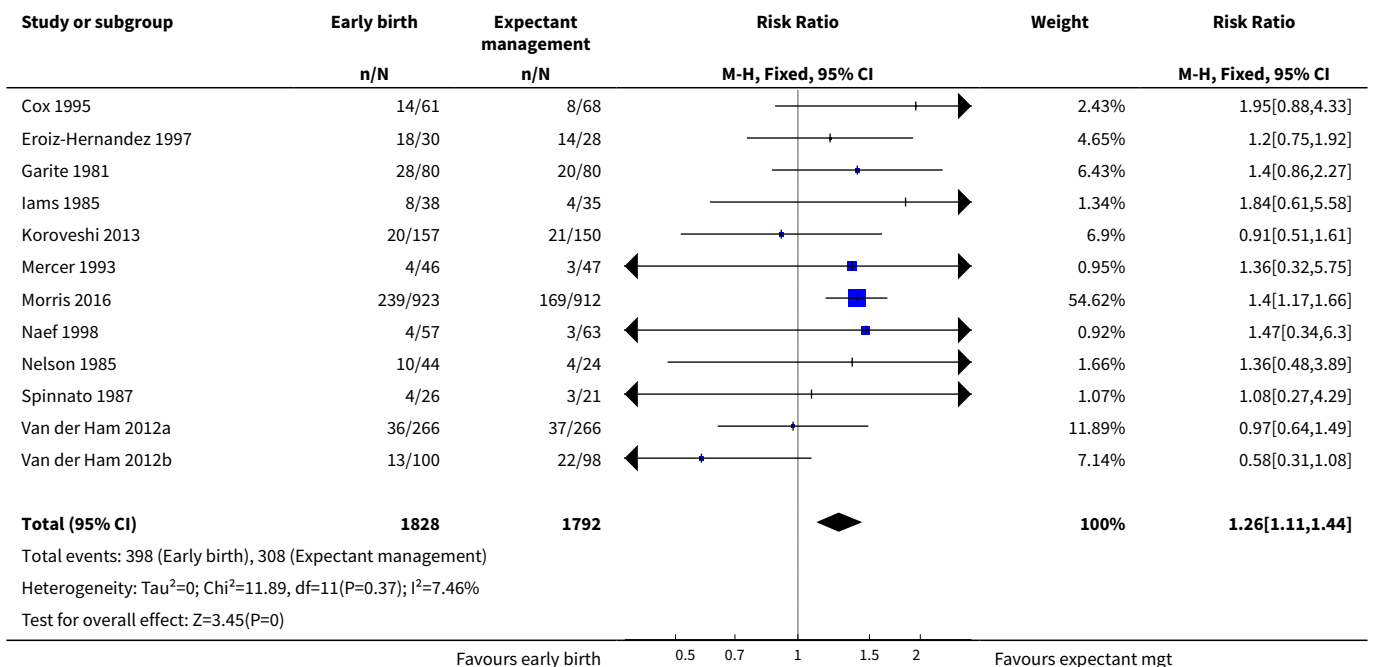

Analysis 1.2. Comparison 1 Any planned birth versus expectant management: by type, Outcome 2 Neonatal infection confirmed with positive blood culture.

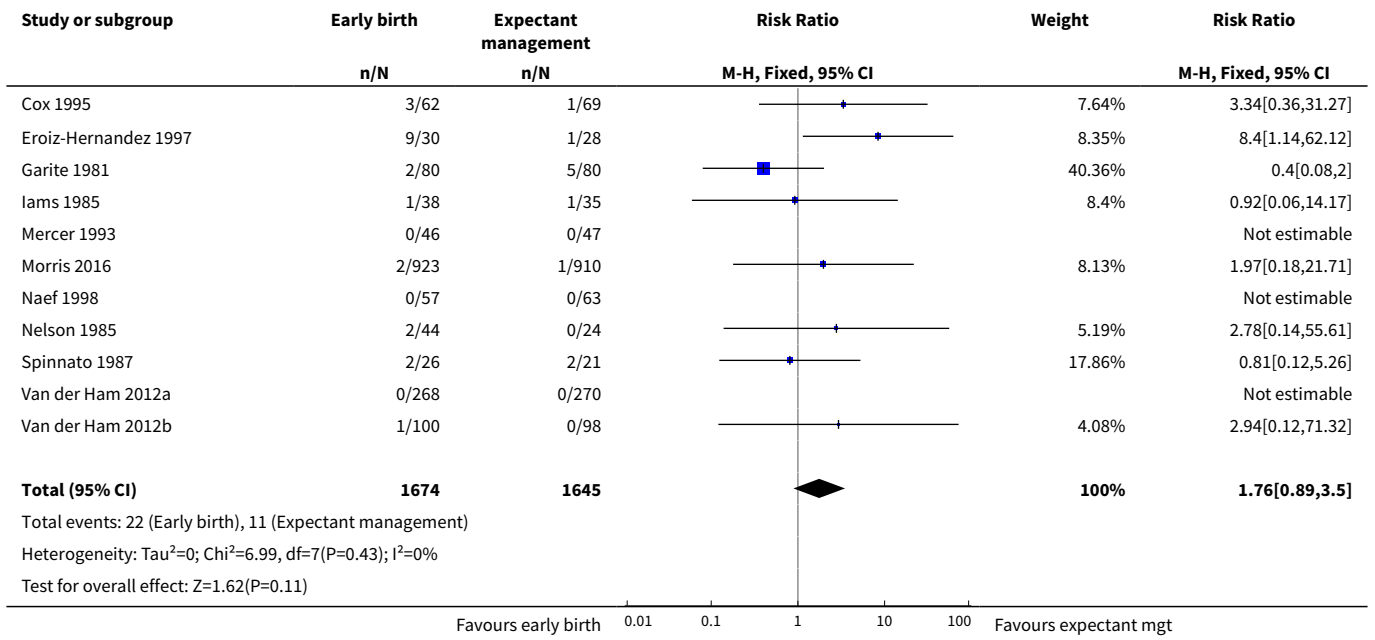

Analysis 1.3. Comparison 1 Any planned birth versus expectant management: by type, Outcome 3 Respiratory distress syndrome.

Analysis 1.4. Comparison 1 Any planned birth versus expectant management: by type, Outcome 4 Caesarean section.

Analysis 1.5. Comparison 1 Any planned birth versus expectant management: by type, Outcome 5 Perinatal mortality.

Analysis 1.6. Comparison 1 Any planned birth versus expectant management: by type, Outcome 6 Intrauterine death.

Analysis 1.7. Comparison 1 Any planned birth versus expectant management: by type, Outcome 7 Cord prolapse.

Analysis 1.8. Comparison 1 Any planned birth versus expectant management: by type, Outcome 8 Gestational age at birth (weeks).

Analysis 1.9. Comparison 1 Any planned birth versus expectant management: by type, Outcome 9 Neonatal death.

Analysis 1.10. Comparison 1 Any planned birth versus expectant management: by type, Outcome 10 Suspected neonatal infection.

Analysis 1.11. Comparison 1 Any planned birth versus expectant management: by type, Outcome 11 Neonatal treatment with antibiotics.

Analysis 1.12. Comparison 1 Any planned birth versus expectant management: by type, Outcome 12 Need for ventilation.

Analysis 1.13. Comparison 1 Any planned birth versus expectant management: by type, Outcome 13 Duration of oxygen therapy (days).

Analysis 1.14. Comparison 1 Any planned birth versus expectant management: by type, Outcome 14 Umbilical cord arterial pH.

Analysis 1.15. Comparison 1 Any planned birth versus expectant management: by type, Outcome 15 Birthweight (g).

Analysis 1.16. Comparison 1 Any planned birth versus expectant management: by type, Outcome 16 Apgar score less than 7 at 5 minutes.

Analysis 1.17. Comparison 1 Any planned birth versus expectant management: by type, Outcome 17 Abnormality on cerebral ultrasound.

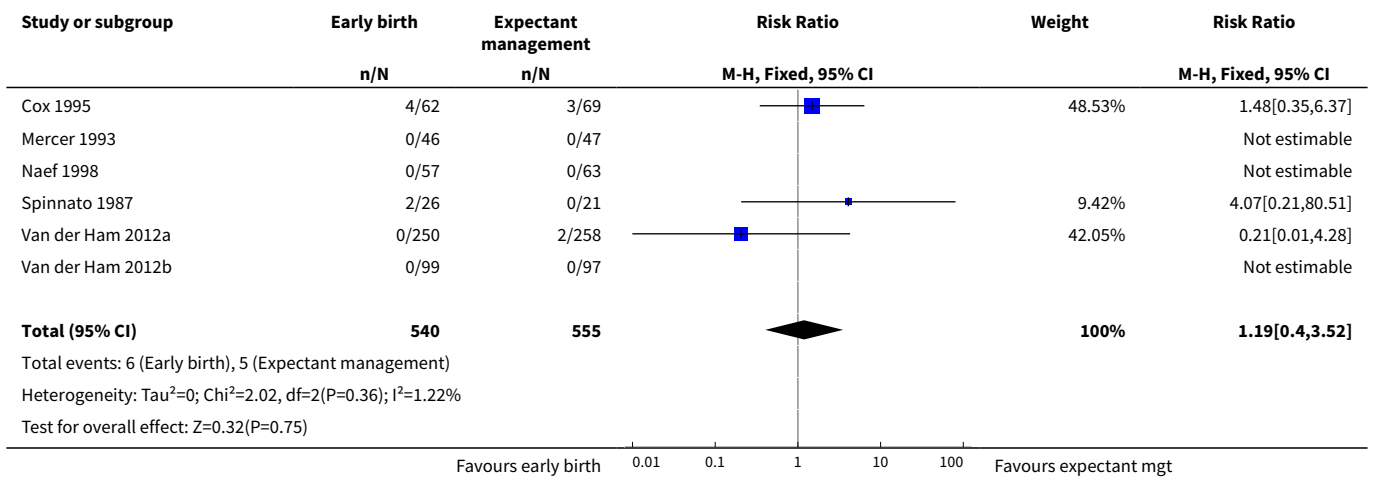

Analysis 1.18. Comparison 1 Any planned birth versus expectant management: by type, Outcome 18 Periventricular leukomalacia.

Analysis 1.19. Comparison 1 Any planned birth versus expectant management: by type, Outcome 19 Cerebroventricular haemorrhage.

Analysis 1.20. Comparison 1 Any planned birth versus expectant management: by type, Outcome 20 Necrotising enterocolitis.

Analysis 1.21. Comparison 1 Any planned birth versus expectant management: by type, Outcome 21 Severe respiratory distress.

Analysis 1.22. Comparison 1 Any planned birth versus expectant management: by type, Outcome 22 Admission to neonatal intensive care unit.

Analysis 1.23. Comparison 1 Any planned birth versus expectant management: by type, Outcome 23 Length of stay in neonatal intensive care unit (days).

Analysis 1.24. Comparison 1 Any planned birth versus expectant management: by type, Outcome 24 Duration (days) from birth to neonatal hospital discharge.

Analysis 1.25. Comparison 1 Any planned birth versus expectant management: by type, Outcome 25 Chorioamnionitis.

Analysis 1.26. Comparison 1 Any planned birth versus expectant management: by type, Outcome 26 Endometritis.

Analysis 1.27. Comparison 1 Any planned birth versus expectant management: by type, Outcome 27 Postpartum fever.

Analysis 1.28. Comparison 1 Any planned birth versus expectant management: by type, Outcome 28 Placental abruption.

Analysis 1.29. Comparison 1 Any planned birth versus expectant management: by type, Outcome 29 Induction of labour.

Analysis 1.30. Comparison 1 Any planned birth versus expectant management: by type, Outcome 30 Use of epidural/spinal anaesthesia.

Analysis 1.31. Comparison 1 Any planned birth versus expectant management: by type, Outcome 31 Vaginal birth.

Analysis 1.32. Comparison 1 Any planned birth versus expectant management: by type, Outcome 32 Operative vaginal birth.

Analysis 1.33. Comparison 1 Any planned birth versus expectant management: by type, Outcome 33 Caesarean section for fetal distress.

Analysis 1.34. Comparison 1 Any planned birth versus expectant management: by type, Outcome 34 Duration (days) of maternal hospitalisation.

Analysis 1.35. Comparison 1 Any planned birth versus expectant management: by type, Outcome 35 Duration (days) of antenatal hospitalisation.

Analysis 1.36. Comparison 1 Any planned birth versus expectant management: by type, Outcome 36 Duration (days) of maternal hospitalisation (excluding trials with antenatal discharge).

Analysis 1.37. Comparison 1 Any planned birth versus expectant management: by type, Outcome 37 Time (hours) from randomisation to birth.

Analysis 1.38. Comparison 1 Any planned birth versus expectant management: by type, Outcome 38 Disability at 2 years, abnormal CBCL.

Analysis 1.39. Comparison 1 Any planned birth versus expectant management: by type, Outcome 39 Disability at 2 years, abnormal ASQ.

Analysis 1.40. Comparison 1 Any planned birth versus expectant management: by type, Outcome 40 Maternal satisfaction.

Analysis 1.41. Comparison 1 Any planned birth versus expectant management: by type, Outcome 41 Breastfeeding > 12 weeks.

Comparison 2. Any planned birth versus expectant management (subgroup analysis by corticosteroid usage)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Neonatal infection	12	3652	Risk Ratio (M-H, Fixed, 95% CI)	0.94 [0.68, 1.32]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Antenatal corticosteroids	0	0	Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.2 No antenatal corticosteroids	6	495	Risk Ratio (M-H, Fixed, 95% CI)	0.98 [0.48, 2.03]
1.3 Some antenatal corticosteroids	6	2850	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.64, 1.41]
1.4 Not known	1	307	Risk Ratio (M-H, Fixed, 95% CI)	0.80 [0.25, 2.55]

WHAT'S NEW

Date	Event	Description
30 September 2016	New citation required and conclusions have changed	Twelve trials included for this update. There are no clear differences in the incidence of neonatal sepsis between women delivered immediately or managed expectantly in preterm prelabour rupture of the membranes prior to 37 weeks' gestation. Early planned birth is associated with an increase in the incidence of neonatal respiratory distress syndrome, neonatal mortality and the likelihood of caesarean section. Expectant management is associated with an increased incidence of chorioamnionitis.
30 September 2016	New search has been performed	The search and methods have been updated. We have used the GRADE approach to assess the quality of the body of evidence and included a 'Summary of findings' table: Summary of findings table 1.

HISTORY

Protocol first published: Issue 2, 2004
 Review first published: Issue 3, 2010

Date	Event	Description
31 January 2008	Amended	Converted to new review format.
24 January 2008	Amended	We have amended the protocol to make the gestational age for women with preterm prelabour rupture of membranes before 37 weeks' gestation more inclusive.

CONTRIBUTIONS OF AUTHORS

Dr Sarah Buchanan wrote the first draft of the initial review. Diana Bond was responsible for this update. Professor Jonathan Morris and Dr Kate Levett assisted with evaluation of trials for inclusion and independently extracting data. Dr Kate Levett assisted with independent assessment of bias. All authors commented on and edited the final version of the review.

DECLARATIONS OF INTEREST

Diana M Bond: I was employed as the Multi-Center Trial Co-ordinator for the NHMRC funded PPRMPT trial which is included in this review. The NHMRC has had no input or influence regarding the publication of this review.

Philippa Middleton: none known.

Kate M Levett: acted as a trial co-ordinator for the NHMRC (National Health and Medical Research Council) funded PPRMPT trial, one of the included trials.

David P van der Ham: was Chief Investigator and first author of the PPROMEXIL trials. Jonathan Morris and Diana Bond were responsible for data extraction and assessment of all these trial reports.

Caroline A Crowther: was involved in the planning of the PPRMPT trial.

Sarah L Buchanan: was involved in the planning of the PPRMPT trial.

Jonathan Morris: was the Chief Investigator and first author for the NHMRC- (National Health and Medical Research Council) funded PPRMPT trial.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

The methods section has been updated.

We removed the following specifier from our inclusion criteria: studies that planned early birth should be within 24 hours of randomisation. We left the definition of planned early birth to be specified by the authors of the included trials. We did, however, perform a subgroup analysis of those trials in which early birth was specified to be less than 24 hours from randomisation versus those trials in which this was not specified. This analysis was important as the trials were very heterogeneous with respect to the time at which birth was planned. By increasing the duration of time from randomisation to planned birth, the anticipated observed differences in outcomes between the early birth and the expectant management group would be less apparent.

It was not possible to extract data on early onset neonatal sepsis as initially specified in the protocol. Therefore, we further categorised neonatal sepsis into subgroups of: neonatal sepsis proven with positive blood culture (and included those trials that specified their sepsis outcome was defined by a positive culture); presumed sepsis; and neonatal treatment with antibiotics.

We included a new subgroup analysis for timing of intervention of early birth with a cutoff of 24 hours.

The protocol specified that there would be a subgroup analysis by gestational age at randomisation with three groups:

- less than 30 weeks' gestation;
- 30 to 33 weeks' plus six days' gestation;
- 34 to 37 weeks' gestation.

However, seven of the trials included women that were able to be included in more than one gestational age group. As individual participant data were not available for assessment, we performed subgroup analysis to assess gestational age in five trials that randomised women greater than 34 weeks' gestation and in five trials that randomised women less than 34 weeks' gestation.

Vaginal birth was removed from the list of maternal outcomes in the subgroup analysis as this was just mirrored data in relation to caesarean section.

For subgroup analyses of antibiotic and corticosteroid usage, an additional subgroup was added to each category to include those trials where only some women received the intervention.

In this update, 2016, we used the GRADE approach to assess the quality of the body of evidence and produced a 'Summary of findings' table.
