ABSTRACT

Background

This is an update of the Cochrane review published in 2002.

Colorectal cancer (CRC) is a major cause of morbidity and mortality in industrialised countries. Experimental evidence has supported the hypothesis that dietary fibre may protect against the development of CRC, although epidemiologic data have been inconclusive.

Objectives

To assess the effect of dietary fibre on the recurrence of colorectal adenomatous polyps in people with a known history of adenomatous polyps and on the incidence of CRC compared to placebo. Further, to identify the reported incidence of adverse effects, such as abdominal pain or diarrhoea, that resulted from the fibre intervention.

Search methods

We identified randomised controlled trials (RCTs) from Cochrane Colorectal Cancer's Specialised Register, CENTRAL, MEDLINE and Embase (search date, 4 April 2016). We also searched ClinicalTrials.gov and WHO International Trials Registry Platform on October 2016.

Selection criteria

We included RCTs or quasi-RCTs. The population were those having a history of adenomatous polyps, but no previous history of CRC, and repeated visualisation of the colon/rectum after at least two-years' follow-up. Dietary fibre was the intervention. The primary outcomes were the number of participants with: 1. at least one adenoma, 2. more than one adenoma, 3. at least one adenoma greater than or equal to 1 cm, or 4. a new diagnosis of CRC. The secondary outcome was the number of adverse events.

Data collection and analysis

Two reviewers independently extracted data, assessed trial quality and resolved discrepancies by consensus. We used risk ratios (RR) and risk difference (RD) with 95% confidence intervals (CI) to measure the effect. If statistical significance was reached, we reported the number needed to treat for an additional beneficial outcome (NNTB) or harmful outcome (NNTH). We combined the study data using the fixed-effect model if it was clinically, methodologically, and statistically reasonable.

Main results

We included seven studies, of which five studies with 4798 participants provided data for analyses in this review. The mean ages of the participants ranged from 56 to 66 years. All participants had a history of adenomas, which had been removed to achieve a polyp-free colon at baseline. The interventions were wheat bran fibre, ispaghula husk, or a comprehensive dietary intervention with high fibre whole food sources alone or in combination. The comparators were low-fibre (2 to 3 g per day), placebo, or a regular diet. The combined data showed no statistically significant difference between the intervention and control groups for the number of participants with at least one adenoma (5 RCTs, $n = 3641$, RR 1.04, 95% CI 0.95 to 1.13, low-quality evidence), more than one adenoma (2 RCTs, $n = 2542$, RR 1.06, 95% CI 0.94 to 1.20, low-quality evidence), or at least one adenoma 1 cm or greater (4 RCTs, $n = 3224$, RR 0.99, 95% CI 0.82 to 1.20, low-quality evidence) at three to four years. The results on the number of participants diagnosed with colorectal cancer favoured the control group over the dietary fibre group (2 RCTs, $n = 2794$, RR 2.70, 95% CI 1.07 to 6.85, low-quality evidence). After 8 years of comprehensive dietary intervention, no statistically significant difference was found in the number of participants with at least one recurrent adenoma (1 RCT, $n = 1905$, RR 0.97, 95% CI 0.78 to 1.20), or with more than one adenoma (1 RCT, $n = 1905$, RR 0.89, 95% CI 0.64 to 1.24). More participants given ispaghula husk group had at least one recurrent adenoma than the control group (1 RCT, $n = 376$, RR 1.45, 95% CI 1.01 to 2.08). Other analyses by types of fibre intervention were not statistically significant. The overall dropout rate was over 16% in these trials with no reasons given for these losses. Sensitivity analysis incorporating these missing data shows that none of the results can be considered as robust; when the large numbers of participants lost to follow-up were assumed to have had an event or not, the results changed sufficiently to alter the conclusions that we would draw. Therefore, the reliability of the findings may have been compromised by these missing data (attrition bias) and should be interpreted with caution.

Authors' conclusions

There is a lack of evidence from existing RCTs to suggest that increased dietary fibre intake will reduce the recurrence of adenomatous polyps in those with a history of adenomatous polyps within a two to eight year period. However, these results may be unreliable and should be interpreted cautiously, not only because of the high rate of loss to follow-up, but also because adenomatous polyp is a surrogate outcome for the unobserved true endpoint CRC. Longer-term trials with higher dietary fibre levels are needed to enable confident conclusion.

PLAIN LANGUAGE SUMMARY

Does dietary fibre prevent the recurrence of colorectal adenomas and carcinomas?

We asked

Does nutritional supplement of dietary fibre prevent recurrence of precancerous polyps and cancer in the bowel in participants with a history of polyps having been removed to achieve a polyp-free colon at baseline for the intervention.

Background

Colorectal (bowel) cancer is common worldwide but is especially prevalent in industrialised countries. Genes, diet and lifestyle all seem to be important in the development of bowel cancer. Several communities with low bowel cancer rates have diets that are rich in fibre. Increasing the levels of fibre in the diet in industrialised countries might therefore help to reduce the rate of bowel cancer.

Search Date

The evidence is current to 4 April 2016.

Study characteristics

Seven studies met the inclusion criteria. However, only five studies with 4798 participants provided data for this review. The mean ages of the participants ranged from 56 to 66 years. The participants all had a history of adenomas and would have had at least one procedure to remove them to achieve a polyp-free colon at baseline. The interventions in the included studies were wheat bran fibre, ispaghula husk, or a comprehensive dietary intervention with high fibre whole food sources used alone or in combination. These were compared to low-fibre (2 to 3 g per day), placebo, or a regular diet.

Key results

This review found that increasing fibre in a Western diet for two to eight years did not lower the risk of bowel cancer. Paradoxically, after four years participants receiving dietary fibre had higher rates of bowel cancer compared with the control group, with the absolute increase in risk being one percent.

Quality of evidence

The quality of evidence was low. The high risk of bias of included studies, small sample size, large number of missing data and the use of indirect measures gave us little confidence on the findings of this review.

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Dietary fibre (all study interventions) versus control for the prevention of colorectal adenomas and carcinomas

Dietary fibre (all study interventions) versus control for the prevention of colorectal adenomas and carcinomas

Patient or population: people with a history of colorectal adenomas

Settings: out-patient setting

Intervention: dietary fibre (all study interventions) versus control

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Control	Dietary fibre (all study interventions) versus control				
Number of participants with at least one recurrent adenoma Follow-up: 2 to 4 years	Study population		RR 1.04 (0.95 to 1.13)	3641 (5 studies)	⊕⊕⊕⊕ low a,b	
	349 per 1000	363 per 1000 (332 to 395)

Number of participants diagnosed with colorectal cancer Follow-up: 3 to 4 years	Study population		RR 2.70 (1.07 to 6.85)	2794 (2 studies)	⊕⊕⊕⊕ low ^{a,c}	The incidence of colorectal cancer is very low, so when risk was calculated by risk difference (RD), the difference between groups was very small. RD = 0.01, 95% CI 0.00 to 0.01
	4 per 1000	12 per 1000 (4 to 14)				
	Moderate					
	5 per 1000	14 per 1000 (5 to 16)				

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RD:** Risk difference; **RR:** Risk ratio

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

^a Risk of bias: downgraded by one level due to high risk of detection/performance bias and attrition bias.

^b Indirectness: downgraded by one level as adenoma was a surrogate outcome for CRC.

^c Imprecision: downgraded by one level as the data was under powered and the sample size was below the optimal information size.

BACKGROUND

Description of the condition

Colorectal cancer (CRC) is a leading cause of morbidity and mortality in industrialised nations, and is the third most common cancer worldwide with an estimated 1.24 million new cases of CRC diagnosed in 2008 (CRUK 2012). Globally, the incidence of CRC varies 10-fold with the highest rates found in Australia and New Zealand, North America and Europe; the lowest rates are found in South-Central Asia and Africa (Jemal 2011). Incidence rates from 27 European Union countries found that the highest incidences occur in Slovakia for men (91 cases per 100,000) and Denmark for women (50 cases per 100,000), while the lowest rates are in Greece for both sexes (24 cases per 100,000 for men and 17 per 100,000 for women) (GLOBOCAN 2008). These geographical differences are thought to be due to dietary and environmental factors, with the disease occurring mainly in high-income countries with a Western culture (Boyle 2000, Center 2009), although these figures may be affected by ascertainment bias, due to underreporting in low- and middle-income countries. Age is an important risk factor with the risk of CRC increasing in people after the age of 40, and increasing markedly at 50 years, with more than 90% of CRC occurring in those aged 50 or older and the prevalence rising across all five-year age categories, reaching a peak at 70 to 74 years of age (Corley 2013; Giovannucci 2006; Ries 2008).

Colorectal cancers mostly arise from dysplastic adenomatous polyps, and develop from the cumulative effect of sequential genetic alterations (multistep carcinogenesis), which can develop sporadically, or develop due to an inherited genetic cancer predisposition (Arnold 2005; Shussman 2014). It is estimated that 70% of CRCs develop sporadically, whilst 30% of CRCs are due to an inherited form of the disease (Jasperson 2010). Sporadic forms of CRC are thought to be related to lifestyle factors, and the geographical variation in CRC incidence and findings from migrant studies (McCredie 1999; Winkels 2014) suggest that diet (Gonzalez 2006; Terry 2001; Winkels 2014), and other lifestyle factors (Fu 2012; Potter 1993) play an important role in the aetiology of the disease. In 1971, based on the observation that CRC was rare in rural areas of many African countries, Burkitt hypothesized that the consumption of dietary fibre in those regions was protective (Burkitt 1971). Further, he postulated that the high intake of refined carbohydrates in Western countries increased the risk of developing CRC.

Description of the intervention

At present, there is no consensus on how dietary fibre should be defined. The original standard classification (Trowell 1976) describes dietary fibre as being composed of remnants of plant cells that are resistant to hydrolysis by human alimentary enzymes. This includes all indigestible polysaccharides such as celluloses, hemicelluloses, oligosaccharides, pectins, gums and waxes as well as lignin, a chemical compound most commonly derived from wood that is also present in plants. Dietary fibre is further classified as soluble (i.e. pectin, agar) or insoluble (cellulose, heteroxylans and lignified cell walls (wheat bran)), with the soluble form being less protective against cancer (Bunzel 2005; Ferguson 1996; Murphy 2012). Some have suggested that resistant starch, the portion of starch that remains undigested in the small intestine, actually functions as a dietary fibre (Prosky 2000), though it is not part of the standard definition. More recently, the European Food and Safety Authority (EFSA) defined dietary fibre

as non-digestible carbohydrates plus lignin, including non-starch polysaccharides: cellulose; hemicelluloses; pectins; hydrocolloids (i.e. gums, mucilages, glucans); resistant oligosaccharides, fructo-oligosaccharides, galacto-oligosaccharides, other resistant oligosaccharides; resistant starch, consisting of physically enclosed starch, some types of raw starch granules, retrograded amylose, chemically or physically modified starches, or both; and lignin associated with the dietary fibre polysaccharides (EFSA 2010). Another limitation in examining the relationship between dietary fibre and the risk of CRC is that individuals with high fibre content in their diet are likely to have healthier diets and lifestyles in general, and this can result in residual confounding, especially as the effect of this factor is difficult to separate in epidemiological studies (Huxley 2013).

Most, but not all, experimental studies in humans and animals support the protective effects of dietary fibre in the development of CRC (Alberts 1996a; Aune 2011a; Egeberg 2010; Fung 2010; Kritchevsky 1999; Reddy 1999). Protection is thought to be mediated through two main mechanisms referred to as direct and indirect (Ferguson 1996; Lupton 1999; Sowa 2000). The direct mechanism postulates that dietary fibre reduces exposure of the gastrointestinal mucosa to carcinogens or tumour promoters through absorption, increased nutrient dilution and shortening faecal transit time. The indirect mechanism addresses the protective role that bacteria in the colon may play through a number of enzymatic processes. For instance butyrate, a chemical formed in the colon by bacterial fermentation of dietary fibre, is thought to reduce the activity of tumour promoters. In addition to these proposed mechanisms, the source of dietary fibres has also been identified as an important contributing factor. Data from studies in humans and other animals has consistently shown wheat bran to be superior to pectin, oat or corn bran (Dhingra 2012).

Two previously published meta-analyses reported a similar protective effect of fibre and other dietary consumption on the incidence of CRC. In 1990, the first meta-analysis examined the effects of dietary fibre and vegetables on the incidence of CRC. A search of all epidemiologic studies published between 1970 and 1988 was carried out. The authors critically assessed 23 case-control studies, 15 correlation studies, two cohort studies and three time-trend studies. The combined odds ratio for data that were combined from 12 case-control studies was 0.57 (95% CI 0.50 to 0.64) (Trock 1990). Studies that demonstrated "equivocal support for protective effect" were excluded. In 1992, a second meta-analysis reviewed studies that were published between 1975 and 1988 and examined the effects of fibre, vitamin C, and beta-carotene on CRC risk (Heine-Broring 2015; Howe 1992; Jung 2013). Thirteen case control studies were identified, and data from a total of 5287 people with CRC and 10,470 controls were combined. Using logistic regression analysis, the risk ratio (RR) of CRC for the highest versus lowest quintile of fibre intake was 0.53 (95% CI 0.47 to 0.61). However, when the authors included only studies in which the participants used validated diet questionnaires and in which qualitative data on dietary habits and cooking methods were reported, consumption of dietary fibre was not shown to be protective (Friedenreich 1994; Wrieden 2007). The findings from both meta-analyses are tempered by the presence of a number of methodological weaknesses as well as the problem of selection and recall bias commonly associated with case control studies.

In a population-based cohort study in which 61,463 Swedish women were followed for 9.6 years, a weak association was found between increased fruit consumption and a decreased risk of CRC, though there was no association between cereal fibre intake and CRC (Aoyama 2014; Aune 2011b; Terry 2001). These results persisted after known confounders such as the use of multivitamins, exercise and decreased smoking and alcohol intake were adjusted for. The authors also noted a positive association between several healthy lifestyle changes and increased consumption of fibre, fruits and vegetables. Other large observational studies, however, have reported that dietary fibre and consumption of fruits and vegetables were not associated with a reduced risk of CRC (Fuchs 1999; Michels 2000). Two American cohort studies, the Nurses Health Study, that followed 88,757 women, and the Health Professionals' Follow-up Study, that followed 47,325 men for 16 and 10 years respectively, found that CRC risk was unaffected by the intake of dietary fibre, fruits and vegetables. Asano and colleagues (Asano 2002) carried out a Cochrane review (which is the original version of the current review) investigating the effect of dietary fibre on the incidence or recurrence of colorectal adenomas, the incidence of CRC, and incidence of adverse effects that resulted from the fibre intervention. This review included five studies with 4349 participants, and reported a range of interventions including wheat bran fibre, ispaghula husk, or a comprehensive dietary intervention with high fibre whole food sources alone or in combination. The findings of the review by Asano 2002 is consistent with those of Fuchs 1999 and Michels 2000.

How the intervention might work

Mechanisms underlying how dietary fibre might reduce the risk of CRC are unclear. Proposed theories include that fibre may play a role in binding potential carcinogens in the colon and its ability to absorb larger quantities of water thereby increasing faecal bulk and shortening transit time. In addition, bacterial fermentation may lower the pH of the colon through the production of short-chain fatty acids (Harris 1993).

Why it is important to do this review

To date, the results from observational studies assessing the effects of dietary fibre on the development of CRC have been inconclusive, despite some evidence with large sample size supporting a reduction in risk (Kunzmann 2015; Song 2015). In addition, the methodological limitations inherent in these observational studies make it difficult to interpret the findings. A systematic review of randomised controlled trials is therefore required in order to better evaluate data surrounding this important issue.

OBJECTIVES

To assess the effect of dietary fibre on the recurrence of colorectal adenomatous polyps in people with a known history of adenomatous polyps and on the incidence of CRC compared to placebo. Further, to identify the reported incidence of adverse effects, such as abdominal pain or diarrhoea, that resulted from the fibre intervention.

METHODS

Criteria for considering studies for this review

Types of studies

We included randomised controlled trials (RCTs; parallel or cluster) and quasi-RCTs comparing dietary fibre supplementation to a control.

Types of participants

We included participants with a history of adenomatous polyps, but not CRC in this review. All participants had to have undergone at least one documented procedure that directly visualised the colon and rectum at baseline and was repeated at least two years from the baseline investigation. The polyps could be either new incidences or recurrent adenomatous polyps, however, once detected by the colonoscopy test, appropriate procedures had to have been performed (i.e. polypectomy) to ensure that the colon or rectum were free of polyps at baseline.

Types of interventions

Studies included in this review had an intervention of dietary fibre. Dietary fibre is composed of the remnants of plant cells resistant to hydrolysis by human alimentary enzymes and included all indigestible polysaccharides (celluloses, hemicelluloses, oligosaccharides, pectins, gums, waxes) and lignin. We have also included resistant starches in the definition of dietary fibre for the purposes of this review.

Types of outcome measures

Primary outcomes

1. Number of participants with at least one adenomatous polyp
2. Number of participants with more than one adenomatous polyp
3. Number of participants with at least one adenomatous polyp that is 1 cm or greater
4. Number of participants with a new diagnosis of CRC

The diagnosis of adenomatous polyps or CRC was confirmed pathologically.

Secondary outcomes

1. Number of participants that reported at least one adverse event

Search methods for identification of studies

Electronic searches

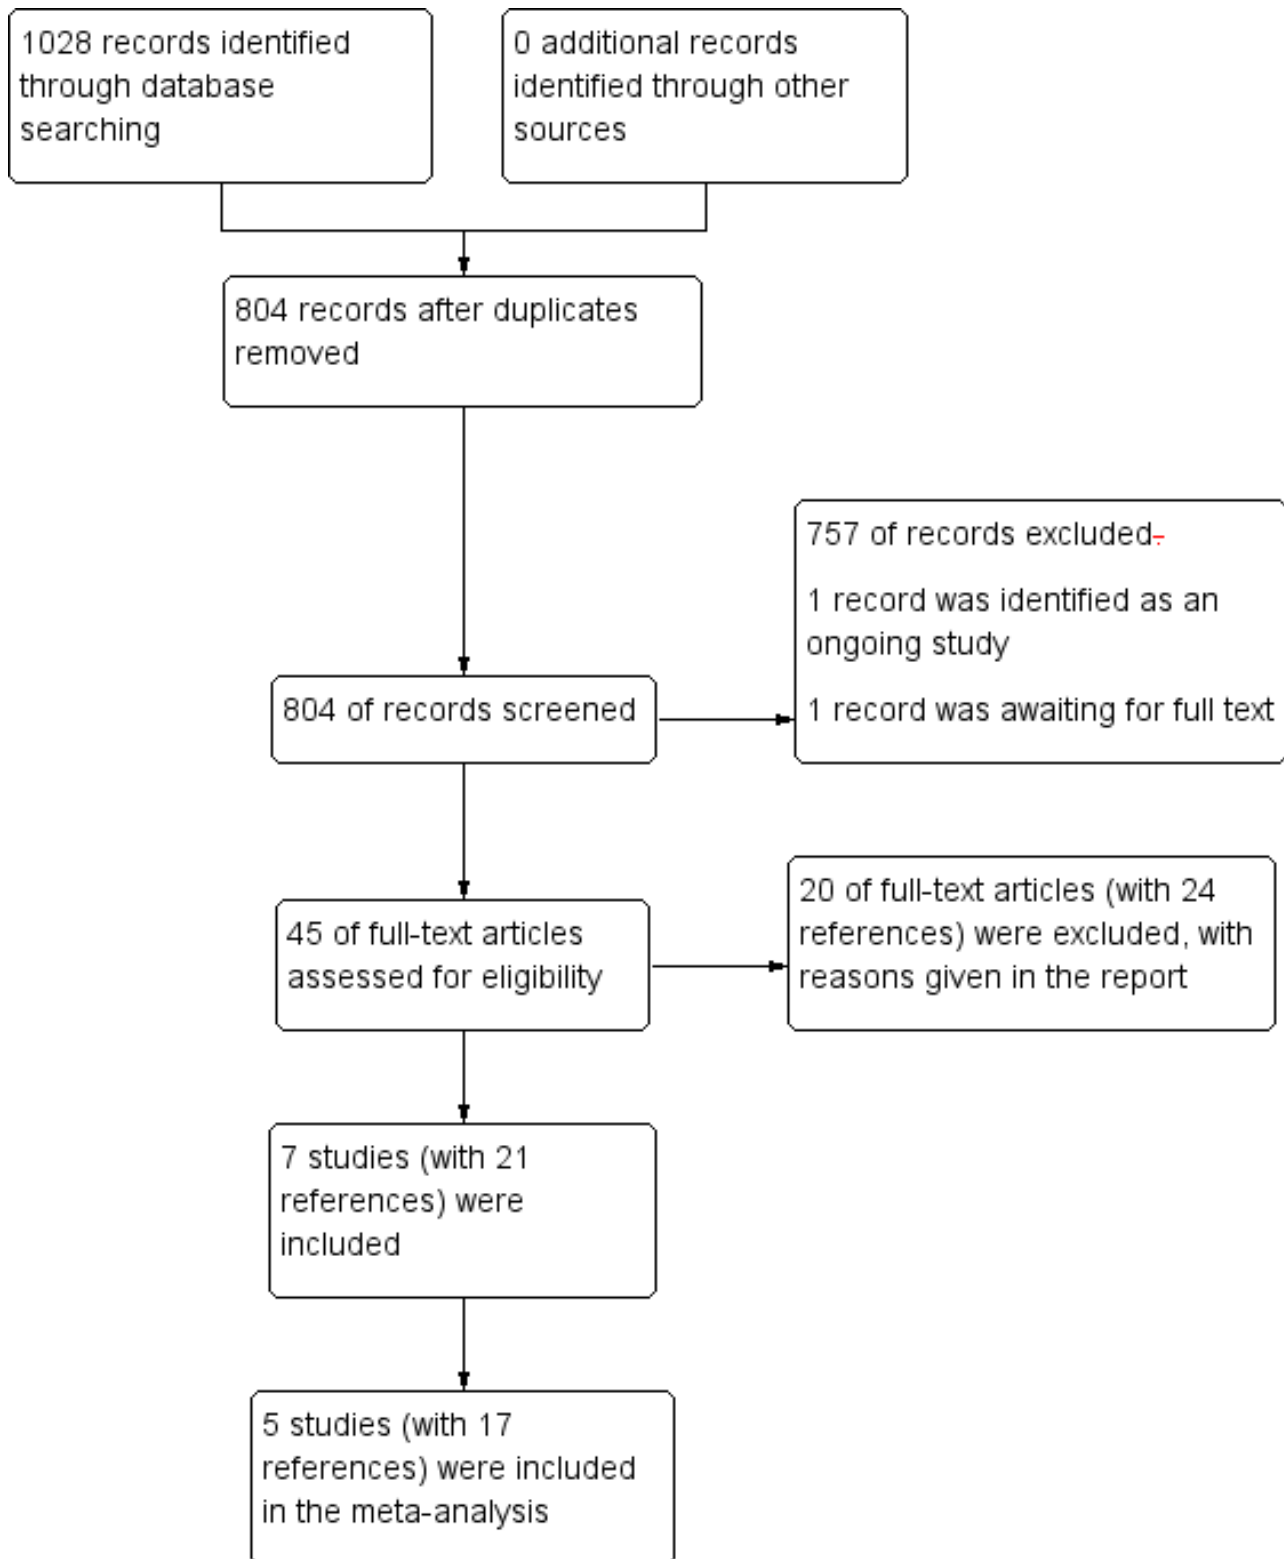

We identified RCTs from Cochrane Colorectal Cancer's Specialised Register (4 April 2016), the Cochrane Central Register of Controlled Trials (CENTRAL, 2016, Issue 4 in the Cochrane Library) (Appendix 1), MEDLINE (Ovid), 1950 to 4 April 2016 (Appendix 2) and Embase (Ovid), 1974 to 4 April 2016 (Appendix 3).

No language or publication status restrictions were applied.

Searching other resources

We handsearched reference lists from published studies, journal articles and bibliographies of relevant systematic reviews. We also searched ClinicalTrials.gov and WHO International Trials Registry Platform to identify any ongoing trials. See Figure 1.

Figure 1. Study flow diagram

Data collection and analysis

Selection of studies

Two reviewers (YY and JL) independently performed two stages of screenings. First, titles and abstracts of all references identified

through the searches were screened and clearly irrelevant reports were excluded. Second, full texts of potentially eligible studies and abstracts that were difficult to determine inclusion for were retrieved for further assessment and assessed according to the pre-defined inclusion criteria. We excluded reports that did not meet

the inclusion criteria and listed reasons for their exclusion. We resolved any discrepancies by discussion. We included all eligible studies irrespective of whether measured outcomes were reported on.

Data extraction and management

In this update, two reviewers (CW and YQC) independently extracted data on methods, participants, interventions and outcomes using a standardised data extraction form, which we piloted prior to the data extraction. Data was then entered into Review Manager 5 (RevMan 5) software for analysis (RevMan 2014). We resolved any disagreements by discussion and where uncertainty remained we consulted a third person (TS/RA).

Assessment of risk of bias in included studies

Two authors (EC and YY) assessed the quality of the trials using the Cochrane 'Risk of bias' tool described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011).

We independently evaluated the quality of the included trials and assessed the following risk of bias domains:

1. random sequence generation;
2. allocation concealment;
3. blinding of participants and personnel;
4. blinding of outcome assessment;
5. incomplete outcome data;
6. selective reporting bias; and
7. other potential sources of bias (such as recruitment rate, limited frequency of colonoscopy follow ups).

We judged each domain as high risk, low risk or unclear risk according to criteria used in the Cochrane 'Risk of bias' tool (see Appendix 4) (Higgins 2011). We sought clarification from the trialists if the published data provided inadequate information for the review. We tried to retrieve trial protocols of included studies to assess selective reporting bias. We presented the results of the risk of bias assessment in two figures (Figure 2; Figure 3).

Figure 2.

Figure 3.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding (performance bias and detection bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

Measures of treatment effect

As the outcomes were binary, we reported the risk ratio (RR) and risk difference (RD) with 95% confidence intervals (CI). If the RD was statistically significant, we calculated the number needed to treat for an additional beneficial outcome (NNTB) or the number needed to treat for an additional harmful outcome (NNTH). We assessed the studies clinically and methodologically to see if it was reasonable to consider combining data. If so, we used a fixed-effect model for the analysis.

Unit of analysis issues

The unit of analysis was the individual participant. There were no unit of analysis issues. However, if there had been cluster-randomised trials (such as randomisations by clinician or practice), in which the clustering effect had not been incorporated by study authors, we would have accounted for this by dividing binary data by a design effect using the mean number of participants per cluster (m) and the intra-class correlation coefficient (ICC) (Design effect = 1 + (m-1)*ICC) (Donner 2002).

Dealing with missing data

Where data were missing, we attempted to contact study authors for further information. The current update reported data from original trials regardless of whether the trialists had employed intention-to-treat (ITT) analysis. However, for those data derived from completers only, we conducted best/worst case scenario sensitivity analyses to assess the impact of missing data on the estimates of effect.

Assessment of heterogeneity

We evaluated the statistical heterogeneity in the data using the I^2 statistic (Higgins 2003). If the I^2 statistic for heterogeneity was significant (i.e. 50% or greater), we scrutinised the studies to identify potential factors that could explain the heterogeneity (e.g. variations in mean age of participants between studies). We evaluated clinical heterogeneity in included studies by assessment of study population characteristics.

Assessment of reporting biases

If there had been 10 or more studies, we would have used funnel plots to investigate reporting bias as described in the Cochrane Handbook for Systematic Reviews of Interventions (Sterne 2011). However, as we identified only five relevant studies, and fewer than 10 studies has limited power to detect small-study effects (Egger 1997), we did not produce any funnel plots.

Data synthesis

We performed the meta-analysis using the RevMan 5 software provided by Cochrane (RevMan 2014). Despite the differences between the trials, we used a fixed-effect model meta-analysis that uses the assumption that there was one true effect size underlying all the studies in the analysis, and that all differences in observed effects were due to sampling error (Borenstein 2010), as random-effects models produce poor estimates when there are small numbers of studies (Higgins 2011).

Summary of findings

We evaluated the quality of evidence using the Grading of Recommendation Assessment, Development and Evaluation (GRADE) approach for all primary outcomes for the comparison of dietary fibre (all study interventions) versus control (Schünemann 2011) (see [Summary of findings for the main comparison](#)). The quality of evidence could be downgraded by one (serious concern) or two levels (very serious concern) for the following reasons: risk of bias, inconsistency (unexplained heterogeneity, inconsistency of results), indirectness (indirect population, intervention, control, outcomes), imprecision (wide confidence interval, single trials), or publication bias. The quality could also be upgraded by one level due to a large summary effect.

RESULTS

Description of studies

Details of the included and excluded studies are listed in the tables of [Characteristics of included studies](#) and of [Characteristics of excluded studies](#).

Results of the search

The 2012 search of the databases yielded 781 references (Figure 1), and the subsequent update search performed in April 2016 yielded additional 247 references. The number was reduced to 804 records after duplicates were removed. Of these, we excluded 757 at title and abstract level. We identified one record to be an ongoing study and another record was a conference abstract, which we were unable to trace as a full publication. Forty-five full-text articles were short-listed for further scrutiny, out of which we excluded 20 studies (with 24 references). Finally, we included seven studies (encompassing 21 references), of which five studies (encompassing 17 references) contributed data to meta-analysis.

Included studies

Study design and length

All included studies were described as being randomised. The study length ranged from one year (Alberts 1996b) to four years (Schatzkin 2000), with the latter being subject to a further follow-up at eight years.

Study participants

Seven studies with 4960 participants met the inclusion criteria, however, only five studies with 4798 participants provided data for this review. The two largest studies were both conducted in USA (Alberts 2000; Schatzkin 2000), and the other five included studies were conducted in USA (Alberts 1996b; Decosse 1989), 10 European countries (Bonithon-Kopp 2000), Australia (MacLennan 1995), and Canada (McKeown-Eyssen 1994). The mean ages of the participants ranged from 56 to 66 years. The participants all had a known history of adenomas and would have had at least one procedure to remove them to achieve a polyp-free colon at baseline.

Types of Interventions

Three of the studies included wheat bran fibre (WBF) supplementation as the sole intervention or a supplement to a low fat diet/calcium or ascorbic acid (4 g a day) and alpha-tocopherol (400 mg a day) intake. The doses ranged from 13.5 g a day WBF (Alberts 1996b; Alberts 2000), 22.5 g a day WBF (Decosse 1989), 25 g a day WBF (MacLennan 1995), and 20 g WBF per 100 g snack to supplement the diet to reach a goal of 50 g of dietary fibre a day (McKeown-Eyssen 1994). One study included 3.5 g a day of ispaghula husk supplementation as a fibre intervention (Bonithon-Kopp 2000). Another study used a comprehensive dietary intervention that obtained a high fibre diet through whole foods (Schatzkin 2000). These are relatively high fibre intake compared to the average Western diet, as the average fibre intake is 12.8 g a day for women and 14.8 g a day for men in the UK (British Nutrition Foundation 2015).

The control groups were characterised by low-fibre (2 to 3 g a day) (Alberts 1996b; Alberts 2000; Decosse 1989; McKeown-Eyssen 1994), placebo (Bonithon-Kopp 2000; MacLennan 1995), or a regular diet (Schatzkin 2000).

Types of outcome measures

All of the included studies reported the number of participants with at least one recurrent adenoma. Two studies reported the number of participants with more than one adenomatous polyp (Alberts 2000; Schatzkin 2000) and four studies reported the number of participants that had at least one adenomatous polyp of 1 cm

or greater (Alberts 2000; Bonithon-Kopp 2000; MacLennan 1995; Schatzkin 2000). Two studies reported the number of participants that developed colorectal cancer (CRC) although this was not a pre-defined endpoint (Alberts 2000; Schatzkin 2000). Adverse events (other than CRC) were reported in two studies (Alberts 2000; Bonithon-Kopp 2000). Only one of these two studies reported the number of participants that reported at least one adverse event (Bonithon-Kopp 2000). Two studies reported outcomes that were not predefined in our protocol including compliance, [³H]thymidine labeling, dietary analysis and polyp number ratios (Alberts 1996b; Decosse 1989). Therefore we did not extract data from these two studies.

Excluded studies

We excluded 20 studies, out of which 15 were not RCTs. One study had a minority of participants who had had a procedure to remove polyps and data were unavailable for these participants, and furthermore, the control group received aspirin rather than placebo (Burn 2011a). One study (Lanza 2001) focused only on the changes in dietary intake for the included study Schatzkin 2000. In one study (Limburg 2011), the intervention was a prebiotic supplement, and not dietary fibre. One article (Vitanzo 2000) was only a summary of existing evidence. In Kunzmann 2015, the author compared flexible sigmoidoscopy with usual medical care, which did not meet our inclusion criteria for interventions.

Studies awaiting classification

We identified one conference abstract (Macrae 2014), but we were unable to locate the full-text report or unpublished data for interim analysis.

Ongoing studies

We identified one ongoing study (Ishikawa 2000), but we were unable to retrieve unpublished data for interim analysis.

Risk of bias in included studies

The risk of bias assessment across studies is shown in Figure 2 and Figure 3.

Allocation

All studies were randomised. Six studies described the random sequence generation (Alberts 1996b; Bonithon-Kopp 2000; Decosse 1989; MacLennan 1995; McKeown-Eyssen 1994; Schatzkin 2000) and were judged at low risk of selection bias; In Alberts 2000 there was a large discrepancy in the number (175) of people randomised to the intervention and control group. Therefore we suspected the randomisation procedure may have been unsuccessful, and consequently rated this domain as high risk of bias.

Allocation concealment was described in two studies (Alberts 1996b; Bonithon-Kopp 2000) and judged as low risk of bias, whilst no details were available in the remaining studies.

Blinding

Participants were aware of their treatment regimes in three studies (Alberts 2000; McKeown-Eyssen 1994; Schatzkin 2000). Another study (MacLennan 1995) described the trial as being partially double-blinded, with no further details. One study (Bonithon-Kopp 2000) blinded participants and investigators, but it was unclear if the assessors were blinded. There were no details on the blinding

of outcome assessment for six studies (Alberts 1996b; Alberts 2000; Bonithon-Kopp 2000; Decosse 1989; MacLennan 1995; Schatzkin 2000). We judged detection bias to be low in one study (McKeown-Eyssen 1994).

Incomplete outcome data

We rated three studies (Bonithon-Kopp 2000; MacLennan 1995; McKeown-Eyssen 1994) as high risk of attrition bias due to high dropout rates (ranging from 17% to 27.8% of the total sample size), in total 267 out of 1290 participants. We considered it possible that the proportion of missing outcomes compared with observed events could have had a clinically relevant impact on the intervention effect estimate. Two studies (Alberts 2000; Decosse 1989) reported moderate dropout rates (8.4% and 8.8% respectively), in total 300 out of 3508 participants. However, the reasons for loss to follow-up were not reported, thus we judged these studies as unclear risk of attrition bias. We rated two studies (Alberts 1996b; Decosse 1989) as low risk of attrition bias due to low (5% to 6%) dropout rates (9 out of 162 participants in total); one of these two studies used intention-to-treat analysis (Decosse 1989).

Selective reporting

We rated all the included studies as low risk of selective reporting bias, as all pre-defined primary outcomes appeared to have been reported.

Other potential sources of bias

For one study (Bonithon-Kopp 2000), the recruitment was lower than intended as the original intended sample size to detect a 15% difference in new adenoma formation rate was 210 participants in each arm, but the number of people who completed the study in the treatment arm was 198, and 178 in the placebo arm. Another potential source of bias in this study was the limited frequency of colonoscopy follow-ups, as over half of the participants failed to provide data at follow-up as they did not receive colonoscopy. These (i.e. recruitment rate or limited frequency of colonoscopy follow-up) were not an issue in the other six studies (Alberts 1996b; Alberts 2000; Decosse 1989; MacLennan 1995; McKeown-Eyssen 1994; Schatzkin 2000).

Effects of interventions

See: [Summary of findings for the main comparison](#) Dietary fibre (all study interventions) versus control for the prevention of colorectal adenomas and carcinomas

1. Dietary fibre versus control

1.1 Number of participants with at least one recurrent adenoma (within two to four years)

All five included studies reported an outcome of the number of participants with at least one recurrent adenoma. There were no statistically significant differences between the treatment and the control (Analysis 1.1: n = 3641, 5 RCTs, RR 1.04, 95% CI 0.95 to 1.13). We rated the quality of evidence as low due to high risk of detection/attrition bias and adenoma being as a surrogate outcome for CRC (Summary of findings for the main comparison). The best/worst case scenario sensitivity analysis that includes participants who were lost to follow-up by making assumptions as to the outcomes they had, showed that the pooled estimates were not robust as the conclusions drawn from the three analyses would differ, and

therefore these missing data had an important impact on our findings ([Analysis 7.1](#)).

1.2 Number of participants with more than one adenoma (within three to four years)

No statistically significant difference was found between the treatment and the control groups for the number of participants with more than one adenoma ([Analysis 1.2](#): $n = 2542$, 2 RCTs, RR 1.06, 95% CI 0.94 to 1.20). We rated the quality of evidence as low due to high risk of detection/attrition bias and adenoma being as a surrogate outcome for CRC ([Summary of findings for the main comparison](#)). The sensitivity analysis incorporating missing data in a best scenario favoured dietary fibre in lowering the risk of more than one adenoma ([Analysis 7.2](#)), however, the sensitivity analysis in a worst case scenario had a contrary result ([Analysis 7.2](#)) indicating that the missing data had an important impact on our findings.

1.3 Number of participants with at least one adenoma 1 cm or greater (within three to four years)

There was no statistically significant difference between the treatment and the control in the number of participants with at least one adenoma 1 cm or greater ([Analysis 1.3](#): $n = 3224$, 4 RCTs, RR 0.99, 95% CI 0.82 to 1.20). We rated the quality of evidence as low due to high risk of detection/attrition bias and adenoma being as a surrogate outcome for CRC ([Summary of findings for the main comparison](#)). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings ([Analysis 7.3](#)).

1.4 Number of participants diagnosed with colorectal cancer (within three to four years)

A statistically significantly higher number of participants were diagnosed with CRC in the dietary fibre group compared with the control group ([Analysis 1.4](#): $n = 2794$, 2 RCTs, RR 2.70, 95% CI 1.07 to 6.85, NNT 134, 95% CI 39 to 3247). The risk of being diagnosed with CRC was increased by 170% in the dietary fibre group relative to the control group. Calculated as the absolute risk increase, CRC was 1% higher in the dietary fibre group (RD 0.01, 95% CI 0.00 to 0.01). One-year data by [Schatzkin 2000](#) revealed no significant difference in CRC rates ($n = 1905$, RR 1.98, 95% CI 0.36 to 10.77). We rated the quality of evidence as low due to high risk of detection/attrition bias, and under-powered data ([Summary of findings for the main comparison](#)). The best/worst case scenario sensitivity analysis showed that the pooled estimate of effect was not robust, and the missing data had an important impact on our findings ([Analysis 7.4](#)).

1.5 Number of participants that reported at least one adverse event

In this subgroup, no study reported data for this outcome.

2. Wheat bran fibre (WBF) versus control

2.1 Number of participants with at least one recurrent adenoma (within three to four years)

The data available from two studies on wheat bran fibre showed no statistically significant difference between this treatment and the control group ([Analysis 2.1](#): $n = 1195$, 2 RCTs, RR 1.01, 95% CI 0.87 to 1.18). The best/worst case scenario sensitivity analysis showed

that the pooled estimate of effect was not robust. The missing data had important impact on our findings ([Analysis 8.1](#)).

2.2 Number of participants with more than one adenoma (within three to four years)

We found no statistically significant difference between the treatment groups for the number of participants with more than one adenoma ([Analysis 2.2](#): $n = 637$, 1 RCT, RR 1.11, 95% CI 0.97 to 1.29). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings ([Analysis 8.2](#)).

2.3 Number of participants with at least one adenoma 1 cm or greater (within three to four years)

No statistically significant difference was found between the wheat bran fibre and control groups in the number of participants with at least one adenoma 1 cm or greater ([Analysis 2.3](#): $n = 637$, 1 RCT, RR 1.04, 95% CI 0.83 to 1.31). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings ([Analysis 8.3](#)).

2.4 Number of participants diagnosed with colorectal cancer

In this subgroup, no study reported data for this outcome.

2.5 Number of participants that reported at least one adverse event

In this subgroup, no study reported data for this outcome.

3. Wheat bran fibre (WBF) and low fat diet versus control

3.1 Number of participants with at least one recurrent adenoma (within two years)

There was no significant difference between the treatment groups in the number of participants with at least one recurrent adenoma ([Analysis 3.1](#): $n = 165$, 1 RCT, RR 1.19, 95% CI 0.64 to 2.18). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings ([Analysis 9.1](#)).

3.2 Number of participants with more than one adenoma

In this subgroup, no study reported data for this outcome.

3.3 Number of participants with at least one adenoma 1 cm or greater

In this subgroup, no study reported data for this outcome.

3.4 Number of participants diagnosed with colorectal cancer

In this subgroup, no study reported data for this outcome.

3.5 Number of participants that reported at least one adverse event

In this subgroup, no study reported data for this outcome.

4. Wheat bran fibre with or without low fat diet versus control

4.1 Number of participants with at least one recurrent adenoma (within two to four years)

No statistically significant difference was found between the wheat bran diet (with or without low fat) and the control groups in the number of participants with at least one recurrent adenoma

(Analysis 4.1: $n = 1360$, 3 RCTs, RR 1.03, 95% CI 0.88 to 1.19). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 10.1).

4.2 Number of participants with more than one adenoma (within three years)

Data from one study showed no statistically significant difference in the number of participants with more than one adenoma between the treatment and control groups (Analysis 4.2: $n = 637$, 1 RCT, RR 1.11, 95% CI 0.97 to 1.29). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 10.2).

4.3 Number of participants with at least one adenoma 1 cm or greater (within three to four years)

We found no statistically significant difference in the treatment and control groups regarding the number of participants with at least one adenoma 1 cm or greater (Analysis 4.3: $n = 943$, 2 RCTs, RR 1.02, 95% CI 0.81 to 1.27). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 10.3).

4.4 Number of participants diagnosed with colorectal cancer

In this subgroup, no study reported data for this outcome.

4.5 Number of participants that reported at least one adverse event

In this subgroup, no study reported data for this outcome.

5. Comprehensive dietary intervention versus control

5.1 Number of participants with at least one recurrent adenoma (after four years)

One study reported no statistically significant difference between a comprehensive dietary intervention and the control group on the number of participants with at least one recurrent adenoma after four years (Analysis 5.1: $n = 1905$, 1 RCT, RR 1.00, 95% CI 0.90 to 1.12). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 11.1).

5.2 Number of participants with at least one recurrent adenoma (after eight years)

After eight years, no statistically significant difference was found in the number of participants with at least one recurrent adenoma (Analysis 5.2: $n = 1905$, 1 RCT, RR 0.97, 95% CI 0.78 to 1.20). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 11.2).

5.3 Number of participants with more than one adenoma (after four years)

After four years, no statistically significant difference was found in the number of participants with more than one adenoma (Analysis 5.3: $n = 1905$, 1 RCT, RR 1.01, 95% CI 0.83 to 1.24). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 11.3).

5.4 Number of participants with more than one adenoma (after eight years)

After eight years, there was still no statistically significant difference between the treatment and control groups in the number of participants with more than one adenoma (Analysis 5.4: $n = 1905$, 1 RCT, RR 0.89, 95% CI 0.64 to 1.24). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 11.4).

5.5 Number of participants with at least one adenoma 1 cm or greater (after four years)

There was no statistically significant difference in the number of participants with at least one adenoma 1 cm or greater between the dietary intervention and control groups (Analysis 5.5: $n = 1905$, 1 RCT, RR 0.88, 95% CI 0.60 to 1.28). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 11.5).

5.6 Number of participants diagnosed with colorectal cancer

In this subgroup, no study reported data for this outcome.

5.7 Number of participants that reported at least one adverse event

In this subgroup, no study reported data for this outcome.

6. Ispaghula husk versus control

6.1 Number of participants with at least one recurrent adenoma (after three years)

A statistically significantly higher number of participants in the ispaghula husk group ($P = 0.05$) had at least one recurrent adenoma than the control group (Analysis 6.1: $n = 376$, 1 RCT, RR 1.45, 95% CI 1.01 to 2.08, NNTH 11, 95% CI 5 to 495). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 12.1).

6.2 Number of participants with more than one adenoma

In this subgroup, no study reported data for this outcome.

6.3 Number of participants with at least one adenoma 1 cm or greater (after three years)

We found no statistically significant difference in the number of participants with at least one adenoma 1 cm or greater between the two treatment groups (Analysis 6.2: $n = 376$, 1 RCT, RR 1.80, 95% CI 0.55 to 5.87). The best/worst case scenario sensitivity analysis showed contrary results indicating that missing data had an important impact on our findings (Analysis 12.2).

6.4 Number of participants diagnosed with colorectal cancer

In this subgroup, no study reported data for this outcome.

6.5 Number of participants with at least one adverse effect (after three years)

No statistically significant difference was found in the number of participants with at least one adverse effect, between the two groups (Analysis 6.3: $n = 376$, 1 RCT, RR 0.90, 95% CI 0.18 to 4.40). The best/worst case scenario sensitivity analysis showed contrary

results indicating that missing data had an important impact on our findings (Analysis 12.3).

DISCUSSION

Summary of main results

Various clinical endpoints (such as CRC or presence of adenomatous polyps) are collected in various phases of clinical trials. CRC is relatively difficult to observe in a RCT, as it may take a long time to develop and, even if trials are conducted with sufficiently long follow-up periods, increasing numbers of participants may be lost to follow-up as the trial progresses. Due to these difficulties inherent in using CRC as an end point, several different biomarkers of CRC have been relied on in cancer chemoprevention trials (Einspahr 1997; Emerson 1993). Studies in this review have focused on the presence of adenomatous polyps, clinically identifiable precursors of CRC (Einspahr 1997; Stryker 1987; Winawer 1993a), as a surrogate outcome.

Data from five trials including 4798 participants, compared increased dietary fibre supplementation to a control group. Over a period of two to eight years, there was no evidence that dietary fibre reduced the recurrence of colorectal adenomas (Analysis 1.1: RR 1.04, 95% CI 0.95 to 1.13). In Analysis 1.4 CRC was statistically significantly higher (17/1426; NNT_H = 134) in the dietary fibre group compared with the control group (6/1368) at four years. However, Schatzkin 2000 reported one-year CRC data, and no statistically significant difference was found between the dietary fibre (4/958) and control (2/947) groups. The finding was expected given the low event rate and the relatively small sample size. Although the increase in the incidence of CRC at four years was small in absolute terms (number per 1000 people), an intervention such as dietary fibre is sold to the general population as 'healthy', therefore this could translate into fairly large numbers of people overall depending on the numbers of people following such lifestyle advice. However, the numbers of participants in the analyses for CRC were too small to be confident in the result. In addition, the results of all the meta-analyses were adversely affected by large numbers of participants being lost to follow-up (attrition bias); when we made assumptions about the outcomes of these missing participants (worst/best case scenarios) based on completer analyses, the result of all the analyses changed sufficiently to alter the conclusions that would be drawn.

In addition, results from the four-year Polyp Prevention Trial II (Schatzkin 2000) were the most heavily weighted in the analysis, due to its large sample size and high event rate. In this study, increased consumption of dietary fibre from whole foods, vegetables and fruits, and decreased intake of fat, had no effect on the rate of recurrence of adenomas. A four-year subsequent follow-up revealed that there was no statistically significant difference in the number of participants with at least one recurrent adenoma (Analysis 5.2: $n = 801$, 1 RCT, RR 0.96, 95% CI 0.80 to 1.15). At eight years, the number of participants who were given the high fibre intervention who had more than one polyp was not statistically significantly different from the control group (Schatzkin 2000). However, this particular analysis was under powered, thus we are unable to conclude if there was really no difference between groups.

While three other included studies that added wheat bran fibre (WBF) supplementation to the intervention reported no effect on

recurrent adenomas (Alberts 2000; MacLennan 1995; McKeown-Eyssen 1994), the European Cancer Prevention study (Bonithon-Kopp 2000) actually reported an increase in recurrent adenomas in the ispaghula husk intervention group compared to controls. The biological basis of this finding is unclear.

This review has employed surrogate outcomes such as the occurrence of adenomatous polyps as a risk reference for CRC. However, any conclusions based on surrogate outcomes must be interpreted with caution. Although somatic mutation theory is a classical theory in cancer development, we should not ignore the role of carcinogenesis and other external factors, such as lifestyle, smoking history and alcohol consumption Baker 2007, which can lead to unequal conversion rate from adenomatous to cancer between experimental and control groups. Thus, readers should interpret the results with caution.

Overall completeness and applicability of evidence

We included seven studies, however only five studies provided data for meta-analyses. Only two studies reported rates of CRC (Alberts 2000; Schatzkin 2000); the primary outcome of the other studies was adenomas. One of these trials included only 100 participants, and was therefore very underpowered. The other trial recruited 2079 participants, but event rates were very low, therefore, any analyses of the benefits of dietary fibre in reducing the risk of CRC were underpowered. These limitations are a source of uncertainty in our results.

In addition, CRC develops typically 10 years after the adenoma begins to develop (Half 2009). Consequently, the main outcome in the studies was the surrogate outcome of adenomatous polyp, as participants were followed-up for less than 10 years. There is a need to demonstrate that the effect of treatment on a surrogate endpoint predicts the effect of treatment on the true endpoint (i.e. CRC). The strength and direction of the relationship between the surrogate outcome and the definitive outcome over a specified time interval should be also be known (Grizzle 1999). Although most CRCs develop from an adenomatous polyp, only a small fraction of adenomas develop into cancer and better predictive biomarkers are needed or, in their absence, longer-term trials are needed.

Quality of the evidence

Another potential confounding factor is the possibility that the consumption of dietary fibre was not high enough. However, the reported level of dietary fibre intake in several of the studies was comparable to historic levels of fibre consumption in South Africa where there is a low incidence of CRC (Segal 2000). In the Wheat Bran Fibre (WBF) trial, the intake of dietary fibre was increased to 27 g a day in the intervention group versus 18.2 g a day in the control group (Alberts 2000). Dietary fibre in the Australian Polyp Prevention Trial was increased by 7 g a day in the treatment group (MacLennan 1995). When intensive nutritional counselling was provided, dietary fibre from whole foods, with or without WBF, increased to 30 g to 35 g a day (McKeown-Eyssen 1994; Schatzkin 2000). It must be noted, however, that the Toronto Polyp Prevention Study was unable to achieve their goal of 50 g a day of dietary fibre (McKeown-Eyssen 1994), suggesting that compliance with high levels of dietary fibre intake may be problematic in a Western population. Further, intake of dietary fibre from other sources may be reduced when high levels of WBF are part of the intervention (Ishikawa 2000b).

It has also been suggested that enrolling participants at an earlier age and prolonging the duration of the trial may help uncover the benefits of a high dietary fibre intake. The rationale for enrolling older participants rests on the observation that those who are already diagnosed with a colorectal adenoma have a higher risk of developing subsequent adenomas, thereby reducing the total number of participants needed in a clinical trial. The downside of employing data from a high risk population is that the external validity or generalisability of the trial, subsequently the systematic review, is limited and may not be applicable to the general population. There is a possibility that the high risk population is less responsive to fibre and that fibre may have beneficial effect in those who have yet to show signs of disease. Further, while prolonging the duration of a trial in a cohort that is already undergoing endoscopic surveillance may seem reasonable, the potential for subject 'burnout' from a comprehensive dietary intervention, intensive nutritional counselling and increased costs make this option less realistic.

For the risk of bias in included studies, we considered attrition bias a major concern. The sensitivity analysis in best and worst case scenarios showed contrary results, which means that the missing data had a significant impact on our results. Although the blinding of participants and outcome assessors was not well conducted among studies, we did not regard the performance or detection bias as significant, as the detection and performance bias has little impact on objective outcomes.

Potential biases in the review process

Despite the high prevalence of CRC in industrialised countries, the development of clinical trials designed to assess primary prevention strategies is hampered by the slow progression of the disease and the large number of participants required. Nevertheless, though CRC was not the primary outcome, two of the included studies reported an increase in the incidence of CRC in the fibre intervention groups (Alberts 2000; Schatzkin 2000).

Of the 14 cases in Schatzkin 2000 who had CRC, six were diagnosed within the first year and four of these six cases were in the intervention group. Thus, the difference between the CRC rates in the intervention and control groups (NNT_H = 134) is more likely to be a chance occurrence given the wide confidence interval around NNT_H (95% CI 39 to 3247). The wide confidence interval could have resulted from low participant numbers, a low event rate or any other uncertainty, thus the clinical significance of the above result is debatable and impact of fibre on CRC cannot be concluded on the basis of these numbers.

Outcome data were not reported separately according to gender and therefore our analyses were not subgrouped. Alberts 2000 and Bonithon-Kopp 2000 performed baseline adjustment for gender and found no evidence that outcomes were affected. However, Schatzkin 2000 also adjusted for sex and reported that recurrence of adenomas in women was significantly higher in the fibre group with an unadjusted risk ratio of 1.30 (95% CI 1.04 to 1.63; P = 0.03). Jacobs 2006 combined the results of both the Alberts 2000 and Schatzkin 2000 studies to find the interaction between sex, fibre and adenoma recurrence. The pooled analysis reported the effects of dietary intervention using logistic regression models and found that colorectal adenoma recurrence in the fibre group for men was associated with significantly reduced risk of recurrence, odds ratio 0.81 (95% CI 0.67, 0.98). There may be potential for systematic

gender-dependent errors, and as stated in the Jacobs 2006 study, the mechanism for the occurrence of differential effects remains unclear, and further investigation is required.

Agreements and disagreements with other studies or reviews

Our findings from these five RCTs are at odds with some cohort studies that report benefits from dietary fibre. In the Aune 2011a meta-analysis of cohort studies, the risk of CRC was significantly lower (RR 0.88, 95% CI 0.82 to 0.94) in participants measured by total high fibre intake, and also for intake of high whole grains. However, the authors found no statistically significant difference in cohorts comparing high versus low fruit fibre intake, high versus low vegetable fibre intake, or high versus low legume fibre intake. Additionally, no formal assessment of risk of bias was conducted and it is unclear if confounding variables affected the results, although attempts were made to adjust for these.

Other factors are likely to contribute to the reduced risk found in cohorts consuming higher dietary fibre. Typically, healthier diets are accompanied by healthier lifestyles and better nutrition, and the reverse is true for people consuming low fibre diets. It is plausible that those cohort-participants with higher total dietary fibre accrued benefits from consuming foods with higher nutrition, especially vitamin D, calcium and folate, which are associated with reduced risk of CRC (Pericleous 2013). The vitamin and mineral content of refined foods such as white bread, white rice, white pasta and breakfast cereals is greatly reduced once the bran and germ are removed (Hegedüs 1985), and attempts are often made (depending on the legal requirements of individual countries) to restore nutrients lost during the manufacturing process (Bonner 1999). Other potential confounding factors that increase the risk of CRC include smoking (Liang 2009), sedentary lifestyles (Slattery 2004; Wolin 2009) and obesity (Frezza 2006) and it is these risk factors that are clustered in people with poor-quality, low-dietary-fibre diets (Burke 1997; Ma 2000; Poortinga 2007; Suh 2013).

A number of explanations have been proposed for the apparent lack of association between dietary fibre and the development of CRC in clinical trials. Volunteer bias has been one such proposal. Participation in trials that entail nutritional interventions generally requires a significant commitment on the part of the participants. In addition, participants are likely to engage in healthier lifestyles that could potentially counteract any benefit derived from the dietary intervention. Though participants in the included trials were shown to consume more dietary fibre than the average American (approximately 15 g to 20 g a day versus 11.1 g to 13.4 g a day respectively) (Ganji 1995; Lanza 1987), there was no difference in smoking habits, body mass index, percentage of total caloric intake from fat, or use of multivitamins (Balluz 2000; Chao 2000; Ganji 1995; Kuczmarski 1997; Lyle 1998; Ruchlin 1999; Sundquist 2001). Consistent with previous reports (Hixson 1991; Neugut 1993; Winawer 1993b), there was also a high rate of recurrent adenomas (20% to 40%). Taken together, these observations suggest that volunteer bias did not play a significant role.

AUTHORS' CONCLUSIONS

Implications for practice

Both lifestyle and diet are considered to be important environmental factors that influence the risk of developing

colorectal cancer (CRC), though it is unlikely that one component plays a dominant role. To date, the evidence from randomised controlled trials (RCTs) included in this review does not support that increased dietary fibre intake reduces the risk of CRC or reduces the risk of recurrence of adenomatous polyps within a two- to eight-year period compared with control groups. Nevertheless, the reliability of these data is questionable due to a variety of reasons such as the conduct of the trials, the large number of missing data, small sample sizes, surrogate outcome employed and so on, thus limiting our confidence in any findings derived from this data set. There is some indication that CRC may be increased by high fibre intake, but the data were insufficient and under-powered to support such an association. We have no reliable evidence to refute the use of dietary fibre.

Implications for research

One ongoing trial will provide new information regarding the association between dietary fibre intake and the development of new or recurrent colorectal adenomas or CRC ([Ishikawa 2000b](#)). This is the first "non-Western" trial, being carried out in Japan, in which dietary fibre and WBF has been included as an intervention for the prevention of recurrent colorectal adenomas. It remains to be seen whether the results from this trial will be consistent with the included studies in this review, in which using WBF did not

add additional benefit. The internationally recognised healthy fibre intake, as recommended by the American Cancer Society and the British Nutrition Foundation, is between 30 g to 40 g a day. Although we recognise the challenge of encouraging people to maintain a high level of high fibre intake, where possible, future trials should aim for the intervention group to have that level of intake and preferably higher. Longer trial duration will also help to identify the preferred endpoint of CRC, but we understand long-term trials may not be possible due to cost and other practical issues. Thus, we encourage the trial duration to be as long as resources allow.

ACKNOWLEDGEMENTS

We are grateful to:

1. the Cochrane Colorectal Cancer and Dr. Arne Ohlsson for advice on the protocol and final review;
2. trialists Dr D Alberts, V Jazmaji, Dr Faivre, Dr Bonithon-Kopp, and Dr I Akedo for responding to requests for further information;
3. Dr J Baron for expert assistance regarding completeness of our list of included studies.

The current review authors would like to thank Tracey Asano and Robin McLeod for their contribution to the earlier version of the review.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]
Alberts 1996b

Methods	Allocation: randomisation numbers were computer-generated Blindness: only one of the biostatisticians had access to the uncoded list of participant names, agent codes, and agent identities Median duration: 3 months' run-in period + 9 months' treatment duration Setting: USA
Participants	Inclusion criteria: age 50-75 years, a complete colonoscopy with colonic polyp removal within 24 months of study entry, no history of invasive cancer, severe metabolic disorders, or other life-threatening acute or chronic diseases, a performance status of 0-1 (Southwest Oncology Group performance status criteria) adequate dietary intakes of calories and protein N = 100 Sex: % male: 49.4 Age: mean: 66-70 years Exclusion criteria: dietary fibre intake of ≥ 30.0 g/d or elemental calcium intake of ≥ 2.0 g/d, serum creatinine levels of ≥ 1.3 mg/dL, and serum bilirubin levels of ≥ 2.0 mg/dL Baseline dietary fibre intake g/day: 15.6-20.0 Baseline characteristics similar for each group: not tested
Interventions	1. Low fibre/low calcium group: WBF 2.0 g + 250 mg calcium per day. N = 24.2 2. High fibre/low calcium group: WBF 13.5 g + 250 mg calcium per day. N = 26.3 3. Low fibre/high calcium group: WBF 2.0 g + 1500 mg calcium per day. N = 21.4 4. High fibre/high calcium group: WBF 13.5 g + 1500 mg calcium per day. N = 22
Outcomes	Unable to use: Compliance [³ H]thymidine labeling of normal colonic epithelial cells in 24-h outgrowth culture [³ H]thymidine labeling in crypt organ culture

Alberts 1996b (Continued)

Notes None.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation numbers were computer-generated
Allocation concealment (selection bias)	Low risk	Only one of the biostatisticians had access to the uncoded list of participant names, agent codes, and agent identities.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	No details
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No details
Incomplete outcome data (attrition bias) All outcomes	Low risk	5 participants dropped out of the study during the first 3 months of post randomisation treatment because of supplement adherence problems, 2 participants refused participation in the rectal mucosal biopsy procedures
Selective reporting (reporting bias)	Low risk	It appears all pre-defined outcomes were reported
Other bias	Unclear risk	No details

Alberts 2000

Methods	Allocation: randomized Blindness: "double" Median duration: 34 months (high-fibre group) and 36 months (low-fibre group) to last follow-up colonoscopy Setting: outpatients, multicenter, USA
Participants	Inclusion criteria: age 40-80 yrs, removal of ≥ 1 colonic adenoma(s) > 3 mm at colonoscopy within 3 months of study entry, adequate nutritional status, normal renal and liver function Exclusion criteria: invasive cancer ≤ 5 years, ≥ 2 first degree relatives with CRC previous colon resection N = 1429 Sex: % male (low-fibre group/high-fibre group): 65.2/67.1 Age: mean (low-fibre group/high-fibre group): 66.0/66.8 years Baseline dietary fibre intake g/day: ~ 19 g Baseline characteristics similar for each group: yes
Interventions	1. High-fibre group: WBF 13.5 g/d. N = 802 2. Low-fibre group: WBF 2.0 g/d. N = 627
Outcomes	Adenoma recurrence

Alberts 2000 (Continued)

Adenoma size

Multiple adenomas

Colorectal cancer occurrence

Notes

1. Adenoma defined as recurrent if found during any endoscopic procedure after the 1-year colonoscopy
2. Colonoscopy +/- polypectomy at 1 and 3 years after randomisation

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	The sequence generation was described as randomised, however, there was a large discrepancy (175 people) in the number of between intervention and control group suggesting that randomisation was not generated successfully and may be biased.
Allocation concealment (selection bias)	Low risk	"The treatment assignments were not revealed to the participants, their physicians, or members of the study staff."
Blinding (performance bias and detection bias) All outcomes	High risk	Described as double-blind but participants were aware of receiving cereal
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Described as double-blind but not stated who was blinded
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Reasons for loss to follow-up not reported, 126 out of 1429 participants (8.8%) dropped out from the study early
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported
Other bias	Unclear risk	No details

Bonithon-Kopp 2000

Methods	<p>Allocation: randomised after stratification according to centre, in a 3-group parallel design</p> <p>Blindness: double</p> <p>Duration: 3 years' follow-up</p> <p>Setting: multicenter in 10 countries (Belgium, Denmark, France, Germany, Ireland, Israel, Italy, Portugal, Spain, and the UK)</p>
Participants	<p>Inclusion criteria: complete colonoscopy demonstrating ≥ 2 adenomas or 1 adenoma ≥ 5 mm, age 35-75, at entry with a complete colonoscopy and a clean colon (Faivre 1997), no debilitating disease</p> <p>Exclusion criteria: FAP, IBD, colonic resection, CRC, contraindication to calcium or fibre.</p> <p>N = 665</p> <p>Sex: % male (calcium/fibre/placebo) 65.9/64.6/60.1</p> <p>Age: mean (calcium/fibre/placebo) 58.8/59.1/59.3 years</p> <p>Baseline dietary fibre intake g/day: ~ 19 g</p>

Bonithon-Kopp 2000 (Continued)

Baseline characteristics similar for each group: yes

Interventions	<ol style="list-style-type: none"> 1. Calcium gluconolactate and carbonate 2 g twice daily. N = 218 2. Ispaghula husk 3.5 g/d. N = 226 3. Control group: placebo. N = 221
Outcomes	Adenoma recurrence Adenoma size Adverse effects
Notes	<ol style="list-style-type: none"> 1. Colonoscopy +/- polypectomy 3 years after randomisation 2. Adenoma defined as recurrent if found during any endoscopic procedure at least 1 year after the index colonoscopy 3. 552/640 underwent the 3-year colonoscopy (86%) 4. Stopped treatment: calcium/fibre/placebo: 20%/17%/14%. Overall, 69%/79%/82% were \geq 80% compliant with treatment 5. Baseline dietary fibre was approximately 20 g/d

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation after stratification according to centre, in a 3-group parallel design
Allocation concealment (selection bias)	Low risk	Independent randomisation centre
Blinding (performance bias and detection bias) All outcomes	Low risk	Participants, staff in the clinical centre, and study investigators were not aware of the treatment assignments.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	It is unclear if outcome assessors were blinded.
Incomplete outcome data (attrition bias) All outcomes	High risk	Full reasons for loss to follow-up not given. High attrition rate 17.0%, 113 out of 665 participants dropped out from the study early.
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported.
Other bias	High risk	Recruitment was lower than intended. The original intended sample size to detect a 15% difference in new adenoma formation rate was 210 participants in each arm, but the number of people who completed the study in the treatment arm was 198, and 178 in the placebo arm.

Decosse 1989

Methods	Allocation: randomly assigned based on a table of random numbers Blindness: quote: "Only the pharmacist and the statistician knew the treatment allocations. One patient, a nurse, obtained a chemical analysis of her placebo capsule; all other patients and investigators remained blinded." (p.1291)
---------	---

Decosse 1989 (Continued)

Duration: 4 years

Setting: USA

Participants	<p>Inclusion criteria: adults with familial adenomatous polyposis; each of these participants had had a total colectomy and ileorectal anastomosis at least 1 year before entry into the trial</p> <p>Exclusion criteria: not stated</p> <p>N = 62. (4 participants withdrew from the study early)</p> <p>Sex: % male 36.2</p> <p>Age: mean (Group 1/Group 2/Group 3) 35.2/31.0/34.7 years</p> <p>Baseline dietary fibre intake g/d: not reported</p> <p>Baseline characteristics similar for each group: no, the gender distribution was not similar</p>
Interventions	<ol style="list-style-type: none"> 1. Low-fibre supplement (2.2 g/d) + placebo. N = 22 2. Low-fibre supplement (2.2 g/d) + ascorbic acid (4 g/d) and alpha-tocopherol (400 mg/d). N = 16 3. High-fibre supplement (22.5 g/d) + ascorbic acid (4 g/d) and alpha-tocopherol (400 mg/d). N = 20
Outcomes	<p>Unable to use:</p> <p>Adverse events (no adverse symptoms or findings could be attributed to the treatment agents)</p> <p>Compliance</p> <p>Dietary analysis</p> <p>Polyp number ratios</p>
Notes	<p>This study was supported by Public Health Service grants CA-31711 and CA-43601 from the National Cancer Institute, National Institutes of Health, Department of Health and Human Services</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Participants were randomly assigned based on a table of random numbers.
Allocation concealment (selection bias)	Unclear risk	No details
Blinding (performance bias and detection bias) All outcomes	Low risk	"Only the pharmacist and the statistician knew the treatment allocations. One patient, a nurse, obtained a chemical analysis of her placebo capsule; all other patients and investigators remained blinded." (p.1291)
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No details
Incomplete outcome data (attrition bias) All outcomes	Low risk	4 participants withdrew from the study early. ITT analysis was used.
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported.
Other bias	Unclear risk	No details

MacLennan 1995

Methods	Allocation: randomised trial with a 2 x 2 x 2 factorial design Blindness: unclear Duration: 48 months Setting: multicenter, Australia
Participants	Inclusion criteria: age 30-74 yrs, ≥ one adenoma, polyp-free colon post colonoscopy Exclusion criteria: IBD, bowel resection, FAP, cancer, medically supervised diet N = 424* Sex: % male (monitoring at 24 months/48 months) 66.7/68.0 Age: mean (monitoring at 24 months/48 months) 56.3/55.9 years Baseline dietary fibre intake g/d: not reported Baseline characteristics similar for each group: yes
Interventions	1. WBF 25 g /d. N = 193* 2. No WBF supplement. N = 197*
Outcomes	Adenoma recurrence Adenoma size
Notes	Other Interventions arms not used: 1. Fat reduction to 25% of total energy, baseline counselling by dietician then periodic further counselling 2. BC 20 mg/d Control: 1. Unmodified diet 2. Placebo capsule daily *The study randomised 424 participants, however, they did not report the number of participants in each group. Only data from 390 participants were reported with 193 in the WBF group and 197 in the WBF supplement group, respectively. So we conducted the sensitivity analysis based on 390 participants

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomized trial with a 2 x 2 x 2 factorial design, following pre-randomisation stratification. Randomisation was computerised
Allocation concealment (selection bias)	Unclear risk	No details
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Described as partially double-blind but did not state who was blinded.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Described as partially double-blind but did not state who was blinded.

MacLennan 1995 (Continued)

Incomplete outcome data (attrition bias) All outcomes	High risk	Full reasons for loss to follow-up not given. High attrition rate (27.8%), 118 participants lost to follow-up at 48 months
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported.
Other bias	Unclear risk	No details

McKeown-Eyssen 1994

Methods	Allocation: randomised Blindness: no Duration: 24 months Setting: 7 Toronto hospitals, Canada
Participants	Inclusion criteria: ≥ 1 pathologically confirmed colorectal adenomatous polyp, after polypectomy for adenomatous colorectal polyps, age < 85 years Exclusion criteria: FAP, celiacs, severe osteoporosis, cancer < 5 years, medical or dietary treatment for IBD, diverticular disease, renal or liver disease, anaemia, gallbladder disease, hiatal hernia N = 201 Sex: % male (low fat, high fibre diet/normal diet) 56.6/52.9 Age: mean 57.9/57.7 years Baseline dietary fibre intake g/d: 18 g (intervention), 15 g (control) Baseline characteristics similar for each group: protein, carbohydrates. vitamin D, riboflavin and total calories significantly higher in the intervention group; majority of baseline markers were not significantly different
Interventions	1. Low fat, high fibre diet: dietary targets of 20% of calories from fat sources and at least 50 g of dietary fibre/d, high WBF snack 20 g of fibre per 100 g package available, monthly nutritional counselling. N = 99 2. Normal diet: low WBF snack of 3 g of fibre per 50 g package, counselling on Canadian guidelines for a nutritionally balanced diet every 4 months. N = 102
Outcomes	Adenoma recurrence
Notes	1. Colonoscopy +/- polypectomy 2 years after randomisation 2. Adenoma defined as recurrent if it occurs in a region of the colon documented as free of polyps at the initial examination 3. 165/201 had follow-up colonoscopy. Of these 165 participants, 23 withdrew from counselling (10 in the control group and 13 in the treatment group) 4. Treatment group reduced fat intake to approximately 25% of calories, increased fibre by 6.9 g per 1000 kcal and fruit and vegetables by 66% 5. No adverse effects reported
Risk of bias	
Bias	Authors' judgement Support for judgement

McKeown-Eyssen 1994 (Continued)

Random sequence generation (selection bias)	Low risk	Randomised by stratification
Allocation concealment (selection bias)	Unclear risk	No details
Blinding (performance bias and detection bias) All outcomes	High risk	Participants were aware of the details of their diet
Blinding of outcome assessment (detection bias) All outcomes	Low risk	The endoscopist performed both the initial and follow-up examinations without knowledge of the participants's dietary assignment
Incomplete outcome data (attrition bias) All outcomes	High risk	Reasons for loss to follow-up not described. High attrition rate (17.9%) 36 out of 201 participants lost to follow-up
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported
Other bias	Unclear risk	No details

Schatzkin 2000

Methods	Allocation: randomised Blindness: no Duration: 4 years (with a further follow-up after an additional 4 years) Setting: 8 clinical centres, USA
Participants	Inclusion criteria: ≥ 1 large bowel adenoma removed within 6 months, polyp-free colon post colonoscopy, age ≥ 35 years Exclusion criteria: CRC, bowel resection, IBD, FAP, weight $> 150\%$ of recommended, lipid-lowering drugs N = 2079 Sex: % male (intervention/control) 65.8/63.2 Age: mean (intervention/control) 61.0/61.1 Baseline dietary fibre intake g/d: not reported Baseline characteristics similar for each group: yes
Interventions	1. Treatment: dietary targets of 20% of calories from fat, 18 g of dietary fibre/1000 kcal, and 5-8 servings of fruits and vegetables/d. Over 50 h of dietary counselling. N = 1037 2. Control: general dietary guidelines with no additional information provided. N = 1042
Outcomes	Adenoma recurrence Colorectal cancer occurrence Adenoma size Multiple adenomas
Notes	1. Colonoscopy +/- polypectomy at 1 and 4 years after randomisation.

Schatzkin 2000 (Continued)

2. Adenoma defined as recurrent if it was found during any endoscopic procedure after the 1-year colonoscopy
3. Treatment group reduced fat intake to approximately 25% of calories, doubled fibre intake to 30-35 g/d
4. Adverse effects not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation stratified by clinical centre. Assignment done by a computer programme
Allocation concealment (selection bias)	Unclear risk	No details
Blinding (performance bias and detection bias) All outcomes	High risk	Participants were aware of treatment regimens.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Participants were aware of allocation, but were told not to tell the endoscopist.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Reasons for loss to follow-up were reported, 174 out of 2079 participants (8.4%) dropped out from the study.
Selective reporting (reporting bias)	Low risk	All measured outcomes were reported.
Other bias	Unclear risk	None identified

BC: beta carotene

CRC: colorectal cancer

IBD: inflammatory bowel disease

FAP: familial adenomatous polyposis

ITT: intention-to-treat

RCT: randomised controlled trial

WBF: wheat bran fibre

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Alberts 1996c	Not RCT. Review article
Almendingen 2009	Not RCT
Burn 2011a	Participants were diagnosed with Lynch syndrome in this study. Only a minority of participants had a procedure to remove polyps and data were unavailable for the few participants who had the procedure. Furthermore, the control group intervention was aspirin rather than placebo.
Campos 2005	Not RCT. Review article
Dove-Edwin 2001	Not RCT. Review article

Study	Reason for exclusion
Faivre 1998	Not RCT. Review article
Faivre 2002	Not RCT. Review article
French 2003	Not RCT. Review article
Gatof 2002	Not RCT. Review article
Hirose 2004	Not RCT. Review article
Ho 1991	Feasibility study, not RCT. Outcome measures were not by direct visualisation
Jacobs 2006	Not RCT, but pooled analysis from two trials which has been included by our review
Kunzmann 2015	The interventions did not meet inclusion criteria: flexible sigmoidoscopy vs usual medical care.
Lanza 2001	Article is only on the changes in dietary intake for included study Schatzkin 2000 .
Limburg 2011	The intervention was ORAFIT_Synergy1 probiotic supplement, and not dietary fibre
Rock 2007	Not RCT. Review article
Sengupta 2001	Not RCT. Review article
Shike 1999a	Not RCT. Review article
Vitanzo 2000	This is only a summary of the included Alberts 2000 study. No additional new data
Witte 1996	Not RCT

RCT: randomised controlled trial

Characteristics of studies awaiting assessment *[ordered by study ID]*

[Macrae 2014](#)

Methods	Double blind, randomised, cross-over placebo-controlled trial
Participants	Participants with Familial Adenomatous Polyposis (FAP)
Interventions	Dietary butyrylated high amylose maize starch vs placebo
Outcomes	No details This is a conference abstract, awaiting full report
Notes	Awaiting full report

Ishikawa 2000 (Continued)

Methods	RCT
Participants	People with CRA
Interventions	Wheat bran fibre
Outcomes	Rate of CRA, CRC
Starting date	1997
Contact information	NA
Notes	Authors of this review tried to contact Dr Ishikawa (last email sent on 6 April 2016) for further information, but have not received a reply.

CRA: colorectal adenoma
 CRC: colorectal cancer
 RCT: randomised controlled trial

DATA AND ANALYSES
Comparison 1. Dietary fibre (all study interventions) versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	5	3641	Risk Ratio (M-H, Fixed, 95% CI)	1.04 [0.95, 1.13]
2 Number of participants with more than one adenoma	2	2542	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.94, 1.20]
3 Number of participants with at least one adenoma 1 cm or greater	4	3224	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.82, 1.20]
4 Number of participants diagnosed with colorectal cancer	2		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
4.1 One- year data	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	1.98 [0.36, 10.77]
4.2 Up to 4 years	2	2794	Risk Ratio (M-H, Fixed, 95% CI)	2.70 [1.07, 6.85]

Analysis 1.1. Comparison 1 Dietary fibre (all study interventions) versus control, Outcome 1 Number of participants with at least one recurrent adenoma.

Analysis 1.2. Comparison 1 Dietary fibre (all study interventions) versus control, Outcome 2 Number of participants with more than one adenoma.

Analysis 1.3. Comparison 1 Dietary fibre (all study interventions) versus control, Outcome 3 Number of participants with at least one adenoma 1 cm or greater.

Analysis 1.4. Comparison 1 Dietary fibre (all study interventions) versus control, Outcome 4 Number of participants diagnosed with colorectal cancer.

Comparison 2. Wheat bran fibre versus control

Outcome or subgroup title	No. of studies	No. of partici- pants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	2	1195	Risk Ratio (M-H, Fixed, 95% CI)	1.01 [0.87, 1.18]
2 Number of participants with more than one adenoma	1	637	Risk Ratio (M-H, Fixed, 95% CI)	1.11 [0.97, 1.29]
3 Number of participants with at least one adenoma 1 cm or greater	1	637	Risk Ratio (M-H, Fixed, 95% CI)	1.04 [0.83, 1.31]

Analysis 2.1. Comparison 2 Wheat bran fibre versus control, Outcome 1 Number of participants with at least one recurrent adenoma.

Analysis 2.2. Comparison 2 Wheat bran fibre versus control, Outcome 2 Number of participants with more than one adenoma.

Analysis 2.3. Comparison 2 Wheat bran fibre versus control, Outcome 3 Number of participants with at least one adenoma 1 cm or greater.

Comparison 3. Wheat bran fibre and low fat diet versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	1	165	Risk Ratio (M-H, Fixed, 95% CI)	1.19 [0.64, 2.18]

Analysis 3.1. Comparison 3 Wheat bran fibre and low fat diet versus control, Outcome 1 Number of participants with at least one recurrent adenoma.

Comparison 4. Wheat bran fibre with or without low fat diet versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	3	1360	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.88, 1.19]
2 Number of participants with more than one adenoma	1	637	Risk Ratio (M-H, Fixed, 95% CI)	1.11 [0.97, 1.29]
3 Number of participants with at least one adenoma 1 cm or greater	2	943	Risk Ratio (M-H, Fixed, 95% CI)	1.02 [0.81, 1.27]

Analysis 4.1. Comparison 4 Wheat bran fibre with or without low fat diet versus control, Outcome 1 Number of participants with at least one recurrent adenoma.

Analysis 4.2. Comparison 4 Wheat bran fibre with or without low fat diet versus control, Outcome 2 Number of participants with more than one adenoma.

Analysis 4.3. Comparison 4 Wheat bran fibre with or without low fat diet versus control, Outcome 3 Number of participants with at least one adenoma 1 cm or greater.

Comparison 5. Comprehensive dietary intervention versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma (4 years)	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	1.00 [0.90, 1.12]
2 Number of participants with at least one recurrent adenoma (8 years)	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	0.97 [0.78, 1.20]
3 Number of participants with more than one adenoma (4 years)	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	1.01 [0.83, 1.24]
4 Number of participants with more than one adenoma (8 years)	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	0.89 [0.64, 1.24]
5 Number of participants with at least one adenoma 1 cm or greater	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	0.88 [0.60, 1.28]

Analysis 5.1. Comparison 5 Comprehensive dietary intervention versus control, Outcome 1 Number of participants with at least one recurrent adenoma (4 years).

Analysis 5.2. Comparison 5 Comprehensive dietary intervention versus control, Outcome 2 Number of participants with at least one recurrent adenoma (8 years).

Analysis 5.3. Comparison 5 Comprehensive dietary intervention versus control, Outcome 3 Number of participants with more than one adenoma (4 years).

Analysis 5.4. Comparison 5 Comprehensive dietary intervention versus control, Outcome 4 Number of participants with more than one adenoma (8 years).

Analysis 5.5. Comparison 5 Comprehensive dietary intervention versus control, Outcome 5 Number of participants with at least one adenoma 1 cm or greater.

Comparison 6. Ispaghula husk versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	1	376	Risk Ratio (M-H, Fixed, 95% CI)	1.45 [1.01, 2.08]
2 Number of participants with at least one adenoma 1 cm or greater	1	376	Risk Ratio (M-H, Fixed, 95% CI)	1.80 [0.55, 5.87]
3 Number of participants with at least one adverse effect	1	376	Risk Ratio (M-H, Fixed, 95% CI)	0.90 [0.18, 4.40]

Analysis 6.1. Comparison 6 Ispaghula husk versus control, Outcome 1 Number of participants with at least one recurrent adenoma.

Analysis 6.2. Comparison 6 Ispaghula husk versus control, Outcome 2 Number of participants with at least one adenoma 1 cm or greater.

Analysis 6.3. Comparison 6 Ispaghula husk versus control, Outcome 3 Number of participants with at least one adverse effect.

Comparison 7. Sensitivity analysis 1. Dietary fibre (all study interventions) versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Number of participants with at least one recurrent adenoma	5		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.1 Completers only	5	3641	Risk Ratio (M-H, Fixed, 95% CI)	1.04 [0.95, 1.13]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.2 Best case scenario	5	4536	Risk Ratio (M-H, Fixed, 95% CI)	0.61 [0.57, 0.66]
1.3 Worst case scenario	5	4536	Risk Ratio (M-H, Fixed, 95% CI)	1.73 [1.60, 1.88]
2 Number of participants with more than one adenoma	2		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
2.1 Completers only	2	2542	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.94, 1.20]
2.2 Best case scenario	2	3508	Risk Ratio (M-H, Fixed, 95% CI)	0.43 [0.38, 0.47]
2.3 Worst case scenario	2	3508	Risk Ratio (M-H, Fixed, 95% CI)	2.48 [2.23, 2.77]
3 Number of participants with at least one adenoma 1 cm or greater	4		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
3.1 Completers only	4	3224	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.82, 1.20]
3.2 Best case scenario	4	4335	Risk Ratio (M-H, Fixed, 95% CI)	0.22 [0.19, 0.26]
3.3 Worst case scenario	4	4335	Risk Ratio (M-H, Fixed, 95% CI)	4.15 [3.56, 4.85]
4 Number of participants diagnosed with colorectal cancer	2		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
4.1 One- year data - completers only	1	1905	Risk Ratio (M-H, Fixed, 95% CI)	1.98 [0.36, 10.77]

Appendix 4. Criteria for judging risk of bias in the 'Risk of bias' assessment tool

Random sequence generation

Selection bias (biased allocation to interventions) due to inadequate generation of a randomised sequence.

Criteria for a judgement of 'low risk' of bias

The investigators describe a random component in the sequence generation process such as:

- referring to a random number table;
- using a computer random number generator;
- coin tossing;
- shuffling cards or envelopes;
- throwing dice;
- drawing of lots;
- minimisation*.

*Minimisation may be implemented without a random element, and this is considered to be equivalent to being random.

(Continued)

Criteria for the judgement of 'high risk' of bias	<p>The investigators describe a non-random component in the sequence generation process. Usually, the description would involve some systematic, non-random approach, for example:</p> <ul style="list-style-type: none"> • sequence generated by odd or even date of birth; • sequence generated by some rule based on date (or day) of admission; • sequence generated by some rule based on hospital or clinic record number. <p>Other non-random approaches happen much less frequently than the systematic approaches mentioned above and tend to be obvious. They usually involve judgement or some method of non-random categorisation of participants, for example:</p> <ul style="list-style-type: none"> • allocation by judgement of the clinician; • allocation by preference of the participant; • allocation based on the results of a laboratory test or a series of tests; • allocation by availability of the intervention.
Criteria for the judgement of 'unclear risk' of bias	Insufficient information about the sequence generation process to permit judgement of 'low risk' or 'high risk'

Allocation concealment

Selection bias (biased allocation to interventions) due to inadequate concealment of allocations prior to assignment.

Criteria for a judgement of 'low risk' of bias	<p>Participants and investigators enrolling participants could not foresee assignment because one of the following, or an equivalent method, was used to conceal allocation:</p> <ul style="list-style-type: none"> • central allocation (including telephone, web-based and pharmacy-controlled randomisation); • sequentially numbered drug containers of identical appearance; • sequentially numbered, opaque, sealed envelopes.
Criteria for the judgement of 'high risk' of bias	<p>Participants or investigators enrolling participants could possibly foresee assignments and thus introduce selection bias, such as allocation based on:</p> <ul style="list-style-type: none"> • using an open random allocation schedule (e.g. a list of random numbers); • assignment envelopes were used without appropriate safeguards (e.g. if envelopes were unsealed or nonopaque or not sequentially numbered); • alternation or rotation; • date of birth; • case record number; • any other explicitly unconcealed procedure.
Criteria for the judgement of 'unclear risk' of bias	Insufficient information to permit judgement of 'low risk' or 'high risk'. This is usually the case if the method of concealment is not described or not described in sufficient detail to allow a definite judgement – for example if the use of assignment envelopes is described, but it remains unclear whether envelopes were sequentially numbered, opaque and sealed.

Blinding of participants and personnel

Performance bias due to knowledge of the allocated interventions by participants and personnel during the study.

Criteria for a judgement of 'low risk' of bias	<p>Any one of the following:</p> <ul style="list-style-type: none"> • no blinding or incomplete blinding, but the review authors judge that the outcome is not likely to be influenced by lack of blinding; • blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken.
--	--

(Continued)

Criteria for the judgement of 'high risk' of bias	Any one of the following: <ul style="list-style-type: none"> no blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding; blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.
---	---

Criteria for the judgement of 'unclear risk' of bias	Any one of the following: <ul style="list-style-type: none"> insufficient information to permit judgement of 'low risk' or 'high risk'; the study did not address this outcome.
--	---

Blinding of outcome assessment

Detection bias due to knowledge of the allocated interventions by outcome assessors.

Criteria for a judgement of 'low risk' of bias	Any one of the following: <ul style="list-style-type: none"> no blinding of outcome assessment, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding; blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.
--	--

Criteria for the judgement of 'high risk' of bias	Any one of the following: <ul style="list-style-type: none"> no blinding of outcome assessment, and the outcome measurement is likely to be influenced by lack of blinding; blinding of outcome assessment, but likely that the blinding could have been broken, and the outcome measurement is likely to be influenced by lack of blinding.
---	--

Criteria for the judgement of 'unclear risk' of bias	Any one of the following: <ul style="list-style-type: none"> insufficient information to permit judgement of 'low risk' or 'high risk'; the study did not address this outcome.
--	---

Incomplete outcome data

Attrition bias due to amount, nature or handling of incomplete outcome data.

Criteria for a judgement of 'low risk' of bias	Any one of the following: <ul style="list-style-type: none"> no missing outcome data; reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias); missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk not enough to have a clinically relevant impact on the intervention effect estimate; for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes not enough to have a clinically relevant impact on observed effect size; missing data have been imputed using appropriate methods.
--	--

Criteria for the judgement of 'high risk' of bias	Any one of the following: <ul style="list-style-type: none"> reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate;
---	---

(Continued)

- for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size;
- ‘as-treated’ analysis done with substantial departure of the intervention received from that assigned at randomisation;
- Potentially inappropriate application of simple imputation.

Criteria for the judgement of ‘unclear risk’ of bias

Any one of the following:

- insufficient reporting of attrition/exclusions to permit judgement of ‘Low risk’ or ‘High risk’ (e.g. number randomized not stated, no reasons for missing data provided);
- the study did not address this outcome.

Selective reporting

Reporting bias due to selective outcome reporting.

Criteria for a judgement of ‘low risk’ of bias

Any of the following:

- the study protocol is available and all of the study’s pre-specified (primary and secondary) outcomes that are of interest in the review have been reported in the pre-specified way;
- the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were pre-specified (convincing text of this nature may be uncommon).

Criteria for the judgement of ‘high risk’ of bias

Any one of the following:

- not all of the study’s pre-specified primary outcomes have been reported;
- one or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not pre-specified;
- one or more reported primary outcomes were not pre-specified (unless clear justification for their reporting is provided, such as an unexpected adverse effect);
- one or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis;
- the study report fails to include results for a key outcome that would be expected to have been reported for such a study.

Criteria for the judgement of ‘unclear risk’ of bias

Insufficient information to permit judgement of ‘low risk’ or ‘high risk’. It is likely that the majority of studies will fall into this category.

Other bias

Bias due to problems not covered elsewhere in the table.

Criteria for a judgement of ‘low risk’ of bias

The study appears to be free of other sources of bias.

Criteria for the judgement of ‘high risk’ of bias

There is at least one important risk of bias. For example, the study:

- had a potential source of bias related to the specific study design used; or
- has been claimed to have been fraudulent; or
- had some other problem.

Criteria for the judgement of ‘unclear risk’ of bias

There may be a risk of bias, but there is either:

- insufficient information to assess whether an important risk of bias exists; or
- insufficient rationale or evidence that an identified problem will introduce bias.

WHAT'S NEW

Date	Event	Description
4 April 2016	New citation required but conclusions have not changed	New searches performed. Two new identified RCTs included in this update.

HISTORY

Protocol first published: Issue 1, 2002

Review first published: Issue 2, 2002

Date	Event	Description
24 June 2013	New citation required but conclusions have not changed	New search run and one further report with 8- year follow- up data added. Converted to new review format.
13 November 2001	New citation required and conclusions have changed	Substantive amendment

CONTRIBUTIONS OF AUTHORS

Yibo Yao - screened the search results, helped write the report

Tao Suo - provided advice for study inclusion and helped write the report

Roland Andersson - provided advice for study inclusion

Yong Qing Cao - performed data extraction

Chen Wang - performed data extraction

Jingen Lu - screened the search results

Evelyne Chui - statistical support and helped write the report.

DECLARATIONS OF INTEREST

Yibo Yao - none

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

This updated review has been performed according to the required methodological expectations of Cochrane intervention reviews (MECIR).

We added sensitivity analysis in the 'Dealing with missing data' section to test whether the missing data has an important impact to the results. We stated in our text that "...for those data derived from completers only, we conducted sensitivity analysis in best/worst case scenario to assess the impact of missing data on the estimates of effect". We also added the results of sensitivity analysis for each outcomes in the 'Effects of interventions' section. We discussed the impact of missing data in the 'Discussion, Quality of the evidence' section by stating that "For the risk of bias in included studies, we considered the attrition bias as a major concern. The sensitivity analysis in best and worst case scenarios showed contrary results, which means the missing data did have a significant impact on our results."
