Supporting Information

ABSTRACT: Due to its expression in various malignant tumors, the neurotensin receptor 1 (NTS₁R) has been suggested and explored as a target for tumor diagnosis and therapy. Animal model-based investigations of various radiolabeled NTS₁R ligands derived from the hexapeptide neurotensin(8–13) (NT(8–13)), e.g. ⁶⁸Ga- and ¹⁸F-labeled compounds for PET diagnostics, give rise to optimize such radiotracers for clinical use. As NT(8–13) is rapidly degraded in vivo; structural modifications are required in terms of increased metabolic stability. In this study, the stabilization of the peptide backbone of NT(8–13) against enzymatic degradation was systematically explored by performing an *N*-methyl scan, replacing Ile¹² by *tert*-butylglycine¹² (Tle¹²) and *N*-terminal acylation. *N*-Methylation of either arginine, Arg⁸, or Arg⁹, combined with the Ile¹²/Tle¹² exchange, proved to be most favorable with respect to NTS₁R affinity ($K_i < 2$ nM) and stability in human plasma ($t_{1/2} > 48$ h), a valuable result regarding the development of radiopharmaceuticals derived from NT(8–13).

KEYWORDS: Peptide, neurotensin, NT(8–13), neurotensin receptor, plasma stability

The neuromodulator neurotensin (NT), a 13 amino acid peptide (Figure 1), is found in the central nervous system

Figure 1. Amino acid sequences of neurotensin, 1 (NT(8–13), in blue) and 2, as well as major enzymatic cleavage sites (in red) of 1.^{3,24,25} EC 3.4.24.15: metalloendopeptidase 24.15, EC 3.4.24.16: metalloendopeptidase 24.16, EC 3.4.24.11: neutral endopeptidase 24.11, EC 3.4.15.1: angiotensin converting enzyme (ACE).^{24,25} ^aBarroso et al.⁴¹ ^bKeller et al.⁴²

(CNS), mediating e.g. analgesic effects, as well as in the periphery (primarily in the gastrointestinal tract).^{1,2} The carboxy-terminal hexapeptide of NT (NT(8–13) (1), Figure 1), is biologically equi-active to NT.³ The physiological effects of NT are mediated by three cell-surface receptors: the NT receptors 1 and 2 (NTS₁R, NTS₂R), both G-protein coupled receptors,⁴ and the NTS₃R, which belongs to the Vps10p-domain receptor family.^{2,5} The NTS₁R has increasingly gained interest as a target for tumor diagnosis and therapy, as it was

reported to be (over)expressed in a variety of malignancies, among them the prognostically poor pancreatic adenocarcinoma, Ewing's sarcoma, breast cancer, and colorectal carcinoma.^{6–9} Thus, radiolabeled NTS₁R ligands harbor the potential of being used as radiopharmaceuticals. The majority of such compounds (e.g., ⁶⁸Ga- and ¹⁸F-labeled for PET diagnostics, ¹⁷⁷Lu-labeled for radioendotherapy) has been derived from the agonist 1.^{10–19} Noteworthy, also NTS₁R ligands derived from nonpeptidic antagonists have been explored as radiodiagnostics and radiotherapeutics.^{20,21} Recently reported data of a clinical trial on the treatment of pancreatic adenocarcinoma in men by ¹⁷⁷Lu-labeled NTS₁R antagonists give reason to develop clinical trial candidates with improved properties.²² Therefore, peptidic NTS₁R ligands, such as radiolabeled derivatives of 1, should be considered for clinical trials.

A major drawback of peptide 1 is its rapid degradation in vivo by peptidases (see Figure 1).^{23,24} Enzymatic degradation of 1 occurs at three major sites: the Arg⁸–Arg⁹ bond, the Pro¹⁰–Tyr¹¹ bond, and the bond between Tyr¹¹ and Ile¹² (cf. Figure 1).^{24,25} The predominant approaches to stabilize the backbone of 1 are *N*-methylation of Arg⁸ or Arg⁹, *N*-terminal acylation, and the exchange of Ile¹² by *tert*-butylglycine (Tle).^{10–15,17,26–38} However, for some interesting analogs

^aReagents and conditions: (I) Fmoc strategy SPPS using HBTU/HOBt and DIPEA, solvent: DMF/NMP (80:20 v/v), 35 °C, 2 × 1 h or 2 × 2 h, Fmoc-deprotection: 20% piperidine in DMF/NMP (80:20 v/v), rt, 2 × 8–10 min; (II) (1) hexafluoro-2-propanol (HFIP)/CH₂Cl₂ (1:3 v/v), rt, 2 × 20 min, (2) TFA/H₂O (95:5 v/v), rt, 3 h; (III) DIPEA, solvent: CH₂Cl₂, 35 °C, 14 h; (IV) DIPEA, solvent: DMF/NMP (80:20 v/v), rt, 1 h; overall yields 77% (2), 67% (3), 56% (4), 18% (5), 15% (6), 42% (7), 38% (8), 20% (9), 56% (11), 85% (12).

of **1**, such as *N*-methylated derivatives, investigations on the stability are lacking.^{33,39} It is worth mentioning that described derivatives of **1**, containing Tle¹² instead of Ile¹², include additional structural modifications throughout;^{10–12,29,31,32,38,40} that is, [Tle¹²]NT(8–13) (**2**, cf. Figure 1) has not been reported to date to the best of the authors' knowledge. Therefore, it is difficult to estimate the impact of the Ile¹²/Tle¹² exchange on the stability of Tle¹²-containing derivatives of **1**.

Aiming at a systematic study on the stabilization of the NT(8–13) core structure, we synthesized compound **2**, performed an *N*-methyl scan of **1**, combined *N*-methylation with the Ile¹²/Tle¹² exchange, and, additionally, prepared *N*-terminally acylated derivatives of **1**. All compounds were studied with respect to NTS₁R binding and plasma stability.

Peptides **2**, **3**,³⁴ **4**,³³ **5**,^{33,39} **6**,³³ **7**, **8**, and **9**³³ were prepared by solid-phase peptide synthesis (SPPS) according to the 9-fluorenylmethoxycarbonyl (Fmoc) protecting group strategy using 1-hydroxybenzotriazole (HOBt)/*O*-(1*H*-benzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HBTU) and diisopropylethylamine (DIPEA) for amide bond formation (Scheme 1). Coupling of Fmoc-protected amino acids to the secondary amino group of *N*-methylated amino acids turned out to be the yield limiting factor in the cases of **5**, **6**, and **9** (overall yields 18%, 15%, and 20%, respectively). The *N*-terminally propionylated derivative **11** was obtained by treatment of the respective resin-bound, side chain-protected, but *N*-terminally deprotected precursor peptide with succinimidyl propionate (**10**) followed by cleavage off the resin and side chain deprotection. By contrast, the *N*-terminally propionylated peptide **12** was prepared by solution phase treatment of **2** with compound **10** (Scheme 1).

NTS₁R binding data (*K_i* values) were determined for **1–9**, **11**, and **12** by competition binding with [³H]UR-MK300⁴² ([³H]**13**, for structure see Figure S1, Supporting Information) at intact hNTS₁R expressing HT-29 colon carcinoma cells (Table 1). The replacement of Ile¹² by Tle¹² in **1** (compound **2**) resulted in a minor decrease in NTS₁R affinity (*K_i* values of **1** and **2**: 0.33 vs 1.17 nM, cf. Table 1). Regarding the *N*-methyl scan of **1** (peptides **3–6** and **9**), methylation at Arg⁸ or Arg⁹ (**3**, **4**) did not affect NTS₁R affinity (*K_i* < 0.5 nM, Table 1). By contrast, *N*-methylation of Tyr¹¹, Ile¹², or Leu¹³ (**5**, **6**, **9**) led to a considerable decrease in NTS₁R affinity (*K_i* values: > 1,000 nM, 60 nM and 880 nM, respectively, cf. Table 1). As expected, the combination of the *N*-methylation at Arg⁸ or Arg⁹ with the

^aDetermined by radioligand competition binding with [³H]**13** at HT-29 cells; mean values from two (**1**, **2**), three (**3**, **4**) or four (**6–9**, **11**, **12**) independent experiments, each performed in triplicate (for *n* > 2 *K_i* values are given ± SEM; in the case of *n* = 2 individual *K_i* values are given in square brackets). ^bThe initial concentration of the peptides in plasma/PBS (1:2 v/v) was 100 μM; presented are mean values ± SEM from three independent experiments (SEM not given if no decomposition was observed). ^cKeller et al.⁴² ^dOrwig et al.³⁴ ^eHärterich et al.³³ n.d. = not determined.

replacement of Ile¹² by Tle¹² (peptides 7 and 8) resulted in NTS₁R affinities comparable to that of 2 (Table 1). The N-terminally propionylated analogs of 1 and 2 (compounds 11 and 12) exhibited K_i values (NTS₁R) of 1.0 and 18 nM, respectively.

Figure 2 illustrates a general decrease in NTS₁R affinity caused by the replacement of Ile¹² by Tle¹² in 1, 3, 4, and 11, respectively.

Figure 2. Decrease in NTS₁R affinity (increase in K_i) resulting from the exchange of Ile¹² by Tle¹² in 1, 3, 4, and 11 (black bars) giving 2, 7, 8, and 12 (gray bars), respectively. Note: the scales of the Y-axes are different.

giving 2, 7, 8, and 12, respectively, and a dependency of the extent of the decrease in affinity on the primary structure of the peptides. This is in agreement with reported NTS₁R binding data of derivatives of 1 containing Tle¹².^{10,11,27,31,38,40}

In order to investigate the effect of N-methylation (3–9), Ile¹²/Tle¹² exchange (2, 7, 8, 12), and N-terminal acylation (11, 12) on the stability of the peptides against enzymatic

cleavage, the stability of all compounds was investigated in human plasma at 37 °C for up to 48 h (Figure 3, Table 1). Whereas N-methylation of Arg⁸ or Arg⁹ in 1 (compounds 3 and 4) significantly enhanced the peptide stability in plasma compared to 1, methylation of Tyr¹¹, Ile¹², and Leu¹³ (5, 6, 9) did not lead to higher plasma stabilities. Strikingly, peptide 2, which differed from 1 only with respect to the replacement of Ile¹² by Tle¹², proved to be as unstable as 1 (Figure 3, Table 1). However, the combination of the Ile¹²/Tle¹² exchange with N-methylation of Arg⁸ or Arg⁹ (7, 8) resulted in significantly higher plasma stabilities (*t*_{1/2} > 48 h) compared to 3 and 4. These results confirmed that both N-terminal (cleavage between Arg⁸ and Arg⁹) and C-terminal (cleavage between Tyr¹¹ and Ile¹²) degradation are highly relevant, and they revealed that the former occurs faster than the latter. As in the case of N-terminal methylation of 1 (peptide 3), N-terminal propionylation of 1 (peptide 11) resulted in a moderate increase in enzymatic stability compared to 1 (*t*_{1/2} of 11 between 1 and 2 h, cf. Table 1). The combination of N-terminal propionylation with an Ile¹²/Tle¹² exchange (compound 12) led to an excellent plasma stability as also observed in the case of combining N-terminal methylation with an Ile¹²/Tle¹² exchange (peptide 7) (Figure 3, Table 1).

Figure 4 provides an overview of the major degradation fragments identified by LC-HRMS. The Arg⁸–Arg⁹, Pro¹⁰–Tyr¹¹, and Tyr¹¹–Ile¹² bonds were identified as the major cleavage sites (Figure 4), being in agreement with reported data on the metabolic stability of 1.^{24,25} As outlined above, the present study suggests that cleavage of Arg⁸ in 1 occurs faster than its C-terminal degradation. This is, on the one hand, in agreement with reports in the literature;²⁴ on the other hand, it is in disagreement with other reports, which suggest an Ile¹²/Tle¹² exchange as the most crucial structural modification with respect to metabolic stabilization.^{27,28}

In conclusion, the synthesis and investigation of N-methylated derivatives of NT(8–13) (1), N-terminally acylated derivatives of 1, and analogs containing Tle¹² instead of Ile¹² revealed that only the combination of appropriate N-terminal (e.g., N-methylation

of Arg⁸) and C-terminal (replacement of Ile¹² by Tle¹²) structural modifications in **1** affords highly stable (plasma half-life >48 h) congeners of **1** (compounds **7**, **8**, and **12**). Fortunately, two of the most stable compounds (**7**, **8**) exhibited the highest NTS₁R affinities of the investigated analogs of **1**. This work answers open questions concerning the controversially discussed impact of various structural modifications of **1** on the enzymatic stability, thus supporting the development of stable radiolabeled derivatives of **1**, which harbor the potential of being used as radiopharmaceuticals.
