<sup>2</sup>Department of Pathology, Faculty of Veterinary Medicine, Mansoura University, Mansoura, Dakahlia 35516, Egypt

**Background:** Apocynin (APO) is a bioactive phytochemical with prominent anti-inflammatory and anti-oxidant activities. Designing a nano-delivery system targeted to potentiate the gastric antiulcerogenic activity of APO has not been investigated yet. Chitosan oligosaccharide (COS) is a low molecular weight chitosan and its oral nanoparticulate system for potentiating the antiulcerogenic activity of the loaded APO has been described here.

**Methods:** COS-nanoparticles (NP<sub>s</sub>) loaded with APO (using tripolyphosphate [TPP] as a cross-linker) were prepared by ionic gelation method and fully characterized. The chosen formula was extensively evaluated regarding in vitro release profile, kinetic analysis, and stability at refrigerated and room temperatures. Ultimately, the in vivo antiulcerogenic activity against ketoprofen (KP)-induced gastric ulceration in rats was assessed by macroscopic parameters including Paul's index and antiulcerogenic activity, histopathological examination, immunohistochemical (IHC) evaluation of cyclooxygenase-2 (COX-2) expression level in ulcerated gastric tissue, and biochemical measurement of oxidative stress markers and nitric oxide (NO) levels.

**Results:** The selected NP<sub>s</sub> formula with COS (0.5 % w/v) and TPP (0.1% w/v) was the most appropriate one with drug entrapment efficiency percentage of 35.06%, particle size of 436.20 nm, zeta potential of +38.20 mV, and mucoadhesive strength of 51.22%. It exhibited a biphasic in vitro release pattern as well as high stability at refrigerated temperature for a 6-month storage period. APO-loaded COS-NP<sub>s</sub> provoked marvelous antiulcerogenic activity against KP-induced gastric ulceration in rats compared with free APO treated group, which was emphasized by histopathological, IHC, and biochemical studies.

**Conclusion:** In conclusion, APO-loaded COS-NP<sub>s</sub> could be considered as a promising oral phytopharmaceutical nanoparticulate system for management of gastric ulceration.

**Keywords:** apocynin, chitosan oligosaccharide, tripolyphosphate, nanoparticles, antiulcerogenic activity

## Introduction

Advances in nanotechnology involving bioactive phytochemicals have provided numerous innovative delivery systems; including polymeric nanoparticles (PNPs). Oral PNPs have gained much attention as drug carriers because of their nanoscopic size, bioadhesion, targetability, and controlled release of drugs in the GIT, hence conferring enhanced bioavailability.<sup>1</sup> Their ability to cross directly and/or adhere to the mucosa represents a prerequisite step prior to the translocation process of particles.<sup>2</sup>

From this perspective, bioadhesion plays a substantial role in delivering the drugs across the epithelia and subsequently averting hepatic first pass metabolism and enzymatic degradation in the GIT.<sup>1</sup>

Among natural mucoadhesive polymers, chitosan (CS) is the most extensively studied cationic polysaccharide for construction of PNPs owing to its characteristic features.<sup>3</sup> Ionic gelation technique, a physical cross-linking process, is an efficient method adopted to prepare CS-NP<sub>s</sub> based on ionic interaction between positively charged primary amino groups of CS and negatively charged groups of polyanion like tripolyphosphate (TPP) (the most preferable cross-linker with safety and multivalent properties).<sup>4</sup> Such positively charged CS-NP<sub>s</sub> possess mucoadhesive and permeation enhancing properties.<sup>5</sup>

Despite the aforementioned advantages of CS, its poor aqueous solubility in physiological pH is considered the major limitation (readily soluble in acidic medium only). Besides, the degree of deacetylation, molecular weight (MW), and type of CS can influence its solubility.<sup>6,7</sup> Therefore, CS derivatives have emerged in recent years to circumvent such limitation. Among them; CS oligosaccharide (COS), an oligomer of  $\beta$ -(1-4)-linked D-glucosamine, is a low MW CS, typically below 10 kDa (Figure 1A). Its superior merits such as high water solubility, low viscosity, biocompatibility, biodegradability, mucoadhesiveness, and permeation enhancing capability boost its potential application in pharmaceutical and biomedical fields.<sup>6,7</sup> COS has been reported as a biopolymer possessing versatile biological activities.<sup>8</sup>

**Figure 1** Chemical structures of the polymer and the drug.

**Note:** (A) COS and (B) APO.

**Abbreviations:** APO, apocynin; COS, chitosan oligosaccharide.

The anti-inflammatory activity of COS was verified both in vitro and in vivo.<sup>9-11</sup>

Gastric ulcer has long been rated as one of the most prevalent gastrointestinal inflammatory disorders affecting approximately 10% of the world's population. The pathogenesis of gastric ulcer is related to the disruption of the homeostasis between offensive factors and defensive factors.<sup>12</sup> Despite the availability of different drug categories for treatment of gastric ulcer such as proton pump inhibitors and H<sub>2</sub> receptor antagonists, their clinical evaluation has demonstrated numerous side effects and high incidence of relapse.<sup>13</sup> Apocynin (APO) (Figure 1B) (4-hydroxy-3-methoxyacetophenone) is a bioactive phytochemical extracted from the roots of *Apocynum cannabinum* (Canadian hemp) or *Picrorhiza kurroa* native to the Himalayas. It possesses eminent anti-inflammatory and anti-oxidant activities that have been substantiated on a diversity of cell lines and animal models.<sup>14-16</sup> APO's mechanism is renowned through specific inhibition of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase as well as suppression of a series of inflammatory mediators.<sup>17,18</sup> However, for successful prospective administration, the literatures recently published APO as nanoparticulate systems to overcome its poor oral bioavailability as a prime challenge.<sup>19-22</sup>

COS has been proven a promising candidate for preparation of several nano-delivery systems targeted to potentiate the therapeutic efficacy of the loaded drugs.<sup>23-26</sup> However, to the best of our knowledge, only one article was published by Ye et al which stated the preparation of COS-NP<sub>s</sub> using TPP as a cross-linker and evaluated the efficiency of such COS-TPP NP<sub>s</sub> as a non-viral vector for DNA delivery.<sup>7</sup> Likewise, a sole pharmacological study manifested the gastroprotective activity of APO, as a free drug, against ethanol-induced gastric ulcer in rats.<sup>27</sup> Nevertheless, designing a nano-delivery system targeted to potentiate the gastric antiulcerogenic activity (AA) of APO has not been investigated yet.

This context paves the way to devote the current study to fabricate and extensively evaluate a novel oral phyto-pharmaceutical nanoparticulate system composed of COS-NP<sub>s</sub> loaded with APO (using TPP as a cross-linker) in order to reconnoiter its potential for effective gastric AA.

## Materials and methods

### Materials

APO, TPP, mucin from porcine stomach, ketoprofen (KP), and bovine serum albumin (BSA) were purchased from

Sigma-Aldrich Co. (St Louis, MO, USA). COS (2~6 glucosamine units, deacetylation degree >98%) was kindly supplied by Yaizu Suisankagaku Industry Co., Ltd. (Shizuoka, Japan). Sodium carboxymethylcellulose (sodium CMC) was obtained from EL-Nasr Pharmaceutical Chemicals Co., Cairo, Egypt. Oxidative stress markers and nitric oxide (NO) assay kits were procured from Biodiagnostic, Egypt. All other solvents were of analytical reagent grades.

## Preparation of APO-loaded COS-NP<sub>s</sub>

COS-NP<sub>s</sub> were prepared according to the ionic gelation method which is based on an ionic interaction between the positively charged amino group of COS solution and the negatively charged phosphate group of TPP solution (Table 1).<sup>7</sup> In brief, COS was dissolved in deionized water (DW) at various concentrations (0.3, 0.4 or 0.5% w/v). Next, 4 mL aqueous solution of APO (0.2% w/v) containing different concentrations of TPP (0.1, 0.15 or 0.2% w/v) was slowly dropped into 10 mL COS solution through a disposable insulin syringe with a dropping rate of 0.2 mL/min under magnetic stirring (1,000 rpm) at room temperature. The stirring was continued for 30 minutes to allow further cross-linking reaction. Finally, COS-NP<sub>s</sub> were collected by centrifugation at 10,000 rpm for 20 minutes (Benchtop Centrifuge, Sigma Laborzentrifugen GmbH, Germany), washed with DW, and then freeze-dried (Freeze dryer, SIM FD8-8T, SIM international, USA) for further characterization study. The same procedure was adopted for preparation of plain COS-NP<sub>s</sub>.

## Characterization of APO-loaded COS-NP<sub>s</sub>

### Drug entrapment efficiency

The drug entrapment efficiency percentage (DEE %) was estimated indirectly by measuring the amount of free APO

(unentrapped drug) in the supernatant of the medicated COS-NP<sub>s</sub> dispersion after centrifugation at 10,000 rpm for 20 minutes. Unentrapped APO amount was quantified spectrophotometrically at 272 nm (Spectro UV-VIS double beam, Labomed Inc., USA) against the corresponding plain COS-NP<sub>s</sub> supernatant as a blank. The DEE (%) was calculated according to the following Equation (1).<sup>28</sup>

$$\text{DEE (\%)} = \frac{W_t - W_f}{W_t} \times 100 \quad (1)$$

where  $W_t$  is the total amount of APO and  $W_f$  is the amount of free APO in the supernatant.

### Particle size, polydispersity index (PDI), and zeta potential (ZP) measurements

Measurement of particle size, PDI, and ZP of the freshly prepared APO-loaded COS-NP<sub>s</sub> was carried out using Malvern Zetasizer Nano ZS (Malvern Instruments, Malvern, UK) after appropriate dilution with DW. Dynamic light scattering (DLS) and laser Doppler microelectrophoresis techniques were applied to particle size and ZP measurements, respectively.

### Mucoadhesive strength

All APO-loaded COS-NP<sub>s</sub> formulations were evaluated regarding their mucoadhesive strength based on the interaction between the negatively charged mucin and the positively charged COS-NP<sub>s</sub>.<sup>24</sup> In brief, equal volumes of mucin (0.5 mg/mL in phosphate buffer saline [PBS] pH 7.4) and NP<sub>s</sub> dispersion (5 mL each) were vortexed, shaken for 1 hour at 37°C, and then centrifuged at 10,000 rpm for 1 hour. UV-VIS spectrophotometer was utilized to quantify the amount of free mucin in the supernatant at 251 nm. The mucin-binding efficiency (%), expressing the

**Table 1** Composition and characterization of APO-loaded COS-NP<sub>s</sub> formulations

| Formulation code | COS concentration (% w/v) | TPP concentration (% w/v) | Particle size (nm) | PDI        | ZP (mV)     | DEE (%)    | Mucin-binding efficiency (%) |
|------------------|---------------------------|---------------------------|--------------------|------------|-------------|------------|------------------------------|
| F1               | 0.3                       | 0.2                       | 904.20±23.01       | 0.388±0.22 | +6.82±0.67  | 19.65±1.07 | 1.30±0.62                    |

| F4               | 0.5                       | 0.1                       | 436.20±24.45       | 0.390±0.07 | +38.20±1.47 | 35.06±1.89 | 51.22±2.99                   |
| F5               | 0.4                       | 0.15                      | 718.90±74.99       | 0.653±0.16 | +28.63±1.14 | 22.59±0.98 | 39.35±3.09                   |

**Notes:** Each value represents the mean ± SD (n=3). Each formulation contains 8 mg APO.

**Abbreviations:** APO, apocynin; COS, chitosan oligosaccharide; DEE, drug entrapment efficiency; NP<sub>s</sub>, nanoparticles; PDI, polydispersity index; TPP, tripolyphosphate; ZP, zeta potential.

mucoadhesive strength of the NP<sub>s</sub>, was calculated according to Equation (2):

$$= \frac{\text{Mucin} - \text{binding efficiency}(\%)}{\text{Total amount of mucin} - \text{free amount of mucin}} \times 100 \quad (2)$$

#### Fourier transform-infrared (FT-IR) spectroscopy

The FT-IR spectra of APO, COS, TPP, and their physical mixture with the same ratio used during the preparation of the chosen formula as well as freeze dried samples of plain and medicated COS-NP<sub>s</sub>, were run using FT-IR Spectrophotometer (Madison Instruments, Middleton, WI, USA). Discs containing 2 mg of each sample with 200 mg potassium bromide were scanned individually over a wave number range of 4,000–500 cm<sup>-1</sup>.

#### Differential scanning calorimetry (DSC)

Thermograms of APO, COS, TPP, and their physical mixture (keeping the same ratio as present in the chosen NP<sub>s</sub> formula) as well as freeze dried plain and medicated COS-NP<sub>s</sub>, were recorded utilizing DSC (DSC 6000; PerkinElmer Inc., Waltham, MA, USA). Samples (4 mg per each) were heated in hermetically sealed aluminum pans covering a temperature range of 30–400°C at a heating rate of 10°C/min under constant dry nitrogen purging at 20 mL/min. DSC runs were implemented using indium as a reference standard for temperature calibration.

#### X-ray diffractometry (XRD)

X-ray diffraction patterns of APO, COS, TPP, and their physical mixture (keeping the same ratio as present in the chosen NP<sub>s</sub> formula) as well as freeze dried plain and medicated COS-NP<sub>s</sub>, were determined employing a Diano X-ray diffractometer (Diano Corp., USA) equipped with Cu K $\alpha$ . The analysis proceeded at a voltage of 45 kV and a current of 9 mA with scanning range from 3° to 50° at 2 $\theta$  angle.

#### Transmission electron microscopy (TEM)

The morphological characteristics of the chosen COS-NP<sub>s</sub> formula were examined by TEM (JEOL 2100; JEOL, Tokyo, Japan). For sample preparation, one drop of freshly prepared NP<sub>s</sub> dispersion was cast onto carbon coated copper grid and excess dispersion was wiped off with filter paper. After complete drying of the sample at room temperature, it was inspected directly with TEM without staining. Digital Micrograph and Soft Imaging Viewer

software were employed for image capture and analysis process, respectively.

#### In vitro drug release

The in vitro release profile of APO from COS-NP<sub>s</sub>, compared with its diffusion from aqueous solution, as a control, was examined using vertical Franz diffusion cells with diffusional surface area of 7.07 cm<sup>2</sup>. The donor and receptor compartments of the diffusion cells were separated by Spectrapor<sup>®</sup> membrane (MW cutoff: 12,000–14,000 Da, Spectrum Medical Industries Inc., LA, USA) that was equilibrated overnight with 0.1 M HCl (pH 1.2) simulating gastric pH before conducting the experiment. Briefly, 2 mL medicated COS-NP<sub>s</sub> dispersion in DW or aqueous drug solution with an equivalent amount of 4 mg APO each was introduced into the donor compartment, whereas 50 mL 0.1 M HCl (pH 1.2) was placed in the receptor one. The whole assembly of the diffusion cells was shaken by thermostatically controlled shaking incubator (GFL Gesellschaft für Labortechnik, Burgwedel, Germany) at 100 rpm/min and maintained at 37±0.5°C throughout the experiment. At an appointed time interval, samples (3 mL) were withdrawn from the receptor compartment and replenished with an equivalent volume of fresh release medium equilibrated at 37±0.5°C. The collected samples were filtered through 0.45  $\mu$ m membrane filter (EMD Millipore, Billerica, MA, USA) and the released drug was analyzed spectrophotometrically at 275 nm. Finally, the cumulative APO released (%) was calculated at each time interval and plotted against time.

#### Kinetic analysis of the drug release data

To gain a profound insight into the drug release mechanism from the NP<sub>s</sub>, the in vitro release data of the chosen APO-loaded COS-NP<sub>s</sub> formulation were fitted to different kinetic models, namely; zero order, first order, Higuchi,<sup>29</sup> and Korsmeyer-Peppas (Equation (3)):<sup>30</sup>

$$(m_t/m_\infty = kt^n) \quad (3)$$

where,  $m_t/m_\infty$  is the fraction of drug released after time  $t$ ,  $k$  is the kinetic constant, and  $n$  is the diffusional exponent for drug release that equals the slope of  $\log m_t/m_\infty$  vs  $\log$  time curve. The proper kinetic model expressing the predicted drug release mechanism was chosen based on the highest coefficient of determination ( $R^2$ ) value.

## Stability study

The stability studies of the chosen COS-NP<sub>s</sub> loaded with APO were carried out at refrigerated (4±1°C) and room (25±2°C/60±5% relative humidity; RH) temperatures for 6 months. The freshly prepared COS-NP<sub>s</sub> dispersions in DW were filled into screw capped glass bottles and then stored at the previously mentioned temperatures.<sup>1</sup> The NP<sub>s</sub> were assessed monthly for particle size, PDI, and ZP as well as drug retention (%) using Equation (4).

$$\text{Drug retention (\%)} = \frac{\text{DEE at each time interval}}{\text{DEE initial}} \times 100 \quad (4)$$

## Evaluation of AA against KP-induced gastric ulcer in rats

### Animals

Male Wistar albino rats, 200–220 g body weight, were caged and acclimated for 1 week before carrying out the experiments in a standard controlled room (temperature of 25±1°C, RH of 55±5%, and photoperiod regimen of 12 hour light/12 hour dark cycles) with free access to food and water. All animal experiments followed a protocol approved by the Ethical Committee of the Faculty of Pharmacy, Mansoura University, Egypt, in accordance with “principles of laboratory animal care NIH publication revised 1985”.

## Induction of ulcer and treatment regimen design

The rats were fasted overnight with free access to water prior to starting the experimental protocol. Intragastric gavage was utilized to facilitate the oral administration of KP, free APO, or medicated COS-NP<sub>s</sub> (chosen formula, F4) to rats (each one was prepared as suspension in sodium CMC [1% w/v]). In this study, two treatment regimens were evaluated against KP-induced gastric ulcer in rats; 1) concurrent induction and treatment regimen, where APO or APO-loaded COS-NP<sub>s</sub> and KP were administered simultaneously, 2) post-treatment regimen, where KP was administered first and after 8 hours APO or APO-loaded COS-NP<sub>s</sub> was administered.

### Concurrent induction and treatment regimen

Twenty-four animals were divided into four groups (six rats per group) and treated as follows: Group I: normal control (no KP nor APO). Group II: positive control which received two consecutive doses of 50 mg/kg KP only within 8-hour interval.<sup>31,32</sup> Group III: received concurrent oral administration of both KP and free APO suspensions (50 and

14 mg/kg, respectively).<sup>31,33</sup> After 8 hours, the rats received a dose of KP only. Group IV: similarly treated as group III but with APO-loaded COS-NP<sub>s</sub> (F4) containing an equivalent dose of APO (14 mg/kg) instead of free APO.

### Post-treatment regimen

KP was administered first and after 8 hours, APO was taken. Twenty-four animals were divided into four groups (six rats per group) and each treated as follows: Group I: normal control (no KP nor APO). Group II: positive control which received oral KP suspension (50 mg/kg) to induce gastric ulcer in rats within 8 hours. Group III: received oral KP suspension (50 mg/kg) and after 8 hours received free APO suspension (14 mg/kg) and then once daily for 4 consecutive days. Group IV: similarly treated as group III but with APO-loaded COS-NP<sub>s</sub> (F4) containing an equivalent dose of APO (14 mg/kg) instead of free APO.

At the end of both treatment regimens, rats were sacrificed (8 hours after the last treatment in case of concurrent induction and treatment regimen and 24 hours after the last treatment in case of post-treatment regimen). Their stomachs were rapidly removed, opened along the greater curvature, gently rinsed out with normal saline, and processed for the forthcoming evaluations.

## Macroscopic examination of gastric ulceration

The mucosal surfaces of the stomachs were photographed and macroscopically examined for ulcerogenic lesions (black spots).<sup>34</sup> The mean number of ulcers and percentage incidence of rats with ulcers (percentage of rats with ulcers) were estimated. Moreover, Paul's index (PI; an integral indicator of the number of lesions induced per experimental group) and AA (the activity was recognized when AA value was at least two units) were evaluated according to Equations (5 and 6), respectively.<sup>35,36</sup>

$$\text{PI} = \frac{\text{mean number of ulcers} \times \text{percentage incidence of rats with ulcers}}{100} \quad (5)$$

$$\text{AA} = \frac{\text{PI of positive control group (KP alone)}}{\text{PI of treated group (APO alone or NPs)}} \quad (6)$$

After completion of macroscopic examination, each stomach was divided into two portions. The first portion was processed for pathological studies and the second one was subjected to biochemical evaluations.

## Preparation of gastric tissue samples for pathological studies

Autopsy samples were taken from freshly excised clean stomachs and fixed in a 10% buffered formalin solution for 24 hours. Formalin-fixed stomachs were washed, dehydrated by ascending grades of ethyl alcohol, cleared in xylene, embedded in paraffin wax, and serially sectioned (5  $\mu$ m) for the following examinations.

### Histopathological examination

One set of gastric tissue sections was picked up on slides, deparaffinized, and stained with hematoxylin and eosin (H&E), as previously reported.<sup>37</sup> The second and third sets of sections were stained with alcian blue and toluidine blue for detection of mucus glycoproteins and mast cells, respectively.<sup>27,38</sup>

### Immunohistochemical (IHC) detection of cyclooxygenase-2 (COX-2) expression

Another set of sections was immunostained to evaluate COX-2 expression level in gastric tissue by EnVision method, following the manufacturer's instructions (Thermo Fisher Scientific, Waltham, MA, USA). Briefly, sections were deparaffinized in xylene, then rehydrated in gradual descending concentrations of ethyl alcohol followed by PBS (pH 7.4). For antigen retrieval, glass jars containing tissue section slides in 0.01 M sodium citrate buffer (pH 6.0) were placed in a microwave oven for 8 minutes at 600 W to enhance immunoreactivity. The endogenous peroxidase activity was blocked with 3% hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) for 5 minutes at room temperature. After rinsing with PBS (pH 7.4), tissue sections were incubated with primary antibody (anti-COX-2 [1:50] in PBS containing 1% BSA) overnight at 4°C. After triple washing with PBS, the sections were incubated with secondary antibody (biotinylated anti-immunoglobulin) for 1 hour at room temperature, followed by washing and development of antigen-antibody visualization with 0.04% 3, 3'-diaminobenzidine tetrahydrochloride, as a chromogen, for 1 minute. Finally, the sections were washed and then counter-stained with Mayer's hematoxylin. All pathological changes were examined blindly using a light microscope (Olympus Corporation, Tokyo, Japan). The sections treated for immunostaining were scored from 0 to 3 as follows: absent staining =0, weak staining =1, moderate staining =2, and strong staining =3.<sup>39</sup> Such scoring clearly reflected the capability to realize the positive reactions under high, medium, and low power microscopic magnifications.

## Preparation of gastric tissue homogenate for biochemical studies

Gastric mucosal tissue was weighed, homogenized in 10 volumes of ice-cold phosphate buffer (100 mM, pH 7.4) using a homogenizer (Benchmark D1000, USA), and then centrifuged (10,000 g for 10 minutes at 4°C).<sup>36</sup> Aliquots of the homogenate were stored at -80°C for the subsequent measurements.

### Measurement of oxidative stress markers

Levels of malondialdehyde (MDA), superoxide dismutase (SOD), and reduced glutathione (GSH) were measured in gastric mucosal homogenates of the different experimental groups using their respective assay kits according to the manufacturer's instructions (Biodiagnostic).

### Measurement of NO

The level of NO in gastric mucosal homogenate was measured based on Griess method using a specified kit as indicated by the manufacturer's instructions (Biodiagnostic).<sup>32</sup>

## Statistical analysis

Data were expressed as mean  $\pm$  SD of three experiments. In vivo data were presented as mean  $\pm$  standard error of the mean (SEM) of six experiments. Statistical analysis was accomplished by one-way ANOVA followed by Tukey-Kramer multiple comparisons test using Graphpad prism software version 5.00 (GraphPad Software, Inc., La Jolla, CA, USA). The *p*-values at level *p*<0.05 were considered statistically significant.

## Results and discussion

### Preparation and characterization of APO-loaded COS-NP<sub>s</sub> formulations

In the present study, APO-loaded COS-NP<sub>s</sub> were successfully prepared by ionic gelation method. As shown in Table 1, different concentrations of COS and TPP were used to determine the most appropriate nanoparticulate system with respect to particle size, PDI, ZP, DEE (%), and mucoadhesive strength. APO concentration was maintained constant at 2 mg/mL in all formulations, which is the maximum value recorded according to the solubility data.<sup>40</sup> The following parameters were evaluated to clarify the effect of interaction between COS and TPP on NP<sub>s</sub> properties.

## DEE

Table 1, interestingly, reveals that the concentration of both COS and TPP dictate (in antagonist mode) the outcome values of DEE (%), particle size, as well as mucin-binding efficiency of the NP<sub>s</sub> (F1 and F4). It might be speculated that high concentration of COS in the presence of low concentration of TPP indorsed the interaction between COS and APO slowly, resulting in high DEE (%) and binding efficiency of the small particle size (F4). However, with F1, the lower concentration of COS was captured rapidly by the high one of TPP, therefore, the chance for APO to be encapsulated was reduced. As a result, particle size increased, while mucin-binding efficiency decreased.

## Particle size, PDI, and ZP measurements

Particle size is one of the main important determinants in mucosal and epithelial tissue uptake of NP<sub>s</sub>, as well as their intracellular trafficking, thereby influencing the therapeutic performance.<sup>41</sup> The data elucidated that an increment in the concentration of the polymer and reduction of that of TPP resulted in a dramatic drop in the particle size of the medicated COS-NP<sub>s</sub> from 904.20±23.01 to 436.20±24.45 nm in case of F1 and F4, respectively (Table 1). Such decrease in particle size might be assigned to a higher degree of cross-linking reactions and production of compact NP structure.<sup>28,42</sup>

The index of particle size distribution is expressed as PDI. It has an impact on the pharmacokinetic parameters and the therapeutic efficacy of the medicated NP<sub>s</sub> formulations based on its value, ranging from 0 to 1. PDI values lower than 0.5 indicate homogenous nature of the dispersion and those greater than 0.5 indicate a heterogeneous one. Unequal particle size (PDI >0.5) can influence the surface area of NP<sub>s</sub> available for absorption and hence can cause irregularity of the pharmacokinetic parameters with subsequent effect on the therapeutic efficacy of the formulation.<sup>43</sup> In our study, most of the NP<sub>s</sub> formulations had PDI values lower than 0.5, pointing to their homogenous (narrow-size) distribution.

ZP is a prime parameter representing the surface charge density of NP<sub>s</sub>, which strongly influences their stability, mucoadhesive property, and cellular uptake ability.<sup>1,7</sup> As summarized in Table 1, the ZP values of all the prepared formulae were positively charged with the maximum one obtained in case of F4 (+38.20±1.47 mV). Such a trend could be correlated to the existence of free protonated amino groups (-NH<sub>3</sub><sup>+</sup>) of COS polymer which

are specifically more available in case of F4 with higher polymer concentration, hence leading to much stronger electrostatic repulsion between NP<sub>s</sub>. These data are in concordance with other investigations.<sup>24,43</sup> In general, ZP values higher than +30 mV or lower than -30 mV elicit good stability of the NP<sub>s</sub> owing to the electrostatic repulsion between each other.<sup>44,45</sup>

## Mucoadhesive strength

Possession of mucoadhesive properties has a great influence on broadening the scope of application of PNP<sub>s</sub>. In the present work, APO-loaded COS-NP<sub>s</sub> formulations exhibited marked increase in the mucin-binding efficiency (%) concomitant with the increment in the ZP values as presented in Table 1. F4 with ZP of +38.20±1.47 mV, possessed the maximum mucin-binding efficiency (%) (51.22±2.99%). The mucoadhesive characteristics of COS are correlated with the electrostatic interaction between the positively charged amino groups of COS and negatively charged sialic acid groups of mucin.<sup>24</sup> Such interaction promotes the gastric residence time and cellular uptake of NP<sub>s</sub>, which is essential for effective mucosal delivery of therapeutics.<sup>1</sup> Compared with the mucoadhesive strength of the medicated formula (F4), the corresponding plain COS-NP<sub>s</sub> showed higher value (62.70±3.07%) because of the presence of more COS available for interaction with mucin.<sup>43</sup> There is ample evidence attesting to the effect of CS type, MW, and degree of deacetylation as well as PNP<sub>s</sub> components on the mucoadhesive characteristics of CS NP<sub>s</sub>.<sup>24,46</sup>

The aforementioned data, with all appreciated values of the properties required in NP<sub>s</sub>, substantiated that F4 was the chosen formula with respect to maximum DEE (%) of 35.06±1.89%, low particle size of 436.20±24.45 nm, low PDI of 0.390±0.07, high ZP of +38.20±1.47 mV, and high mucoadhesive strength of 51.22±2.99% (Table 1), therefore, it was subjected to the forthcoming evaluations.

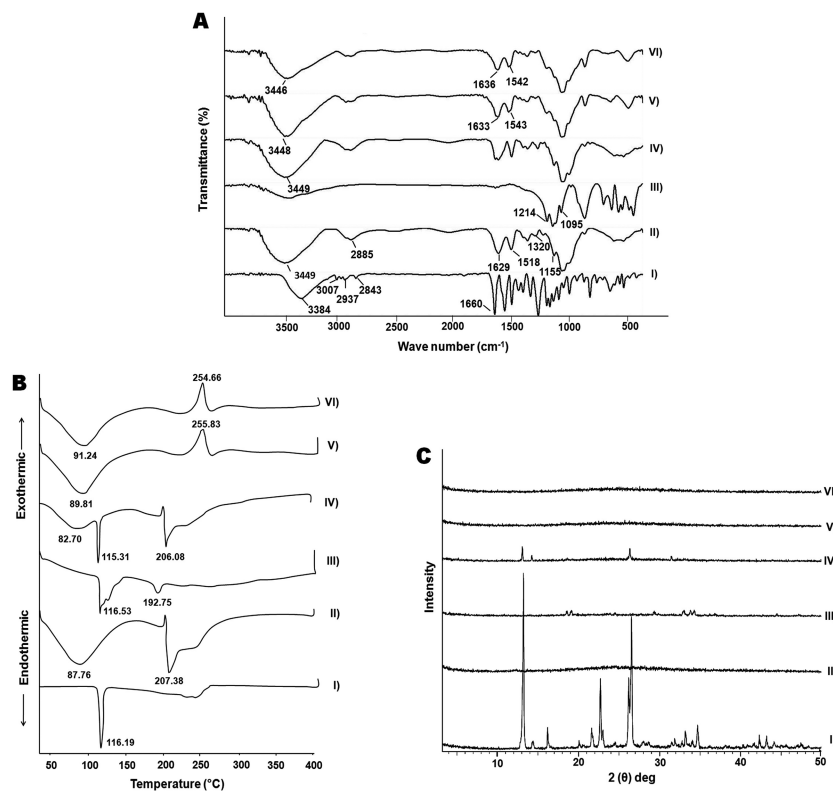

## FT-IR spectroscopy

The FT-IR spectra of COS-NP<sub>s</sub> (F4) and their ingredients are presented in Figure 2A. The spectrum of APO displayed all the characteristic bands of the functional groups of the drug: 3384 (phenyl-OH), 3007 (aromatic -H), 2937 (alkane C-H), 2843 (alkane C-H), and 1,660 cm<sup>-1</sup> (ketone C=O).<sup>40</sup> COS spectrum elicited a strong and broad overlapped peak at 3,449 cm<sup>-1</sup> assigned to -NH<sub>2</sub> and -OH stretching vibrations. A weak band at 2,885 cm<sup>-1</sup> originated from -CH stretching. The absorption bands at 1,629 cm<sup>-1</sup> and

1,518  $\text{cm}^{-1}$  were characteristic for the amide I (C=O vibration mode) and amide II (N-H bending vibration mode) of COS, respectively.<sup>47</sup> The peak at 1,155  $\text{cm}^{-1}$  pointed to asymmetric stretch of C-O-C. Furthermore, the peak at 1,320  $\text{cm}^{-1}$  for C-N stretching vibration of type I amine was observed.<sup>44</sup> TPP spectrum showed a peak at 1,214 that referred to P=O and another peak at 1,095  $\text{cm}^{-1}$ , which could be attributed to P-O-R vibration of the phosphate group.<sup>48</sup> The spectrum of the physical mixture of NP<sub>s</sub> components was similar to that of COS, which might be attributed to dilution of the drug and TPP by the polymer. Plain and medicated NP<sub>s</sub> spectra were synchronized with each other, where amide I and amide II peaks of COS were shifted, verifying the cross-linking between amino groups of COS and phosphate groups of TPP through ionic interaction.<sup>28</sup> Additionally, the characteristic peaks of APO disappeared in medicated NP<sub>s</sub> spectrum, indicating the drug entrapment in the NP<sub>s</sub> matrix and the possibility of interaction between APO, specifically, its phenyl -OH group with COS of the NP<sub>s</sub>. These results correlate with an earlier report.<sup>1</sup>

## DSC

Figure 2B depicts the DSC thermograms of APO, COS, TPP, and their physical mixture as well as plain and medicated COS-NP<sub>s</sub> (F4). A characteristic sharp endothermic peak of APO was detected at 116.19°C corresponding to its melting point. COS thermogram disclosed a broad endothermic peak at 87.76°C and another endothermic peak at 207.38°C which might be ascribed to the water evaporation and polymer decomposition, respectively.<sup>47</sup> TPP showed two endothermic peaks at 116.53°C and 192.75°C. Regarding the physical mixture, the distinguished endothermic peaks of the components were noticed at their respective positions with marked absence of those of TPP, owing to the dilution factor. Interestingly, both plain and medicated COS-NP<sub>s</sub> thermograms matched each other, along with vanishing of the decomposition peak of COS. Besides, the disappearance of APO peak was evident in the medicated NP<sub>s</sub> thermogram suggesting the drug entrapment in the matrix of the polymeric nanoparticulate system.<sup>49</sup> Moreover, the noticeable exothermic

**Figure 2** FT-IR spectra (A), DSC thermograms (B), and XRD patterns (C).

peaks at 255.83°C and 254.66°C in plain and medicated NP<sub>s</sub> thermograms, respectively, might be attributed to the cross-linking reactions and formation of new structural entity with specific thermal characteristics. These findings are in line with a previous report.<sup>50</sup>

### XRD

As shown in Figure 2C, APO diffractogram manifested intense diffraction peaks at 2θ of 13.12, 14.32, 21.67, 22.70, 26.22, and 26.56°, thereby indicating the crystalline nature of the drug.<sup>40</sup> On the other hand, the amorphous pattern of COS was observed.<sup>51</sup> The crystallinity of TPP was revealed by prominent diffraction peaks at 2θ of 18.65, 19.19, 24.62, 29.45, 33.09, 33.94, and 34.39°. In case of the physical mixture, the diffractogram was a combination of those of COS and APO with clear absence of the peaks of TPP due to dilution factor. The diffractogram of the medicated COS-NP<sub>s</sub> (F4) coincided with that of the plain one, along with disappearance of the characteristic peaks of APO. Hence, the encapsulation of the drug within the COS matrix of the NP<sub>s</sub> in amorphous or molecular dispersed state exists. Earlier, similar manner was authenticated for other drugs loaded in CS NP<sub>s</sub>.<sup>28,49</sup>

### TEM

Morphological analysis revealed that APO-loaded COS-NP<sub>s</sub> (F4) were spherical in shape with smooth surfaces, as observed by TEM (Figure 3). Noteworthy, the particle size of the NP<sub>s</sub> measured by DLS (436.20 nm) (Table 1) was larger than that estimated by TEM (<200 nm) because of the presence of NP<sub>s</sub> as aqueous dispersion in the hydrated state (hydrodynamic diameter), that might lead to swelling of COS matrix of the individual NP<sub>s</sub>, and/or aggregation of single particles. In case of TEM, these factors are diminished owing to the existence of the NP<sub>s</sub> in the dried state (actual diameter). Analogous findings and explanations have been documented for other CS-TPP NP<sub>s</sub>.<sup>1,28,52</sup>

### In vitro drug release

The in vitro release pattern of APO from COS-NP<sub>s</sub> (F4) in comparison with its diffusion from aqueous solution is depicted in Figure 4 using 0.1 M HCl (pH 1.2) as a release medium to mimic the gastric environment. It was evident that the drug was completely diffused (100%) from its aqueous solution into the release medium within 1 hour. Such pattern could be related to the amphoteric nature of free APO that permits its solubility in both acidic and basic media. Therefore, in acidic pH, formation of hydrogen bond between phenolic

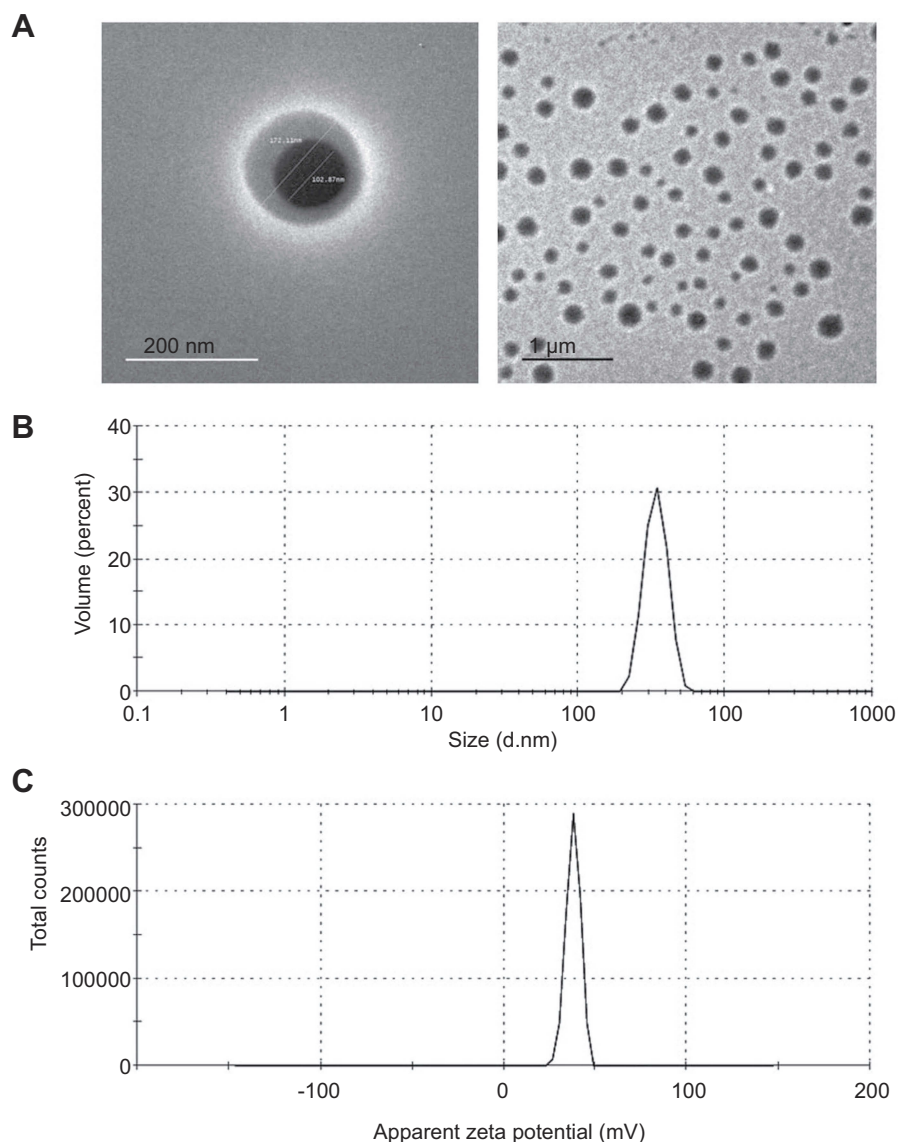

OH group of APO and water (H<sub>2</sub>O) molecules of the medium may boost the complete diffusion of the free drug.<sup>19</sup> On the other hand, APO loaded in COS-NP<sub>s</sub> exhibited biphasic release pattern characterized by initial burst phase (33.69 ± 0.525%) in the first 3 hours followed by sustained phase (43.89 ± 0.115%) up to 24 hours. Free drug adsorbed onto the NP<sub>s</sub> surface and drug entrapped near the surface may account for the initial burst release.<sup>44,45</sup> The sustained release pattern is presumably due to swelling of the polymer matrix based on the weak basic nature of COS that facilitates the protonation of its amino groups in the acidic environment leading to repulsion of polymer chains, with subsequent entry of water into the particles and slow diffusion of APO from the polymeric nanoparticulate matrix.<sup>6</sup> Owing to the preparation of NP<sub>s</sub> by ionic gelation method and swelling characteristics of the polymer, NP<sub>s</sub> could be considered as nanogel or nanoscaffold delivery systems. Collectively, these results imply that orally administered APO-loaded COS-NP<sub>s</sub> can quickly confer therapeutic concentration of the drug through initial burst release. This is further maintained at the therapeutic level by the sustained release phase. Such suggestion resembles an earlier study.<sup>45</sup>

### Kinetic analysis of the drug release data

The kinetic release data of APO from the chosen COS-NP<sub>s</sub> implied that Higuchi model was the best fitted one (diffusion of the drug through the PNP<sub>s</sub> matrix represents the rate limiting step). Further analysis by Korsmeyer-Peppas empirical equation established a Fickian mechanism (n < 0.5), indicating that the drug release from NP<sub>s</sub> was mainly governed by diffusion (Table 2). Likewise, other drugs loaded in CS-NP<sub>s</sub> followed the same kinetic behavior.<sup>2,52</sup>

### Stability study

As summarized in Table 3, the stability of the chosen formula (F4) after storage at both refrigerated and room temperatures was estimated with respect to particle size, PDI, ZP, and drug retention (%) for 6 consecutive months. Compared with the freshly prepared APO-loaded COS-NP<sub>s</sub> samples, insignificant difference was detected regarding the evaluation parameters after storage at refrigerated temperature throughout the designated periods. On the other hand, at room temperature storage, significant (*p* < 0.05) increment in particle size and decrease in ZP were recorded, while other parameters were in the acceptable range. These data highlighted the superlative stability of the chosen formula at 4°C, hence maintaining its efficacy for a long-term storage period. Fan et al declared similar findings with respect to the storage stability study of CS/TPP NP<sub>s</sub> at the same designated temperatures.<sup>53</sup>

## Evaluation of AA against KP-induced gastric ulcer in rats

### Macroscopic examination of gastric ulceration

KP-induced gastric ulcer in rats is considered an established model for screening the AA of the investigated drugs either free or loaded in pharmaceutical delivery systems. As documented, KP causes gastric ulceration via numerous mechanisms encompassing, suppressed prostaglandins' (PGs) production, decreased gastric mucous secretion, altered mucosal oxidative stresses, and NO levels as well as stimulated COX-2 and other inflammatory mediators' expression levels.<sup>31,32</sup>

Figure 5 illustrates macroscopic gross appearance of gastric mucosal tissues obtained from different rat groups following concurrent induction and treatment regimen as well as post-treatment regimen. Besides, macroscopic evaluation parameters of ulceration were summarized in Table 4 for both treatment regimens.

In case of concurrent induction and treatment regimen (Figure 5A), normal control group (I) elicited normal gastric mucosa. On the other hand, oral KP administration of two successive doses 8 hours apart (positive control; group II) provoked exacerbated gastric ulcerogenic lesions in the form of multiple black spots. Therefore, such group

**Figure 4** The in vitro release pattern of APO from COS-NPs<sub>s</sub> (F4) in comparison with its diffusion from aqueous solution.

**Note:** Each point represents the mean  $\pm$  SD (n=3).

**Abbreviations:** APO, apocynin; COS, chitosan oligosaccharide; NP<sub>s</sub>, nanoparticles.

experienced a high percentage incidence of ulcers (100%) and the highest PI value (36.83) (Table 4). Compared with positive control group, ulcerogenic lesions were relatively reduced in rats that received concurrent administration of KP and APO (group III), but the percentage incidence of ulcers (100%) and PI (24.50) were still high. Interestingly, much less ulceration was observed in APO-loaded COS-NP<sub>s</sub> concurrently treated rats (group IV), expressed by marked reduction of percentage incidence of ulcers (66.66%) and lowest PI (4.55) compared with both positive control group (II) and free APO concurrently treated group (III). It might be inferred from Table 4 that the NP<sub>s</sub> (group IV) taken once acted as a depot in the stomach mucosa for APO sustained release, ameliorating the AA even when KP was administered to the rats in two consecutive doses 8 hours apart. These aforementioned results could be considered a therapeutic “cherish” for those patients on KP treatment for long periods as analgesic or anti-inflammatory. One might look to the prepared NP<sub>s</sub> as a “scaffold” for APO sustained release in the gastric mucosa?

Similar macroscopic findings were manifested in post-treatment regimen of rat groups (Figure 5B). Table 4 depicts that consecutive administration of APO-loaded COS-NP<sub>s</sub> (group IV) once daily for 4 days after once dosing with KP (post-treatment regimen) resulted in a significant decrease in the average number of ulcers and the percentage incidence of rats with ulcers. This means that progress in recovery from an already existing gastric ulcer can take place by repeated administration of once daily NP<sub>s</sub>. Compared with free APO, NP<sub>s</sub> had the highest efficacy and strength. As reported, the AA is acceptable if its value is (at least) two units.<sup>35,36</sup> Thence, APO-loaded COS-NP<sub>s</sub> treated group in both treatment regimens showed potentiated AA expressed by higher AA values (AA =8.09, 19.13) relative to those of free APO treated groups (AA =1.50, 1.75) in case of concurrent and post-treatment regimens, respectively (Table 4). These findings conferred preliminary screening for the gastric AA of medicated COS-NP<sub>s</sub> which would be further emphasized by histopathological, IHC, and biochemical studies.

## Histopathological examination

### H&E stain

Regarding concurrent induction and treatment regimen (Figure 6A), normal glandular mucosa and submucosa were observed in gastric tissue of normal control group (I). In contrast, positive control rats exhibited extensive areas of erosions, ulcerations, degeneration, and necrosis of the mucosal epithelial cells as well as thickened submucosa with severe congestion, marked leukocytic cells infiltration, and edema (II). Reduced thickness of mucosa due to loss of superficial epithelial layers, congested blood vessels, edema, and mild leukocytic cells' infiltration in submucosa were observed in rats that received free APO (III). Meanwhile, mucosa and submucosa retained their normal structures in APO-loaded COS-NP<sub>s</sub> treated group (IV).

Abbreviations: APO, apocynin; COS, chitosan oligosaccharide; NP<sub>s</sub>, nanoparticles; PDI, polydispersity index; RH, relative humidity; ZP, zeta potential.

In case of post-treatment regimen (Figure 6B), no histopathological alterations were noticed in stomach tissue of normal control rats (I). On the contrary, the stomach of positive control group showed multifocal areas of erosions, ulcerations, degeneration, and necrosis of the mucosal epithelial cells along with moderate submucosal congestion, marked leukocytic cells' infiltration, and edema (II). Focal areas of small erosions were observed in mucosa with mild leukocytic cells' infiltration and edema in submucosa of APO post-treated rats (III). Obviously, the gastric tissue retained its normal histopathological integrity in APO-loaded COS-NP<sub>s</sub> post-treated rats (IV). Noteworthy, the histopathological examination was consistent with PI of different rat groups supporting the potentiated AA of the medicated COS-NP<sub>s</sub>.

### Alcian blue stain

Histochemical staining of stomach tissues using alcian blue stain for detection of mucus glycoproteins is presented in Figure 7. Rat groups that followed the concurrent treatment regimens (Figure 7A) revealed that normal surface and mucosal glycoproteins' deposition was observed in normal control group (I). Loss of glycoproteins' secretion was detected nearby ulcer and erosion in both positive control and free APO concurrent treated rats (II and III, respectively). Surprisingly, medicated COS-NP<sub>s</sub> group preserved normal gastric mucosal glycoproteins' deposition (IV). Similar histochemical staining data were noticed in animals that received the post-treatment regimen (Figure 7B).

Indeed, mucus glycoproteins have a pivotal defense mechanism in protection against gastric ulceration through formation of a viscoelastic mucus gel layer which protects and lubricates the underlying epithelium of gastric tissue.<sup>54</sup> The pronounced effect of the medicated NP<sub>s</sub> to restore and retain the mucus glycoproteins could be relevant to the benefits of both APO and COS, firstly, the ability of orally administered APO to increase the gastric mucin content in case of ulceration,<sup>27</sup> and in addition, the mucoadhesive property of COS.<sup>24</sup> In our study, such mucoadhesiveness was greatly supported by in vitro-in vivo correlation results (in vitro mucin-binding efficiency [%] as summarized in Table 1 and in vivo histochemical staining of mucus glycoproteins).

### Toluidine blue staining

For detection of mast cells, gastric tissues of rats were stained with toluidine blue as illustrated in Figure 8. In

case of concurrent induction and treatment regimen (Figure 8A), the number of mast cells markedly increased in the submucosa of both positive control and free APO treated groups, particularly in underlining area of mucosal damage (II and III, respectively) in comparison with those of normal and medicated NP<sub>s</sub> treated animals (I and IV, respectively). On the other hand, in post-treatment regimen (Figure 8B), positive control rats manifested mild increase in the number of

mast cells (II), whereas few numbers of mast cells were observed in the other investigated groups (I, III, and IV). The fluctuation in the degree of increment of mast cells in the positive control groups in both treatment regimens could be linked with the induction dose of KP (two successive doses vs one dose in concurrent and post-treatment regimens, respectively). Mast cells are the key inflammatory cells which, upon activation by various stimuli, release a variety of mediators such as

**Figure 6** Histopathological examination of glandular stomach of rats following (A) concurrent induction and treatment regimen and (B) post-treatment regimen.

**Notes:** (I) Normal control group, (II) positive control group, (III) free APO treated group, and (IV) APO-loaded COS-NPs (F4) treated group. Oral dose of free or loaded APO was 14 mg/kg. leukotrienes, histamine, and platelet activating factor, contributing to gastric mucosal injury and ulceration.<sup>38</sup> The concomitant increment in mast cells upon induction with KP could be explained on the basis that nonsteroidal anti-inflammatory drugs decrease PGs which are extremely potent inhibitors of mast cell degranulation.<sup>55</sup> The anti-inflammatory effect of APO<sup>15-17</sup> that seems to be further potentiated upon loading in COS-NP<sub>s</sub> might account for the reduction in mast cell numbers and degranulation.

## IHC detection of COX-2 expression

The IHC evaluation of gastric COX-2 expression is shown in Figure 9. Regarding concurrent induction and treatment regimen (Figure 9A), positive control group exhibited strong COX-2 expression in area of mucosal damage as well as epithelial cells near area of mucosal damage and underlining submucosa (II). Gastric tissue sections from APO concurrent treated rats showed focal positive signal of COX-2 expression in area of mucosal damage staining epithelial cells and

**Figure 8** Histochemical staining of glandular stomach of rats with toluidine blue stain following (A) concurrent induction and treatment regimen and (B) post-treatment regimen. **Notes:** (I) Normal control group, (II) positive control group, (III) free APO treated group, and (IV) APO-loaded COS-NP<sub>s</sub> (F4) treated group. Oral dose of free or loaded APO was 14 mg/kg. Thick black arrows point to mucosal damage. Thin black arrows in insert point to mast cells. Thin red arrows point to leukocytic cells' infiltration. Toluidine blue stain, 100 $\times$  and insert 200 $\times$ .

**Abbreviations:** APO, apocynin; COS, chitosan oligosaccharide; M, mucosa; NP<sub>s</sub>, nanoparticles; SM, submucosa.

infiltrated leukocytes (III). Like normal control group (I), weak positive signal of COX-2 expression appeared in few epithelial cells of rats that received APO-loaded COS-NP<sub>s</sub> (IV). Similar findings were noticed for post-treatment regimen (Figure 9B).

Statistical analysis of positive signal expression of COX-2 in both treatment regimens elucidated its significant decrement in rats that received medicated COS-NP<sub>s</sub> when compared with positive control or free APO treated groups (Figure 9C a and b).

According to reported investigations, the integrated capability of both APO and COS combination to downregulate the COX-2 expression evoked by several stimuli, could explain the pronounced effect of medicated COS-NP<sub>s</sub>.<sup>10,56,57</sup>

## Biochemical studies

### Measurement of oxidative stress markers

Oxidative stresses are critically implicated in the pathogenesis of gastric ulceration.<sup>58</sup> The gastric tissue levels of oxidative stresses (MDA, SOD, and GSH) in both treatment regimens are shown in Figure 10. The data demonstrated that orally administered KP (positive control groups) induced highly significant elevated MDA levels ( $p < 0.001$ ) along with depleted SOD and GSH levels ( $p < 0.001$ ) in comparison with normal control animals. Moreover, the free APO treated groups did not elicit any significant change relative to positive control groups. Noteworthy, the APO-loaded COS-NP<sub>s</sub> treated groups had greatly normalized oxidative stress levels ( $p < 0.001$ ) as compared with positive control groups. Besides, their superlative significant effect over

that of free APO treated ones was prominently evident. Such effect might be mediated via the anti-oxidant activity of APO (a specific NADPH oxidase inhibitor)<sup>18</sup> which seems to be augmented upon formulation as a nanoparticulate delivery system. Also, the anti-oxidant property of COS cannot be ignored.<sup>9</sup>

### Measurement of NO

The data of both treatment regimens (Figure 11) revealed that rats subjected to KP administration (positive control groups) had a highly significant increment of gastric mucosal NO levels ( $p < 0.001$ ) as compared with normal rats. Such increment was significantly ( $p < 0.001$ ) abrogated in rats treated with APO-loaded COS-NP<sub>s</sub>.

Several lines of evidence have demonstrated the defensive role of NO as a gastroprotective mediator against gastric ulceration through enhancement of mucosal blood flow, stimulation of gastric mucus secretion, and reduction of leukocytic cells' infiltration.<sup>59–61</sup> Notwithstanding, upregulation or downregulation of NO can cause deleterious gastric mucosal damage.<sup>62,63</sup> The marked effectiveness of the medicated COS-NP<sub>s</sub> could be assigned to the activity of the drug and the polymer in normalizing the upregulated NO content in ulcerated gastric tissue.<sup>10,17</sup>

Collectively, the previously mentioned in vivo data were in harmony with each other, supporting the potentiated AA of orally administered APO-loaded COS-NP<sub>s</sub> against KP-induced gastric ulceration in both regimens. Such marvelous AA could be strongly related to several combined factors enumerated as follows: 1) the

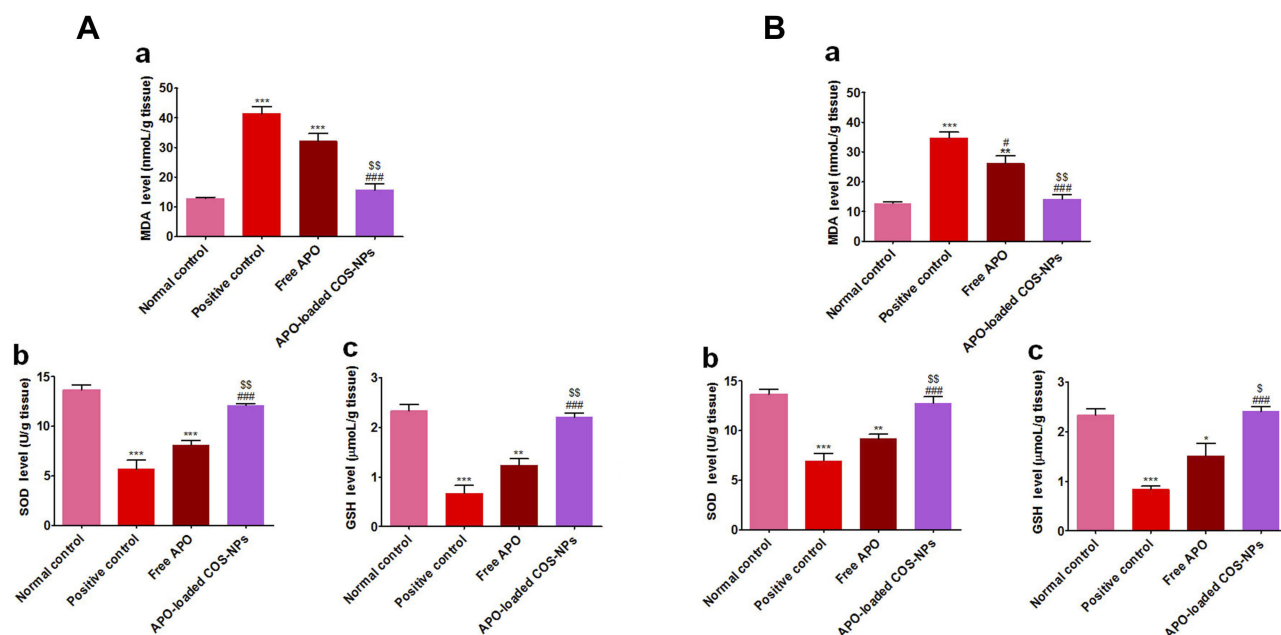

**Figure 9** Positive signal for IHC staining of COX-2 in rats' gastric tissues following (A) concurrent induction and treatment regimen and (B) post-treatment regimen. Statistical analysis of intensity of COX-2 positive signal in rats' gastric tissues (C) following (a) concurrent induction and treatment regimen and (b) post-treatment regimen. **Notes:** (I) Normal control group, (II) positive control group, (III) free APO treated group, and (IV) APO-loaded COS-NP<sub>s</sub> (F4) treated group. Oral dose of free or loaded APO was 14 mg/kg. Thick black arrows point to strong COX-2 expression in areas of mucosal necrosis. Yellow arrows in insert point to positive signal. IHC counterstained with Mayer's hematoxylin, 100× and insert 200×. Kruskal–Wallis test (non-parametric test) was applied followed by Dunn's multiple comparison test. \* $p < 0.05$  and \*\* $p < 0.01$  vs normal control group. # $p < 0.05$  vs positive control group. \$ $p < 0.05$  APO-loaded COS-NP<sub>s</sub> (F4) treated group vs free APO treated group. **Abbreviations:** APO, apocynin; COS, chitosan oligosaccharide; COX-2, cyclooxygenase-2; IHC, immunohistochemical; M, mucosa; NP<sub>s</sub>, nanoparticles; SM, submucosa.

mucoadhesive property of COS can prolong the gastric residence time of the NP<sub>s</sub> and subsequently sustain the release of APO and decrease the frequency of dosing;<sup>23,24</sup> 2) the permeation enhancing characteristic of COS could augment the paracellular uptake of NP<sub>s</sub> via reversible opening of the tight junctions between epithelial cells as well as the transcellular uptake of NP<sub>s</sub> across the epithelial cells;<sup>7</sup> 3) unlike microparticles, the cellular uptake of NP<sub>s</sub> is much easier for immune cells, like macrophages, in the inflamed area, leading to their selective accumulation in the ulcerative tissues;<sup>64,65</sup> 4) both APO and COS possess anti-inflammatory and anti-oxidant activities that reflect their pharmacological effect on gastric ulcers.<sup>8,9,15–18</sup>

## Conclusion

In summary, APO-loaded COS-NP<sub>s</sub> were successfully prepared by ionic gelation method. Maximum DEE % was achieved owing to the electrostatic interaction between the polymer and the drug. The results of FT-IR, DSC, and XRD of the chosen formula confirmed the drug entrapment in the matrix of the polymeric nanoparticulate system. Furthermore, the TEM displayed its nanosized and spherical shape. The in vitro release pattern of APO from COS-NP<sub>s</sub> exhibited a biphasic pattern (initial burst phase and sustained release phase) that can quickly confer therapeutic concentration of the drug which will be sustained over a long period of time. The prominent in vivo AA of APO-loaded COS-NP<sub>s</sub> was proven by histopathological, IHC, and biochemical

studies. One might look to the prepared NP<sub>s</sub> as a “scaffold” for APO sustained release in the gastric mucosa. Actually, APO-loaded COS-NP<sub>s</sub> deserve profound attention for their prospective application as a promising phytopharmaceutical nanoparticulate system for potentiated gastric AA.

## International Journal of Nanomedicine

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-nanomedicine-journal>

Dovepress

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
