The serotonergic (5-HTergic) system arising from the dorsal raphe nucleus (DRN) is implicated in various physiological and behavioral processes, including stress responses. The DRN is comprised of several subnuclei, serving specific functions with distinct afferent and efferent connections. Furthermore, subsets of 5-HTergic neurons are known to coexpress other transmitters, including GABA, glutamate, or neuropeptides, thereby generating further heterogeneity. However, despite the growing evidence for functional variations among DRN subnuclei, relatively little is known about how they map onto neurochemical diversity of 5-HTergic neurons. In the present study, we characterized functional properties of GAD67-expressing 5-HTergic neurons (5-HT/GAD67 neurons) in the rat DRN, and compared with those of neurons expressing 5-HTergic molecules (5-HT neurons) or GAD67 alone. While 5-HT/GAD67 neurons were absent in the dorsomedial (DRD) or ventromedial (DRV) parts of the DRN, they were selectively distributed in the lateral wing of the DRN (DRL), constituting 12% of the total DRL neurons. They expressed plasmalemmal GABA transporter 1, but lacked vesicular inhibitory amino acid transporter. By using whole-cell patch-clamp recording, we found that 5-HT/GAD67 neurons had lower input resistance and firing frequency than 5-HT neurons. As revealed by *c-Fos* immunohistochemistry, neurons in the DRL, particularly 5-HT/GAD67 neurons, showed higher responsiveness to exposure to an open field arena than those in the DRD and DRV. By contrast, exposure to contextual fear conditioning stress showed no such regional differences. These findings indicate that 5-HT/GAD67 neurons constitute a unique neuronal population with distinctive neurochemical and electrophysiological properties and high responsiveness to innocuous stressor.

## Introduction

Serotonin (5-HT) exerts a tonic modulatory effect on a wide variety of physiological and behavioral processes (Lucki, 1998). 5-HT-producing neurons in the dorsal raphe nucleus (DRN) provide the majority of 5-HT innervations mainly to lateral forebrain areas, such as the basal ganglia, amygdala, and prefrontal cortex (Jacobs and Azmitia, 1992). Activation of 5-HTergic neurons in the DRN facilitates learned defensive behaviors (Zanrossi et al., 2001), while their inhibition by microinjection of GABA or benzodiazepine chlordiazepoxide exerts anxiolytic effects that attenuate suppression of conditioned punishing stimulus on lever-pressing behavior (Thiébot et al., 1980). Thus, 5-HT released from DRN neurons plays an important role in the regulation of anxiety responses.

Although the DRN is defined as a single nucleus, it is composed of subregions, which are clusters of neurons with distinct

morphological features (Jacobs and Azmitia, 1992). They are organized into two main rostrocaudal subdivisions and further divided into six subnuclei: rostral, caudal, interfascicular, dorsomedial (DRD), ventromedial (DRV), and lateral “wing” (DRL) parts. They are topographically organized so that neurons in respective subnuclei innervate distinct targets and receive discrete afferent inputs (Jacobs and Azmitia, 1992). Importantly, these anatomically distinct subnuclei show differential responsiveness to various stressors (Hale and Lowry, 2011), suggesting that changes in neuronal activity of a limited subset of 5-HTergic neurons may have important implications in specific physiological and behavioral responses. Moreover, subpopulations of 5-HTergic neurons differently coexpress neuropeptides and transmitters, generating further complexity within topographically organized subnuclei (Jacobs and Azmitia, 1992; Michelsen et al., 2007). Accordingly, despite the growing evidence for rostral–caudal and dorsal–ventral variations in DRN responses, relatively little is known about correlation with unique neurochemical properties of 5-HTergic neurons.

The firing activity of 5-HTergic neurons in the DRN is controlled by two main mechanisms, i.e., autoregulatory influences arising from 5-HTergic neurons themselves and heteroregulation by local neurons and afferents, including GABAergic, glutamatergic, and dopaminergic inputs (Piñeyro and Blier, 1999). Of these, GABAergic and 5-HTergic transmissions can negatively regulate 5-HT release (Gallager and Aghajanian, 1976; Piñeyro and Blier, 1999), and are thereby considered possible targets of

therapeutic interventions. Interestingly, some 5-HTergic neurons have been shown to express GABA or its synthetic enzyme glutamic acid decarboxylase (GAD) (Nanopoulos et al., 1982; Belin et al., 1983; Fu et al., 2010; Hioki et al., 2010), suggesting a possible corelease of 5-HT and GABA. In this regard, these neurons may have a unique mechanism that controls their firing activity through autoregulatory feedback inhibition. However, functional properties of these neurons in the DRN remain largely unexplored.

In the present study, we characterized GAD67-expressing 5-HTergic neurons (5-HT/GAD67 neurons) in the DRN. We found that 5-HT/GAD67 neurons are localized to the DRL, constituting a unique neuronal population with distinct neurochemical and electrophysiological properties. Furthermore, these neurons show high responsiveness to innocuous stress compared with 5-HTergic neurons lacking GAD67 (5-HT neurons) and GAD67-expressing neurons lacking 5-HTergic markers (GAD67 neurons).

## Materials and Methods

**Animal.** The first-breeder Wistar/ST rats were purchased from Nippon SLC and bred in our laboratory. Male rats at 3–4 weeks of age were used for analysis unless noted otherwise. Rats were group housed in a room with a 12 h light/dark cycle (with lights on at 7:00 P.M.) and a temperature-controlled environment ( $22 \pm 1^\circ\text{C}$ ) with food and water *ad libitum*. All animals were treated in accordance with the guidelines for the Care and Use of Laboratory Animals of the Animal Research Committee of the Hokkaido University.

**Drug.** Diazepam (0.1 or 0.5 mg/kg; Wako Pure Chemical Industries) suspended in 0.9% saline containing 1% arabic gum (Nacalai Tesque) was injected intraperitoneally.

**Immunohistochemistry.** Rats were anesthetized with sodium pentobarbital (60 mg/kg, i.p.) and transcardially perfused via the left ventricle with 0.9% saline followed by 4% paraformaldehyde in 0.1 M sodium phosphate buffer (PB), pH 7.2. After removal from the skull, brains were immersed overnight in the same fixative at  $4^\circ\text{C}$ , placed in 0.1 M PB containing 10–30% sucrose at  $4^\circ\text{C}$ , and sectioned at 30  $\mu\text{m}$  thickness in a Leica HM 300 cryostat. Sections were collected in 0.01 M PBS, pH 7.2, containing 0.1% Triton X-100 (PBSTx) and stored for at least 1 h before immunohistochemical staining. All immunohistochemical incubations were done at room temperature. For immunofluorescence, sections were washed three times in PBSTx between incubations. Sections were incubated successively with 10% normal donkey serum for 20 min and a mixture of primary antibodies overnight: mouse anti-GAD67 (1:2000; MAB5406, Millipore Bioscience Research Reagents), goat anti-5-HT transporter (HTT) (Somogyi et al., 2004), rabbit anti-c-Fos (1:20,000; PC38T, Calbiochem), mouse anti-tryptophan hydroxylase (TPH; 1:2000; T0678, Sigma-Aldrich), guinea pig anti-parvalbumin (PV) (Nakamura et al., 2004), guinea pig anti-vesicular inhibitory amino acid transporter (VIAAT; 1  $\mu\text{g}/\text{ml}$ ) (Miyazaki et al., 2003; Miura et al., 2006), and rabbit anti-GABA transporter-1 (GAT-1; 1:1000; AB1570, Millipore Bioscience Research Reagents) antibodies. Then they were incubated with a mixture of fluorophore-linked species-specific secondary antibodies, Alexa 488 and Alexa 647 (Invitrogen), and indocarbocyanine (Cy3; Jackson ImmunoResearch) at a dilution of 1:200 for 1 h. Image were taken with a confocal laser-scanning microscope FV1000 or FV-10i (Olympus). To avoid cross talk between multiple fluorophores, Alexa 488, Cy3, and Alexa 647 fluorescent signals were acquired sequentially using the 488, 543, and 633 nm excitation laser lines, respectively. All images show single optical sections ( $640 \times 640$  pixels; pixel size, 110 nm).

Immunoperoxidase for c-Fos was performed by using the avidin–biotin immunoperoxidase technique. After incubation in PBS and normal goat serum, sections were successively incubated with c-Fos antibody for 48 h, biotinylated goat anti-rabbit IgG (Vector Laboratories) for 1 h, and avidin-biotinylated horseradish peroxidase complex (Vectastain Elite ABC Kit, Vector Laboratories) for 1 h. Immunoreaction was visualized by trans-

**Table 1. The primer sequences and estimated product lengths for single-cell RT-PCR**

Gene	Sequence	Product length (bp)
TPH2	Forward: 5'-TACGGCACCCGACTTGAC-3' Reverse: 5'-TGGCCACATCCACCAATAC-3'	84
GAD67	Forward: 5'-CAAGTTCTGGCTGATGTGGA-3' Reverse: 5'-GCCACCTGTGTAGCTTTTC-3'	231
NSE	Forward: 5'-ATAGTGGGCGATGACCTGAC-3' Reverse: 5'-ATGAACGTGTCTCCCTTTC-3'	200
VIAAT	Forward: 5'-GGGCTGGAACCTGACAAA-3' Reverse: 5'-GGAGGATGGCTAGGGTAG-3'	65

Primer sequences and estimated product lengths for RT-PCR are shown. The primers are used for both the first and second PCR amplifications. The concentration of the primers is 1  $\mu\text{M}$  for the first PCR and 10  $\mu\text{M}$  for the second PCR.

ferring the sections to 50 mM Tris-HCl buffer, pH 7.6, containing 0.05% diaminobenzidine, 0.6% nickel ammonium sulfate, and 0.01%  $\text{H}_2\text{O}_2$ .

**Fluorescent in situ hybridization.** Procedures for double fluorescent *in situ* hybridization (FISH) labeling were reported previously (Yamasaki et al., 2010). To fresh frozen sections we applied  $\sim 300$  ng/ml of fluorescein- or digoxigenin (DIG)-labeled riboprobes that were antisense to cDNAs of mouse GAD67 (nucleotide residues 1036–2015; GenBank accession number NM\_008077), TPH2 (nucleotide residues 1–1000; GenBank accession number NM\_173391.3), and GAT-1 (nucleotide residues 380–2179; GenBank accession number NM\_178703). DIG and fluorescein were detected by the two-step method: the first detection was with peroxidase-conjugated anti-fluorescein antibody (Roche Diagnostics; 1:500, 1 h) and the FITC-TSA Plus amplification kit (PerkinElmer), and the second detection was with peroxidase-conjugated anti-DIG antibody (Roche Diagnostics; 1:500, 1 h) and the Cy<sub>3</sub>-TSA Plus amplification kit (PerkinElmer). Residual activities of peroxidase introduced during the first detection were inactivated by incubation of sections with 0.6%  $\text{H}_2\text{O}_2$  for 30 min. The specificity of FISH was confirmed by blank labeling using control sense cRNA probes. Images were taken with an FV1000 confocal laser-scanning microscope (Olympus).

**Electrophysiological recording.** Under deep anesthesia with diethyl ether, rats were decapitated, and coronal brain slices through the DRN (250  $\mu\text{m}$  thick) were cut with a Leica VT1000S slicer in ice-cold low- $\text{Na}^+$  solution with a specific composition (in mM): 215 sucrose, 2.5 KCl, 4  $\text{MgCl}_2$ , 4  $\text{MgSO}_4$ , 1  $\text{CaCl}_2$ , 26  $\text{NaHCO}_3$ , 1.6  $\text{NaH}_2\text{PO}_4$ , and 20 glucose bubbling with 95%  $\text{O}_2$  and 5%  $\text{CO}_2$ . For recovery, slices were incubated for 30 min in a mixed solution of 50% low- $\text{Na}^+$  solution and 50% normal bathing solution [containing the following (in mM): 125 NaCl, 2.5 KCl, 2  $\text{CaCl}_2$ , 1  $\text{MgSO}_4$ , 1.25  $\text{NaH}_2\text{PO}_4$ , 26  $\text{NaHCO}_3$ , and 20 glucose, pH 7.4], which was bubbled continuously with a mixture of 95%  $\text{O}_2$  and 5%  $\text{CO}_2$  at  $37^\circ\text{C}$ , followed by a mixed solution of 10% low- $\text{Na}^+$  solution and 90% normal bathing solution at  $37^\circ\text{C}$ . Whole-cell patch-clamp recordings were made from DRN neurons in coronal acute slices using an upright microscope (BX51WI; Olympus) equipped with an infrared-CCD camera system (Hamamatsu Photonics) in normal bathing solution at  $32^\circ\text{C}$ . The resistance of the patch pipette was 3–6 M $\Omega$  when filled with the standard intracellular solution containing the following (in mM): 6 KCl, 130 K D-gluconate, 10 NaCl, 10 HEPES, 0.5 EGTA, 0.1  $\text{CaCl}_2$ , 2  $\text{MgCl}_2$ , 4 Na-ATP, and 0.4 Na-GTP, pH 7.3, adjusted with KOH. The lateral wing subdivision of the DRN (DRL) was selected as the recording region because the density of GAD67-positive 5-HT neurons was relatively higher than in ventral or dorsal parts of the DRN (Hioki et al., 2010). After whole-cell recording from DR neurons held at a membrane potential of  $-70$  mV and switched to current-clamp recording mode, membrane potentials were recorded with an Axopatch 200B amplifier (Molecular Devices) and obtained by stepwise current injections (from  $-0.2$  to 0.5 nA; duration, 500 ms). Capacitance compensation and bridge-balance adjustment were made simultaneously. The pCLAMP 9 software (Molecular Devices) was used for stimulation and data acquisition. Signals were filtered at 3 kHz and digitized at 20 kHz. The liquid junction potential was  $\sim 10$  mV between the pipette solution and the normal bath solution, which was subtracted from the recorded data.

**Figure 1.** Selective localization of 5-HT/GAD67 neurons in the lateral wing of the dorsal raphe nucleus. **A**, FISH for TPH2 mRNA showing the distribution of 5-HTergic neurons in the DRN, median raphe nucleus (MRN), and B9 raphe nucleus (B9). **B<sub>1</sub>–E<sub>2</sub>**, Double FISH for TPH2 mRNA (green) and GAD67 mRNA (red) in the DRN (**B<sub>1</sub>–B<sub>3</sub>**) with high-power views of the DRL (**C<sub>1</sub>, C<sub>2</sub>**), DRD (**D<sub>1</sub>, D<sub>2</sub>**), and DRV (**E<sub>1</sub>, E<sub>2</sub>**). In the DRN, neurons expressing GAD67 mRNA (arrowheads) are preferentially distributed in the DRL. **F<sub>1</sub>, F<sub>2</sub>**, Double immunofluorescence HTT (green) and GAD67 (red) in the DRL. GAD67 is detected in perikarya (asterisk) and axonal varicosities (arrowheads) of 5-HT/GAD67 neurons. Scale bars: **A**, (in **B<sub>3</sub>**) **B<sub>1</sub>–B<sub>3</sub>**, 1 mm; (in **C<sub>2</sub>**) **C<sub>1</sub>, C<sub>2</sub>**, (in **D<sub>2</sub>**) **D<sub>1</sub>, D<sub>2</sub>**, (in **E<sub>2</sub>**) **E<sub>1</sub>, E<sub>2</sub>**, 1  $\mu$ m; (in **F<sub>2</sub>**) **F<sub>1</sub>, F<sub>2</sub>**, 5  $\mu$ m.

*Single-cell mRNA collection and reverse-transcription polymerase chain reaction.* After whole-cell patch-clamp recording, the intracellular contents of each neuron were aspirated with negative pressure into the glass-electrode pipette that was used for recording and ejected into 10  $\mu$ l RNase-free water (Promega). These samples (putatively containing mRNA) were immediately stored at  $-80^{\circ}\text{C}$ . The mRNA was converted to cDNA with the QuantiTect Reverse Transcription Kit (Qiagen). For cDNA amplification, PCR was performed with the SYBR GreenER qPCR SuperMix for ABI PRISM (Invitrogen) in the ABI PRISM 7000 Sequence Detection System (Applied Biosystems). The primer sequences and estimated product lengths are listed in Table 1. PCR was conducted under the following conditions:  $50^{\circ}\text{C}$  for 2 min and  $95^{\circ}\text{C}$  for 10 min, followed by 40 cycles of  $94^{\circ}\text{C}$  for 30 s and  $54^{\circ}\text{C}$  for 30 s using a programmable thermal controller (PTC-100TM; MJ Research). PCR products were visualized using ethidium bromide staining after electrophoresis in a 3% agarose gel. Amplification of neuron-specific enolase cDNA confirmed that aspiration from the neuron was successful. PCR reactions without cDNA templates (containing only a pipette solution, bath solution, or noncellular debris) or with non-reverse transcription (RT) template were used as negative controls.

*Open field stress.* The open field (OF) stress test was used to induce mild and novel environmental stress on rats. The OF apparatus was a square chamber (90 cm long by 90 cm wide by 40 cm high). The central or peripheral zone was defined as a central square of 30 cm length by 30 cm width or a 10 cm width of inner circumference, respectively. To evaluate the locomotor activity, the traveled distance was recorded and automatically analyzed by the LimeLight 2 software package (Actimetrics), and the total number of crossings (the times animals crossed the lines dividing  $9 \times 9$  squares in the open field) was also recorded for 30 min. Anxiolytic drug, diazepam, or vehicle (0.9% saline containing 1% arabic gum) was administered intraperitoneally 30 min before exposing the OF apparatus. Tested rats and home cage controls were fixed for immunohistochemistry 2 h after OF stress.

*Contextual fear conditioning stress.* The contextual fear conditioning (CFC) stress test was used to induce severe and memory-dependent stress on rats. The detailed procedures were described previously (Ohmura et al., 2008, 2010). To quantify fear responses, electrical footshocks were administered five times (2 s; 0.3 mA; 30 s intervals) in a chamber 24 h before the test. Non-footshock rats, exposed only to the chamber, were used as control groups. Rats were reexposed to the cham-

ber without footshocks for 15 min, and freezing behavior was analyzed automatically by the FreezeFrame software package (Actimetrics). Freezing behavior was defined as a lack of movement, except for respiration, accompanied by an arched back and retraction of the ears. We intraperitoneally administered diazepam or vehicle 30 min before reexposure to the shock box. Tested rats were fixed for immunohistochemistry 2 h after CFC stress.

**Semiquantitative cell counting.** Procedures of immunoperoxidase-stained c-Fos-positive cell counting were reported previously (Izumi et al., 2011). We selected representative sections positioned between 6.95 and 7.05 mm posterior to bregma from each rat. Unit areas of the brain were digitally recorded with a CCD camera (CCD-IRIS; Sony) connected to a photomicroscope (BX50; Olympus) and a densitometric video image analysis system (MCID system; InterFocus Imaging). The number of c-Fos-positive cells was counted in three rostrocaudal sections every 20  $\mu\text{m}$  in the DRD, DRV, and DRL, and assessed by automated selection of cells within the unit areas ( $200 \times 200 \mu\text{m}$ ) that satisfied the following criteria: (1) the gray value of the cell nucleus was higher than the threshold value (threshold gray value 5–50% higher than the background gray value), and (2) nuclei had a diameter of 4–12  $\mu\text{m}$  (to exclude cell debris and artifacts). The background gray value was determined in a part of each unit area containing no nuclei. Finally, the number of c-Fos-positive cells was averaged in respective regions of the DRN.

**Data analysis.** Differences between multiple group comparisons were performed using a one-way or two-way ANOVA with Bonferroni's *post hoc* test, if the differences in the variance of these multiple groups were not significant. The  $\alpha$  level was set at 5%. When the difference in the variance of multiple groups was significant, a Kruskal–Wallis test was performed. Subsequently, multiple comparison was performed using the Mann–Whitney *U* test, setting the  $\alpha$  level at 5%; that is, the  $\alpha$  level was set at 1.7% (5%/3), 0.71% (5%/7), or 0.33% (5%/15) for multiple comparisons, because the number of comparisons was 3 (three groups), 7 (four groups), or 15 (nine groups), respectively. Differences between two groups were compared using Student's *t* test when the difference in the variance of two groups was not significant. If the difference of variance in two groups was significant, comparisons were performed using the Mann–Whitney *U* test.

## Results

### 5-HT/GAD67 neurons are distributed in the lateral wing of DRN

To identify 5-HTergic and GABAergic neurons, we first examined the cellular expression of TPH2 and GAD67 mRNAs, respectively, by double-labeling FISH. TPH2 mRNA was strongly expressed in the DRN, median raphe nucleus, and B9 raphe nucleus (Fig. 1A). In the DRN, TPH2 mRNA was detected in the DRL, DRD, and DRV (Fig. 1B<sub>1</sub>, green). GAD67 mRNA-expressing neurons were densely distributed in the DRL, whereas they were few in the DRD and DRV (Fig. 1B<sub>1</sub>, red). In the DRL, some neurons were colabeled for TPH2 and GAD67 mRNAs (arrowheads; 17.5%, 36 of 205 cells), while others were labeled for

**Figure 2.** 5-HT/GAD67 neurons in the DRL transiently increase at  $\sim$ 4 weeks of age. **A–F**, Double FISH for TPH2 mRNA (green) and GAD67 mRNA (red) in the DRN (**A**, **C**, **E**) with high-power images of the DRL (**B**<sub>1</sub>, **B**<sub>2</sub>, **D**<sub>1</sub>, **D**<sub>2</sub>, **F**<sub>1</sub>, **F**<sub>2</sub>) at 2, 4, and 8 weeks of age. 5-HT neurons expressing GAD67 mRNA (arrowheads) are occasionally observed in the DRL at 4 weeks of age (**D**<sub>1</sub>, **D**<sub>2</sub>), but not in 2 or 8 weeks (**B**<sub>1</sub>, **B**<sub>2</sub>, **F**<sub>1</sub>, **F**<sub>2</sub>). Scale bars: (in **E**) **A**, **C**, **E**, 500  $\mu\text{m}$ ; (in **F**<sub>2</sub>) **B**<sub>1</sub>, **B**<sub>2</sub>, **D**<sub>1</sub>, **D**<sub>2</sub>, **F**<sub>1</sub>, **F**<sub>2</sub>, 20  $\mu\text{m}$ .

**Figure 3.** Patterns of single-cell RT-PCR in the DRL. Three neuron types are classified based on the expression of TPH2 and GAD67 mRNAs: the 5-HT neuron expressing TPH2 mRNA only (left), 5-HT/GAD67 neuron expressing both TPH2 and GAD67 mRNAs (middle), and GAD67 neuron expressing GAD67 mRNA only (right). Note that 5-HT neurons and 5-HT/GAD67 neurons express no detectable levels of VIAAT mRNA, whereas GAD67 neurons highly express it. Neuron-specific enolase (NSE) is used as a positive control. Lane M indicates a 100 bp DNA ladder. Values in parentheses indicate the expected length of each PCR product.

TPH2 mRNA or GAD67 mRNA (Fig. 1C<sub>1</sub>, C<sub>2</sub>). Neurons coexpressing TPH2 mRNA and GAD67 mRNA were very rare in the DRD (2.1%, 2 of 94 cells; Fig. 1D<sub>1</sub>, D<sub>2</sub>) and DRV (0%, 0 of 219; Fig. 1E<sub>1</sub>, E<sub>2</sub>). By double immunofluorescence for HTT, a marker for 5-HTergic neurons, some 5-HT neurons in the DRL were demonstrated to coexpress GAD67 in their perikarya and axonal varicosities (Fig. 1F<sub>1</sub>, F<sub>2</sub>, asterisks and arrowheads, respectively). Thus, 5-HT/GAD67 neurons are mainly distributed in the DRL.

Furthermore, the extent of GAD67 expression in DRL 5-HT neurons differed significantly among different age groups. By double-labeling FISH, we found that the percentage of 5-HT/GAD67 neurons at 4 weeks of age was 22.0% of the total TPH2 mRNA-positive cells (27 of 123 cells; Fig. 2C, D<sub>1</sub>, D<sub>2</sub>). This was considerably higher than the percentages at 2 and 8 weeks [0.5% (1 of 190 cells) and 1.7% (3 of 179 cells), respectively; Fig. 2A, B<sub>1</sub>, B<sub>2</sub>, E, F<sub>1</sub>, F<sub>2</sub>]. Thus, GAD67 expression in 5-HT neurons transiently increases at  $\sim$ 4 weeks and decreases thereafter.

**Figure 4.** Lack of VIAAT expression in 5-HT and 5-HT/GAD67 neurons in the DRL. **A<sub>1</sub>–B<sub>1</sub>**, Double FISH for VIAAT mRNA (red; **A<sub>1</sub>–B<sub>1</sub>**) and TPH2 mRNA (green; **A<sub>1</sub>, A<sub>2</sub>**) or GAD67 mRNA (green; **B<sub>1</sub>**). Signals for VIAAT mRNA are detected in most of the GAD67 mRNA-positive cells (asterisks; **B<sub>1</sub>**), but not in TPH2 mRNA-positive neurons (**A<sub>1</sub>, A<sub>2</sub>**). **C<sub>1</sub>–D<sub>2</sub>**, Triple immunofluorescence for HTT (blue), GAD67 (green), and VIAAT (red). There are three neuron types based on the expression of HTT and GAD67: HTT-positive 5-HT neurons (H), HTT/GAD67-positive 5-HT/GAD67 neurons (H/G), and GAD67-positive GAD67 neurons (G). The images in **D<sub>1</sub>** and **D<sub>2</sub>** are enlarged views of a GAD67 neuron in **C<sub>1</sub>–C<sub>3</sub>**. Note the diffuse VIAAT immunolabeling in perikarya of GAD67 neurons, but not 5-HT or 5-HT/GAD67 neurons. **E, F**, Double immunofluorescence for HTT (red) and VIAAT (green) in the dIPAG (**E**) and the RVLM (**F**). Scale bars: **A<sub>2</sub>** (for **A<sub>1</sub>, A<sub>2</sub>**), **C<sub>2</sub>** (for **C<sub>1</sub>–C<sub>3</sub>**), 20  $\mu$ m; **B<sub>1</sub>, D<sub>2</sub>** (for **D<sub>1</sub>, D<sub>2</sub>**), **E, F**, 5  $\mu$ m.

To quantitatively classify the neurochemical phenotype of DRL neurons, we performed single-cell RT-PCR using the total RNA sampled from individual neurons after the whole-cell patch-clamp recording (see Fig. 6). Representative patterns are shown in Figure 3. According to the pattern of mRNA expression, DRL neurons were classified into four types: 5-HT neurons expressing TPH2 mRNA only (Fig. 3, left), 5-HT/GAD67 neurons expressing both TPH2 and GAD67 mRNAs (middle), GAD67 neurons expressing GAD67 mRNA only (right), and undefined neurons lacking neither mRNAs. Of the total analyzed 82 neurons, 5-HT neurons accounted for 52.4% (43 neurons), 5-HT/GAD67 neuron for 12.2% (10 neurons), GAD67 neuron for 4.9% (4 neurons), and undefined neurons for 30.5% (25 neurons). Therefore, 5-HT/GAD67 neurons are selectively distributed in the lateral wing of DRN and constitute 12% of the total DRL neurons.

### 5-HT/GAD67 neurons lack VIAAT

We also examined the expression of VIAAT mRNA by single-cell RT-PCR (Fig. 4). All of the GAD67 neurons examined coexpressed VIAAT mRNA. Unexpectedly, none of the 5-HT/GAD67 neurons showed amplified signals for VIAAT mRNA. The lack of VIAAT expression in 5-HT/GAD67 neurons was further assessed by FISH and immunofluorescence (Fig. 5). Because the absence of VIAAT mRNA in 5-HT/GAD67 neurons was unexpected, we tested this by FISH as well. Although most of the GAD67 mRNA-expressing neurons coexpressed VIAAT mRNA in the DRL (Fig. 5*B<sub>1</sub>, B<sub>2</sub>*, asterisks; 327 of 355 cells, 92.1%), VIAAT mRNA was detected in none of the TPH2 mRNA-expressing neurons (Fig. 5*A*; 0 of 36 cells). Triple immunofluorescence for GAD67, VIAAT, and HTT showed that GAD67-positive neurons (Fig. 5*C<sub>1</sub>–D<sub>2</sub>*, G) were diffusely labeled for VIAAT. However, perikarya of 5-HT neurons (Fig. 5*C<sub>1</sub>, C<sub>2</sub>*, H) and 5-HT/GAD67 neurons (Fig. 5*C<sub>1</sub>, C<sub>2</sub>*, H/G) lacked immunolabeling for VIAAT. The lack of VIAAT labeling was also true in HTT-positive axons and terminals in the dorsolateral periaqueductal gray (dIPAG) and the rostral ventrolateral medulla (RVLM), i.e., major projection targets of the DRL (Fig. 5*E<sub>1</sub>, E<sub>2</sub>*). Thus, 5-HT/GAD67 neurons lack the expression of VIAAT, a molecule essential for vesicular filling of GABA.

### 5-HT/GAD67 neurons express GAT-1

Deletion of VIAAT gene in mice severely reduces, but does not completely eliminate, inhibitory neurotransmission (Wojcik et al., 2006). This fact is taken to be due to the efflux of GABA by reverse operation of plasmalemmal GATs (Attwell et al., 1993). By FISH and immunofluorescence, we investigated in the DRL the expression of GAT-1 (Fig. 5), a GAT subtype preferentially localized on GABAergic neurons (Itouji et al., 1996; Morara et al., 1996). Double FISH labeling (Fig. 5*A*) revealed that there were a few neurons coexpressing GAT-1 and TPH2 mRNAs in the DRL (Fig. 5*B<sub>1</sub>, B<sub>2</sub>*, asterisks), but not in the DRD (Fig. 5*C<sub>1</sub>, C<sub>2</sub>*), or DRV (Fig. 5*D<sub>1</sub>, D<sub>2</sub>*). By immunofluorescence, GAT-1 labeling was frequently found along neuronal processes labeled for HTT (Fig. 5*E<sub>1</sub>, E<sub>2</sub>*, white arrowheads) and also along processes protruding from perikarya of 5-HT/GAD67 neurons colabeled for HTT and GAD67 (yellow arrowheads). Therefore, 5-HT/GAD67 neurons express GAT-1, a molecule mediating GABA transport across the cell membrane.

Therefore, 5-HT/GAD67 neurons express GAT-1, a molecule mediating GABA transport across the cell membrane.

### Distinct electrophysiological properties of 5-HT/GAD67 neurons

To examine functional characteristics of 5-HT/GAD67 neurons, whole-cell patch-clamp recordings were performed from DRL neurons in acute coronal slices (Fig. 6*A, B*). After each recording,

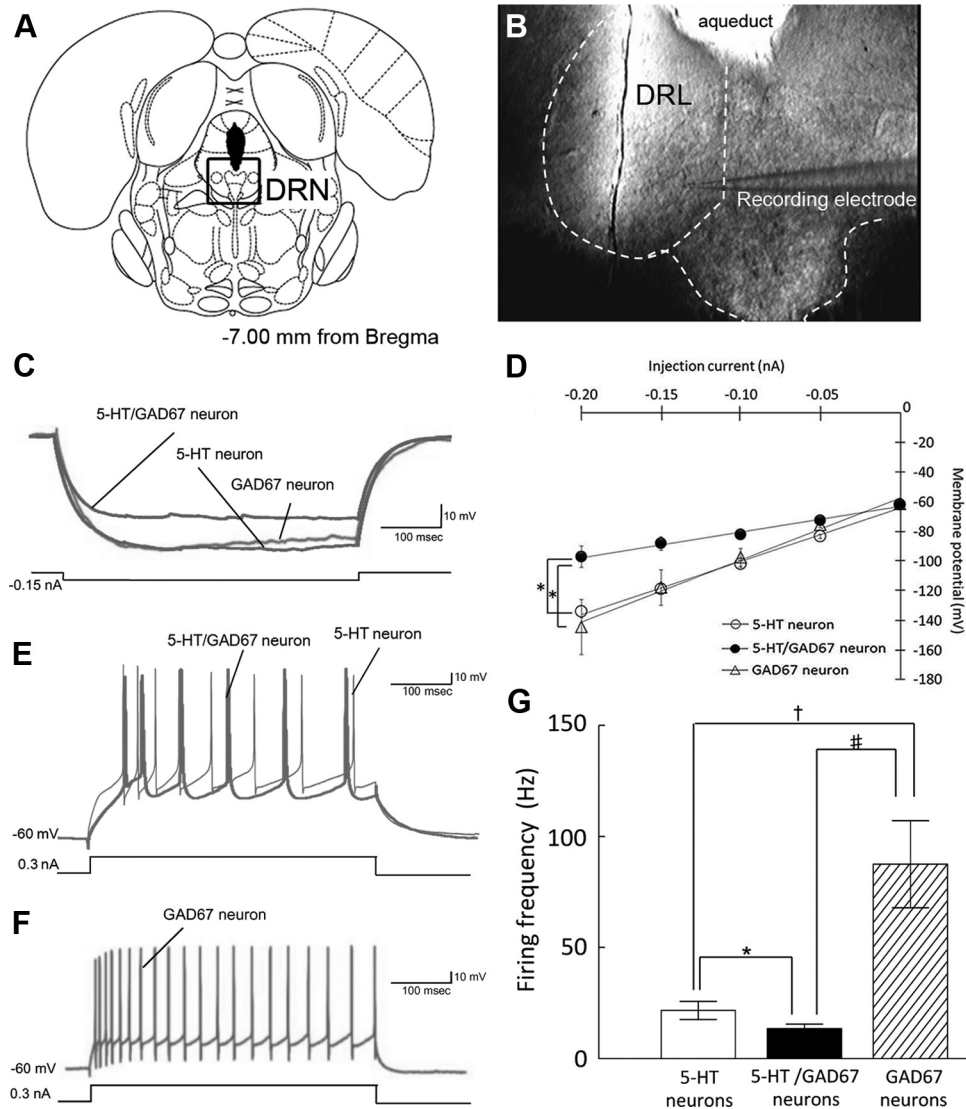

**Figure 5.** Expression of GAT-1 in 5-HT/GAD67 neurons. **A–D<sub>2</sub>**, Double FISH for GAT-1 (green) and TPH2 (red) mRNA in the DRN (**A**) with high-power views of the DRL (**B<sub>1</sub>**, **B<sub>2</sub>**), DRD (**C<sub>1</sub>**, **C<sub>2</sub>**), and DRV (**D<sub>1</sub>**, **D<sub>2</sub>**). Some neurons in the DRL coexpress GAT-1 and TPH2 mRNAs (asterisks). **E<sub>1</sub>**, **E<sub>2</sub>**, Triple immunofluorescence for HTT (green), GAT-1 (red), and GAD67 (blue) in the DRL. GAT-1 is often detected in HTT-positive fibers (white arrowheads), and also in somatodendritic processes protruding from the soma of HTT/GAD67-positive neurons (yellow arrowheads). The inset shows diffuse perikaryal labeling for GAD67 in this 5-HT/GAD67 neuron (asterisk). Scale bars: **A**, **B<sub>2</sub>** (for **B<sub>1</sub>**, **B<sub>2</sub>**), **C<sub>2</sub>** (for **C<sub>1</sub>**, **C<sub>2</sub>**), **D<sub>2</sub>** (for **D<sub>1</sub>**, **D<sub>2</sub>**), 20  $\mu$ m; **E<sub>1</sub>**, **E<sub>2</sub>**, inset, 5  $\mu$ m.

5-HT neurons, 5-HT/GAD67 neurons, and GAD67 neurons were classified by single-cell RT-PCR (Fig. 3). In current-clamp recordings, the amplitude of action potentials in GAD67 neurons was significantly smaller than that in other neuron types ( $F_{(2,54)} = 4.372$ ;  $p < 0.05$ ), while no differences were found in the duration of action potentials, afterhyperpolarization, or resting membrane potential (Table 2). Figure 6C shows a representative recording of membrane potential changes evoked by a negative current injection to 5-HT neurons, 5-HT/GAD67 neurons, and GAD67 neurons, from which the current–voltage characteristics were plotted (Fig. 6D). The input resistance in 5-HT/GAD67 neurons ( $191.02 \pm 25.85$  M $\Omega$ ) was significantly lower than that in 5-HT neurons ( $360.82 \pm 20.72$  M $\Omega$ ) and GAD67 neurons ( $418.41 \pm 95.49$  M $\Omega$ ;  $F_{(2,54)} = 8.51$ ;  $p < 0.05$ ). Figure 6, E and F, shows the firing pattern during injection of 0.3 nA positive currents. The firing frequency in 5-HT/GAD67 neurons was significantly lower than that in 5-HT neurons and GAD67 neurons (5-HT neurons,  $37.42 \pm 3.26$  Hz; 5-HT/GAD67 neurons,

$12.90 \pm 1.77$  Hz; GAD67 neurons,  $87.50 \pm 19.62$  Hz;  $F_{(2,54)} = 20.91$ ;  $p < 0.05$ ; Fig. 6G). Therefore, 5-HT/GAD67 neurons exhibit lower input resistance and firing frequency compared to other neuron types in the DRL. Moreover, 5-HT/GAD67 neurons show larger amplitudes of action potentials than GAD67 neurons.

#### Open field stress preferentially induces diazepam-sensitive c-Fos expression in the DRL

To compare the responsiveness of DRN neurons to innocuous stress, we placed animals to a novel OF arena and examined c-Fos expression 2 h after the OF stress test. In each subdivision of the DRN, the density of c-Fos-positive cells was significantly increased after OF stress (Fig. 7). Of these, OF stress induced significantly higher increase in the DRL ( $447.66 \pm 104.92$  cells/mm<sup>2</sup>;  $n = 12$ ; Fig. 7D) than in the DRD ( $178.19 \pm 76.67$  cells/mm<sup>2</sup>;  $n = 12$ ; Fig. 7E) and DRV ( $182.66 \pm 76.50$  cells/mm<sup>2</sup>;  $n = 12$ ;  $F_{(8,294)} = 9.88$ ;  $p < 0.0033$ ; Fig. 7F).

**Figure 6.** Electrophysiological characterization of DRN neurons using whole-cell patch-clamp recording. **A, B**, DRN position (**A**) and representative photograph of a coronal slice submerged in our recording chamber depicting the position of an electrode for the recording of membrane potentials (**B**). **C**, Representative recording of membrane potential changes evoked by negative current injection to 5-HT neuron, 5-HT/GAD67 neuron, and GAD67 neuron. **D**, Summarized linear voltage–current plot for recorded cells from both neuronal types. The input resistance of 5-HT/GAD67 neurons ( $191.02 \pm 25.82 \text{ M}\Omega$ ) is significantly lower than 5-HT neurons ( $360.82 \pm 20.72 \text{ M}\Omega$ ) and GAD67 neurons ( $418.41 \pm 95.49 \text{ M}\Omega$ ;  $F_{(2,54)} = 8.51$ ;  $*p < 0.05$ ). **E, F**, Representative recordings of membrane potential changes evoked by a positive current injection of 0.3 nA to a 5-HT neuron, 5-HT/GAD67 neuron, and GAD67 neuron. **G**, Summarized bar graph of the firing frequency of 5-HT/GAD67 neurons, which is significantly lower than that of 5-HT neurons and GAD67 neurons (5-HT neurons,  $37.42 \pm 3.26 \text{ Hz}$ ; 5-HT/GAD67 neurons,  $12.90 \pm 1.77 \text{ Hz}$ ; GAD67 neurons,  $87.50 \pm 19.62 \text{ Hz}$ ;  $F_{(2,54)} = 20.905$ ;  $*, \#, \dagger p < 0.05$ ).

**Table 2. Analysis of membrane potential parameters**

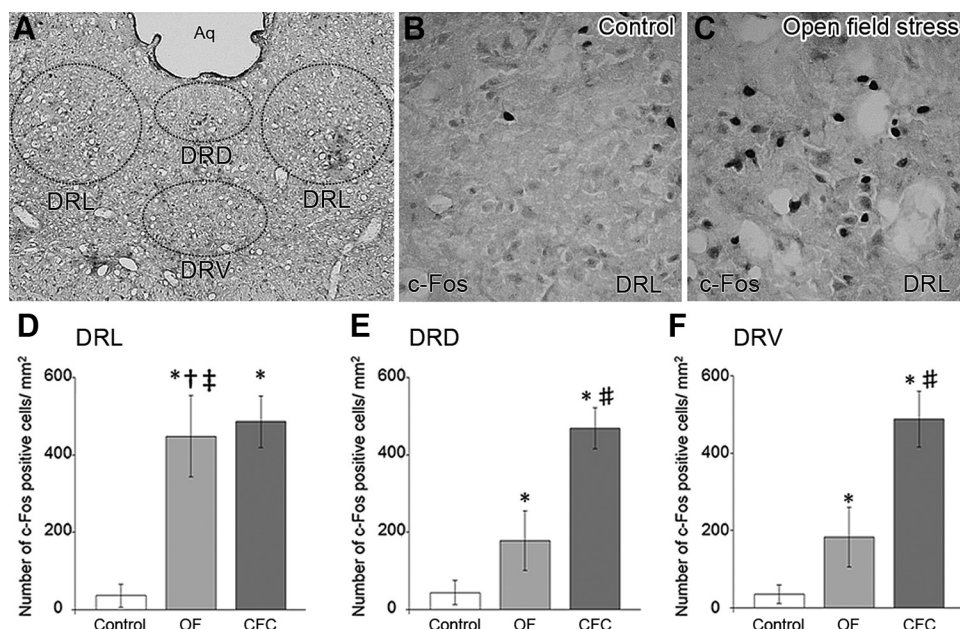

Parameter	5-HT neuron (n = 43)	5-HT/GAD67 neuron (n = 10)	GAD67 neuron (n = 4)
Resting membrane potential (mV)	$-61.82 \pm 1.67$	$-64.91 \pm 4.14$	$-52.13 \pm 17.17$
Threshold (mV)	$-27.36 \pm 1.05$	$-31.06 \pm 1.50$	$-24.06 \pm 7.04$
Action potential amplitude (mV)	$70.37 \pm 2.65$	$68.94 \pm 3.94$	$45.30 \pm 5.59^*$
Action potential duration (ms)	$2.22 \pm 0.12$	$1.98 \pm 0.24$	$1.78 \pm 0.22$
Afterhyperpolarization (mV)	$-25.66 \pm 1.22$	$-24.14 \pm 1.31$	$-29.00 \pm 7.91$

Significantly lower amplitudes of action potentials are observed in GAD67 neurons among the three neuronal groups ( $F_{(2,54)} = 4.372$ ;  $*p < 0.05$ ). No significant differences were found in the action potential duration [ $F_{(2,54)} = 0.982$ , not significant (n.s.)], afterhyperpolarization ( $F_{(2,54)} = 0.856$ , n.s.), or resting membrane potential ( $F_{(2,54)} = 1.707$ , n.s.) among the three groups.

We then tested whether the c-Fos expression was selectively induced due to emotional stress, especially anxiety, we administered diazepam, a major benzodiazepine anxiolytic drug, 30 min before OF stress test (Fig. 8). Low-dose diazepam (0.1 mg/kg, i.p.)

did not affect OF stress-induced c-Fos expression in all three subdivisions (DRL,  $332.42 \pm 173.33 \text{ cells/mm}^2$ ,  $n = 6$ ; DRD,  $175.13 \pm 54.86 \text{ cells/mm}^2$ ,  $n = 6$ ; DRV,  $178.33 \pm 56.80 \text{ cells/mm}^2$ ,  $n = 6$ ). However, high-dose diazepam (0.5 mg/kg, i.p.) significantly reduced c-Fos expression in the DRL ( $98.06 \pm 47.78 \text{ cells/mm}^2$ ;  $n = 12$ ; Fig. 8A), but not in the DRD ( $185.47 \pm 51.46 \text{ cells/mm}^2$ ;  $n = 12$ ; Fig. 8B) or DRV ( $175.91 \pm 57.27 \text{ cells/mm}^2$ ,  $n = 12$ ; Fig. 8C) (DRL,  $F_{(5,174)} = 23.85$ ; DRD,  $F_{(5,174)} = 7.15$ ; DRV,  $F_{(5,174)} = 10.52$ ;  $p < 0.0071$  for each). Administration of high-dose diazepam increased the ratio of moving distance in the central zone of an OF arena (vehicle,  $1.88 \pm 1.06\%$ ,  $n = 12$ ; diazepam, 0.1 mg/kg,  $1.97 \pm 1.15\%$ ,  $n = 6$ ; 0.5 mg/kg,  $6.21 \pm 1.94\%$ ,  $n = 12$ ;  $F_{(2,27)} = 26.94$ ;  $p < 0.05$ ; Fig. 8D) and reduced the ratio in the peripheral zone (vehicle,  $81.39 \pm 5.02\%$ ,  $n = 12$ ; diazepam, 0.1 mg/kg,  $78.01 \pm 8.67\%$ ,  $n = 6$ ; 0.5 mg/kg,  $71.20 \pm 5.75\%$ ,  $n = 12$ ;  $F_{(2,27)} = 7.45$ ;  $p < 0.05$ ; Fig. 8E) without affecting

**Figure 7.** The number of c-Fos positive cells induced by emotional stress. **A**, A low-power photograph of c-Fos immunolabeling in the DRN. **B**, **C**, High-power photographs showing basal c-Fos expression of home cage controls (**B**) and open field stress-induced c-Fos expression (**C**) in the DRL. **D–F**, The number of stress-induced c-Fos-positive neurons in the DRL (**D**), DRD (**E**), and DRV (**F**). The density of OF stress-induced c-Fos-positive neurons is significantly higher in the DRL ( $447.66 \pm 104.92$  cells/mm<sup>2</sup>;  $n = 12$ ) than in the DRD ( $178.19 \pm 76.67$  cells/mm<sup>2</sup>;  $n = 12$ ) and DRV ( $182.66 \pm 76.50$  cells/mm<sup>2</sup>;  $n = 12$ ). CFC stress-induced c-Fos expression is not different among the DRL ( $485.02 \pm 65.00$  cells/mm<sup>2</sup>;  $n = 10$ ), DRD ( $467.50 \pm 52.72$  cells/mm<sup>2</sup>;  $n = 10$ ), and DRV ( $487.76 \pm 72.27$  cells/mm<sup>2</sup>;  $n = 10$ ;  $F_{(8,294)} = 9.88$ ;  $p < 0.0033$ ). \* $p < 0.0033$  (control vs OF or CFC in the same brain region); # $p < 0.0033$  (OF vs CFC in the same brain region); † $p < 0.0033$  (OF in the DRD vs OF in the DRL); ‡ $p < 0.0033$  (OF in the DRV vs OF in the DRL). Aq, Aqueduct.

the total moving distance (vehicle,  $3746.22 \pm 1168.60$  cm,  $n = 12$ ; diazepam, 0.1 mg/kg,  $3174.31 \pm 731.40$  cm,  $n = 6$ ; 0.5 mg/kg,  $3778.29 \pm 1316.09$  cm,  $n = 12$ ;  $F_{(2,27)} = 0.56$ , not significant; Fig. 8F). Thus, the high-dose diazepam lowers the anxiety level. Therefore, the DRL is more responsive to innocuous OF stress than the DRD and DRV, and an effective dose of diazepam does suppress OF stress-induced c-Fos expression in the DRL.

#### Contextual fear conditioning stress induces diazepam-sensitive c-Fos expression in all DRN subdivisions

When exposing animals to CFC stress, a memory-dependent, noxious emotional stress, robust increase in the density of c-Fos-positive cells was observed in all three subdivisions of the DRN (DRL,  $485.02 \pm 65.00$  cells/mm<sup>2</sup>,  $n = 10$ ; DRD,  $467.50 \pm 52.72$  cells/mm<sup>2</sup>,  $n = 10$ ; DRV,  $487.76 \pm 72.27$  cells/mm<sup>2</sup>); however, no significant regional differences were discerned in the CFC stress test (Fig. 7D–F;  $F_{(8,294)} = 9.88$ ;  $p < 0.0033$ ). Likewise, high-dose diazepam significantly suppressed CFC stress-induced c-Fos expression in all three subdivisions of the DRN (DRL,  $233.63 \pm 78.60$  cells/mm<sup>2</sup>,  $n = 10$ ,  $F_{(3,92)} = 5.52$ , Fig. 9A; DRD,  $169.04 \pm 52.05$  cells/mm<sup>2</sup>,  $n = 10$ ,  $F_{(3,92)} = 0.22$ , Fig. 9B; DRV,  $171.98 \pm 82.39$  cells/mm<sup>2</sup>,  $n = 10$ ,  $F_{(3,92)} = 6.28$ , Fig. 9C;  $p < 0.017$  for each). CFC stress-induced freezing behaviors were also reduced significantly with high-dose diazepam (control plus vehicle,  $21.16 \pm 4.41\%$ ; control plus diazepam, 0.5 mg/kg,  $18.04 \pm 1.90\%$ ;  $n = 6$ , respectively; CFC plus vehicle,  $69.93 \pm 10.43\%$ ; CFC plus diazepam, 0.5 mg/kg,  $35.51 \pm 13.31\%$ ;  $n = 10$ , respectively; Fig. 9D;  $F_{(3,28)} = 2.83$ ;  $p < 0.05$ ). Thus, noxious emotional stress induces diazepam-sensitive c-Fos expression in all DRN subdivisions nonselectively.

#### 5-HT/GAD67 neurons are more responsive to OF stress than to CFC stress

Finally, we examined which types of DRL neurons were responsive to emotional stress by triple immunofluorescence for c-Fos,

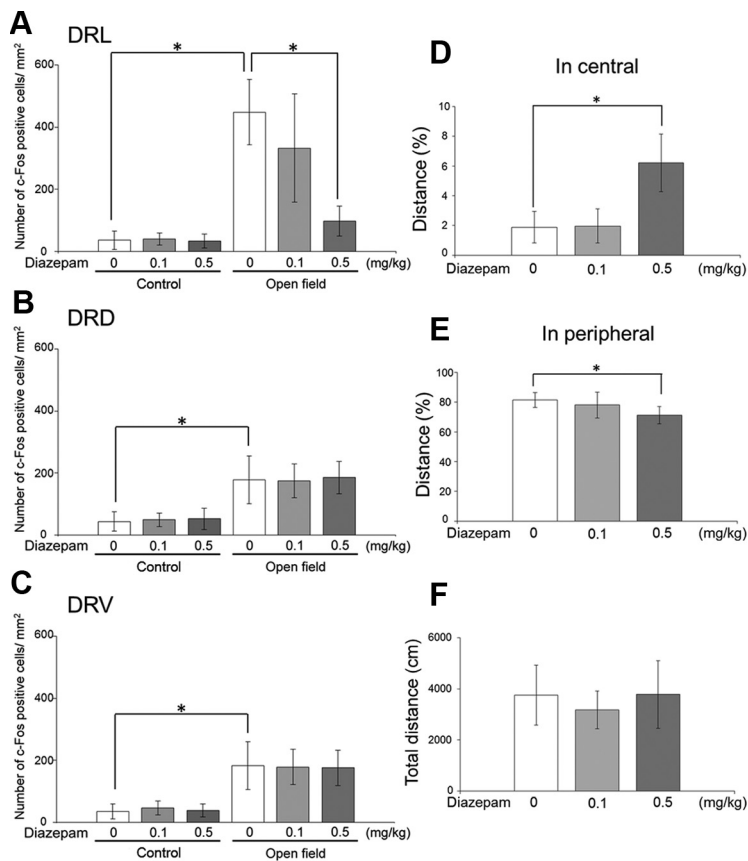

TPH2, and PV. To identify GABAergic neurons, we adopted PV instead of GAD67, because most of the PV-positive neurons were labeled for GAD67 (15 of 18 cells; 83%), and also because intense somatic labeling for PV was suited for reliable cell counting (Fig. 10A<sub>1</sub>–A<sub>3</sub>). We calculated the percentage of PV-positive neurons in the total neurons colabeled for TPH2 and c-Fos (Fig. 10B<sub>1</sub>–B<sub>4</sub>). In OF stress test, the majority of TPH2/c-Fos-positive neurons (128 of 199 cells; 64.3%) were PV positive (Fig. 10C, left). In the CFC stress test, the majority of TPH2/c-Fos-positive neurons (210 of 352 cells; 59.7%) were PV negative (Fig. 10C, right). Therefore, 5-HT/GAD67 neurons in the DRL are more responsive to OF stress than CFC stress.

#### Discussion

The DRN, the primary center of 5-HTergic projections to the entire forebrain and limbic regions, is comprised of heterogeneous subnuclei that have distinct morphological features and afferent and efferent connections. Growing evidence suggests that anatomically distinct subregions serve distinct functions, and neurochemical heterogeneity in the nucleus generates further complexity. In this study, we examined 5-HT/GAD67 neurons in the rat DRN and have disclosed their distinct anatomical, neurochemical, and electrophysiological properties and also their distinct responsiveness to emotional stressors.

In the DRN, significant populations of 5-HT-producing neurons coexpress various neurotransmitters, including dopamine, GABA, glutamate, nitric oxide, and neuropeptides such as corticotropin-releasing factor (Hioki et al., 2010). In the present study, we showed that 5-HT/GAD67 neurons were selectively located in the DRL. Considering that VGLUT3, GAD67, and tyrosine hydroxylase are expressed in distinct subregions and neuronal populations within the DRN (Hioki et al., 2010), it is likely that 5-HT/GAD67 neurons comprise a distinct subset in the DRN. We also revealed that 5-HT/GAD67 neurons, which were identified as those coexpressing TPH2 and GAD67 mRNAs, con-

**Figure 8.** A high dose of diazepam suppresses OF stress-induced c-Fos expression in the DRL and exerts anxiolytic effect on open field behavior. **A–C**, The number of OF stress-induced c-Fos-positive neurons and the effect of diazepam on c-Fos expression in the DRL (**A**), DRD (**B**), and DRV (**C**). Control rats are kept in their home cages. OF stress-induced c-Fos expression is not affected by a low dose of diazepam (0.1 mg/kg, i.p.) in each subdivision of the DRN. However, this expression is reduced with 0.5 mg/kg diazepam in the DRL ( $98.06 \pm 47.78$  cells/mm<sup>2</sup>;  $F_{(5,174)} = 23.85$ ;  $n = 12$ ), but not the DRD ( $185.47 \pm 51.46$  cells/mm<sup>2</sup>;  $F_{(5,174)} = 7.15$ ;  $n = 12$ ) or DRV ( $175.91 \pm 57.27$  cells/mm<sup>2</sup>;  $F_{(5,174)} = 10.52$ ;  $n = 12$ ). \* $p < 0.0071$  for each. **D–F**, The anxiolytic effect of diazepam on open field behavior. Diazepam (0.5 mg/kg, i.p.) increases the ratio of moving distance in the central zone of the open field (vehicle,  $1.88 \pm 1.06\%$ ; diazepam, 0.5 mg/kg,  $6.21 \pm 1.94\%$ ;  $F_{(2,27)} = 26.94$ ; \* $p < 0.05$ ;  $n = 12$ ; **D**) and reduces the ratio of moving distance in the peripheral zone of the open field (vehicle,  $81.39 \pm 5.02\%$ ; diazepam, 0.5 mg/kg,  $71.20 \pm 5.75\%$ ;  $F_{(2,27)} = 7.45$ ; \* $p < 0.05$ ;  $n = 12$ ; **E**) without changing the total moving distance (vehicle,  $3746.22 \pm 1168.60$  cm; diazepam, 0.5 mg/kg,  $3778.29 \pm 1316.09$  cm;  $n = 12$ ;  $F_{(2,27)} = 0.56$ , not significant; **F**).

stituted 12.2–17.5% and 22.0% of the total and TPH2-positive neurons in the DRL, respectively. However, other studies reported that coexistence of 5-HT/TPH2 and GABA/GAD is absent or very rare in the rat DRN: 0.1% in the entire DRN (Stamp and Semba, 1995) and 2% in the DRL (Hioki et al., 2010). In this regard, we observed a considerable decrease in neuronal population coexpressing 5-HT and GAD67 between 4 and 8 weeks of age. Accordingly, this large difference could be attributable to the difference in age as well as detection methods and their restricted localization within the DRN.

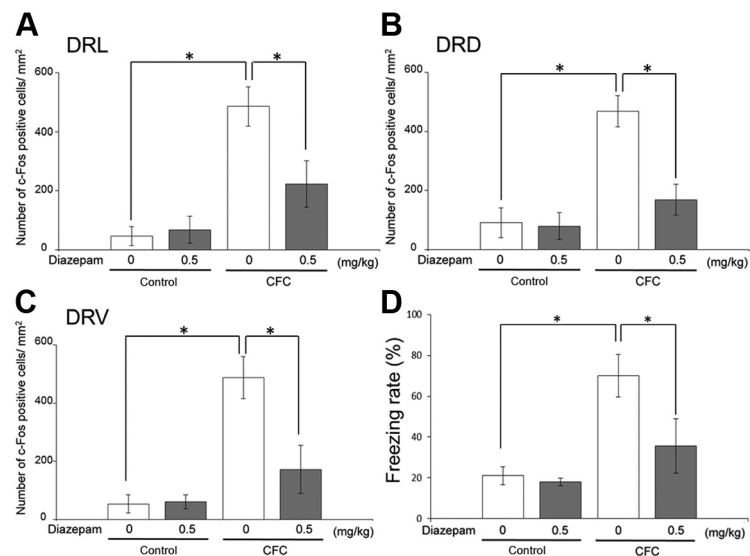

At conventional synapses, GABA is released into the synaptic cleft by exocytosis of GABA-filled vesicles. In the present study, expression of VIAAT, which fills GABA and glycine into synaptic vesicles (McIntire et al., 1997; Aubrey et al., 2007), was not detected in 5-HT/GAD67 neurons by single-cell RT-PCR, double FISH, and immunofluorescence. This unexpected finding prompted us to hypothesize that 5-HT/GAD67 neurons might release GABA into the extracellular space via nonvesicular release. In this regard, GAT has been proposed to mediate nonvesicular GABA release by its reverse operation (Attwell et al., 1993). Indeed, GAT-1 has been shown to mediate GABA release in cultured hippocampal

neurons under physiological conditions, and that contributes to keeping ambient GABA concentration high enough to mediate tonic inhibition through GABA<sub>A</sub> receptors (Wu et al., 2007). Our present observation that GAT-1 is expressed in 5-HT/GAD67 neurons suggests this possibility, which needs to be validated in future studies. If 5-HT/GAD67 neurons do conduct GABA synthesis and release, what is its role in 5-HTergic neurons? Because GAT's cotransport GABA, 2Na<sup>+</sup>, and Cl<sup>-</sup>, reverse GABA transport preferably occurs if the membrane potential is made positive enough or if [Na<sup>+</sup>]<sub>i</sub> rises to high enough levels. Thus, GAT-mediated GABA release is prone to occur during active firing of 5-HT/GAD67 neurons. Because GABA is a major inhibitory transmitter, it is likely that corelease of GABA in elevated activities of 5-HT/GAD67 neurons suppresses the excitability of their own and neighboring neurons. GABA is also known to exert neurotrophic effects and promote the synaptogenesis during early development (Reprea and Ben-Ari, 2005). Moreover, GABA is a metabolite en route from glutamate to the tricarboxylic acid cycle. This GABA shunt pathway protects cells from injury and oxidative stress by supplying succinate and NADH and preventing accumulation of reactive oxygen intermediates (Waagepetersen et al., 1999; Lamigeon et al., 2001; Sauer et al., 2007). Therefore, the GABAergic nature of 5-HT/GAD67 neurons will be expected to provide the neurons with the ability to modulate neuronal excitability under some circumstances or to promote neuronal differentiation and survival.

5-HTergic neurons in the DRL have been reported to have active and passive intrinsic membrane properties that make them more excitable than those in the DRV (Crawford et al., 2010). In the present study, we further revealed that 5-HT/GAD67 neurons exhibited lower input resistance and firing frequency than 5-HT neurons. Considering that the input resistance reflects both the density of the resting ion channels on the membrane and the cell size, our results suggest that 5-HT/GAD67 neurons have larger membrane surface area and more resting channels to conduct ions compared to 5-HT neurons. It can be speculated that the differences in firing patterns are likely due to distinct expression patterns of voltage-dependent ion channels, including Kv4.3 selectively expressed in the DRN (Serodio and Rudy, 1998). Kv4.3 is activated at subthreshold voltages and shows pronounced inactivation with sustained depolarization at these voltages, enabling neurons to fire rhythmically at low frequencies through a sequence of activation followed by inactivation during interspike intervals (Connor and Stevens, 1971a,b; Rush and Rinzel, 1995). Thus, although the differences in expression profiles of voltage-dependent ion channels, including Kv4.3, between 5-HT/GAD67 and 5-HT neurons remain unknown, there are intrinsic membrane properties that make 5-HT/GAD67 neurons fire at lower frequency.

Hale et al. (2008) reported that the exposure of rats to an OF arena markedly increases c-Fos expression in both TPH-positive and TPH-negative neurons in the DRL. In the present study, we confirmed this and further revealed that diazepam suppressed the OF stress-induced c-Fos expression at a dose that effectively lowered the anxiety level. Furthermore, PV-positive 5-HT neurons in the DRL, which are largely equivalent to 5-HT/GAD67 neurons, were more responsive to OF stress than PV-negative 5-HT neurons (i.e., 5-HT neurons). On the other hand, CFC stress robustly induced c-Fos expression in all DRN subdivisions examined, and this was significantly suppressed by diazepam. Considering higher plasma corticosterone concentrations induced by CFC stress than OF stress (Hirata et al., 2008; Hirata et al., 2009), the different neuronal responses between the two tests might be related to different types and intensities of stressors. While exposing animals to an OF arena drives the motivation of novelty-seeking behavior on one hand, it also increases the anxiety on the other hand, because of the novelty of unfamiliar environments (Gray and McNaughton, 2003; Padilla et al., 2010; Molander et al., 2011). Our observation that administration of diazepam suppressed both anxiety-related behavior and c-Fos expression in the DRL without affecting the total moving distance supports this notion. In contrast, c-Fos expression induced by OF stress in the DRD and DRV was resistant to diazepam. Because these nuclei project not only to the basolateral amygdala (Hale et al., 2008), but also to the medial prefrontal cortex and nucleus accumbens (Van Bockstaele et al., 1993), the c-Fos induction in these nuclei may be related to the cognition or novelty-seeking behaviors. Together, these findings suggest that neurons in the DRL, particularly 5-HT/GAD67 neurons, are highly sensitive to innocuous stressors, in which activation of diazepam-sensitive GABA<sub>A</sub> receptors may be involved.

Subdivisions of the DRN innervate distinct targets and receive disparate afferent inputs (Abrams et al., 2004; Lee et al., 2005, 2007; Hale et al., 2008), including 5-HTergic interactions within the DRN (Lemos et al., 2006; Kirby et al., 2007). Neurons in the DRL have been deemed to play a distinctive, crucial role in the response to stressors. Various types of stressors, including OF stress, social stress, and swim stress, along with anxiogenic drugs or reagents activates DRL neurons preferentially (Roche et al., 2003; Abrams et al., 2005; Berton et al., 2007; Hale et al., 2008; Johnson et al., 2008). 5-HTergic neurons in the ventrolateral periaqueductal gray (vlPAG), which is overlapped or embedded in the DRL, project to major sympathoexcitatory regions, the dIPAG and the RVLM, i.e., the adrenergic C1 region (Johnson et al., 2004). Microstimulation of the dIPAG in rodents and humans produces marked sympathoexcitatory responses, such as tachycardia and hypertension, thus facilitating rapid autonomic and behavioral “fight-or-flight” responses. Microstimulation of the DRL/vlPAG, by contrast, results in sympathetic inhibition (Beckett and Marsden, 1997; Underwood et al., 1999; Bago and Dean, 2001; Johnson et al., 2004). The emerging hypothesis is that neu-

**Figure 9.** Diazepam suppresses c-Fos expression induced by CFC stress in all DRN subdivisions and exerts an anxiolytic effect. **A–C**, The number of CFC stress-induced c-Fos-positive neurons and the effect of diazepam on c-Fos expression in the DRL (**A**), DRD (**B**), and DRV (**C**). Controls indicate non-footshock groups. Diazepam (0.5 mg/kg, i.p.) reduces CFC stress-induced c-Fos expression in all regions of the DRN (DRL,  $233.63 \pm 78.60$  cells/mm<sup>2</sup>,  $F_{(3,92)} = 5.52$ ,  $p < 0.017$ ,  $n = 10$ , **A**; DRD,  $169.04 \pm 52.05$  cells/mm<sup>2</sup>,  $F_{(3,92)} = 0.22$ ,  $p < 0.017$ ,  $n = 10$ , **B**; DRV,  $171.98 \pm 82.39$  cells/mm<sup>2</sup>,  $F_{(3,92)} = 6.28$ ,  $p < 0.017$ ,  $n = 10$ , **C**). **D**, The anxiolytic effect of diazepam on freezing behavior in CFC stress. Control indicate non-footshock groups. Diazepam (0.5 mg/kg, i.p.) reduces freezing behavior (control plus vehicle,  $21.16 \pm 4.41\%$ ; control plus diazepam, 0.5 mg/kg,  $18.04 \pm 1.90\%$ ;  $n = 6$ , respectively; CFC plus vehicle,  $69.93 \pm 10.43\%$ ; CFC plus diazepam, 0.5 mg/kg,  $35.51 \pm 13.31\%$ ;  $n = 10$ , respectively;  $F_{(3,28)} = 2.83$ ;  $p < 0.05$ ).

rons in the DRL/vlPAG are activated and help inhibit sympathetic excitation as a part of normative response to innocuous stressors (Crawford et al., 2010). This circuit is dysregulated in a rat model of panic disorder, in which decreased activation of this region accompanies excessive panic-like response to a mild stressor (Johnson et al., 2008). In this regard, 5-HT/GAD67 neurons, which constitute a unique neuronal population in the DRL with distinct neurochemical and electrophysiological properties and high responsiveness to innocuous stress, seem intriguing in stress-related physiological response and also in stress-related disorders.
