Abstract: Selective vectorization of Cisplatin (CisPt) to Glioblastoma U87 cells was exploited by the fabrication of a hybrid nanocarrier composed of magnetic γ -Fe₂O₃ nanoparticles and nanographene oxide (NGO). The magnetic component, obtained by annealing magnetite $Fe₃O₄$ and characterized by XRD measurements, was combined with NGO sheets prepared via a modified Hummer's method. The morphological and thermogravimetric analysis proved the effective binding of γ -Fe₂O₃ nanoparticles onto NGO layers. The magnetization measured under magnetic fields up to 7 Tesla at room temperature revealed superparamagnetic-like behavior with a maximum value of $M_S = 15$ emu/g and coercivity H_C \approx 0 Oe within experimental error. The nanohybrid was found to possess high affinity towards CisPt, and a rather slow fractional release profile of 80% after 250 h. Negligible toxicity was observed for empty nanoparticles, while the retainment of CisPt anticancer activity upon loading into the carrier was observed, together with the possibility to spatially control the drug delivery at a target site.

Keywords: magnetic targeting; graphene oxide; maghemite; glioblastoma; cisplatin

1. Introduction

Malignant glioma is one of the most aggressive brain tumors, and the major cause of death from central nervous system cancers (median survival times less than 15 months from diagnosis) [\[1–](#page-11-0)[5\]](#page-11-1). Glioma treatment is still one of the most difficult challenges for oncologists [\[6\]](#page-11-2), and current therapies involve surgical intervention to achieve tumor debulking followed by adjuvant radio- and chemo-therapy [\[7\]](#page-11-3). Chemotherapy approaches are of paramount importance in the case of the most devastating and lethal grade IV glioma (Glioblastoma Multiforme, GBM), because the extensive tumor infiltration into the

surrounding brain parenchyma makes surgery un-effective [\[8\]](#page-11-4). However, the therapeutic efficiency of chemotherapy is remains unsatisfactory for two main reasons: (i) the rare brain penetration of the anticancer agents systemically administered through the blood brain barrier (BBB) [\[9\]](#page-11-5), and (ii) the poor glioma targeting of employed chemotherapeutics [\[10\]](#page-11-6). The latter issue is the main obstacle in the clinical treatment of Glioma with *cis*-diamminedichloroplatinum(II) (CisPt) [\[11\]](#page-11-7), one of the most effective anticancer agents. CisPt suffers from a nonselective distribution between normal and tumor tissues, with the insurgence of severe adverse side effects, including acute nephrotoxicity, myelosuppression, and chronic neurotoxicity in adults [\[12–](#page-11-8)[14\]](#page-12-0), and lifelong health issues when the therapy was given in children [\[15](#page-12-1)[,16\]](#page-12-2). Therefore, it is patently clear that, for an effective Glioma treatment, there is an urgent need for powerful and targeted CisPt delivery systems in order to promote preferential accumulation in cancer cells and thereby reduce the side effects [\[17\]](#page-12-3). Taking advantage of the peculiar features of tumor tissues such as the leaky neovasculature and the lack of functional lymphatic drainage, a wide range of nanoparticle drug carriers have been explored for this purpose [\[18\]](#page-12-4).

Among others, graphene nanomaterials, mainly in the form of nanographene oxide (NGO), possess superior physicochemical, thermal, optical, mechanical, and biological properties [\[19–](#page-12-5)[21\]](#page-12-6). NGO is widely explored for drug delivery applications by virtue of the large surface area (four times higher than that of any other nanomaterials) and the high stability of its water dispersion due to the richness of oxygen containing functional groups (e.g., carboxyl, epoxide, and hydroxyl groups) [\[22–](#page-12-7)[24\]](#page-12-8). The suitability of NGO for the preparation of CisPt delivery vehicles with high loading efficiency is related to the presence of either the sp²-aromatic structure or the abundant oxidized sp³-portion on the edge, top, and bottom surfaces of each sheet [\[25–](#page-12-9)[27\]](#page-12-10), allowing the drug interaction through diverse mechanisms, including π - π stacking and hydrogen bonding [\[28–](#page-12-11)[35\]](#page-12-12).

More interestingly, functionalized NGO was found to highly accumulate in U87 human glioblastoma subcutaneous tumor xenografts [\[36](#page-13-0)[,37\]](#page-13-1), confirming that such nanocarriers can be considered a valuable tool for delivering CisPt to brain cancers. The efficiency of NGO delivery vehicles can be maximized by the incorporation of magnetic materials allowing the nanocarrier to be selectively driven into tumor tissues by the application of an external magnetic field [\[38\]](#page-13-2). In particular, magnetic nanoparticles based on iron oxide (maghemite γ -Fe₂O₃ or magnetite Fe₃O₄) were widely used for this purpose due to their biocompatibility and superparamagnetic properties [\[39,](#page-13-3)[40\]](#page-13-4). The resulting NGO hybrid nanodevices were proposed as effective tools for glioblastoma treatment using Doxorubicin [\[41\]](#page-13-5) and Irinotecan [\[42\]](#page-13-6) as cytotoxic agents. Although possessing favorable properties for magnetic drug vectorization, the different chemical stabilities of Fe₃O₄ and γ -Fe₂O₃ may affect the toxicity of the delivery vehicle [\[43\]](#page-13-7). The lower chemical stability of Fe₃O₄ resulted in the release of Fe²⁺ ions from the nanoparticle cores, which can catalyze the formation of reactive oxygen species (ROS) damaging cell membrane and organelles, with the insurgence of adverse long-term side effects [\[44\]](#page-13-8). On the other hand, γ -Fe₂O₃ was found to be a better material owing to either the magnetic features or the high chemical stability [\[45\]](#page-13-9).

In the present study we explored the possibility to employ NGO–Iron oxide nanohybrids (γ -Fe₂O₃@NGO) as a CisPt carrier for glioblastoma treatment by intercalating γ -Fe₂O₃ nanoparticles into NGO sheets. After characterizing the physical, chemical, and morphological properties, CisPt was loaded onto the nanocarrier for several drug-to-carrier ratios and their cytotoxicity was tested on human U87 cell lines.

2. Results and Discussion

2.1. Properties of γ*-Fe2O3@NGO Nanohybrid*

As previously reported, the size of NGO is a parameter that strongly affects the drug delivery effectiveness of NGO-based systems in vitro and in vivo [\[46,](#page-13-10)[47\]](#page-13-11). Specifically, low-sized NGOs (lateral dimension \approx 100 nm) have been reported to have the best performance [\[46\]](#page-13-10).

The average size of our graphite oxide (GO) particles, as assessed by scanning electron microscopy (SEM), revealed an average size (lateral width) of 350–400 nm. These particles were therefore subsequently sonicated until NGO with lateral width of 80–100 nm and a thickness of 6.3 nm was attained (10 NGO sheets, assuming an interlayer distance of 0.7 nm) [\[48\]](#page-13-12) (Figure 1a–c).

Figure 2. Schematic representation of the preparation of γ-Fe₂O₃@NGO.

Maghemite (γ-Fe₂O₃) nanoparticles were chosen to provide magnetic properties to the nanohybrids temperature in its bulk form [\[40\]](#page-13-4). Superparamagnetism is crucial for application in biomedicine, because, despite the strong response to an external magnetic field, the absence of residual magnetic properties upon removal of the external field prevents nanoparticles from aggregation in biological biomedicine, because, despite the strong response to an external magnetic field, the absence of because of their high chemical stability, biocompatibility, and large magnetic moment at room residual magnetic properties upon removal of the external field prevents nanoparticles from

environment [\[49](#page-13-13)[–52\]](#page-13-14). γ-Fe₂O₃ nanoparticles (average size of 10 nm, see Figure [1d](#page-2-0),f) were synthesized by annealing of magnetite $Fe₃O₄$ prepared by a chemical co-precipitation technique of FeCl₃ and FeCl₂ solutions [\[53,](#page-13-15)[54\]](#page-13-16), and then coated with oleic acid/sodium oleate to enhance their dispersion in water media and thus the biocompatibility features [\[55\]](#page-13-17). Since previously reported data proved the presence of transport systems importing fatty acids into the brain with high affinity and efficiency, it is reasonable to hypothesize that this coating strategy could be appropriate for targeting the blood brain barrier [\[56\]](#page-14-0). \mathcal{F}_{F} igure 1d, \mathcal{F}_{F} and \mathcal{F}_{F} and \mathcal{F}_{F} and \mathcal{F}_{F} are prepared by a chemical prepared by a chemical prepared by \mathcal{F}_{F} $\text{er } \text{pos}$.

Despite the evidence of Fe₃O₄ to γ -Fe₂O₃ oxidation from the change of color of the sample (from black to reddish-brown color, see Figure [3\)](#page-3-0), we investigated this phase change by XRD measurements. Figure [3](#page-3-0) showed the XRD patterns of both compounds, and the *d*-spacing values emulated well the data deduced from the Joint Committee on Powder Diffraction Standards (JCPDS) cards 19-629 (Fe₃O₄) and 39-1346 (γ -Fe₂O₃). besphe the evidence of $\text{reg}O_4$ to γ -rego $_3$ oxidation from the change of color of the sample (from

This result indicated that the thermal treatment of as prepared Fe₃O₄ produced γ-Fe₂O₃ (maghemite) crystal form [\[57\]](#page-14-1).

The magnetization vs. field M(H) curves for the annealed γ -Fe₂O₃ nanoparticles showed nearly closed hysteresis loops, with zero coercivity (Figure 4). closed hysteresis loops, with zero coercivity (Figure [4\)](#page-4-0).

nanoparticles. The insets show the Zero-field cooled (black) and field-cooled (orange) magnetization nanoparticles. The insets show the $\frac{1}{2}$ $\frac{1}{$ curves for Fe₃O₄, γ -Fe₂O₃, and γ -Fe₂O₃@NGO, taken with H_{FC} = 100 Oe. **Figure 4.** Hysteresis loops M(H) for Fe₃O₄ (black) and γ -Fe₂O₃ (red) and γ -Fe₂O₃@NGO (blue)

attaining a value of MS = 59.36 emu/g and MS = 49.25 emu/g at H = 70 kOe for Fe₃O₄ and γ -Fe₂O₃, respectively. After assembling γ -Fe₂O₃ into NGO the Ms value was 15.02 emu/g, consistent with a \approx 30.5% wt. of magnetic material into NGO matrix, confirming the dispersion on magnetic nanoparticle into the hybrid platform. The coercivity values at room temperature were HC ≈ 0 for all samples. The zero field cooling (ZFC) and field cooling (FC) curves at $H_{FC} = 100$ Oe of Fe₃O_{4, γ -Fe₂O₃} and γ -Fe₂O₃@NGO samples reflected similar features, i.e., a broad maximum in the ZFC curves originated from the distribution of blocking temperatures due to the distribution of particle sizes (see inset of Figure [4\)](#page-4-0). The maxima were centered around $T \approx 194$, 245, and 242 for Fe₃O₄, γ -Fe₂O₃, and γ -Fe₂O₃@NGO, respectively. These broad maxima are consistent with the blocking of the smallest nanoparticles at these temperatures, while the presence of irreversible behavior up to the $\frac{1}{2}$ is the temperature (400 K) success that a fraction of the preset particles are still blocked above highest temperature (400 K) suggests that a fraction of the largest particles are still blocked above
room temperature The magnetization did not fully saturate within our experimentally available fields (\rm{H} = 70 kOe), room temperature. room temperature.

For the NGO sample (Figure [5a](#page-4-1)), the mass loss in the range 150–250 °C with the maximum in the derivative %M/ \degree C graph at 215 \degree C (arrow (1)) was ascribed to the decomposition of decorated oxygen functionalities on the basal graphene structure, while between 400 and 525 °C (maximum $\frac{1}{100}$) and $\frac{1}{100}$ at 490, see arrow (2)), a high weight loss occurs due to the discard of more thermally stable oxygen
a consequence of the effective binding of \overline{S} of \overline{S} of \overline{S} or \overline{S} or \overline{S} or \overline{S} or \overline{S} groups. On the other hand, for γ -Fe₂O₃@NGO (Figure [5b](#page-4-1)), these mass losses were found to shift to lower temperatures (maximum in the derivative %M/°C graph at 170 °C and 305 °C, respectively) as a consequence of the effective binding of γ -Fe₂O₃ nanoparticles onto NGO layers. germany start with the other hand, for ϵ (allow (1)) was assisted to the decomposition of decorated

Before testing the efficiency of γ-Fe2O3@NGO nanohybrid as CisPt carrier, we evaluated the

2.2. Evaluation of Carrier Performances (*γ-Fe2O3*, NGO3, NGO3, NGO, and γ-Fe2O3, NGO3, NGO3, NGO3, NGO3, NGO3, NGO

Before testing the efficiency of γ -Fe₂O₃@NGO nanohybrid as CisPt carrier, we evaluated the toxicity of the empty nanoparticles (γ -Fe₂O₃, NGO, and γ -Fe₂O₃@NGO) on human glioblastoma U87 cell lines at a concentration range of 0–25 µg mL⁻¹. This range of concentration was selected because of the absence of any sign of aggregation as per Dynamic light-scattering (DLS) measurements. The viability values (>96% for all samples and concentrations, see Figure [6\)](#page-5-0) proved the high biocompatibility of all nanoparticle systems, confirming their suitability as drug carrier [\[58\]](#page-14-2).

The ultimate aim of the study is to check the suitability of γ -Fe₂O₃@NGO to selectively vectorize the cytotoxic drug to the tumor site under magnetic actuation. Indeed a key requirement for this nanocarrier is the ability to retain the drug until it reaches the target site. γ -Fe₂O₃@NGO was found to possess high affinity for CisPt (Drug Loading Efficiency of 0.37 mg mg⁻¹) and the release profiles were recorded after loading the drug by a soaking procedure (drug to carrier ratio of 10% by weight).

Figure 6. Figure 6. Figure 6. Figure 2. *Figure 7. Figure 7. <i>Figure 7.* **Figure 7.** *Figure 7.* **Figure 6.** U87 viability after treatment with empty γ -Fe $_2$ O₃ (**red**) and NGO (**grey**) and γ -Fe $_2$ O₃@NGO (**black**).

Table 1. R² values and kinetic parameters for CisPt release according to the applied mathematical model.

CisPt loaded γ-Fe₂O₃@NGO were employed in different drug-to-carrier ratios (concentration ranges of 0–25 μg mL⁻¹ and 0–10 μM for carrier and drug, respectively, see Figure 8). From the data in Figure [8,](#page-7-1) it is clear that the lowest toxic concentrations of CisPt (10 μ M) is unchanged after loading on the different carriers, with γ -Fe₂O₃@NGO being the most effective vehicle for killing cells.

To investigate the possibility of obtaining a selective vectorization of the drug, a proof of concept experiment was designed by incubating U87 cells with 10 μM CisPt loaded γ-Fe₂O₃@NGO for 24 h kept under the effect of a magnetic field generated by a permanent Nd-Fe-B magnet. As a result of the magnetic carrier driven spatial concentrations of the drug, a selective cell death at the region close to the magnet was reached, even at low drug concentration (10 µM), with no relevant toxicity detected on the region where the magnetic forces were negligible (Figure [9\)](#page-8-0).

The distribution used during this and α software designed using α software designed by α and β and study was approximately 100 nm in lateral size and 6 nm in thickness. NGO particles were prepared as reported previously [\[46\]](#page-13-10). The resultant material of graphite oxide

3.3. Synthesis of Maghemite Nanoparticles

Maghemite γ -Fe₂O₃ nanoparticles were synthesized in a three-step procedure as follows: first, the magnetite $Fe₃O₄$ nanoparticles were prepared by co-precipitation method in basic medium [\[53\]](#page-13-15). The synthesis of $Fe₃O₄$ nanoparticles is shown in Equation (6):

$$
2\text{FeCl}_3 + \text{FeCl}_2 + 8\text{NaOH} \rightarrow \text{Fe}_3\text{O}_4 \text{ (s)} + 4\text{H}_2\text{O} + 8\text{NaCl} \tag{6}
$$

Briefly, 2.25 g of FeCl₃·6H₂O and 0.825 g of FeCl₂·4H₂O were mixed in an alkaline solution (NaOH, 1.7 g). The mixture stirred at 65–80 °C for 12 h. The resultant material was filtrated and washed many times by distilled water and ethanol.

Subsequently, magnetite $Fe₃O₄$ nanoparticles were employed as starting material for the synthesis of maghemite γ-Fe₂O₃. An initial amount of 1.0 g of Fe₃O₄ was placed in furnace and heated up to 450 $°C$ in the presence of Argon and H_{2(g)} for 12 h [\[54](#page-13-16)[,57\]](#page-14-1). Thereafter, the reaction was quenched down to room temperature. The resulting material was collected, washed several times in deionized water and ethanol, dried in an oven at 65 \degree C for 3 h. A second annealing was applied at the same conditions in order to identify the structure of $Fe₂O₃$ whether it was maghemite or hematite form.

In the final step, 0.5 g of γ -Fe₂O₃ were heated to 60 °C for 15 min separately. Consequently, an excess of sodium oleate (20% wt/vol) was added under vigorous stirring for 15 min. Oleate functionalized nanoparticles were collected by magnetic decantation to remove the non-magnetic materials. The product was washed with water and acetone several times, filtrated and dried in an oven at 40 ◦C for 2 h.

The relevant X-ray diffraction patterns were performed by using Pert Pro MPD PW3040/60 X-ray diffractometer with Co K_{α} radiation (λ = 0.179278 nm) at ambient temperature.

3.4. Synthesis of γ*-Fe2O3@NGO Nanohybrid*

An amount of 0.5 g of NGO -100 nm particles was sonicated for 15 min in order to homogenize it in distilled water. The solution was heated up to 60 °C for 15 min directly; an excess of γ -F_{e2}O₃ system was added and stirred for 15 min. The final material was separated by magnetic decantation, washed with water and acetone, filtrated and dried in an oven at $40\degree C$ for 2 h. TEM images were recorded on HRTEM/Tecnai F30 [300 kV] (FEI, Hillsboro, OR, USA). TGA was performed on a STA 409 PC/PG-Luxx analyzer (Netzsch, Selb, Germany). Measurements were conducted in a nitrogen atmosphere (flow of 10 mL min−¹), with an initial sample weight of ∼10 mg in the temperature range 50–900 ◦C at a heating rate of 10 $^{\circ}$ C min⁻¹.

Drug loading efficiency (DLE) of γ -Fe₂O₃@NGO for CisPt was estimated by mixing drug and carrier in a 1:1 ratio (by weight) and determining the amount of unloaded CisPt by UV-Vis on a Jasco V-530 UV/Vis spectrometer (Jasco Europe s.r.l., Milan, Italy) at 301 nm [\[64\]](#page-14-7). DLE was calculated according to the following Equation (7):

$$
DLE\left(mg\;mg^{-1}\right) = \frac{W_D}{W_C} \tag{7}
$$

where W_D and W_C are the amount of loaded drug and carrier, respectively. In our condition, to ensure the same amount of drug being loaded on the three carriers (γ -Fe₂O₃@NGO, γ -Fe₂O₃, or NGO) the CisPt loading procedure was performed by mixing, in separate experiments, variable amounts of CisPt solution with the carriers and drying the products under vacuum at RT.

3.5. Magnetic Characterization

Magnetization curves were measured as function of temperature M(T) in the 4 K \leq T \leq 400 K temperature rage, in a SQUID magnetometer (MPMS 5000 from Quantum Design). The Zero-field-cooling (ZFC) and Field-cooling (FC) curves were measured under a field-cooling field H_{FC} = 100 Oe Hysteresis loops M(H) were taken at 4 K and 300 K within the −70 kOe $\leq H \leq +70$ kOe field range. For all these measurements, the colloids were conditioned in cylindrical sample holders and diamagnetic signal were extracted from the total magnetization.

3.6. In Vitro Cisplatin Release

Release experiments were performed by dialysis methods using 5.0 mL phosphate buffer saline $(10^{-3}$ M, pH 7.4) was releasing media and dialysis tubing cellulose membranes of 25 mm average flat width and 12,000 MW cutoff (Fisher Scientific, Waltham, MA, USA). 5.0 mg nanoparticles (γ -Fe₂O₃@NGO, γ -Fe₂O₃, and NGO) loaded with CisPt were inserted into the dialysis tubes and subject to dialysis. At predetermined time intervals, the amount of CisPt in the releasing media was determined by UV-Vis on a Jasco V-530 UV/Vis spectrometer (Jasco Europe s.r.l., Milan, Italy) at 301 nm [\[64\]](#page-14-7). The cumulative amount of drug released (*F*) was calculated using the following Equation (8):

$$
F = \frac{M_t}{M_0} \tag{8}
$$

where M_t and M_0 are the amounts of drug in solution at time t and loaded into the carrier, respectively. Sink conditions were maintained through the experiment: the maximal theoretical concentration of dissolved CisPt was 0.33 mM, with its solubility being 3.3 mM in these conditions [\[65\]](#page-14-8).

3.7. Cell Growth Inhibition Assays

Human Glioblastoma cells (U87) were grown as a monolayer in a humidified atmosphere at 37 ◦^C and in 5% CO₂ in the presence of Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% Fetal bovine serum (FBS), 1% L-glutamine, and 1% penicillin–streptomycin. Treatment effects on U87 cell growth were measured on the basis of the metabolic activity of cells using Alamar Blue assays [\[66\]](#page-14-9). Briefly, cells were plated in clear transparent 96-well plates at an optimized cell density of 2.5×10^3 cells per well 48 h prior to treatment. Cells were then treated with either CisPt loaded or unloaded carriers (γ -Fe₂O₃@NGO, γ -Fe₂O₃, NGO) and effects on cell growth assessed 72 h later. Treatments involved the combination of CisPt and carrier concentrations of 2.5; 5.0; 10.0 µM and 2.0; 5.0; 10.0; 25.0 μg mL⁻¹, respectively. Resazurin reduction was measured (excitation 530 nm, emission 590 nm) on a Versamax microplate reader (Molecular Devices, Sunnyvale, CA, USA).

To evaluate the magnetic vectorization ability, viability experiments were performed by treating 250 X 10³ cells seeded in a 35 mm petri dish with 10 μM CisPt loaded on γ -Fe $_{2}$ O $_{3}$ @NGO for 24 h under the effect of a magnetic field generated by a permanent magnet (100 G).

All chemicals were purchased by from Merck/Sigma Aldrich, Taufkirchen, Germany.

3.8. Statistical Analysis

Three experiments were carried out in triplicate. Values were expressed as means \pm standard error of the mean. For viability assay, statistical significance was assessed by one-way analysis of variance followed by post-hoc comparison test (Tukey's test). Significance was set at *p* < 0.01.

4. Conclusions

The possibility of CisPt delivery to specific target sites by remote actuation was reached by combining γ -Fe₂O₃ magnetic nanoparticles ensembled into a NGO nanoplatform. The correct assembly of the components was responsible for the efficiency of γ-Fe₂O₃@NGO as a drug delivery system. While NGO conferred high loading capabilities to the nanosystems, the magnetic nanoparticles provided the magnetic actuation capabilities for targeting and delivery of therapeutics.

The mathematical model of the CisPt release profiles suggested a sustained reversible second-order kinetics, which implies low amounts of CisPt released during the first seconds of the experiments. This type of release profile is of major importance if low toxicity levels are required for in vivo applications.

These findings, considered together with the retainment of CisPt toxicity upon loading and the possibility to increase the dose delivered at the target site by a magnetic actuation, make the nanocarrier developed here a valuable tool for applications in cancer therapy.
