Abstract A section-based taxonomy of *Cortinarius*, covering large parts of the temperate North and South Hemispheres, is presented. Thirty-seven previously described sections are reviewed, while another forty-two sections are proposed as new or as new combinations. Twenty additional clades are recovered but not formally described. Furthermore, six new or combined species names are introduced, and one species is neotypified. The structure is supported by morphological characters and molecular evidence, based on two (nrITS and nrLSU) and four (nrITS, nrLSU, *rpb1* and *rpb2*) loci datasets and analysed by Maximum Likelihood methods (PhyML, RAxML). Altogether 789 *Cortinarius* samples were included in the study.

INTRODUCTION

It is self-evident that large fungal genera are in a special need for structuring into lower-rank taxa in order to assist the mycologist in navigating the genus and to provide an overview of its taxonomy. *Cortinarius* is the most diverse and species-rich genus of macrofungi (cf. Niskanen et al. 2016). Historically, several systems of subgenera, sections, and other infrageneric taxa were erected in *Cortinarius*, based on the macromorphology of geographically limited samplings. These taxa were in many cases emended, combined, or divided as micromorphological, chemical, and later molecular data became available from a widening geographical span. In his ground-breaking work, Moser in Singer (1986) listed all then known sections and other supraspecific taxa of the genus, a base that was later used to expand the taxonomy in different directions (e.g., Bidaud et al. 1994, Brandrud et al. 1994: 31). We expect this process to continue, especially when considering that many geographical areas (e.g., Africa) remain poorly sampled, and will no doubt prove to contain additional *Cortinarius* taxa.

Many studies during the past twenty years have explored different aspects of the phylogeny of *Cortinarius*. Most of the species are described from Europe (c. 1900 out of a total 2700 worldwide), followed by North America, which means that the Northern Hemisphere tends to dominate in extant works (cf. Peintner et al. 2004). But in their barcoding study, Garnica et al. (2016) addressed the genus on a global scale and revealed a cladal

structure of c. 900 species based on the internal transcribed spacer regions (nrITS) of the nuclear ribosomal DNA. Garnica et al. (2016: Fig. S2) also produced a phylogram of a limited sampling based on five loci, annotated with support figures. This showed that the genus contains two major lineages that appear to be endemic to the Northern Hemisphere, namely sect. *Calochroi* and subg. *Telamonia* s.str., thus corroborating previous works on these particular groups (Høiland & Holst-Jensen 2000, Frøslev et al. 2006b, Niskanen 2008, Ortega et al. 2008, Garnica et al. 2009, 2011, Niskanen et al. 2012, cf. Soop & Gasparini 2011). In addition, several other works provide the outline of a phylogeny-based infrageneric taxonomy for selected groups within the genus, based on northern taxa (Brandrud et al. 2013, 2014, Liimatainen et al. 2014, Saar et al. 2014).

On the other hand, it is evident from the cited works, as well as from other studies (Peintner et al. 2004, Garnica et al. 2005, Stensrud et al. 2014, Soop 2016, Soop et al. 2018), that the genus contains many lineages that are shared between the Northern and Southern Hemispheres, as well as others that appear to be endemic to either. They are often also widely distributed within their hemispheres; for example, a substantial number of clades are shared between North America and Europe (Garnica et al. 2011, Harrower et al. 2011, Niskanen et al. 2012, Ammirati et al. 2013, Liimatainen et al. 2015). One notes, however, that so far little has been done on the *Cortinarius* taxonomy in north-eastern Asia and in Africa, leaving an important gap in our knowledge of the genus (cf. Horak 1983).

A common result from many of the cited phylogenetic studies, is that most traditional subgenera (such as *Phlegmacium* and *Telamonia*) turn out to be polyphyletic, while many smaller, lower-rank taxa look promising for structuring the genus from well-supported monophyletic clades. The phylogenetic delineation of well-supported subgenera within *Cortinarius* remains to be achieved through the sequencing of additional genes, or more promisingly, using a phylogenomics approach. In the interim, sections suggest themselves as suitable, monophyletic building-blocks, that may be used later to construct higher taxa. Consequently, in this study we aimed at the following:

- Combine morphological markers with suitable genetic markers to map the sections of the genus, based on as large a sample set as possible.
- Use existing sections or other suitable taxa as far as possible, sometimes in the form of new combinations. When not possible, describe new sections.
- Provide, for each proposed section, a list of species, either species sampled in the study, or putative species that we assume to be members.
- Map out the geographical distribution of *Cortinarius* sections, with particular attention to the Southern Hemisphere, an area that has so far been sparingly studied (Horak 1983).

With this approach to a supraspecific taxonomy, based on a large number of globally sampled species, we hope to provide a useful framework for expanding the taxonomy of the genus, into higher ranks (e.g., subgenera) or lower ranks (e.g., subsections), as further supported clades become apparent. Thus, in a future effort the sections may be combined or divided, or they may form the basis for new combinations.

MATERIALS AND METHODS

Geographical scope

As mentioned in the Introduction, due to scarcity of material, African and Northeast-Asian species are grossly under-represented. The following principal areas have been sampled: Europe, North/Central/South America, Australia, and New Zealand.

Taxonomic scope

All the samples are specimens of *Cortinarius* s.lat., including the genera *Cuphocybe*, *Protoglossum*, *Quadrispora*, *Rapacea*, *Rozites*, *Thaxterogaster*, and *Hymenogaster* p.p., these being synonyms of *Cortinarius* (Peintner et al. 2001, 2002, Gasparini 2013, 2016). We also include the genus *Gigasperma*. Two important boreal groups, *Calochroi* and *Telamonia* s.str., are represented only by a few token species, due to several recent and ongoing studies cited in the Introduction, which explore the infrageneric ranks involved.

Molecular sampling

Sequences from 634 collections were chosen from GenBank (<http://www.ncbi.nlm.nih.gov/>) or UNITE (<http://unite.ut.ee/>), and another 346 sequences were newly generated in this study (Table 1). For a detailed description of the methods used for DNA extraction and PCRs see Soop et al. (2016) and Papp & Dima (2018). Where possible, type collections were included in the dataset; 140 samples represent holo-, neo-, epi- or paratypes. All samples were sequenced in the nrITS (ITS1+5.8S+ITS2) region, and in addition most were sequenced in one or more of the nrLSU, *rpb1*, and *rpb2* regions. Seventy collections are represented only by ITS; in these cases the taxon was considered important to confirm a position in the phylogeny. When many sequences of a species were available and their similarity in a separate alignment (not shown) was > 99 %, only one or two samples were chosen. Three species in genera *Conocybe*, *Descolea*, and *Flammula* were chosen as outgroup. See Table 1 for GenBank and fungarium voucher numbers, sections, and provenance.

Phylogenetic reconstruction

The sequences were pre-checked and edited in MEGA 5.2 (Tamura et al. 2011). Multiple sequence alignments were performed separately on the individual gene regions using the online version of MAFFT v. 7 (Katoh & Standley 2013).

We generated two datasets: a 2-loci (ITS+LSU) and a 4-loci (ITS+LSU+*rpb1*-*rpb2*) alignment. For the 2-loci dataset ITS and LSU sequences from 730 specimens were aligned separately using the E-INS-i algorithm (Katoh & Standley 2013), following Garnica et al. (2016). The alignments were manually corrected, trimmed and concatenated in SeaView 4 (Gouy et al. 2010). Preliminary analysis was run in PhyML 3.1 (Guindon & Gascuel 2003) using the following settings: GTR+I+G model of evolution, gamma distribution of 10 rate categories, and tree topology search as SPR.

Thereafter FastGap 1.2 (Borchsenius 2009) was used to code the phylogenetically informative insertion/deletion positions (indel) in both the ITS and LSU alignments following the simple indel coding algorithm (Simmons et al. 2001). After concatenating the nucleotide and binary data in SeaView 4, the partitioned alignment was submitted to maximum likelihood analysis using RAxML (Stamatakis 2014) as implemented in raxmlGUI 1.5.2 (Silvestro & Michalak 2012). The GTRGAMMA substitution model for the nucleotide partitions (ITS1+5.8S+ITS2+LSU) and the default setting for binary (indel) data was chosen. Rapid bootstrap analysis with 1 000 replicates was applied for testing branch support.

Based on the results of the 2-loci analyses, we selected representative sequences of species in each putative section to assemble a 4-loci dataset composed of 460 ITS, 417 LSU, 161 *rpb1*, and 87 *rpb2* sequences. For the ITS and *rpb1* loci we used the E-INS-i (Katoh & Standley 2013), for the LSU locus the G-INS-i (Katoh et al. 2005), and for the *rpb2* locus the FFT-NS-i algorithms (Katoh et al. 2002), all under default settings. Referring to the 2-loci dataset (above), we used the same programs for manual inspection of the separate alignments as well as for concatenating the individual alignments and binary data. Six nucleotide (ITS1+5.8S+ITS2+LSU+*rpb1*+*rpb2*) and one binary (indel) partitions were defined in our supermatrix which was then submitted to raxmlGUI (Silvestro & Michalak 2012) with the same options as above. Alignments are available in TreeBase (S22220), newly generated sequences are deposited in GenBank (Table 1). The trees were in all cases edited and visualized in MEGA 7 (Tamura et al. 2013).

Section descriptions

Major morphological characters have been chosen for each new section. Lamellar colour always pertains to immature specimens. Odour, taste, and marginal lamellar elements are mentioned only when significant. The alkaline reaction was made with a 30 % NaOH (or KOH) solution. Unless otherwise specified, stipes are dry, and the hyphae are provided with clamp connections.

RESULTS

The final concatenated 2-loci data matrix comprises 730 sequences and 2 412 sites plus 1 324 binary characters, whereas the 4-loci data matrix comprises 460 sequences and 4 669 sites plus 1 118 binary characters. In total these datasets represent 601 *Cortinarius* species.

The resulting 4-loci and 2-loci phylograms (Fig. 1, 2) reveal a number of distinct clades, many of which exhibit a moderate (60–70 %; cf. Frøslev et al. 2005, Jeewon & Hyde 2016) to robust (80–100 %) bootstrap support values. The PhyML tree is not shown in this study, but its support values for sections and clades are mapped to the 2-loci phylogram (Fig. 2). Not unexpectedly we thereby recover a number of traditionally recognised and named sections and other supraspecific taxa. Other sections, preponderantly those with a bihemispherical or southern distribution, are described here as new. Some of

these new taxa were anticipated in earlier works on the global phylogeny of the genus (Peintner et al. 2004, Garnica et al. 2005), and were sometimes given clade names that inform our section names. We identify 37 previously described sections, while 42 sections are here either described as new or based on taxa previously at a different rank. Monotypic sections (with the exception of *Gigasperma*) are not considered, even if typified by an included species. In addition, due to ongoing research into the taxonomy of several *Cortinarius* groups (including cases of insufficiently known taxa), 20 putative new sections are here discussed merely as named clades.

Morphological similarities among the species of a section are often obvious, even though clear synapomorphies are fairly rare. Especially in lineages with austral members, several phenotypic forms are sometimes present, while possessing other shared attributes that can be used to characterise the section. For example, a section may contain taxa with both agaricoid and sequestrate habits, but which all present a yellowish coloration and a viscid universal veil that may be regarded as sectional traits.

There are many singleton species in our phylograms, which our analysis could not associate with other taxa with any confidence (Fig. 1). Others appear to form loose but consistent associations with low bootstrap values; these are listed as Unsupported Groups in the context of a related section.

TAXONOMY

The sections are presented in a number of main groupings, largely based on the principal lineages recovered in the phylogeny of Fig. S2 in Garnica et al. (2016). The groupings also roughly correspond to subgenera of a traditional taxonomy (e.g., that of Brandrud et al. 1989, 1992, 1994, 1998, 2012) and are ordered accordingly. The following main groupings are used:

1. The type section (*Cortinarius*)
2. Dermocyboid sections
3. Leprocycboid sections
4. Phlegmacioid sections
 - 4.1. Euphlegmacia
 - 4.2. *Calochroi* s.lat.
 - 4.3. Pseudophlegmacia
5. Anomaloid sections
6. *Gigasperma*
7. Myxacioid sections
8. Telamonioid sections
 - 8.1. Subgenus *Telamonina* s.str.
 - 8.2. Other telamonioid sections

For each section, the type is specified and the section or clade members are listed (epithets only, the name *Cortinarius* being subsumed). Our dataset comprises about 20 undescribed species whose formal protologues will be presented in future publications. Another 64 undescribed species are designated as 'cf.' or 'C. sp.'.

Fig. 1 Maximum likelihood (RAxML) phylogenetic tree of a selection of the *Cortinaria* samples included in this study, depicting the supraspecific structure of the genus. The dataset of 460 samples consists of nrITS, nrLSU, *rbp1*, and *rbp2* sequences with binary data from gap coding of ITS and LSU. Seven partitions are used: ITS1: 1–554, 5.8S: 555–705, ITS2: 706–1244, LSU: 1245–2355, *rbp1*: 2356–3901, *rbp2*: 3902–4670, BIN: 4671–6030. Vouchers and abbreviated geographical provenances are included in the labels. Assigned section or clade names are shown with gross morphological traits (i.e., belonging to the main categories of this study) indicated by colours (dark violet = sect. *Cortinarius*; red = dermocyboid sections; greenish yellow = leprocyboid sections; dark blue = Euphlegmacia + *Calochroi*; light blue = Pseudophlegmacia; pink = anomaloid groups; black = sect. *Gigasperma*; green = myxacioid sections; brown = telamonioid sections). RAxML bootstrap support values are shown only above 50 %.

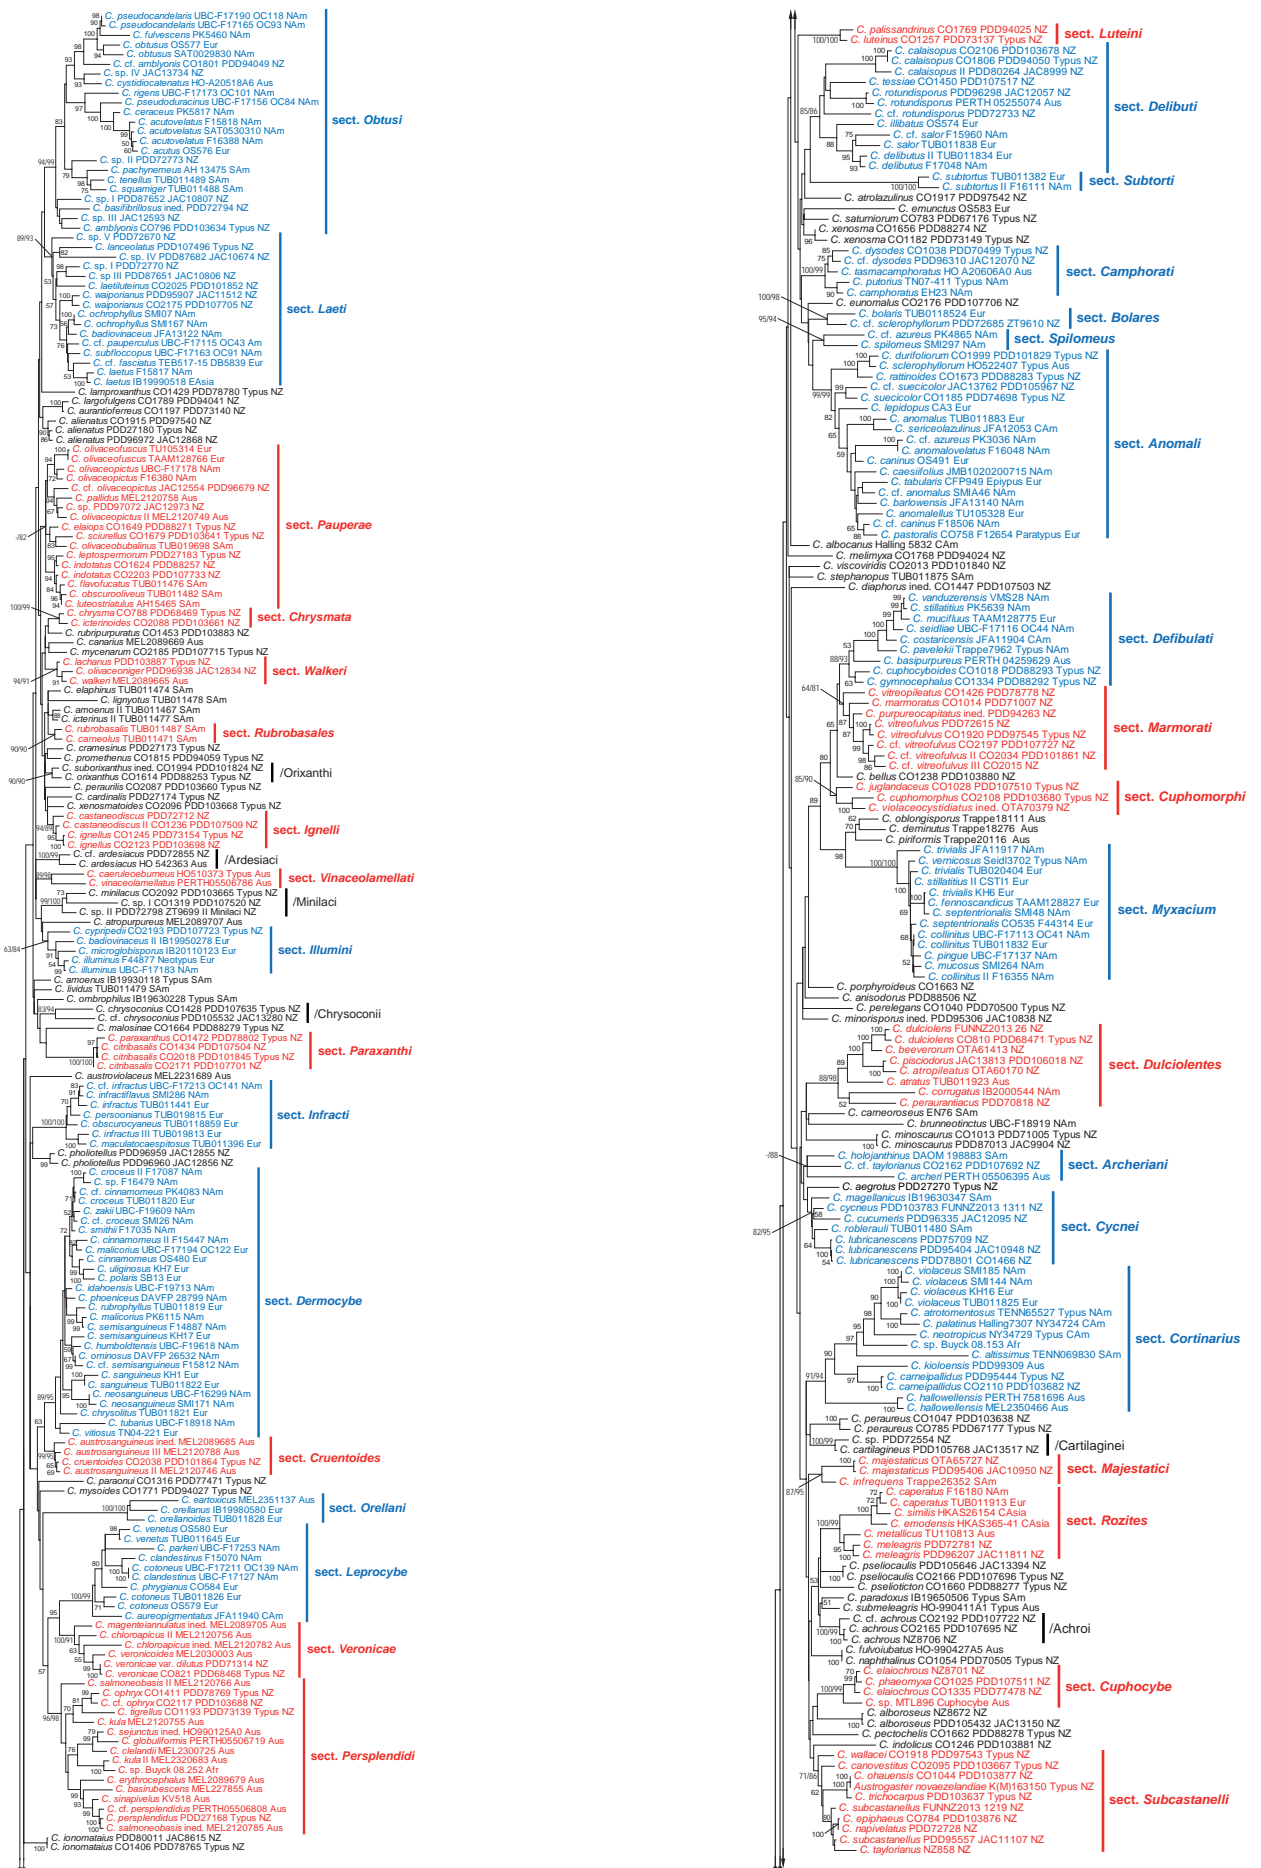

Fig. 2 Maximum likelihood (RAxML) phylogenetic tree based on 730 *Cortinarius* samples and nrITS and nrLSU ribosomal genes with binary data from gap coding (BIN). Five partitions are used: ITS1: 1–610, 5.8S: 611–762, ITS2: 763–1334, LSU: 1335–2412, BIN: 2413–3736. Vouchers and abbreviated geographical provenances are included in the labels. Extant sections are marked blue, while new sections proposed in this study are marked red. Bootstrap support values are shown only above 50%. RAxML support values, followed by the corresponding PhyML values, are shown in bold for sections and clades.

In the species list the second column gives the known geographical provenance (see the abbreviations below). The third column specifies the source of genetic information, unless the species is sampled in both 2-loci and 4-loci trees (the normal case). Species that were only sampled in the 2-loci tree are marked 2L, and those that were sampled with at least one *rpb* sequence in the 4-loci tree are marked R. Species that were not sampled in our analysis, but were shown to belong to the same clade in Garnica et al. 2016 (based on ITS) are marked G2016. A few unpublished results from the ITS sequencing project of the DNA group of the European Cortinarius Association (Journées européennes du Cortinaire, JEC) were included and are marked JEC. Putative taxa that were not sampled in either

study are listed in parentheses; these are taxa that have been described as being (likely) members of the section.

If at least two species were included in a section or clade, the ML bootstrap support (in %) is given. This refers to the 4-loci tree, unless specified otherwise. If the type of a new section is represented in GenBank (GB), this is also noted.

Notes on terminology

Refer to Fig. 3 and 4 for illustrations of some of these terms:

By *agaricoid* is meant the predominant habit of a *Cortinarius* basidiome with a pileus, stipe and distinct lamellae. The opposite term *sequestrate*, refers to a habit where the lamellae are replaced by a gleba, the pileus being more or less closed, and the stipe sometimes rudimentary.

Fig. 3 Phenotypic forms and habits of *Cortinarius* I. a. Agaricoid habit (*C. violaceus*); b. myxacioid habit (*C. collinitus*); c. dermocyboid habit (*C. fervidus*); d. leprocyboid habit (*C. phrygianus*); e. sequestrate habit 1 (*C. beeverorum*); f. sequestrate habit 2 (*C. epiphaeus*). — Photos K. Soop.

Refer to the introductory text of headings 2, 3, 4.1, 5, 7, 8.1 for subgeneric adjectives (*dermocyboideus*, *telamonioides*, etc.). By *rozitoideus* is meant possessing a membranous partial veil (homologous with the cortina), like in the former genus *Rozites*. *Cuphocyboideus* means lacking a cortina, like in the former genus *Cuphocybe*.

Pileocarpic and *stipitocarpic* refer to the development of a *Cortinarius* basidiome (Locquin 1953). The former implies an early expansion of the pileus, leaving an often marginate bulb on the stipe. In the latter case, the stipe develops earlier, leaving the stipe less bulbous, often clavate or cylindrical.

By *borealis* and *australis* we mean occurring in the Northern and Southern Hemisphere, respectively; *bihemispherical* implies

Fig. 4 Phenotypic forms and habits of *Cortinarius* II. a. Phlegmacioid habit, stipitocarpic 1 (*C. varius*); b. phlegmacioid habit, stipitocarpic 2 (*C. papulosus*); c. phlegmacioid habit, pileocarpic (*C. chlorophyllus*); d. telamonioid habit (*C. waiporianus*); e. cuphocyboide habit (*C. phaeomyxa*); f. rozitoide habit (*C. wallacei*). — Photos K. Soop.

both. These terms do not imply an ecological or climatological aspect.

The following geographical abbreviations are used: Eur (Europe), NAM/SAM/CAM (North/South/Central America), Aus (Australia), NZ (New Zealand).

1. Section *Cortinarius* (99 %)

Typus. *C. violaceus* (L.: Fr.) Gray.

<i>altissimus</i>	Guyana	
<i>atrotomentosus</i>	NAM	R
<i>carneipallidus</i>	NZ	R
<i>hallowellensis</i>	Aus	R
<i>kioloensis</i>	Aus, NZ	R
<i>neotropicus</i>	CAM	2L
<i>palatinus</i>	CAM	R
<i>violaceus</i>	Eur, NAM	R
(<i>atroviolaceus</i>)	NZ, SE Asia	
(<i>hercynicus</i>)	Eur	
(<i>jenolanensis</i>)	Aus	
(<i>paraviolaceus</i>)	SE Asia	
(<i>subcalyptrosporus</i>)	NZ	

Notes — The type section of the genus *Cortinarius* is widely distributed globally. The species are characterised by a dark blue to violet coloration overall, due to the (R)- β -dopa pigment, a dry velvety-granulose pileus, and lageniform cheilocystidia. See Harrower et al. (2015b).

The morphologically similar singletons *C. atrolazulinus* (New Zealand) and *C. austroviolaceus* (Australia) are placed in remote positions in our phylogeny, indicating that section characters are convergent. In addition, Moser (1986) described four southern species in the section (of which three from Malaysia, Borneo), but sequences of their holotypes have so far not been available.

2. Dermocyboid sections

This heading regroups taxa that correspond approximately to the *Dermocybe* lineage in Fig. S2 of Garnica et al. (2016). Basidiomata are usually small and slender, characterised by often brightly red/yellow/olive colours, due to anthraquinonic pigments, which also cause a positive (usually red) alkaline reaction in the tissues.

Section *Dermocybe* (Fr.) Gillot & Lucand (100 %)

Typus. *C. cinnamomeus* (L.: Fr.) Gray.

Notes — *Pauperae* contains dermocyboid species, typical for the Southern Hemisphere, of which only two are boreal. They present a yellow, olive, or citrinous coloration, with pigments of the skyrine and hypericine type (Stensrud et al. 2014). Unlike sect. *Dermocybe*, some members possess a glabrous or hygrophanous pileus. Three taxa (see *C. luteostriatulus*) are assumed conspecific with a 99.6 % similarity in the ITS-LSU region. The taxon *C. sp. II* was labelled '*pallidus*' (Stefani et al. 2013), which would be a nom. illeg. (*Cortinarius pallidus* Peck 1889).

Cortinarius sect. *Cruentoides* Soop, *sect. nov.* (100 %)

Typus. *C. cruentoides* Soop, GB (ITS, LSU).
Mycobank MB822924.

<i>austrosanguineus</i> ined.	Aus	R
<i>austrosanguineus</i> II	Aus	R
<i>austrosanguineus</i> III	Aus	R
<i>cruentoides</i>	NZ	R

Basidiomata small, dry, reminiscent of the boreal subsect. *Sanguinei*. Pileus 10–30 mm diam, deep red, minutely granulose-fibrillose. Lamellae red. Stipe cylindrical, reddish. Veil dark red to purple red, rather copious. Context white to pinkish. Alkaline reaction blood red. Spores ellipsoid to subglobose, 6–8 × 4–5 µm, fairly coarsely verrucose. In *Myrtaceae* forests, New Zealand, Australia.

Notes — The section is sister to sect. *Dermocybe*, and might alternatively be considered part of the latter, which then becomes bihemispherical.

Cortinarius sect. *Walkeri* Soop, sect. nov. (99 %)

Typus. *C. walkeri* Cooke & Masee.
MycoBank MB822925.

<i>lachanus</i>	NZ	
<i>olivaceoniger</i>	NZ	
<i>walkeri</i> (<i>austrovenetus</i>)	Aus	R

Basidiomata small to medium-sized, dry to glutinous, yellowish to greenish. Pileus 10–60 mm diam, greenish, often with yellow or blue tints, minutely silky. Stipe cylindrical, pale green, flavescent or blushing. Lamellae citrinous, often blushing. Veil greenish, sparse. Context pale green to pale yellowish. Alkaline reaction blood red. Spores ellipsoid to amygdaloid, 8–10 × 4.5–6 µm, weakly verrucose. In *Nothofagaceae* and *Myrtaceae* forests, New Zealand, Australia.

Notes — The Patagonian sister taxon *C. elaphinus* deviates morphologically, and was described in subg. *Telamonina*. On the other hand, the morphologically similar *C. alienatus* from New Zealand appears as a singleton in our phylogeny.

Cortinarius sect. *Chrysmata* Soop, sect. nov. (100 %)

Typus. *C. chryisma* Soop, GB (ITS, LSU).
MycoBank MB822926.

<i>chryisma</i>	NZ	R
<i>icterinoides</i>	NZ	R

Basidiomata small, pileus dry, brilliantly yellow. Pileus 15–50 mm diam, yellow, finely fibrillose. Lamellae yellow. Stipe cylindrical to clavate, pale yellow. Veil dark yellow, sparse. Context yellow. Alkaline reaction blood red to vinaceous. Spores ellipsoid, 7–10 × 4.5–5.5 µm, weakly to moderately verrucose. In *Nothofagaceae* forests, New Zealand.

Cortinarius sect. *Rubrobasales* Soop & Dima, sect. nov. (93 %)

Typus. *C. rubrobasalis* M.M. Moser & E. Horak.
MycoBank MB822927.

<i>carneolus</i>	SAm	
<i>rubrobasalis</i>	SAm	
<i>teratargus</i>	SAm	G2016

Basidiomata telamonoid, small to medium sized, dry, red-brown. Pileus 30–70 mm diam, red-brown to date brown, minutely fibrillose. Lamellae pale brown to rusty yellow-brown. Stipe ± cylindrical, red-brown to pale reddish or yellowish. Veil incarnate to cinnabar red. Context white to red-brown. Alkaline reaction brownish to black. Spores ellipsoid, 8–10.5 × 4.5–6 µm, weakly verrucose. In *Nothofagaceae* forests, Patagonia.

Cortinarius sect. *Ignelli* Soop, sect. nov. (96 %)

Typus. *C. ignellus* Soop, GB (ITS, LSU).
MycoBank MB822928.

<i>castaneodiscus</i>	NZ	
<i>castaneodiscus</i> II	NZ	
<i>ignellus</i>	NZ	

Basidiomata small, dry to viscid, yellow and reddish. Pileus 15–50 mm diam, yellow to orange-brown with a darker disc. Lamellae yellow-brown to olive yellow or orange. Stipe cylindrical, yellow with reddish veil remnants. Veil yellow to brick red. Context pale yellow to orange. Alkaline reaction red. Spores ovoid to subamygdaloid, 7–9.5 × 5–7 µm, moderately verrucose. In *Nothofagaceae* forests, New Zealand.

Clade *IOrixanthi* (91 %)

<i>orixanthus</i>	NZ	R
<i>suborixanthus</i> ined.	NZ	

Notes — Basidiomata are medium-sized, viscid, coloration yellow to yellow-brown. In *Nothofagaceae* forests.

Unsupported group *Icterinula*

<i>alienatus</i>	NZ	
<i>amoenus</i> II	SAm	2L
<i>cardinalis</i>	NZ	
<i>cramesinus</i>	NZ	
<i>icterinus</i> II	SAm	
<i>mycenarum</i>	NZ	R
<i>papaver</i> (<i>austrocinnabarinus</i>)	NZ, Aus	R
<i>peraurilis</i>	NZ	R
<i>promethenus</i>	NZ	R
<i>rubripurpuratus</i>	NZ	2L
<i>xenosmatoides</i>	NZ	
cf. <i>cramesinus</i>	Aus	2L
(<i>acutipapillatus</i> [<i>mastoideus</i>])	Aus)	
(<i>laetelamellatus</i>)	Aus)	
(<i>vinicolor</i>)	NZ)	

Notes — The group has low support and is intermixed with several of the smaller sections treated above, and all the species in the list are singletons in the present study. Basidiomata are often brightly yellow and red, but *C. xenosmatoides* deviates by its drab telamonoid habit and lack of alkaline reaction. The Australian *C. austrocinnabarinus* is shown by our analysis to be a late synonym of *C. papaver* from New Zealand.

The type of *Dermocybe* sect. *Icterinula*, *D. amoena*, has been sequenced, but is poorly supported as a member of the group in our analysis. ITS sequences of the types of *C. amoenus* and *C. icterinus* are 99.8 % similar. Moreover, under a different interpretation, Garnica et al. (2003) place these two species in a separate clade, which was also recovered in our analysis (marked 'II' in the list). Due to these partial contradictions, *Icterinula* cannot be used as a section name in the present study.

3. Leprocryboid sections

In 1969 Moser described subg. *Leprocrybe*, whose taxa are mainly characterised by yellow/brownish/greenish basidiomata whose context fluoresces in UV light. Many of the taxa have been shown to contain anthraquinonic pigments of the nonaketide pathway (Stensrud et al. 2014). Earlier studies (Peintner et al. 2004, Garnica et al. 2005, 2016) have shown that the subgenus is polyphyletic, while some of its sections are here recovered as clades. The South Pacific taxon *C. canarius* is basal to the leprocryboid clades, despite its original placement in the genus *Dermocybe* (cf. Stefani et al. 2013). Under the present heading we consider taxa that are approximately consistent with the concept of *Leprocrybe* s. Moser. Only a few were sampled in Fig. S2 of Garnica et al. (2016).

Section *Leprocrybe* (M.M. Moser) Melot (100 %)

<i>Typus.</i> <i>C. cotoneus</i> Fr.		
<i>aureopigmentatus</i>	CAm	2L
<i>clandestinus</i>	NAm	2L

<i>cotoneus</i>	Eur, NAm	R
<i>flavifolius</i>	NAm	G2016
<i>parkeri</i>	NAm	
<i>phrygianus</i>	Eur	
<i>venetus</i>	Eur	
(<i>cepistipes</i>)	Eur)	
(<i>melanotus</i>)	Eur)	
(<i>psittacinus</i>)	Eur)	

Notes — The boreal section is characterised by predominantly yellow and greenish olive basidiomata with a strong fluorescence, due to xanthone pigments. Section *Persplendidi* often forms a sister clade. See also Ammirati et al. (2007).

Cortinarius sect. *Persplendidi* Soop & Dima, *sect. nov.* (90 %)

Typus. *C. persplendidus* Gasparini, GB (ITS, LSU).
Mycobank MB822929.
Non subsect. *Splendidi* Bidaud, Moënne-Locc. & Reumaux.

<i>basirubescens</i> (<i>fuscoumbonatus</i>)	Aus	R
<i>clelandii</i>	Aus	R
<i>erythrocephalus</i>	Aus	R
<i>globuliformis</i>	Aus	R
<i>kula</i>	Aus	R
<i>kula</i> II	Aus	R
<i>melleilpileus</i> ined.	Aus	Stefani et al. (2013)
<i>ophryx</i>	NZ	
<i>persplendidus</i>	NZ	R
<i>salmoneobasis</i> ined.	Aus	R
<i>salmoneobasis</i> II	Aus	R
<i>sejunctus</i> ined.	Aus	
<i>sinapivelus</i>	Aus	2L
<i>tigrellus</i>	NZ	2L
cf. <i>persplendidus</i> II	Aus	R
cf. <i>ophryx</i>	NZ	2L

Basidiomata agaricoid or sequestrate, dry, small to medium-sized, typically presenting a dark, tomentose pileus, a clavate stipe, and a yellow and strongly fluorescent context, recalling taxa in sect. *Leprocybe*. A few species dermocyboid (e.g., the blood-red *C. kula*). Anthraquinonic pigments based on the non-aketide pathway (Gill 1995). Pileus 10–60 mm diam, yellow, dark red-brown, dark orange-brown to umber or blackish, fibrillose/tomentose to granulose. Lamellae yellow, orange, or red. Stipe cylindrical to clavate or rudimentary, citrinous to saffron yellow or red. Veil red-brown to dark yellow, darkening, sparse to fairly copious. Context red to yellow. Alkaline reaction red to blackish brown, ± trivial in some species. Spores ovoid to subglobose, 8–11 × 5.5–8 µm, coarsely verrucose. In *Nothofagaceae* and *Myrtaceae* forest, New Zealand, Australia.

Notes — The section appears to be endemic for the South Pacific, but has so far not been recorded in Patagonia. The clade was named *Splendidi* in Garnica et al. (2005) and Stefani et al. (2013); however, to avoid connotation with *Cortinarius splendidus* Peck 1873, or with *C. splendidus* (E. Horak) K. Griffiths 1985, nom. illeg., we propose a new name here.

One of the members, *C. cf. persplendidus* II, has traditionally been named *Dermocybe splendida* in Australia, but forms a sister clade to the latter. *Dermocybe splendida* was described from New Zealand and later recombined as *Cortinarius persplendidus* (Gasparini 2006).

Cortinarius sect. *Veronicae* Soop, *sect. nov.* (99 %)

Typus. *C. veronicae* Soop, GB (ITS).
Mycobank MB822930.

<i>chloroapicus</i> ined.	Aus
<i>chloroapicus</i> II	Aus

<i>magenteiannulatus</i> ined.	Aus	R
<i>veronicae</i>	NZ	R
<i>veronicoides</i>	Aus	R
(<i>vinosipes</i>)	Aus)	

Basidiomata dermocyboid, dry, with cinnabar red to scarlet coloration, recalling the boreal *C. cinnabarinus*, fluorescence yellow. Pileus 20–50 mm diam, cinnabar red, tomentose to finely fibrillose. Lamellae red-orange to brick. Stipe cylindrical, pink to yellowish pink. Veil cinnabar-red or pink, fairly sparse to copious. Context pale yellow. Alkaline reaction blood red on pileus, bluish lilac on stipital veil. Spores subglobose, 5.5–7 × 4.5–5.5 µm, moderately verrucose. In *Nothofagaceae* forest, New Zealand, Australia.

Notes — The section is sister to sect. *Leprocybe* and might be considered part of the latter despite morphological differences (cf. Stefani et al. 2013).

Section Limonii Kühner & Romagn. ex Nezdobjm. (99 %)

Typus. *C. limonius* (Fr.: Fr.) Fr.

<i>araniiti</i>	NZ	2L
<i>armiae</i>	NZ	
<i>aurantiobrunneus</i>	CAM	
<i>caryotis</i>	NZ	R
<i>caryotoides</i>	NZ	2L
<i>kroegeri</i>	NAm	Liimatainen (2016)
<i>limonius</i>	Eur, NAm	
<i>limonius</i> II	Eur, NAm	2L
<i>myrticaryotis</i> ined.	NZ	2L
<i>rubrimarginatus</i>	NZ	
<i>rubrocastaneus</i>	NZ	2L
<i>viscilaetus</i>	NZ	R

Notes — This section, and the morphologically similar sect. *Callistei*, are recovered as well separated but closely related clades in our analyses. The taxa of both sections are characterised by vividly yellow and orange pigments, often with a positive alkaline reaction, but fluorescence is weak. *Limonii* has its core population in New Zealand with at least eight species, and no member has so far been reported from Australia. Two of them, *Cortinarius rubrocastaneus* and *C. rubrimarginatus*, possess remarkable chrysobasidia, a rare feature in *Cortinarius*. See further Soop et al. (2018).

Cortinarius sect. *Callistei* (Liimat., Niskanen & Ammirati) Soop, B. Oertel & Dima, *stat. nov.* (100 %)

Basionym. *Cortinarius* subg. *Callistei* Liimat., Niskanen & Ammirati, Index Fungorum 256: 2. 2015. IF551473.

Typus. *C. callisteus* (Fr.: Fr.) Fr., neotypus GB (ITS).
Mycobank MB823024.

<i>austrolimonius</i> var. <i>ochrovelatus</i>	SAm	R
<i>callisteus</i>	Eur, NAm	
<i>collybianus</i>	NZ	R
<i>controversus</i>	Aus	R
<i>eucollybianus</i>	NZ	
<i>infucatus</i>	Eur, NAm	R
<i>neocallisteus</i>	NAm, Eur	
<i>rubrodactylus</i>	NZ	
<i>tophaceus</i>	Eur, NAm	2L
cf. <i>collybianus</i>	NZ	2L

Notes — *Cortinarius austrolimonius* was described in the South American subg. *Cystogenes*, characterised by the presence of remarkable cheilocystidia. But the type (*C. formosus*) of the subgenus has not been sequenced, and remaining species in the subgenus do not exhibit this character state. Garnica et al. (2003) grouped *C. austrolimonius* var. *ochrovelatus* with *C. pugionipes* and *C. cervinus*, also from South America, but

this affinity is not recovered in our analysis. See further Niskanen et al. (2016).

Section *Orellani* M.M. Moser (100 %)

Typus. *C. orellanus* Fr.

<i>eartoxicus</i>	Aus	2L
<i>orellanoides</i>	Eur, NAm	R
<i>orellanus</i>	Eur, NAm	R
(<i>catarracticus</i>	Aus)	
(<i>fluorescens</i>	SAm)	

Notes — This bihemispherical section was placed by Moser (1969) in subg. *Leprocybe*, and later promoted to subgeneric rank by Gasparini (2004). It is characterised by yellow and orange pigments and is unique in *Cortinarius* by containing appreciable quantities of the lethal toxin orellanine.

Cortinarius sect. *Sinapicoles* (Gasparini) Soop, *stat. nov.* (100 %)

Basionym. *Cortinarius* subser. *Sinapicoles* Gasparini, New Zealand J. Bot. 45: 228. 2007.

Typus. *C. sinapicolor* Cleland.

MycoBank MB822989.

<i>sinapicolor</i>	Aus	
<i>ignotus</i>	NZ	
(<i>wirrabara</i>	Aus)	

Notes — This small southern clade consists of medium-sized, glutinous cortinariae of a golden-yellow colour that react strongly with alkaline solutions. The type of the section is also part of sect. *Pyromyxa* M.M. Moser, a name we cannot use, since no sequence of its type, *C. pyromyxa*, is available.

Cortinarius sect. *Rubicunduli* Soop, B. Oertel & Dima, *sect. nov.* (100 %)

C. stirps rubicundulus M.M. Moser in Singer (1986).

Typus. *C. rubicundulus* (Rea) A. Pearson.

MycoBank MB822931

<i>paurogathwalensis</i> ined.	C Asia	Fungal Diversity Notes (in prep.)
<i>rubicundulus</i>	Eur	R
<i>subgemmeus</i>	NZ	

Basidiomata agaricoid, medium-sized, dry to viscid, coloration yellowish with a tendency to darken on bruising, fluorescence weak. Pileus 15–70 mm diam, pale yellow to yellow-brown with orange-red to dark brown spots and zones, matt, mottled with reddish to pale ochraceous fibrils, blushing to dark orange. Lamellae greyish yellow to pale tan. Stipe cylindrical to clavate, white to greyish yellow, blushing or flavescent. Veil, pale grey to pale ochraceous, blushing and darkening to red or orange, rather copious to sparse. Context pale yellow to tan, ± flavescent when cut and bruised. Alkaline reaction insignificant. Spores ellipsoid to subfusoid, 6–9 × 3.8–5 μm, weakly verrucose. Cheilo- and pleurocystidia prominent, cylindrical or capitate. In *Picea*, *Nothofagaceae*, and *Quercus leucotrichophora* forests, Europe, New Zealand, Asia, respectively.

Notes — These species are recovered on very long branches in a basal position of the phylogeny. The section is a strongly supported sister to *Crassi*, indicating an affinity consistent with some shared morphological characters, such as the cheilocystidia and a soft context.

Cortinarius sect. *Incensi* Soop, *sect. nov.* (79 %)

Typus. *C. incensus* Soop, GB (ITS, LSU).

MycoBank MB822932.

<i>flammuloides</i>	SAm
<i>incensus</i>	NZ

Basidiomata agaricoid, medium-sized, yellowish. Pileus 15–80 mm diam, slightly viscid, saturated to pale yellowish, disk often more orange with brownish stains or squamules. Lamellae whitish to grey-yellow. Stipe cylindrical, often slightly bulbous/clavate, pale yellow to orange, staining brownish. Veil yellow to orange-brown, fairly copious. Context white, often flushing yellow with age or on manipulation. Odour ± spicy. Alkaline reaction yellow to red-brown or red, fluorescence greenish yellow. Spores ellipsoid to subcitriform, 9–12 × 5–6.5 μm, moderately verrucose. In *Nothofagaceae* forest, South Pacific.

Notes — Moser in Singer (1986) assigned the Patagonian member to stirps *Flammuloides* in subg. *Phlegmacium*.

4. Phlegmacioid sections

4.1. Euphlegmacia

Under this provisional name we regroup most of the taxa that were included in Phlegmacioid lineages I and II in Garnica et al. (2016: Fig. S2). They are traditionally and morphologically assigned to subg. *Phlegmacium*, characterised by a viscid pileus, a dry stipe, relatively crowded lamellae, and a more or less robust habit, even though a fair number of exceptions do occur. The *Calochroi* complex is discussed in the next subchapter.

Section *Phlegmacium* (Fr.) Gillot & Lucand (99 %)

Typus. *C. saginus* (Fr.: Fr.) Fr.

<i>norrlandicus</i>	Eur	
<i>populinus</i>	Eur	
<i>saginus</i>	Eur	R

Notes — The section is boreal and includes the type of the traditional subg. *Phlegmacium*. Basidiomata are stipitocarpic and present a yellow to brownish veil. But *C. triumphans*, often assigned here, occupies an isolated position.

Section *Scauri* (Fr.) Henn. (100 %)

Typus. *C. scaurus* (Fr.: Fr.) Fr., neotypus GB (ITS).

<i>chlorophyllus</i>	NZ	
<i>fuligineofolius</i>	NAm	G2016
<i>herpeticus</i>	Eur	2L
<i>montanus</i>	NAm	2L
<i>scaurus</i>	Eur, NAm	R
<i>scaurus</i> II	Eur	2L
<i>singularis</i>	NZ	R
<i>sphagnophilus</i>	Eur, NAm	2L
<i>violaceonitens</i>	Eur	
<i>virentophyllus</i>	NAm	G2016
cf. <i>singularis</i>	NZ	2L
cf. <i>singularis</i> II	NZ	2L
cf. <i>violaceonitens</i>	Eur	2L

Notes — This section is bihemispherical and sister to sect. *Purpurascens*. The morphological and chemical plasticity within the section is remarkably low. The species are characterised by a pileocarpic development, a viscid pileus, often with an olive or greenish tint, and a positive iodine-based reaction (Garnica et al. 2005).

Section *Purpurascens* M.M. Moser (100 %)

Typus. *C. purpurascens* Fr., neotypus GB (ITS).

<i>argyrionus</i>	Aus	G2016
<i>australis</i>	Aus, NZ	
<i>caesibulga</i>	Aus	G2016

<i>campbellae</i>	Aus	2L
<i>chalybaeus</i>	NZ	R
<i>cinereoroseolus</i>	Aus	G2016
<i>collocandoides</i>	Eur	2L
<i>kaimanawa</i>	NZ	R
<i>occidentalis (mutabilis)</i>	NAm, Eur	2L
<i>porphyropus</i>	NAm, Eur	
<i>purpurascens</i>	NAm, Eur	R
<i>rhpiduranus</i>	NZ	
<i>submagellanicus</i>	Aus	
<i>subporphyropus (mendax)</i>	Eur	2L
<i>subpurpurascens</i>	NAm, Eur	G2016
<i>cf. fragilis</i>	Aus	2L

Notes — This section is bihemispherical. Like in *Scauri* (above) the basidiomata present a positive iodine-based reaction, though most deviate by a stipitocarpic habit, and four of the Australian species are sequestrate. In addition, parts of the basidiomata typically darken with a violet tinge on bruising (Saar et al. 2014). *Cortinarius cf. fragilis* appears to be a sequestrate form of a morphospecies that includes the agaricoid *C. submagellanicus*. The morphologically deviating South Pacific singleton *C. persicanus* is a sister.

Section *Multiformes* (Rob. Henry) Moëne-Loec. & Reumaux (100 %)

Typus. *C. multiformis* Fr., neotypus GB (ITS).

<i>armenicorius</i>	Eur, Asia	2L
<i>caesiolamellatus</i>	NAm, Eur	2L
<i>caesiophylloides</i>	Eur, NAm	G2016
<i>frondosomultiformis</i>	Eur	JEC
<i>melleicarneus</i>	Eur	2L
<i>multiformis</i>	NAm, Eur	
<i>pallidirimosus</i>	NAm, Eur	G2016
<i>rufaollutus</i>	Eur	
<i>talimultiformis</i>	Eur	
<i>talus</i>	Eur, NAm	R

Notes — The section appears to be endemic to the Northern Hemisphere. See further Liimatainen et al. (2014) and Brandrud et al. (2014).

Section *Cremeolinae* Soop (93 %)

Typus. *C. cremeolina* Soop, GB (ITS, LSU).

<i>cremeolina</i>	NZ	
<i>cremeolina</i> var. <i>subpicoides</i>	NZ	
<i>cremeorufus</i>	NZ	
<i>dulciorum</i>	NZ	
<i>iringa</i>	NZ	
<i>nebulobrunneus</i>	Aus	2L
<i>cf. austrorapaceus</i>	SAm	
<i>cf. cremeolina</i>	NZ	2L
<i>cf. cremeolina</i> II	NZ	2L

Notes — This is an austral section morphologically similar to the sister sect. *Multiformes*. The Australian taxon, however, is sequestrate. See further Soop (2016).

Section *Claricolores* Moëne-Loec. & Reumaux (95 %)

Typus. *C. claricolor* Fr., neotypus GB (ITS).

<i>blattoi (pseudovariegatus)</i>	Eur, NAm	2L
<i>claricolor</i>	NAm, Eur	R
<i>cumatilis</i>	Eur	R
<i>praestans</i>	Eur	
<i>rex-claricolorum</i>	Eur	G2016

Notes — See further Brandrud et al. (2013).

Clade */Rhizophori* (100 %)

<i>rhizophorus</i>	Eur	R
<i>viscidoamarus</i>	Eur	

Notes — Taxa in this boreal clade possess a slightly bulbous stipe and yellowish tints.

Section *Elastici* (Fr.) Henn. (100 %)

Typus. *C. papulosus* Fr., neotypus GB (ITS).

<i>artosus</i>	NZ	
<i>castaneicolor</i>	NAm	G2016
<i>coelopus</i>	Aus	
<i>luteobrunnescens</i>	Eur, NAm	G2016
<i>ochraceobrunneus</i>	Eur	G2016
<i>papulosus</i>	Eur, NAm	R
<i>cf. papulosus</i>	Eur, NAm	2L

Notes — Taxa in this bihemispherical section possess clavate stipes and often have a characteristic grassy odour. The section is strongly supported as sister to the following one, but is kept segregated from it due to morphological differences.

Section *Percomes* (Moëne-Loec. & Reumaux) Melot (77 %)

Typus. *C. percomis* Fr., neotypus GB (ITS).

<i>aurilicis</i>	Eur	R
<i>cephalixoides</i>	NAm	G2016
<i>citrinifolius</i>	NAm	G2016
<i>nanceiensis</i>	Eur	R

<i>spadicellus</i>	Eur	
<i>varicolor</i>	NAm, Eur	R
<i>violaceomaculatus</i>	Eur	R
cf. <i>varicolor</i>	NAm	2L

Notes — Apart from one Australian species, the section is boreal. It consists of stipitocarpic taxa of *Phlegmacium* habit, though the pileus is sometimes almost dry. The core of the section consists of subsect. *Variocolores* and *Balteati* (Brandrud 1998).

Clade *I Varii* (86 %)

<i>decolorans</i>	Eur	
<i>luteocingulatus</i>	Eur	2L
<i>reverendissimus</i>	Eur	R
<i>variiformis</i>	Eur	2L
<i>variosimilis</i>	NAm, Eur	R
<i>varius</i>	Eur	
cf. <i>variosimilis</i>	NAm	

Notes — Basidiomata are stipitocarpic with an ochraceous pileus, violaceous lamellae, and a white to yellow veil. In coniferous and broad-leaf forests.

Cortinarius decolorans (Pers.) Fr.

Neotypus. Sweden, Gotland, Tjaukle Änge, with *Picea*, K. Soop CO745, herb. S F304386, GenBank KJ421062 (ITS+LSU), hic designatus. MycoBank MBT378826.

Notes — This species was labelled '*C. varius* II' in Garnica et al. (2016). Basidiomata resemble *C. varius*, but (almost) lack violet hues. They match Fries' taxon well (Fries 1821, 1851); we hence propose to neotypify his epithet for the present taxon, even though the name has not often been used in modern literature.

Clade *I Obsoleti* (100 %)

<i>obsoletus</i>	Eur	R
<i>oertelii</i> ined.	Eur	R

Notes — Basidiomata are stipitocarpic with an ochraceous pileus, violaceous lamellae, and a white veil. In broad-leaf forests.

Section *Amoenolentes* Brandrud & Melot (99 %)

Typus. *C. amoenolens* Rob. Henry.

<i>aleoriosmus</i>	Eur	R

<i>aurescens</i>	NAM	JEC
<i>caerulescentium</i>	Eur	R
<i>eucaeruleus</i>	Eur	R
<i>perpallens</i>	Eur	
<i>terpsichores</i>	NAM, Eur	

Notes — Basidiomata are medium-sized, pileocarpic with violaceous hues, resembling species in the sister sect. *Caerulescentes*. In broad-leaf forests.

Clade /*Subolivascetes* (89 %)

<i>atrochalybaeus</i>	NAM, Eur	G2016
<i>barrentium</i> (<i>tauri</i>)	NAM, Eur	R
<i>moëgne-loccozii</i>	Eur	
<i>subolivascens</i>	NAM	
cf. <i>atrochalybaeus</i>	NAM	JEC
cf. <i>velicopia</i>	NAM	2L

Notes — Basidiomata medium-sized, pileocarpic, coloration brown to violaceous. In coniferous and broad-leaf forests.

Cortinarius* sect. *Vinaceolamellati Soop & Gasparini, sect. nov. (86 %)

Typus. *C. vinaceolamellatus* Cleland.
Mycobank MB822935.

<i>caeruleoëburneus</i>	Aus	
<i>vinaceolamellatus</i>	Aus	

Basidiomata medium-sized, stipitocarpic. Pileus 30–60 mm diam, viscid, pale violaceous, brunnescent, finely fibrillose. Lamellae lilac-violet. Stipe clavate, white to pale violet. Veil

white to pale violet, sparse to rather copious. Context white to pale brownish, marbled violet. Alkaline reaction insignificant. Spores ellipsoid to ovoid, $7.5\text{--}10.5 \times 4.5\text{--}6.5 \mu\text{m}$, moderately verrucose. Cheilocystidia prominent in one species. In *Myrtaceae* forests, Australia.

***Cortinarius* sect. *Alboaggregati* Soop, sect. nov. (100 %)**

Typus. *C. alboaggregatus* Soop, GB (ITS).
MycoBank MB822936.

<i>alboaggregatus</i>	NZ	R
<i>pseudotriumphans</i>	SAm	R

Basidiomata medium-sized to large, stipitocarpic. Pileus 35–75 mm diam, viscid, white to yellow-brown, somewhat brunnescent on disk, finely fibrillose, margin involute. Lamellae white, crowded. Stipe tapering downwards or fusoid, rooted, white with rather thick, white girdles, often peronate. Veil white, copious. Context white. Alkaline reaction orange-brown or insignificant. Spores fusoid-amygdaloid, $10.5\text{--}13.5 \times 5.5\text{--}7.5 \mu\text{m}$, moderately verrucose. In *Nothofagaceae* forests, New Zealand and South America.

***Cortinarius* sect. *Cretaces* Soop & Dima, sect. nov. (57 %, 90 % in PhyML tree)**

Typus. *C. cretax* Soop, GB (ITS).
MycoBank MB822937.

<i>austroturmalis</i>	SAm	
<i>caelicolor</i>	SAm	
<i>cervinus</i>	SAm	
<i>cretax</i>	NZ	
<i>effundens</i>	SAm	
<i>lacteus</i>	Aus	2L
<i>pugionipes</i>	SAm	2L
<i>(xiphidipus)</i>	SAm	

Basidiomata medium-sized to large, stipitocarpic, often caespitose. Pileus 25–120 mm diam, viscid, white to yellow-brown, occasionally flavescent or brunnescent on disk, glabrous to finely fibrillose. Lamellae white to pale grey-brown, crowded. Stipe tapering downwards, rooted, white, \pm glabrous. Veil white, sparse. Context white. Odour weak or like bitter almonds. Alkaline reaction insignificant. Spores fusoid-amygdaloid, $6\text{--}10 \times 3\text{--}5.5 \mu\text{m}$, weakly verrucose. In *Nothofagaceae* forests, South Pacific.

Notes — This predominantly Patagonian section is part of stirps *Xiphidipus* (see Moser & Horak 1975), but as no sequence of the paronymous species *C. xiphidipus* is available, we cannot use the name as the base of a new combination. The fungi resemble those of sections *Arguti* and *Alboaggregati*, which are genetically remote.

Clade *Turcopedes* (99 %)

<i>turcopes</i>	NZ
cf. <i>turcopes</i>	NZ

Notes — A small austral clade of stipitocarpic fungi with a blue to blue-green coloration. In *Nothofagaceae* forests.

4.2. *Calochroi* s.lat.

This large monophyletic group of over 80 species appears to be endemic for the Northern Hemisphere. Basidiomata generally present a pileocarpic habit with a wide stipital bulb. Many of the species are rare and most grow exclusively on calcareous soil. Their hosts belong to a range of broad-leaf and coniferous genera, but *Quercus* is a dominant partner, especially in the southern parts of the region.

The phylogeny reveals a number of closely related clades, many of which are recovered as traditional sections. These are not further discussed in this study, having been extensively documented in several dedicated efforts (Frøslev et al. 2006a, b, Ortega et al. 2008, Garnica et al. 2009, 2011). They are represented in Garnica et al. (2016: Fig. S2) by Phlegmacioid clade III.

4.3 Pseudophlegmacia

Under this provisional name we consider taxa that in various respects (habit, viscosity, hygrophanity, etc.) deviate from typical *Phlegmacium*, and/or have sometimes been assigned to other genera or subgenera. Only a few were sampled in Fig. S2 of Garnica et al. (2016).

***Cortinarius* sect. *Lustrati* Ammirati ex Soop, B. Oertel & Dima, sect. nov. (100 %)**

Typus. *C. lustratus* Fr.
MycoBank MB822938

<i>comparioides</i>	CAm	2L
<i>leucophanes (comarostaphylides)</i>	Eur, NAM, CAm	
<i>leucophanes II</i>	NAm	2L
<i>lustratus</i>	Eur	R
<i>oregonensis</i>	CAm	G2016
<i>ovreboii</i>	CAm	

Basidiomata medium-sized to small, stipitocarpic, pale. Pileus 25–70 mm diam, viscid, ivory to creamy-yellow or pale violet, disk yellowish, glabrous to silky. Lamellae greyish, sometimes with a rosy or violet tinge, crowded. Stipe clavate to cylindrical with a small bulb, silky white, often \pm violaceous at apex. Veil white to pale violet, sparse to fairly copious. Context white, occasionally marbled violet. Odour none or farinaceous, sometimes fruity. Alkaline reaction insignificant. Spores $5.5\text{--}8 \times 3.5\text{--}4.5 \mu\text{m}$, ellipsoid, weakly verrucose. In *Pinus*, *Fagaceae*, and *Comarostaphylis* forests, Europe, North/Central America.

Notes — The boreal section forms a well-supported clade with two sister sections in the South Pacific, *Laquelli* and *Austrocyanites*. See further Ammirati et al. (2007).

***Cortinarius* sect. *Laquelli* Soop, sect. nov. (80 %)**

Typus. *C. laquellus* Soop, GB (ITS).
MycoBank MB822939.

<i>laquellus</i>	NZ
<i>urbiculus</i>	NZ

Basidiomata small, stipitocarpic, coloration pale, recalling those of sect. *Lustrati*. Pileus 7–35 mm diam, dry to viscid, matt with a white, velvety or pruinose coating, finely fibrillose. Lamellae pale violet to greyish violet, medium crowded. Stipe cylindrical to clavate, silvery white with a faint violaceous tint. Veil white, fairly copious. Context white, young marbled violet or entirely bright violet-lilac, odour faint, \pm like wax candles, taste \pm bitter. Alkaline reaction insignificant. Spores ellipsoid to subamygdaloid, $6.5\text{--}8.5 \times 3.8\text{--}5 \mu\text{m}$, weakly to moderately verrucose. In *Nothofagaceae* forests, New Zealand.

***Cortinarius* sect. *Thaumasti* Soop, sect. nov. (93 %)**

Typus. *C. thaumastus* Soop, GB (ITS, LSU).
MycoBank MB822965.

<i>chlorophanus</i>	SAm	R
<i>thaumastus</i>	NZ	
<i>vaginatus</i>	SAm	R
<i>(coleopus)</i>	SAm	

Basidiomata small, with a peronate or volvate stipe. Pileus 15–50 mm diam, dry to slightly viscid, hygrophanous, olive-green,

yellow, or apricot-brown to red-orange, finely granulose to fibrillose, with white to ochraceous tufts. Lamellae pale greyish to ochraceous, fairly crowded. Stipe with a ± marginate bulb, white to pale yellow, orange, or olivaceous. Veil white to ochraceous, fairly copious, on stipe fibrillose to peronate with thick tufts near base, sometimes forming a membranous volva or collar. Context greyish ochraceous to olivaceous. Alkaline reaction orange to red-brown in context, red to red-brown on cutis. Spores citriform to amygdaloid, 8–11 × 3.5–5 µm, up to 7 µm wide in one species, weakly verrucose. In *Nothofagaceae* forests, New Zealand and Patagonia.

Notes — Several taxa in this austral section are members of *Cortinarius* subsect. *Coleopodes* (see Moser & Horak 1975). However, since no sequence of the type *C. coleopus* is available, we cannot use *Coleopodes* as a basionym.

Clade *IRufoaurantii* (79 %)

<i>faucium</i> ined.	NZ
<i>rufoaurantius</i>	SAm

Notes — A small austral clade of phlegmacioid/telamonioid taxa. Basidiomata are small to medium-sized, stipitocarpic; the coloration is yellow-brown to orange-brown. In *Nothofagaceae* forests.

Cortinarius rufoaurantius Soop, *nom. nov.*

Basionym: *Cortinarius aurantiorufus* Garnica, in Garnica et al., *Mycologia* 94 (1):136. 2002, *nom. illeg.*
MycoBank MB823022.

Notes — The name *C. aurantiorufus* Bidaud is in use (Bidaud et al. 2001).

Cortinarius sect. *Dulciolentes* Soop, *sect. nov.* (95 %)

Typus. *Cuphocybe melliolens* Soop, GB (ITS).
MycoBank MB822940.

<i>atratus</i> (<i>P. luteum</i>)	Aus, NZ	R
<i>atropileatus</i>	NZ	2L
<i>beeverorum</i>	NZ	
<i>corrugatus</i>	CAm	
<i>dulciolens</i> (<i>Cu. melliolens</i>)	NZ	
<i>peraurantiacus</i>	NZ	
<i>pisciodorus</i>	NZ	

Basidiomata medium-sized to large, cuphocyboid or sequestrate. Pileus 25–100 mm diam, viscid to glutinous, pale greyish brown to ochraceous, dark orange, or copper red, coarsely fibrillose to granulose, margin sometimes striate or sulcate. Lamellae/gleba pale cinnamon to argillaceous, sometimes with a violet tinge, crowded. Stipe cylindrical to clavate or rudimentary, often with a small rounded bulb, fibrillose, white, later darkening with red-brown tufts and squamules. Veil pale ochraceous, darkening to red-brown, fairly copious. Context white, slightly canescent or flavescent, sometimes marbled violet. Odour often aromatic or melleous. Alkaline reaction insignificant. Spores ellipsoid to subglobose, 9.5–17 × 7–11 µm, coarsely verrucose. In *Fagaceae*, *Nothofagaceae*, and *Myrtaceae* forests, South Pacific and Central America.

Notes — The bihemispherical section consists of taxa of varying morphology with the type originally described in the genus *Cuphocybe* and four members sequestrate (formerly in genera *Thaxterogaster* and *Protoglossum*).

Cortinarius sect. *Cuphocybe* (R. Heim) Soop, *comb. & stat. nov.* (100 %)

Basionym. *Cuphocybe* R. Heim, *Rev. Mycol.* 16: 8. 1951.
Typus. *Cuphocybe olivacea* R. Heim.
MycoBank MB822941.

<i>elaiochrous</i> (<i>Cu. olivacea</i>)	NZ	R
<i>phaeomyxa</i>	NZ	
<i>C. sp.</i>	Aus	2L

Notes — The former genus *Cuphocybe* is characterised by phlegmacioid taxa with a lacking cortina, which causes the veil to distribute as scales, tufts, and girdles along the full length of the stipe. Basidiomata are medium-sized to large, glutinous, coloration olive-brown to chocolate brown. Spores ellipsoid, large, 11–16 × 7–9 µm, moderately verrucose. In *Nothofagaceae* forests, South Pacific.

Cortinarius sect. *Rapacea* (E. Horak) Soop, *comb. & stat. nov.* (97 %)

Basionym. *Rapacea* E. Horak, *Kew Bulletin* 54: 789. 1999.
Paronym. *C. series Rapacea* Gasparini.
Typus. *R. mariae* E. Horak.
MycoBank MB822987.

<i>castoreus</i>	NZ	R
<i>mariae</i>	NZ, Aus, N Guinea	R

Notes — Basidiomata are medium-sized to large, robust, dry, sericeocyboid, with large spores (–18 µm). The section type, originally published in the genus *Rapacea* (named after *C. rapaceus* of similar colours), is unique in *Cortinarius* from its almost smooth spores, leaving an olive-yellow deposit. The boreal *C. pinophilus* appears as a sister with high support, but is morphologically not similar.

Section *Crassi* Melot (100 %)

Typus. *C. crassus* Fr., neotypus GB (ITS).

<i>crassus</i>	Eur, NAM	R
<i>eutactus</i>	NZ	

Notes — Taxa in this small bihemispherical section evoke *Phlegmacium*, but were traditionally difficult to place in the taxonomy of the genus. Basidiomata are robust with a clavate stipe, dry, coloured pale to dark brown, with narrow, weakly verrucose spores and prominent cheilocystidia (cf. sect. *Rubicunduli*).

Cortinarius sect. *Majestatici* Soop, *sect. nov.* (89 %)

Typus. *Descolea majestatica* E. Horak, GB (ITS, LSU).
MycoBank MB822942.

<i>infrequens</i>	SAm	
<i>majestaticus</i>	NZ	R

Basidiomata rozitoid or sequestrate, medium-sized, viscid, cutis structure partly cellular. Pileus 30–60 mm diam, glutinous, dark yellow-brown, young with an olivaceous tinge, later darkening to umber, glabrous, margin striate to sulcate. Lamellae/gleba cinnamon, medium crowded. Stipe cylindrical or rudimentary, yellow-brown to pale yellowish grey, with thick yellow-brown fibrils and girdles, collar grey-brown, membranous. Veil yellow-brown, sparse to fairly copious. Context dirty white to yellowish white with an olivaceous tinge. Alkaline reaction red on cutis. Hypodermal cells in pileipellis with vesiculose ends. Spores amygdaloid, 12–14 × 7–8.5 µm, coarsely verrucose. In *Nothofagaceae* forests, South Pacific.

Notes — The type of this small austral section was originally described in the genus *Descolea*, but shares major characters with sect. *Subcastanelli* (Anderson & Orlovich 2016). The South American taxon is sequestrate.

***Cortinarius* sect. *Rozites* (P. Karst.) Soop, B. Oertel & Dima, comb. & stat. nov. (100 %)**

Basionym. *Rozites* P. Karst., Bidrag Kannedom Finlands Natur Folk 32: 290. 1879.

Typus. *C. caperatus* Fr.
MycoBank MB822988.

<i>caperatus</i>	Eur, NAM	R
<i>emodensis</i>	C Asia	2L
<i>fuegianus</i>	SAM	G2016
<i>meleagris</i>	NZ	
<i>metallicus</i>	Aus	2L
<i>similis</i>	N Guinea	
<i>(colombianus)</i>	CAM	

Notes — Taxa published in the former genus *Rozites* are distributed over several clades, of which the above forms the bihemispherical type section. Basidiomata are characterised by a membranous inner veil, homologous with the cortina, amyloid tissues, and strongly dextrinoid spores. One may also note that *Rozites* sect. *Rozites* (autonym) was described by Moser & Horak (1975).

Clade /*Achroi* (100 % in 2-loci tree)

<i>achrous</i>	NZ	
cf. <i>achrous</i>	NZ	2L
<i>(elacatipus)</i>	NZ	
<i>(rugosiceps)</i>	NZ	

Notes — Basidiomata are medium-sized to large, rozitoid, glutinous, hygrophanous, with a pale coloration and large spores. In *Nothofagaceae* forests.

***Cortinarius* sect. *Subcastanelli* Soop, sect. nov. (77 %)**

Typus. *Rozites castanellus* E. Horak & G.M. Taylor.
MycoBank MB822943.

<i>canovestitus</i>	NZ	
<i>epiphaeus</i>	NZ	
<i>ohauensis</i>	NZ	
<i>subcastanellus</i> (<i>R. castanellus</i>)	NZ	
<i>taylorianus</i>	NZ	
<i>trichocarpus</i>	NZ	
<i>wallacei</i>	NZ	R

Basidiomata medium-sized to large of various habits: rozitoid, cuphocyboid, myxacioid, or sequestrate. Pileus 25–90 mm diam, dry to glutinous, red-brown to dark yellow-brown or tan, rarely with a violet tinge, coarsely fibrillose, sometimes with thick, greyish white to reddish tufts, margin striate to rimose when old. Lamellae/gleba cinnamon to yellow-brown or brownish pink, rarely violaceous, crowded to rather distant. Stipe cylindrical to clavate, often with a small rounded bulb, violaceous to white, pale grey, or pale yellow, with thick grey to brownish pink girdles, often with a striate, membranous collar. Veil greyish white to greyish yellow or reddish brown, rather sparse to copious. Context grey to pale grey-brown, ± marbled darker grey, yellow, or violet. Alkaline reaction reddish on cutis or insignificant. Spores ellipsoid to subamygdaloid, 8–14 × 5–8.5 µm, moderately to weakly verrucose. In *Nothofagaceae* forests, New Zealand.

Notes — This section is so far known only from New Zealand. Some of our *C. epiphaeus* samples were labelled *C. napivellatus*, a morphologically almost identical sequestrate fungus. Since the holotype of neither has been sequenced, it is too early to judge on their conspecificity, and we here use the dominant (and priority) epithet.

Cortinarius trichocarpus could be considered an agaricoid form of a morphospecies that includes the sequestrate *C. ohauen-*

sis. Moreover, *C. ohauensis* is a late synonym of *Austrogaster novaezelandiae*, not yet combined into *Cortinarius*.

***Cortinarius* sect. *Subhymenogaster* Soop, B. Oertel & Dima, sect. nov. (100 %)**

Typus. *Hymenogaster sublilacinus* A.H. Sm., GB (ITS).
MycoBank MB822944.

<i>brunnescens</i>	NAM	
<i>lilacinoides</i>	NAM	2L
<i>subcaeruleus</i>	NAM	
<i>(Hymenogaster subolivaceus)</i>	NAM	

Basidiomata sequestrate, globose to ovate or lobed. Peridium 10–55 mm diam, thin, dry, silky, whitish to lilac, flushing brown, purple, or bluish on manipulation. Gleba loculate, cinnamon to rusty brown. Columella white, tenous, dendrous to percurrent, or absent. Odour aromatic. Spores ellipsoid, 9–13 × 6.5–8 µm, weakly to moderately verrucose. In coniferous forests, North America.

Notes — The section is sister to sect. *Caerulescentes*. It has also been informally described as the genus *Cortinogaster* ined. See Smith (1966).

***Cortinarius lilacinoides* Soop, B. Oertel & Dima, nom. nov.**

Basionym. *Hymenogaster sublilacinus* A.H. Sm., Mycologia 58(1): 108. 1966.
MycoBank MB823023.

Notes — The name *C. sublilacinus* is in use (Murrill 1944).

***Cortinarius brunnescens* (A.H. Sm.) Soop, B. Oertel & Dima, comb. nov.**

Basionym. *Hymenogaster brunnescens* A.H. Sm., Mycologia 58(1): 111. 1966.
MycoBank MB822991.

***Cortinarius subcaeruleus* (A.H. Sm.) Soop, B. Oertel & Dima, comb. nov.**

Basionym. *Hymenogaster subcaeruleus* A.H. Sm., Mycologia 58(1): 106. 1966.
MycoBank MB822992.

Section *Cyanites* Nespiak (100 %)

Typus. *C. cyanites* Fr., neotypus GB (ITS).

<i>boreicyanites</i>	Eur	G2016
<i>cyanites</i>	Eur	
<i>spurcus</i>	Eur	G2016
<i>violaceorubens</i>	Eur	R

Notes — A boreal section of similar species, characterised by dry and robust basidiomata, mainly of a greyish blue coloration and reddening context. The type has variously been placed in subg. *Phlegmacium*, *Sericeocybe*, and *Telamonina*.

***Cortinarius* sect. *Austrocyanites* Soop, sect. nov. (97 %)**

Typus. *C. austrocyanites* Soop, GB (ITS, LSU).
MycoBank MB822945.

<i>austrocyanites</i>	NZ, Aus
<i>myxoclaricolor</i>	SAM
<i>poliotrichus</i> ined.	NZ

Basidiomata medium-sized to large, stipitocarpic, phlegmacioid or myxacioid. Pileus 25–100 mm diam, dry to viscid, grey-brown to yellow-brown or olive grey, coarsely grey fibrillose to squamulose. Lamellae greyish blue to argillaceous, crowded. Stipe dry to viscid, clavate with a rounded or marginate bulb, white to bluish. Veil pale grey to pale yellow or white with a

± violet tinge, rather sparse to copious. Context white, often marbled greyish blue to turquoise. Alkaline reaction red-brown to black on cutis, reddish lilac on lamellae. Spores ellipsoid to amygdaloid, 8–12 × 5–7 µm, moderately to rather weakly verrucose. In *Nothofagaceae* forests, South Pacific.

Cortinarius sect. *Austrovaginati* Soop, *sect. nov.* (100 %)

Typus. *C. austrovaginatus* Gasparini, GB (ITS, LSU).
Mycobank MB822946.

<i>austrovaginatus</i>	Aus, NZ	
<i>conei</i>	NZ	
<i>medioscaurus</i>	NZ	R

Basidiomata medium-sized, pileocarpic or sequestrate. Pileus 25–60 mm diam, viscid, yellow-brown to vinaceous brown or violaceous, disk ± red-brown, fibrillose, margin with white to yellow-brown tufts. Lamellae greyish violet to vinaceous, fairly crowded, sometimes sinuate or poorly developed. Stipe with a marginate bulb, sometimes volvate, silvery violet to lilac, coated white to yellowish on bulb. Veil white to greyish yellow, fairly copious. Context white to pale violet, taste sometimes bitter. Alkaline reaction reddish or insignificant. Spores ellipsoid to amygdaloid or citriform, 9–13 × 5.5–8 µm, coarsely verrucose. In *Myrtaceae* and *Nothofagaceae* forests, New Zealand, Australia.

Notes — The type species shows a tendency for sequestrate development, while *C. conei* is strictly sequestrate.

Cortinarius sect. *Verniciori* Soop, *sect. nov.* (99 %)

Typus. *C. verniciorum* Soop, GB (ITS).
Mycobank MB822947.

<i>dulcamarus</i>	NZ	
<i>verniorum</i>	NZ	
<i>C. sp.</i>	NZ	2L

Basidiomata medium-sized to small, stipitocarpic, phlegmacioid or telamonioid. Pileus 15–50 mm diam, viscid, apricot to yellow-brown with a ± orange disk, glabrous to finely fibrillose. Lamellae white to pale grey-brown, medium crowded. Stipe cylindrical to ± clavate, whitish to pale grey-brown, flavescent. Veil white, sparse. Context pale yellow, marbled yellow-brown. Odour melleous or insignificant, taste acerbic to bitter. Alkaline reaction red to red-brown. Spores fusoid to subamygdaloid, 5.5–8 × 3–4 µm, weakly verrucose. In *Nothofagaceae* forests, New Zealand.

Section Infracti (Kühner & Romagn.) Moënné-Locc. & Reumaux (100 %)

Typus. *C. infractus* (Fr.: Fr.) Fr., neotypus GB (ITS).

<i>anfractoides</i>	Eur	JEC
<i>ayanamii</i>	Eur	JEC
<i>infractiflavus</i>	Eur, NAM	2L
<i>infractiflavus</i> II	Eur, India	JEC
<i>infractus</i>	Eur, NAM	
<i>infractus</i> II	Eur	JEC

<i>maculatocaesпитosus</i>	Eur	R
<i>obscurocyaneus</i>	Eur	
<i>persoonianus</i>	Eur	
<i>cf. infractus</i>	NAM	2L

Notes — A boreal section of phlegmacioid, stipitocarpic taxa, whose basidiomata present dark colours with a more or less pronounced olive component, growing with a wide range of coniferous and frondose hosts. It is further characterised by the presence of the alkaloid infractopicrin (Stensrud et al. 2014).

The New Zealand species *C. pholiotellus* is closely related, but is not included due to morphological differences.

Section Subtorti Brandrud & Melot (100 % in 2-loci tree)

Typus. *C. subtortus* Fr., neotypus GB (ITS).

<i>subtortus</i>	Eur, NAM	R
<i>subtortus</i> II	NAM	2L
(<i>amurceus</i>)	Eur	

Notes — A small boreal, phlegmacioid or myxacioid section, characterised by olivaceous-yellow tints and the presence of the alkaloid quinoline (Stensrud et al. 2014). It often appears as a sister to sect. *Delibuti*.

Cortinarius sect. *Purpurelli* Soop, *sect. nov.* (100 %)

Typus. *Rozites violacea* E. Horak, Beih. Nova Hedwigia 52: 516. 1975.
Mycobank MB822950.

<i>ochraceoazureus</i>	SAM	
<i>purpurellus</i> (<i>R. violacea</i>)	SAM	
<i>sarmienti</i> (<i>togularis</i>)	SAM	2L
<i>C. sp.</i>	SAM	2L

Basidiomata stipitocarpic, rozitoid, or sequestrate. Pileus 30–80 mm diam, viscid, violet to greyish purple or yellow-brown, margin sometimes with violaceous tufts. Lamellae white to pale brown or rusty yellow, rather distant, sometimes sinuous/wrinkled and bifurcate. Stipe cylindrical to clavate, violet to whitish, brunnescent, silky, girdled or collared. Veil white to violet, brunnescent, fairly copious. Context white to pale yellowish, brunnescent. Odour rarely strong, sweetish. Alkaline reaction insignificant. Spores ovoid to amygdaloid, 8–11 × 5.5–8 µm, weakly verrucose. In *Nothofagaceae* forests, South America.

Notes — Several members were described in the former genera *Thaxterogaster* and *Rozites* (Horak & Moser 1965).

Cortinarius sect. *Entheosi* Soop, *sect. nov.* (87 % in PhyML tree)

Typus. *C. entheosus* Soop, GB (ITS, LSU).
Mycobank MB824054.

<i>aerugineoconicus</i>	NZ
<i>entheosus</i>	NZ

Basidiomata medium-sized, stipitocarpic, phlegmacioid or myxacioid, with a vivid coloration. Pileus 25–60 mm, viscid, tan to yellowish with a brownish orange disk, or greenish blue, glabrous to finely fibrillose. Lamellae blue to violet, crowded. Stipe cylindrical to ± fusoid, dry or viscid, white to pale blue, fibrillose. Veil white to pale violet, fairly copious. Context grey buff to yellowish, marbled violet. Alkaline reaction blue or insignificant. Spores ellipsoid to amygdaloid, 7.5–10 × 4.5–6 µm, moderately to coarsely verrucose. In *Nothofagaceae* forests, New Zealand.

Cortinarius sect. *Salmaster* Soop, *sect. nov.* (81 %)

Typus. *C. salmaster* Gasparini.
Mycobank MB822951.

<i>salmaster</i>	Aus
<i>salmastrium</i>	NZ

Basidiomata medium-sized to small, stipitocarpic, phlegmacioid or telamonioid, greenish. Pileus 20–35 mm diam, viscid, dark olive brown to greyish green, glabrous to finely fibrillose. Lamellae grey to pale grey-brown, medium crowded. Stipe cylindrical, often rooted, silky white or pale green-grey to pale green-blue. Veil yellowish white to brownish, sparse. Context white to green-grey or lilac. Alkaline reaction insignificant. Spores ellipsoid, 7–8 × 4–5.2 µm, moderately verrucose. In *Myrtaceae* forests, South Pacific.

Section *Malvacei* M.M. Moser (87 %)*Typus.* *C. malvaceus* E. Horak.

<i>malvaceus</i>	SAm	R
cf. <i>castaneiceps</i>	NZ	
(<i>austroalbidus</i>)	SAm)	

Notes — Basidiomata are medium-sized to small, stipitocarpic, phlegmacioid or myxacioid, with a pale lilac coloration. In *Nothofagaceae* forests.

Clade *I Ardesiaci* (100 %)

<i>ardesiacus</i>	Aus
cf. <i>ardesiacus</i>	NZ

Notes — Basidiomata are medium-sized, stipitocarpic, phlegmacioid, coloration grey-brown to brown. In *Myrtaceae* forests.

Clade *I Cartilaginei* (100 %)

<i>cartilagineus</i>	NZ
<i>C. sp.</i>	NZ

Notes — Basidiomata are sequestrate or cuphocyboid, coloration ochraceous. In *Nothofagaceae* forests.

Clade *I Australienses* (100 %)

<i>australiensis</i>	Aus	R
cf. <i>australiensis</i>	NZ R	

Notes — Basidiomata are large, whitish, viscid, with a peronate veil. Spores 9–12 × 5.5–6.5 µm, amygdaloid. The taxa have also been attributed to the genus *Rozites*. In *Myrtaceae* forests.

5. Anomaloid sections

Three sections are bihemispherical and the basidiomata are characterised by a yellowish or reddish veil, a relatively slender habit, and rounded spores. The sections are represented by two lineages in Fig. S2 of Garnica et al. (2016).

Section *Anomali* Konrad & Maubl. (100 %)*Typus.* *C. anomalus* (Fr.: Fr.) Fr., neotypus GB (ITS).

<i>albocyaneus</i>	Eur	G2016
<i>anomalellus</i>	Eur	2L

cf. <i>azureus</i>	NAM	2L
cf. <i>caninus</i>	NAM	2L
cf. <i>durifoliorum</i>	NZ	2L
cf. <i>suecicolor</i>	NZ	

Notes — This section has sometimes been presumed close to the morphologically similar sect. *Delibuti* (below), a relation that is not borne out by our analysis. The New Zealand species *C. eunomalus* appears as basal to this and the following two sections. See further Dima et al. (2016).

Section *Bolares* Kühner & Romagn. (100 %)*Typus.* *C. bolaris* (Fr.: Fr.) Fr., neotypus GB (ITS).

<i>bolaris</i>	Eur, NAM, CAM	R
cf. <i>sclerophyllum</i>	NZ	

Notes — The section is bihemispherical and consists of anomaloid fungi with a brightly red veil.

Section *Spilomei* (Bidaud, Moëgne-Loec. & Reumaux) Cons., D. Antonini & M. Antonini (96 %)*Typus.* *C. spilomeus* (Fr.: Fr.) Fr., neotypus GB (ITS).

<i>ferrusinus</i>	Eur	Ballarà et al. (2017)
<i>spilomeus</i>	Eur	
cf. <i>azureus</i>	NAM	
(<i>depauperatus</i>)	Eur)	

Notes — The section is boreal and consists of anomaloid fungi with a reddish veil.

Section *Delibuti* (Fr.) Sacc. (96 %)*Typus.* *C. delibutus* Fr.

<i>calaisopus</i>	NZ, Aus	
<i>calaisopus</i> II	NZ	2L
<i>delibutus</i>	Eur, NAM	2L
<i>delibutus</i> II	Eur, NAM	R
<i>illibatus</i>	Eur	2L
<i>illitus</i>	SAM	G2016
<i>rotundisporus</i>	Aus, NZ	
<i>salor</i>	Eur, NAM	R
<i>tessiae</i>	NZ	
cf. <i>rotundisporus</i>	NZ	G2016
cf. <i>salor</i>	NAM	2L
(<i>betulinus</i>)	Eur)	
(<i>largodelibutus</i>)	Eur)	
(<i>transiens</i>)	Eur)	

Notes — The species are recognised by the same characters as in sect. *Anomali*, exhibiting in addition a viscid to glutinous veil. Basidiomata are coloured yellow, blue, or green, where the green pigment appears to occur mainly in the South Pacific. Unexpectedly, the European taxon *C. emunctus* is a singleton outside the section.

6. *Cortinarius* sect. *Gigasperma* (E. Horak) Soop & B. Oertel, *comb. & stat. nov.**Basionym.* *Gigasperma* E. Horak, New Zealand J. Bot. 9: 491. 1970.*Typus.* *G. crypticum* E. Horak, GB (ITS).
Mycobank MB822990.

<i>crypticus</i>	NZ
------------------	----

Cortinarius crypticus (E. Horak) Soop & B. Oertel, *comb. nov.**Basionym.* *Gigasperma crypticum* E. Horak, New Zealand J. Bot. 9: 491. 1970.

Mycobank MB822995.

Notes — A small sequestrate fungus with very large, thick-walled, smooth spores. Two other species have been described in *Gigasperma*, none of which, however, is part of *Cortinarius* (Index Fungorum).

7. Myxacioid sections

The subsequent four sections, along with *Cortinarius bellus* (New Zealand), form a robust clade, which contains the type section of subg. *Myxacium*. They are represented by the main *Myxacium* lineage in Fig. S2 of Garnica et al. (2016). Also the sequestrate *C. porphyroideus* from New Zealand may possibly be included.

Section *Myxacium* (Fr.) Gillot & Lucand (100 %)

Typus. *C. collinitus* (Pers.: Fr.) Fr.

<i>alpinus</i>	Eur, NAm	G2016

(<i>viscostriatus</i>)	NZ	

Basidiomata medium-sized, myxacioid or sequestrate. Pileus, 25–60 mm diam, glutinous, white to yellow-brown, purple-brown, chocolate-brown, or lilac, disk often paler grey to ochraceous, glabrous. Lamellae white, greyish or deeply violet, medium crowded. Stipe cylindrical to slightly clavate, sometimes with a small rounded bulb, viscid, white to violaceous-grey. Veil pale violaceous, ± brunnescent, sparse. Context grey-white, some-

times marbled violet. Alkaline reaction insignificant or ± red-brown on cutis. Spores amygdaloid, 11–15 × 6.5–8 µm, moderately to strongly verrucose. Clamp connections present. In *Nothofagaceae* forests, New Zealand.

Notes — The section is so far endemic to New Zealand, but has some morphological similarity with sect. *Myxacium*.

Cortinarius sect. *Cuphomorphi* Soop, sect. nov. (97 %)

Typus. *C. cuphomorphus* Soop, GB (ITS, LSU).
MycoBank MB822953.

<i>cuphomorphus</i>	NZ	
<i>juglandaceus</i>	NZ	
<i>violaceocystidiatus</i> ined.	NZ	2L

Basidiomata medium-sized to small, cuphocybooid, myxacioid, or sequestrate. Pileus 15–55 mm diam, viscid, pale grey-brown to dark brown or violet, ± provided with fibrils and squamules when young, glabrous when older. Lamellae grey-blue, medium crowded to rather distant. Stipe cylindrical, sometimes with a small rounded bulb, dry to viscid, white to grey-brown, young with a violet tinge, sometimes with grey or yellowish squamules over the whole length. Veil pale yellow to ochraceous, fairly copious. Context white to pale violet, marbled grey-blue, odour sweetish, sometimes strong. Alkaline reaction insignificant. Spores amygdaloid, 10–12.5 × 6–8 µm, rather strongly verrucose. Clamp connections sparse or absent. In *Nothofagaceae* forests, New Zealand.

Section *Cycnei* Soop (87 %)

Typus. *C. cycneus* E. Horak.

<i>capitellinus</i>	SAm	Salgado Salomón et al. (2018)
<i>cucumeris</i>	NZ

<i>vibratilis</i>	Eur, NAm	
(<i>decumbens</i>)	Eur	
(<i>emollitus</i>)	Eur	
(<i>galeobdolon</i>)	Eur	
(<i>gemmeus</i>)	NZ	
(<i>ochroleucus</i>)	Eur	

Notes — This section is bihemispherical, consisting of glutinous fungi of a relatively modest size. Many of the taxa are further distinguished by a bitter context. We have only examined *C. melleomitis* samples from New Zealand, whereas the type is described from Patagonia.

Section *Archeriani* M.M. Moser & E. Horak (88 % in PhyML tree)

Typus. *C. archeri* Berk.

<i>archeri</i>	Aus	
<i>holojanthinus</i>	SAm	2L
cf. <i>taylorianus</i>	NZ	2L

Notes — A small South Pacific section of glutinous agaricoid or sequestrate fungi with violaceous and whitish colours.

Clade *ILustrabiles* (100 %)

<i>badiohepaticus</i> ined.	NZ	
<i>lustrabilis</i>	Eur	R

Notes — A small bihemispherical clade of rare taxa that resemble those in sect. *Vibratiles*. Basidiomata are medium-sized to small, myxacioid, coloration red-brown to yellow-brown. In *Fagaceae* and *Nothofagaceae* forests.

8. Telamonioid sections

8.1. Subgenus *Telamonia* s.str.

This large monophyletic entity was recovered as the main *Telamonia* lineage in Fig. S2 of Garnica et al. (2016). It contains the vast majority of species described in the subgenus, and appears to be endemic for the Northern Hemisphere. Basidiomata are dry and generally present a stipitocarpic habit with a hygrophaneous context. Colours are usually drab brownish or greyish, occasionally with a violet component. Many of the species are of a modest size. Recently many new species were described from the northern coniferous taiga belt, making this the most diversified region for *Telamonia* known to date.

The phylogeny reveals a number of clades, many of which are recovered as traditional sections. These are not further discussed in this study, having been extensively documented in several dedicated efforts (e.g., Kytövuori et al. 2005, Niskanen 2008, Niskanen et al. 2009, 2011, 2012, 2013), some of which are currently being pursued.

8.2. Other telamonioid sections

This is a polyphyletic assembly of sections, some bihemispherical. A number of the northern taxa have traditionally been included in subg. *Telamonia* (s.lat.), and their basidiomata look like what is known as 'typical *Telamonia*'. One of these lineages (*Obtusi*) was recovered in Fig. S2 of Garnica et al. (2016). Southern taxa, on the other hand, often exhibit several deviating characters, such as bright colours and a positive alkaline reaction.

Section *Renidentes* Rob. Henry ex Moëne-Loec. & Reumaux (92 %)

Typus. *C. renidens* Fr.

<i>parahumilis</i>	SAm	
<i>renidens</i>	Eur, NAm	R

Notes — The section is bihemispherical. *Cortinarius renidens* appears to be unique in the genus by lacking both universal veil and cortina. Garnica et al. (2005) and Stensrud et al. (2014), report a strong support for including sect. *Austroduracini*

(below), but we prefer to keep them as separate entities since their affinity is inconsistent in our study.

Cortinarius* sect. *Austroduracini Soop & Dima, sect. nov. (87–90 % in 2-loci tree)

Typus. *C. austroduracinus* M.M. Moser.
Mycobank MB822958.

<i>austroduracinus</i>	SAm	R
<i>pyrrhomarmarus</i> ined.	NZ	2L
<i>viridibasalis</i>	SAm	
<i>viscincisus</i>	NZ	

Basidiomata small, telamonioid, yellow-brown to red-brown. Pileus 10–40 mm diam, viscid, yellow-brown to dark red-brown, finely fibrillose. Lamellae greyish or pale cinnamon to dark yellow-brown, medium crowded. Stipe cylindrical, pale brown to greyish yellow with white to dark yellow-brown thin bands or girdles. Veil white to dark yellow-brown, sparse to copious. Context pale brown to yellowish, often marbled brownish. Alkaline reaction insignificant. Spores ellipsoid, 7–9.5 × 4.5–6, moderately to fairly coarsely verrucose. In *Nothofagaceae* forests, South America, New Zealand.

Cortinarius* sect. *Camphorati (Liimat., Niskanen & Ammirati) Soop, B. Oertel & Dima, stat. nov. (100 %)

Basionym. *Cortinarius* subg. *Camphorati* Liimat., Niskanen & Ammirati, Index Fungorum 256: 2. 2015. IF551459.

Synonym. *Cortinarius* sect. *Camphorati* Liimat. & Niskanen, in Niskanen (2008: 19), nom. inval.

Typus. *C. camphoratus* Fr.
Mycobank MB824052.

<i>camphoratus</i>	Eur, NAm	
<i>dysodes</i>	NZ	
<i>putorius</i>	NAm	2L
<i>tasmacamphoratus</i>	Aus	
cf. <i>dysodes</i>	NZ	2L
(<i>austrotorvus</i>)	Aus)	

Notes — This taxon is bihemispherical. Basidiomata are dry with grey-brown and violet colours, but are mainly characterised by a strong, obnoxious odour reminding of acetylene, which appears to be synapomorphic. See further Niskanen (2008) and Niskanen et al. (2015).

Section *Obtusi* Melot (81 %)

Typus. *C. obtusus* (Fr.: Fr.) Fr.

<i>acutovelatus</i>	Eur	2L

Notes — A bihemispherical section of medium-sized to small fungi that often present a yellowish or reddish veil. It appears as a sister to sect. *Obtusi*. See also Garrido-Benavent et al. (2014), Niskanen (2008), Hyde et al. (2016).

Cortinarius sect. *Illumini* (Liimat., Niskanen & Kytöv.) Soop, B. Oertel & Dima, *stat. nov.* (80 %)

Basionym. Cortinarius subg. *Illumini* Liimat., Niskanen & Kytöv., Index Fungorum 256: 2. 2015. IF551474.

Synonym. Cortinarius sect. *Illumini* Liimat., Niskanen & Kytöv. in Niskanen (2008: 19), nom. inval.

Typus. C. illuminus Fr., neotypus GB (ITS, LSU).
Mycobank MB824053.

<i>badiovinaceus</i> II	Eur	
<i>balaustinus</i>	Eur	G2016
<i>cyripedii</i>	NZ	R
<i>illuminus</i>	Eur, NAm	
<i>microglobisporus</i>	Eur	

Notes — A bihemispherical taxon of medium-sized fungi displaying a vividly red-brown pileus and rounded spores. See further Niskanen (2008) and Niskanen et al. (2015).

Cortinarius sect. *Carbonelli* Soop, *sect. nov.* (80 %)

Typus. C. carbonellus Soop, GB (ITS, LSU).
Mycobank MB822959.

<i>carbonellus</i>	NZ	R
<i>rattinus</i>	NZ	

Basidiomata small, telamonioid, grey-brown to dark brown. Pileus 10–45 mm diam, dry, dark grey-brown to bluish grey, or purple-brown, later umber, finely fibrillose. Lamellae purple-brown to violet, greyish blue, or dark grey soon ± black, fairly

crowded. Stipe cylindrical to clavate, silvery grey to yellowish grey with a violet tinge. Veil violet to red-brown, sparse. Context greyish to vinaceous brown, marbled violet. Alkaline reaction orange to reddish lilac in context, cherry red on lamellae. Spores ellipsoid to ± amygdaloid, 7–10 × 4–5.5 µm, moderately to rather weakly verrucose. In *Nothofagaceae* forest, New Zealand.

Unsupported group *Pseudoxenosmatae*

This austral group is formed by sect. *Carbonelli* and the following taxa:

<i>areolatoimbricatus</i>	Aus	R
<i>cupreonatus</i>	NZ	R
<i>exlugubris</i>	NZ	
<i>punctatisporus</i>	SAm	2L
<i>vernificer</i>	NZ	

Notes — The group mainly contains of dry, often robust, sericeocybooid fungi. It receives low support, except in the PhyML tree (89 %). It contains several members of sect. *Xenosmatae* (see Soop 2002). The latter is not recovered in our study, which reveals its type *C. xenosma* as a singleton.

Cortinarius sect. *Paraxanthi* Soop, *sect. nov.* (100 %)

Typus. C. paraxanthus Soop, GB (ITS, LSU).
Mycobank MB822960.

<i>citribasalis</i>	NZ
<i>paraxanthus</i>	NZ

Basidiomata small, telamonioid, yellow-brown to olivaceous. Pileus 15–45 mm diam, dry, olive-brown to orange-brown or mahogany brown, often with an umber disk, finely fibrillose, margin yellow, often with an olive shade. Lamellae yellow-brown to orange, rather distant. Stipe cylindrical, lemon-yellow to yellow-green, base with white or yellow rhizomorphs. Veil greenish yellow, blushing red-brown, sparse. Context brown-yellow or orange to grey-brown, sometimes with an olive tinge. Alkaline reaction reddish or insignificant. Spores ellipsoid to amygdaloid, 7–9.5 × 4–6 µm, moderately to weakly verrucose. In *Nothofagaceae* forest, New Zealand.

Cortinarius sect. *Luteini* Soop, *sect. nov.* (100 %)

Typus. C. luteinus Soop, GB (ITS, LSU).
Mycobank MB822961.

<i>luteinus</i>	NZ
<i>palissandrinus</i>	NZ

Basidiomata small, telamonioid, yellow to red-brown. Pileus 10–30 mm diam, dry, dark yellow to brownish orange or mahogany red, later with a yellow-orange disk, finely fibrillose. Lamellae dark yellow to orange, brick red, or orange-red, distant. Stipe cylindrical, yellow to greyish yellow or pale brownish orange, sometimes ± citrinous, with thin, yellowish fibrils. Veil yellow, later darkening with a reddish tone, sparse. Context greyish yellow, marbled darker yellow. Odour raphanoid. Alkaline reaction weak or red on cutis and lamellae. Spores obtusely ellipsoid, 6.5–8.5 × 4.5–6 µm, moderately verrucose, marginal elements vesiculose, 20–35 × 9–12 µm. In *Nothofagaceae* forest, New Zealand.

Clade *Minilaci* (99 %)

<i>minilacus</i>	NZ	
<i>C. sp. I</i>	NZ	
<i>C. sp. II</i>	NZ	2L

Notes — This austral clade consists of telamonioid fungi with yellow-brown lamellae and subglobose spores. In *Myrtaceae* and *Nothofagaceae* forest.

Clade /Chrysoconii (96 %)

<i>chrysoconius</i>	NZ
cf. <i>chrysoconius</i>	NZ

Notes — Basidiomata are small, telamonioid, coloration yellow with a squamulose pileus. In *Nothofagaceae* forests.

DISCUSSION**Higher ranks**

In the present study we are not formally introducing taxonomic structures of higher rank than section. Robust phylogenetic support for higher ranks, such as subgenera, would presumably require a dataset built on more loci than the current nrITS, nrLSU, *rpb1*, and *rpb2* (cf. Frøslev et al. 2005). It may nevertheless be appropriate, as part of a discussion, to review a few major tentative lineages suggested by our phylograms, albeit with modest support in some cases. The history of a couple of lineages is reviewed in more detail.

- *Anomali* — This lineage would include sect. *Anomali*, *Bolares*, *Camphorati*, and *Spilomei*.
- *Calochroi* — This taxon would form an own lineage with clade */Arcifolii*.
- *Cortinarius* — The type section of the genus would form its own lineage.
- *Crassi* — This lineage would include sect. *Crassi* and *Rubicunduli*.
- *Delibuti* — This lineage would include sect. *Delibuti* and *Subtorti*.
- *Dermocybe* — This lineage would include sect. *Dermocybe*, *Cruentoides*, and *Pauperae*.
- *Icterinula* — This lineage would include sect. *Walkeri*, *Chrysmata*, *Rubrobasales*, *Ignelli*, and clade */Orixanthi*, as well as the singleton species in the unsupported group *Icterinula*.
- *Leprocycbe* — This lineage would include sect. *Leprocycbe*, *Persplendidi*, and *Veronicae*. It is sister to the *Dermocybe* lineage.
- *Limonii* and *Callistei* — The two sections form their own lineages in our phylogeny. The first name was introduced by Kühner & Romagnesi (1953) for a group based on the European *Cortinarius limonius*. Moser (1969) promoted *Limonii* to a section, expanded it with a number of boreal taxa, and attributed it to his new subg. *Leprocycbe*. But he wisely refrained to include the morphologically similar *C. callisteus*, which had originally been present. Orlovich & Oliver (2002) found that *C. rubrocastaneus*, a species from New Zealand, is also part of the section. Our analysis now shows that at least eight recently discovered species belong to the section, making New Zealand the most diversified area for sect. *Limonii* known today (Soop et al. 2018). *Cortinarius callisteus*, on the other hand, is part of the bihemispherical sect. *Callistei*, a separate lineage, consistent with the concept of subg. *Callistei* (Niskanen et al. 2016).
- *Multiformes* — This lineage would include sect. *Cremerolinae*, *Malvacei*, *Multiformes*, and *Vibratiles*.
- *Myxacium* — This lineage would include sect. *Cuphomorphi*, *Defibulati*, *Marmorati*, and *Myxacium*, as well as a number of sequestrate species from the South Pacific.
- *Phlegmacium* I — This lineage would include sect. *Arguti*, *Claricolores*, *Elastici*, *Percomes*, *Phlegmacioides*, *Phlegmacium*, clades */Caligati*, */Obsoleti*, */Rhizophori*, */Varii*, and a number of singleton species. Virtually all species in this lineage have a stipitocarpic development.
- *Phlegmacium* II — This lineage would include sect. *Amoenolentes*, *Aureocistophili*, *Caerulescentes*, *Glaucopodes*, *Subhymenogaster*, clades */Camptori*, */Dionysae*, */Eucaerulei*, */Glaucocephali*, */Subolivascetes*, and a number of singleton species. Virtually all species in this lineage have a pileocarpic development.
- *Rozites* — This lineage would include sect. *Cuphocybe*, *Majestatici*, *Rozites*, *Subcastanelli*, clade */Achroi*, and several rozitoid species from the South Pacific.
- *Scauri* — This lineage would include sect. *Purpurascetes* and *Scauri*, as well as one singleton species from the South Pacific.
- *Telamonia* — This lineage would include *Telamonia* s.str., and possibly sect. *Purpurelli*, which is consistently basal to the former but morphologically different. The subgenus goes back to Fries and circumscribes today, in its traditional sense, at least 900 taxa. These are morphologically fairly homogeneous, presenting a dry, more or less hygrophanous pileus and generally drab brown, grey, or violet colours. Høiland & Holst-Jensen (2000) and Peintner et al. (2004) showed that a large core portion of the subgenus was monophyletic, leaving the common telamonioid sect. *Obtusi* in a separate lineage. The core portion, here termed *Telamonia* s.str., seemed to be confined to the Northern Hemisphere, as later confirmed by Garnica et al. (2005, 2016). These and our own studies show that not only *Obtusi* but several other telamonioid taxa (*Camphorati*, *Illumini*, *Laeti*, *Renidentes*) are positioned outside *Telamonia* s.str. and are in fact bihemispherical (cf. Niskanen 2008). Originally, also a number of austral species were classified as *Telamonia* (Moser & Horak 1975, Grgurinovich 1997, Soop 1998, 2001, 2005, Gasparini & Soop 2008), in many cases despite traits not usually associated with what may be called a ‘typical *Telamonia*’. Our analysis shows that some of these species form endemic sections (e.g., *Austroduracini*) in the South Pacific, genetically well separated from the northern core clade, and no published southern species has so far been shown to belong to *Telamonia* s.str.
- *Telamonioidae* — This lineage would include part of the remains of *Telamonia* s.lat.: sect. *Obtusi*, *Laeti*, and *Illumini* (but neither *Camphorati* nor *Renidentes*), as well as the clade */Minilaci*. It is sister to the *Dermocybe-Icterinula-Leprocycbe* complex, an interesting topology that was also implicitly shown by the 5-loci phylogram of Garnica et al. (2016).

Traditional vs phylogenetic sections

In several cases traditional sections were shown by our study to be polyphyletic, while often retaining a monophyletic core of species around the type. In other cases the sections were broken up into disparate lineages. For example, the boreal sect. *Claricolores* was earlier defined by the fusoid spore shape and caespitose growth, and then contained notably *Cortinarius claricolor*, *C. variegatus*, and *C. turmalis* (cf. Brandrud et al. 1989, 1992, 1994, 1998, 2012). Our analysis recovered *C. variegatus* as a singleton, while *C. turmalis* unexpectedly forms a well-supported clade with the austral *C. picoides*. The new sect. *Turmales* in fact retains the two mentioned character states, while the emended sect. *Claricolores* (Brandrud et al. 2013) shows characters like a sulcate pileus margin, and includes species such as *C. praestans*.

The relatively recent discovery of many new species from the Southern Hemisphere has resolved a number of singletons into small clades, some of which are here described as new bihemispherical sections, like *Turmales* mentioned above. Another example of this pattern is the boreal *Cortinarius crassus*, traditionally considered an odd entity, difficult to place in the

taxonomy, and long the only member of its sect. *Crassi*. But as in the case of *Turmales*, the discovery of the austral *C. eutactus* has revealed *Crassi* as bihemispherical. The two species share the habit and the presence of remarkable cheilocystidia. The pattern is replicated by the boreal *C. rubicundulus* having now found a southern ‘partner’ in *C. subgemmeus*, with which it shares the characters of cheilocystidia and a flavescent context.

In larger clades the core of species sometimes lies in one of the hemispheres. *Cortinarius* sect. *Pauperae*, for example, consists almost exclusively of austral species, *C. olivaceofuscus* in Europe (cf. Høiland 1983) being one of the notable exceptions. Conversely, sect. *Phlegmacioides*, with more than 20 boreal species, contains the single Australian species *C. lavendulensis*. Other sections, such as *Purpurascetes* and *Anomali* exhibit a fairly even distribution between the hemispheres. An extreme case is sect. *Defibulati*, which is found in Europe, North and Central America, the South Pacific, and India. Among the telamonioid sections *Anomali* and *Obtusi* constitute other widely distributed taxa.

A number of lineages appear to occur exclusively in either hemisphere (Soop & Gasparini 2011). In our analysis a conspicuous number of phlegmacioid clades are confined to the North. In the Introduction, we mentioned *Calochroi* s.lat., but also *Multiformes*, *Claricolores*, *Riederi*, *Glaucopodes*, *Arguti*, and *Caerulescentes*, just to name a few, belong to this category. In the South the endemic sect. *Cremaolinae* is closely related to the boreal *Multiformes*, to which there is also a strong morphological resemblance. Other section pairs exhibiting a similar biogeographical pattern are *Leprocybe-Persplendidi* and *Myxacium-Marmorati*.

Biogeographical section concept

Even though a number of sections are bihemispherical, our study corroborates the fact that no *Cortinarius* species is known to occur naturally in both hemispheres (pers. obs., and cf. Harrower et al. 2015a: 705). This could be explained by the strict ectomycorrhizal host specificity within the genus (Wang & Qiu 2006, and cf. also Brandrud 1996 and Kytövuori et al. 2005). Few, if any, of the putative host genera are naturally present in the temperate regions of both hemispheres (the exceptions may be *Quercus* and *Alnus* in South America). A strict analysis of this biogeographical relationship would involve the history of plant evolution, which is beyond the scope of the present study. Such a study was presented by Wilson et al. (2017) on the subject of the genus *Laccaria*. But whereas Wilson et al. (2017) report a distinct north-south split into two major clades for *Laccaria*, our topology shows a mosaic of smaller, intermixed, boreal and austral clades for *Cortinarius*, similar to the clade structure of Garnica et al. (2016).

Looking closer at this structure, one notes that a number of potential section clades can be neatly split into two subclades, one endemic for each hemisphere. This topology often exhibits two important patterns: (a) one can significantly boost the bootstrap support by excluding one of the subclades from the section; and (b) the austral subclade tends to be ‘basal’ in the sense that its branch is shorter than the boreal one. The interesting pattern (b) and its hypothetical connection with the evolution of the genus would be a subject for future research.

With reference to (a), one is faced with the choice of conceiving the clade as one bihemispherical section with lower support, or as two well-supported, geographically separated sections. Where the two subclades are morphologically similar we have sometimes opted for the first choice. For example, we chose to retain a bihemispherical sect. *Illumini* (with a lower support) due to phenotypical similarity across the clade. A contrary example is the pair *Leprocybe-Veronicae*, kept separate due

to morphological differences despite a robust joint support. On the other hand, sect. *Anomali*, *Cortinarius*, and *Delibuti* are examples of bihemispherical, morphologically homogeneous sections with a robust support.

Merits of going beyond ITS/LSU

Comparing the 4-loci tree (Fig. 1) with the 2-loci tree (Fig. 2) one finds that they recover largely the same sections, while the bootstrap support is in many cases higher in the former. The 4-loci tree even reveals several smaller sections that were not present with two loci. It appears, in fact, that the mere addition of an *rpb* sequence to one sample often has a definitely positive effect on clade support (cf. Frøslev et al. 2005). Moreover, this ‘grafting’ of *rpb* sequences sometimes produces an extended effect, which is in retrospect perhaps not so surprising, in that it stabilises not only the ‘grafted’ clade but also neighbouring clades, even if the latter do not include the extra loci.

The use of gap coding (Nagy et al. 2012) has also proved beneficial in the present study in order to confirm many sections and increase their support.

Extent of sampling

As indicated by the number of putative section members listed (in parentheses) under Taxonomy, many species remain to be sequenced in the appropriate loci. In some cases it is especially important to provide the data to confirm (or refute) a proposed section.

Acknowledgements We wish to thank J.F. Ammirati (University of Washington, Seattle, USA) and an anonymous reviewer for their excellent comments that were greatly beneficial for our article. J.A. Cooper and D. Park were supported through the Landcare Research Characterising Land Biota portfolio with funding from the Science and Innovation Group of the New Zealand Ministry of Business, Innovation and Employment. We are grateful to the JEC DNA group, to L.G. Nagy (BRC-HAS, Szeged, Hungary), and to G.M. Kovács (ELTE, Budapest, Hungary) for their support in the molecular study of several specimens. T.E. Brandrud, B. Buyck, G. Saar and G. Schmidt-Stohn are thanked for providing important specimens for this study.
