Abstract

We screened a series of 4-anilinoquinolines and 4-anilinoquinazolines and identified novel inhibitors of *Mycobacterium tuberculosis (Mtb)*. The focused 4-anilinoquinoline/quinazoline scaffold arrays yielded compounds with high potency and the identification of 6,7-dimethoxy-*N*-(4-((4-methylbenzyl)oxy)phenyl)quinolin-4-amine (**34**) with an MIC_{90} value of 0.63-1.25 μM. We also defined a series of key structural features, including the benzyloxy aniline and the 6,7-dimethoxy quinoline ring, that are important for *Mtb* inhibition. Importantly the compounds showed very limited toxicity and scope for further improvement by iterative medicinal chemistry.

Graphical Abstract
Keywords

Anti-tubercular; 4-anilinoquinoline; 4-anilinoquinazoline; *Mycobacterium tuberculosis (Mtb)*

Mycobacterium tuberculosis (Mtb), the causative agent of tuberculosis (TB) in humans,[1] infects nearly a third of the earth's population and caused 1.6 million worldwide deaths in 2017.[2] With nearly ten million new cases of active disease each year, TB is now the leading cause of death from infectious disease globally.[2] Current therapeutic strategies involve the use of a combination of anti-microbial agents including ethambutol, isoniazid, pyrazinamide and rifampicin (Fig. 1).[3] However, more than 5% of *Mtb* infections now involve multidrug-resistant (MDR-TB) and extensively drug-resistant (XDR-TB) *Mtb* strains. MDR-TB is associated with a 50% mortality rate whereas XDR-TB is nearly always fatal.[4] There is an urgent need for new therapeutic strategies.

Human protein kinases are pharmacologically tractable enzymes targeted by more than three dozen approved medicines.[5] Hundreds of additional kinase inhibitors are under clinical and preclinical investigation. There is growing recognition that pathogen kinases may be targeted in the treatment of infectious diseases.[6–7] Considering the conserved ATP-binding site across species, we looked to screen collections of ATP-competitive inhibitors of human kinases for their anti-tubercular activity.

To identify new chemical starting points against *Mtb* we looked to lapatinib, gefitinib, and erlotinib as starting points which have recently been revealed to have activity against *Mtb* (Fig. 2.).[5],[8] We tested the activity of lapatinib, gefitinib, and erlotinib against *Mtb* by measuring luminescence and growth on solid medium across a series of four two-fold dilutions starting at 20 μM (Tab 1).[9–10] The reduction of visible growth on solid medium demonstrated the compounds to be bactericidal.

Gefitinib treatment had no effect relative to the absence of compound. Erlotinib induced a modest effect that appeared to plateau at a signal of approximately 70 %. In contrast, lapatinib showed activity even at 5 μM and reduced the relative *Mtb* signal to below 10 % at 20 μM. This result suggested that the 4-benzyloxy aniline substituent might be important for anti-*Mtb* activity. These compounds demonstrate only limited toxicity in a human skin fibroblast cell line (WS-1) counter screen.[11]

To further explore quinazoline *Mtb* activity, we profiled several focused arrays of compounds to probe the structure activity relationships of the quinoline/quinazoline. We hence synthesized a series of compounds (**1-34**) following up on the results listed in table 1, exploring the 4-anilinoquinoline and 4-anilinoquinazoline scaffolds through nucleophilic aromatic displacement of 4-chloroquin(az)olines. (Sch. 1) We were able to access products in good to excellent yields (55-91 %) consistent with previous reports and without protection of the alcohol substituted quin(az)oline starting material.[11–13]

The first set of compounds probed a replacement of the 6-postion morpholine segment of gefitinib with a simple alcohol on the lapatinib scaffold (Tab. 2).[14] Although neither the 6-OH (**1**) or 7-OH (**2**) quinazoline showed appreciable activity, the 6,7-dihydroxy compound (**3**) began to inhibit *Mtb* growth at higher concentrations. The analogous set of methoxy-substituted compounds (**4-6**) had very similar activity profiles. The 6-OH quinoline (**7**) showed improved activity relative to the matched quinazoline (**1**). The inclusion of fluorine substitution on the phenyl ring distal to the quinazoline (**8-10**) led to markedly increased

activity for all three isomers. At 20 μM, **8-10** all reduced the relative *Mtb* signal to 25-37 %, and a modest but discernable reduction in signal was observed at 1.25 μM. Interestingly, the effect of fluorine substitution led to a different activity pattern from changing quinazoline ring substitution as the modification of **1** to the 7-OH (**11**) or 6,7-(OH)$_2$ (**12**) resulted in a significant loss of activity, even at 20 μM. These results demonstrated that *Mtb* activity was sensitive to changes at multiple parts of the template and that these changes were not necessarily additive. We counter screened **1-12** in human skin fibroblast cells (WS-1) and observed very limited toxicity with **3** and **7** the only compounds in the single digit micromolar range (IC$_{50}$ = 8.8 and 2.5 μM respectively).[15]

The next set of quin(az)olines profiled was prepared to explore the contributions from both the aniline and the core heterocycle (Tab. 3).[11,16] The larger 3,4,5-trimethoxyphenyl aniline was employed on several diversely substituted quinolines and quinazolines (**13-18**) which led to no observable activity except when paired with the 6,7-(OCH$_2$CH$_2$OMe)$_2$-quinazoline of erlotinib (**19**) which had only slight activity at 20 μM. On the other hand, incorporation of the aniline fragment from erlotinib (3-ethynylphenyl) did yield several active compounds, including the quinoline analog of erlotinib (**20**). The erlotinib aniline with a 6,7-(OMe)$_2$-substituted quinoline core (**21**) or quinazoline (**22**) showed activity but not with the 3-cyanoquinoline (**23**). The analogous 3-bromophenyl aniline compounds (**24-26**) showed higher activity than the paired 3-ethynylphenyl compounds. Finally, the aniline substitution from lapatinib (3-Cl-4-(2-F-PhO)Ph) yielded a marginally active quinazoline (**27**) and a highly active quinoline (**28**) that had 10 % *Mtb* signal at 20 μM. We counter screened **13-28** in WS-1 cells and observed limited toxicity in most compounds. However, the bromine substitution appeared to increase toxicity (**24-26**) along with the lapatinib derivatives (**27-28**).

A subsequent set of compounds explored features of the 4-benzyloxyaniline portion of the quinoline template (Tab. 4).[17–18] Variation of the ether linkage to an amide and addition of a hydroxy on the aniline portion revealed an activity pattern where 6,7-dimethoxy substitution with the benzylic arm was active (**29-30**). In contrast, truncation of the benzyl also removed the activity as in acetamide **31**, which had no effect on*Mtb*. The 6-methoxy (**32**) and 7-methoxy (**33**) showed no reduction in *Mtb* signal at 20 μM. However, switching back to the 4-methyl benzyl ether linked compound **34** yielded the most potent activity observed with any compound in the present study, with a robust signal observed even at 1.25 μM. The *Mtb* MIC$_{90}$ for **34** was in the 0.63-1.25 μM range. However, the kill curve plateaued at 5 μM, and no improved killing was observed at higher doses (98 % inhibition at 5 μM; 98 % inhibition at 20 μM) (Fig. 3).

As with the other compound sets, we evaluated **29-34** in human skin fibroblast cells (WS-1) and observed moderate toxicity in the single digit micromolar range for most compounds.[18] Importantly, the anti-*Mtb* effects of compounds appeared to be divergent from the toxic effects in WS-1 cells, suggesting that the *Mtb* effects were not driven by nonspecific cytotoxicity. The most potent anti-*Mtb* compound **34** had WS-1 IC$_{50}$ = 5.4 μM, substantially higher than its *Mtb* MIC$_{90}$ value and within threefold of the IC$_{50}$ values for erlotinib and lapatinib. This result demonstrated that, in the human WS-1 cell line, **34** behaved comparably to two approved medicines.

These structure activity relationships between *Mtb* activity and the 4-anilinoquinoline/ quinazoline scaffold have the potential to inform a medicinal chemistry strategy for enhanced *Mtb* activity. The most sensitive structural changes were found to be in the ring appended to the aniline rather than in the quin(az)oline core.

This body of work provides a number of exciting starting points for further optimization, with limited non-specific toxicity. However, the failure to achieve complete parasite kill led us to deprioritize the series due to the potential for resistance to develop. The mechanism of anti-*Mtb* activity of the quin(az)olines has yet to be defined. These compounds were originally prepared as inhibitors of human kinases targeting the ATP-binding site, a rational starting hypothesis for the mechanism of action is that the effects of these compounds are mediated by inhibition of *Mtb* kinases. However, it is possible that the observed phenotypes may originate from modulation of other, non-kinase ATP-binding proteins in the organism.

Gefitinib, erlotinib, and lapatinib have previously been reported to inhibit the intracellular growth of *Mtb*. Multiple lines of evidence were described suggesting inhibition of the host target epidermal growth factor receptor (EGFR) was responsible for this activity.[15] However our results demonstrate that proteins within the pathogen itself may be targeted as well. The benzyl substituent present in the molecule showed a pivotal effect to potency, as is highlighted by the enhanced activity of **34** relative to **30**. The present results help define a de-risked medicinal chemistry trajectory towards anti-tubercular compounds with targets in both the host and the parasite itself. Such dual acting compounds might offer advantages in efficacy and/or reduction in propensity for resistance.

15. Toxicity cell assay: WS-1 cells were seeded at 400 cells/well in 384 well plates. Cells were treated with compound at 24 h after plating, and cell viability was assessed at 48 h using alamarBlue (ThermoFisher, USA). Fluorescence was measured using Tecan Infinite 200 PRO plate reader with excitation at 535 nM and emission at 590 nM. IC_{50} values were determined by nonlinear regression using Graphpad PrismTM software.
16. Compounds **13-28** prepared as previously described.[11]

17. Compounds **29-34** prepared as previously described.[18]

Figure 1.
Current therapeutic strategies for treatment of *Mycobacterium tuberculosis* infections.
Figure 2.
Structures of clinical quinazolines.
Figure 3.
MIC determination by two different assays for **34** (circle) and lapatanib (triangle). Data points represent the mean of 3 biological replicates with standard deviation. The dashed line labeled 1% inoculum represents an inoculation of 1 % of the number of cells used for compound testing. This control was used to determine 99 % inhibition of growth.
