## ABSTRACT

### Background

The use of clinical signs, or end-tidal anaesthetic gas (ETAG), may not be reliable in measuring the hypnotic component of anaesthesia and may lead to either overdosage or underdosage resulting in adverse effects because of too deep or too light anaesthesia. Intraoperative awareness, whilst uncommon, may lead to serious psychological disturbance, and alternative methods to monitor the depth of anaesthesia may reduce the incidence of serious events. Bispectral index (BIS) is a numerical scale based on electrical activity in the brain. Using a BIS monitor to guide the dose of anaesthetic may have advantages over clinical signs or ETAG. This is an update of a review last published in 2014.

### Objectives

To assess the effectiveness of BIS to reduce the risk of intraoperative awareness and early recovery times from general anaesthesia in adults undergoing surgery.

### Search methods

We searched CENTRAL, MEDLINE, Embase, and Web of Science on 26 March 2019. We searched clinical trial registers and grey literature, and handsearched reference lists of included studies and related reviews.

### Selection criteria

We included randomized controlled trials (RCTs) and quasi-RCTs in which BIS was used to guide anaesthesia compared with standard practice which was either clinical signs or end-tidal anaesthetic gas (ETAG) to guide the anaesthetic dose. We included adult participants undergoing any type of surgery under general anaesthesia regardless of whether included participants had a high risk of intraoperative awareness. We included only studies in which investigators aimed to evaluate the effectiveness of BIS for its role in monitoring intraoperative depth of anaesthesia or potential improvements in early recovery times from anaesthesia.

### Data collection and analysis

Two review authors independently assessed studies for inclusion, extracted data, and assessed risk of bias. We assessed the certainty of evidence with GRADE.

### Main results

We included 52 studies with 41,331 participants; two studies were quasi-randomized and the remaining studies were RCTs. All studies included participants undergoing surgery under general anaesthesia. Three studies recruited only participants who were at high risk of

intraoperative awareness, whilst two studies specifically recruited an unselected participant group. We analysed the data according to two comparison groups: BIS versus clinical signs; and BIS versus ETAG. Forty-eight studies used clinical signs as a comparison method, which included titration of anaesthesia according to criteria such as blood pressure or heart rate and, six studies used ETAG to guide anaesthesia. Whilst BIS target values differed between studies, all were within a range of values between 40 to 60.

### **BIS versus clinical signs**

We found low-certainty evidence that BIS-guided anaesthesia may reduce the risk of intraoperative awareness in a surgical population that were unselected or at high risk of awareness (Peto odds ratio (OR) 0.36, 95% CI 0.21 to 0.60;  $I^2 = 61%$ ; 27 studies; 9765 participants). However, events were rare with only five of 27 studies with reported incidences; we found that incidences of intraoperative awareness when BIS was used were three per 1000 (95% CI 2 to 6 per 1000) compared to nine per 1000 when anaesthesia was guided by clinical signs. Of the five studies with event data, one included participants at high risk of awareness and one included unselected participants, four used a structured questionnaire for assessment, and two used an adjudication process to identify confirmed or definite awareness.

Early recovery times were also improved when BIS was used. We found low-certainty evidence that BIS may reduce the time to eye opening by mean difference (MD) 1.78 minutes (95% CI -2.53 to -1.03 minutes; 22 studies; 1494 participants), the time to orientation by MD 3.18 minutes (95% CI -4.03 to -2.33 minutes; 6 studies; 273 participants), and the time to discharge from the postanesthesia care unit (PACU) by MD 6.86 minutes (95% CI -11.72 to -2 minutes; 13 studies; 930 participants).

### **BIS versus ETAG**

Again, events of intraoperative awareness were extremely rare, and we found no evidence of a difference in incidences of intraoperative awareness according to whether anaesthesia was guided by BIS or by ETAG in a surgical population at unselected or at high risk of awareness (Peto OR 1.13, 95% CI 0.56 to 2.26;  $I^2 = 37%$ ; 5 studies; 26,572 participants; low-certainty evidence). Incidences of intraoperative awareness were one per 1000 in both groups. Only three of five studies reported events, two included participants at high risk of awareness and one included unselected participants, all used a structured questionnaire for assessment and an adjudication process to identify confirmed or definite awareness.

One large study (15,452 participants) reported a reduced time to discharge from the PACU by a median of three minutes less, and we judged the certainty of this evidence to be low. No studies measured or reported the time to eye opening and the time to orientation.

### **Certainty of the evidence**

We used GRADE to downgrade the evidence for all outcomes to low certainty. The incidence of intraoperative awareness is so infrequent such that, despite the inclusion of some large multi-centre studies in analyses, we believed that the effect estimates were imprecise. In addition, analyses included studies that we judged to have limitations owing to some assessments of high or unclear bias and in all studies, it was not possible to blind anaesthetists to the different methods of monitoring depth of anaesthesia.

Studies often did not report a clear definition of intraoperative awareness. Time points of measurement differed, and methods used to identify intraoperative awareness also differed and we expected that some assessment tools were more comprehensive than others.

### **Authors' conclusions**

Intraoperative awareness is infrequent and, despite identifying a large number of eligible studies, evidence for the effectiveness of using BIS to guide anaesthetic depth is imprecise. We found that BIS-guided anaesthesia compared to clinical signs may reduce the risk of intraoperative awareness and improve early recovery times in people undergoing surgery under general anaesthesia but we found no evidence of a difference between BIS-guided anaesthesia and ETAG-guided anaesthesia. We found six studies awaiting classification and two ongoing studies; inclusion of these studies in future updates may increase the certainty of the evidence.

## **PLAIN LANGUAGE SUMMARY**

### **Bispectral index (BIS) for improving intraoperative awareness and early postoperative recovery in adults**

#### **Background**

During surgery under general anaesthesia, the anaesthetist will adjust the amount of anaesthetic drugs to ensure that the patient remains unconscious. This adjustment is made according to clinical signs, such as the patient's heart rate or blood pressure, or end-tidal anaesthetic gas (ETAG) for anaesthesia that is given as a gas, which is a measure of the amount of remaining gas after the patient breathes out. However, using these methods alone may increase the chance that the patient is given too little or too much anaesthetic. Intraoperative awareness, a distressing event in which a patient may become conscious enough to recall events during surgery, is very rare and may be caused by too little anaesthetic. Too much anaesthetic may lead to a longer time needed to reach full recovery. Bispectral index (BIS) is a measurement scale based on the electrical activity in the brain, and by using a monitor of brain activity during anaesthesia, the anaesthetist may use this scale to inform the amount of anaesthesia to give to the patient.

This is an update of a review which was previously published in 2014.

## Study characteristics

The evidence is current to 26 March 2019. We found 52 studies with 41,331 participants. Six studies are awaiting classification (because we did not have sufficient information to assess them), and two studies are ongoing. All studies included people having surgery under general anaesthesia. Three studies included only people who were at high risk of intraoperative awareness, and two studies included only people who were not selected according to high risk of intraoperative awareness. Forty-eight studies compared BIS-guided anaesthesia with anaesthesia guided by clinical signs, and six studies compared BIS-guided anaesthesia with ETAG-guided anaesthesia.

## Key results

We found low-certainty evidence that BIS-guided anaesthesia may reduce the risk of intraoperative awareness. However, events were rare and only five of 27 studies reported incidences. When BIS-guided anaesthesia was used, we found three per 1000 fewer incidences of intraoperative awareness compared to nine per 1000 incidences when anaesthesia was guided by clinical signs. In addition, we found low-certainty evidence that BIS may improve recovery - the time for people to open their eyes was less, as was the time for orientation, and the time to be discharged from the post-anaesthesia care unit.

We found no evidence of a difference in incidences of intraoperative awareness according to whether anaesthesia was guided by BIS or by ETAG, although, again, there were few incidences of awareness (1 per 1000 in each group). Only one study that compared BIS with ETAG-guided anaesthesia measured recovery times; this low-certainty evidence showed that discharge from the postanaesthesia care unit was earlier if anaesthesia was BIS-guided. No studies that compared BIS with ETAG-guided anaesthesia measured the time to eye opening or the time to orientation.

## Certainty of the evidence

We used GRADE to downgrade the evidence for all outcomes to low certainty. The incidence of intraoperative awareness is so rare and, even though we found some large studies, we concluded that the evidence was still imprecise. In addition, we judged many studies to have limitations because of high or unclear risks of bias. For example, all of the anaesthetists were aware of using an additional BIS monitor and we could not be certain how this affected the anaesthetists' standard practice.

In addition, we noted that some studies did not report a clear definition of intraoperative awareness. Time points of measurement differed, and the methods used to identify intraoperative awareness also differed and we expected that some assessment tools were more comprehensive than others.

## Conclusion

Intraoperative awareness is rare, and despite finding a large number of eligible studies, evidence for the effectiveness of using BIS to guide anaesthetic depth is imprecise. We found low-certainty evidence that BIS-guided anaesthesia compared to anaesthesia guided by clinical signs may reduce the risk of intraoperative awareness and improve early recovery times in people having surgery under general anaesthesia. We found no evidence of a difference between BIS-guided anaesthesia and ETAG-guided anaesthesia, and we also judged this evidence to be low certainty.

## SUMMARY OF FINDINGS

### Summary of findings 1. Bispectral index compared to clinical signs for improving intraoperative awareness and early postoperative recovery

#### BIS compared to clinical signs for intraoperative awareness and early postoperative recovery

**Population:** adults undergoing any type of surgery under general anaesthesia; types of anaesthesia included propofol, desflurane, isoflurane, and sevoflurane; people were either selected for being at high risk of intraoperative awareness, were unselected, or study authors did not report risk of awareness in the included participants

**Setting:** hospitals in: Australia; Bangladesh; Belgium; Canada; China; Croatia; Egypt; Finland; Germany; Greece; India; Iran; Israel; Japan; Saudi Arabia; South Korea; Spain; Sweden; Switzerland; Turkey; USA

**Intervention:** BIS-guided anaesthesia, with target values between 40 and 60

**Comparison:** anaesthesia guided by clinical sides

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Number of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with clinical sides	Risk with BIS				
<b>Occurrence of intraoperative awareness</b>  Time points of measure after surgery: 2 to 6 hours; 12 hours; 1 day; 2 days; 3 days; 14 days; 30 days; or time point was not reported  Measurement tools: simple questioning; interviews; or structured questionnaires	Study population		Peto OR 0.36 (0.21 to 0.60)	9765 (27 studies)	⊕⊕⊕⊖ <b>Low<sup>a</sup></b>	Only 5 of 27 studies included incidences of awareness.  Of these 5 studies: 4 used a structured questionnaire, and 1 used an interview method; 2 used an adjudication process to categorise incidences of awareness as 'confirmed' or 'definite'; participants in 1 study were at high risk of awareness, in 1 study were unselected, and in the remaining studies risk of awareness was not specified
	9 per 1,000	3 per 1,000 (2 to 6)				
<b>Time to eye opening</b> (in minutes)	-	MD 1.78 minutes lower (2.53 minutes lower to 1.03 minutes lower)	-	1494 (22 studies)	⊕⊕⊕⊖ <b>Low<sup>b</sup></b>	
<b>Time to orientation</b> (in minutes)	-	MD 3.18 lower (4.03 lower to 2.33 lower)	-	273 (6 studies)	⊕⊕⊕⊖ <b>Low<sup>c</sup></b>	
<b>Time to discharge from the PACU</b>	-	MD 6.86 lower	-	930 (13 studies)	⊕⊕⊕⊖ <b>Low<sup>b</sup></b>	

(in minutes) (11.72 lower to 2.00 lower)

\***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**BIS:** bispectral index; **CI:** confidence interval; **MD:** mean difference; **OR:** odds ratio; **PACU:** postanaesthesia care unit

**GRADE Working Group grades of evidence**

**High certainty:** we are very confident that the true effect lies close to that of the estimate of the effect

**Moderate certainty:** we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

**Low certainty:** our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of the effect

**Very low certainty:** we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect

<sup>a</sup>We downgraded by one level for study limitations owing to the inclusion of some studies with unclear risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout. We downgraded by one level for imprecision; whilst we noted a narrow CI, the effect was dominated by two large trials (with two different populations selected according to the likelihood of intraoperative awareness) and we found many studies with zero events in both arms. We conducted sensitivity analysis to explore alternative statistical models to account for zero events in both arms as well as rare events and found more conservative estimates when we used a random-effects model, thus reducing our certainty in the estimate.

<sup>b</sup>We downgraded by one level for inconsistency owing to the substantial statistical heterogeneity in this effect, and by one level for study limitations owing to the inclusion of some studies with unclear risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout.

<sup>c</sup>We downgraded by one level for imprecision as the evidence was from few studies with few participants, and by one level for study limitation owing to the inclusion of some studies with unclear risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout.

**Summary of findings 2. BIS compared to ETAG for improving intraoperative awareness and early postoperative recovery**

**BIS compared to ETAG for improving intraoperative awareness and early postoperative recovery**

**Population:** adults undergoing any type of surgery under general anaesthesia; types of anaesthesia included propofol, desflurane, isoflurane, and sevoflurane; people were either selected for being at high risk of intraoperative awareness, were unselected, or study authors did not report risk of awareness in the included participants

**Setting:** hospitals in: Canada; India; Sweden; and USA

**Intervention:** BIS-guided anaesthesia, with target values between 40 and 60

**Comparison:** ETAG-guided anaesthesia

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Number of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with ETAG	Risk with BIS				

<b>Occurrence of intraoperative awareness</b>	Study population		Peto OR 1.13 (0.56 to 2.26)	26,572 (5 studies)	⊕⊕⊕⊕ <b>Low</b> <sup>a</sup>	Only 3 of these studies included incidences of awareness.  Of these 3 studies: all used a structured questionnaire; all used an adjudication process to categorise incidences of awareness as 'definite'; 2 studies included only participants who were at high risk for intraoperative awareness, and 1 study included participants who were unselected
	1 per 1,000	1 per 1,000 (1 to 3)				
Time points of measure after surgery: 24 hours; 24 to 72 hours; 72 hours; 30 days; 18 hours after extubation in the ICU						
Measurement tools: structured interviews; or structured questionnaire						
<b>Time to eye opening</b>	-	-	-	-	-	We found no studies that measured or reported this outcome
<b>Time to orientation</b>	-	-	-	-	-	We found no studies that measured or reported this outcome
<b>Time to discharge from the PACU</b>  (in minutes)	Median (IQR): 98 minutes (66 to 140 minutes)	Median (IQR) 3 minutes lower (2 minutes lower to 2 minutes lower)	-	15,452 (1 study)	⊕⊕⊕⊕ <b>Low</b> <sup>b</sup>	

\*The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**BIS:** bispectral index; **CI:** confidence interval; **ETAG:** end-tidal anaesthetic gas; **ICU:** intensive care unit; **IQR:** interquartile range; **OR:** odds ratio; **PACU:** postanaesthesia care unit

**GRADE Working Group grades of evidence**

**High certainty:** we are very confident that the true effect lies close to that of the estimate of the effect

**Moderate certainty:** we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

**Low certainty:** our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of the effect

**Very low certainty:** we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect

<sup>a</sup>We downgraded by one level for imprecision; despite a large number of participants, events were very rare (one per 1000 in the intervention and the comparison group) and the confidence interval for this effect was wide. In addition, we downgraded by one level for study limitations owing to the inclusion of some studies with unclear and high risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout.

<sup>b</sup>We downgraded by two levels for imprecision because the evidence was from one study in which the IQR of time spent in the PACU was wide in both groups.

## BACKGROUND

### Description of the condition

The practice of anaesthesia is based on the concept of components of anaesthesia resulting from separate pharmacological actions of multiple agent administration (Kissin 1997). Many anaesthesiologists rely on somatic signs (motor responses, changes in respiratory pattern) and autonomic signs (tachycardia (abnormally rapid heart rate), hypertension (abnormally high blood pressure), lacrimation (flow of tears), sweating) to guide the dosages of anaesthetic agents in order to achieve the basic goals of anaesthetic management; that is unconsciousness (hypnotic effects), blockade of somatic motor responses, and suppression of autonomic responses to noxious stimulation. However, these clinical signs are not reliable measures of the conscious state of anaesthetized patients (Mahla 1997). The use of these clinical signs in judging the dosages of anaesthetic agents can lead to either overdosage or underdosage, which can result in adverse effects due to too deep or too light anaesthesia. Furthermore, there has been much concern regarding intraoperative awareness, which is an uncommon phenomenon occurring in about 0.1% to 0.2% of the general surgical population (Sebel 2004), but which can lead to a serious psychological disturbance called post-traumatic stress disorder (PTSD), resulting in major depression and suicide. The incidence may approach 1% in surgical patients at high risk for intraoperative awareness such as patients with poor cardiac reserve, or undergoing cardiac surgery or caesarean section, where doses of anaesthetics have to be reduced to a light level of anaesthesia (Mashour 2012; Myles 2004). From a review of reported cases of intraoperative awareness, too light anaesthesia could account for 87% of the cases (Ghoneim 2009). Hence, strategies to provide optimal anaesthesia depth are required to avoid too light anaesthesia.

### Description of the intervention

The bispectral index (BIS) is a dimensionless numerical scale for measuring brain electrical activity. It is derived from cerebral electrical activity (an electroencephalogram (EEG)) captured from the scalp surface at the forehead to reflect the sedative and hypnotic components of anaesthesia (Rampil 1998; Schneider 2010). Its value is a number within a range between 0 to 100, where 0 represents 'no detectable brain electrical activity' and 100 represents 'awake state'.

### How the intervention might work

BIS has been recommended to guide doses of anaesthetics to achieve optimal depth of anaesthesia in individual patients. This is in order to avoid unnecessarily deep or too light anaesthesia due to overdosage or underdosage of the hypnotic medications during maintenance and recovery from anaesthesia (Schneider 2010; Sebel 2001). The recommended range of BIS is between 40 to 60 during maintenance of anaesthesia (Avidan 2011; Myles 2004) and 55 to 70 at 15 minutes prior to the end of surgery (Gan 1997).

### Why it is important to do this review

Several studies have been conducted to assess the effect of BIS monitoring on the utilization of currently available anaesthetic agents, such as propofol, desflurane and sevoflurane (Gan 1997; Johansen 1998; Nelskyla 2001; Song 1997). A survey was conducted among anaesthesiologists regarding the routine use of BIS

monitoring in anaesthesia (Johansen 1998). Although the majority of the respondents found that the monitor was easy to use, and it provided useful information, their comments revealed some ambivalence towards hypnotic titration using a BIS monitor. Most respondents felt that no changes occurred in their individual drug usage. Some respondents who reported a change in their practice felt that the hypnotic medication use might decrease, while analgesic and haemodynamic control agent use might increase. A previous study by Song and colleagues (Song 1997) reported increased use of mivacurium in the BIS-targeted group. Badrinath 1999 reported an increase in the use of intraoperative opioids in the BIS-guided group. The increased use of either a muscle relaxant or an opioid analgesic might relate to the ability to maintain 'lighter' planes of anaesthesia with BIS, to avoid movement and increased blood pressure or heart rate during the operation.

Since 1977, several articles and abstracts regarding the utility of BIS have been published by numerous medical researchers and academic institutions. It has been suggested that close titration of anaesthetic effect with the BIS monitor may improve some measures of patient outcomes and operating suite efficiency. However, the results are still contradictory across studies. Many studies (Anez 2001; Boztuğ 2006; Gan 1997; Kreuer 2003; Muralidhar 2008; Tufano 2000) have reported a significant improvement in anaesthetics delivery in terms of reduced anaesthetic consumption or requirements and improved recovery profiles, but some studies (Bruhn 2005; Kreuer 2005; Luginbuhl 2003; Zohar 2006) have failed to demonstrate these effects.

Nowadays, the impact of BIS monitoring on the incidence of intraoperative awareness is a matter of interest in anaesthesia practice. The optimisation of the depth of anaesthesia may avoid too light anaesthesia which may result in intraoperative awareness. However, because of the low incidence of intraoperative awareness in an unselected surgical population undergoing surgeries with low risk of intraoperative awareness, an extremely large number of patients would be needed to determine the effects of BIS on awareness (Mashour 2012; O'Connor 2001). Questions regarding the utility of BIS, particularly to assess whether it is beneficial in reducing incidences of intraoperative awareness and improving early postoperative recovery are important in the clinical practice of anaesthesia. Additional studies have been published since the last update of this Cochrane Review (Punjasawadwong 2014), and therefore this review includes the most up-to-date evidence for the effectiveness of BIS.

## OBJECTIVES

To assess the effectiveness of bispectral index (BIS) to reduce the risk of intraoperative awareness and early recovery times from general anaesthesia in adults undergoing surgery.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

We included all randomized controlled trials (RCTs) or quasi-randomized trials comparing the use of the bispectral index (BIS) with either clinical signs or end-tidal anaesthetic gas (ETAG) as the standard practice in the titration of anaesthetic agents, regardless of the language of publication of the articles.

We did not include studies with publications that were retracted from journals. And we excluded articles that were only available as abstracts if they were published early than 2005.

### Types of participants

We included men and women over 18 years of age undergoing any type of surgery under general anaesthesia. We included participants who were selected because they were at high risk of intraoperative awareness (using any criteria specified by the study authors), and participants who were unselected, or for whom the study investigators did not specify risk of awareness.

### Types of interventions

We included studies with at least two arms, which used BIS to guide the dose of an intravenous anaesthetic, a hypnotic, or a volatile anaesthetic and compared it with standard practice, which was either clinical signs or ETAG to guide the anaesthetic dose.

Therefore, the review included the following two comparison groups.

- BIS-guided anaesthesia versus clinical signs-guided anaesthesia.
- BIS-guided anaesthesia versus ETAG-guided anaesthesia

We included only studies in which investigators aimed to evaluate the effectiveness of BIS for its role in monitoring intraoperative depth of anaesthesia or potential improvements in early recovery times from anaesthesia.

### Types of outcome measures

We included fewer outcomes in the updated review (see [Differences between protocol and review](#)). For the primary outcome, we included any events (or lack of events) which were described using the term 'intraoperative awareness', regardless of the time of measure, whether formal collection tools were used or whether reported events were subject to an adjudication process.

in the event that study authors differentiated data for intraoperative awareness as definite or confirmed awareness and possible awareness, we included only data in the analysis that were defined as confirmed or definite awareness.

#### Primary outcomes

- Occurrence of intraoperative awareness

#### Secondary outcomes

- Time to eye opening
- Time to orientation
- Time to discharge from the postanaesthesia care unit (PACU)

### Search methods for identification of studies

#### Electronic searches

We identified RCTs through literature searching with systematic and sensitive search strategies as outlined in Chapter 6 of the *Cochrane Handbook of Systematic Reviews of Interventions*

(Lefebvre 2011). We applied no restrictions to language or publication status. We sourced the following databases for relevant trials:

- Cochrane Central Register of Controlled Trials (CENTRAL; 2019; Issue 3)
- MEDLINE (Ovid SP; 1946 to 26 March 2019)
- Embase (Ovid SP; 1974 to 26 March 2019)
- Web of Science (SCI-EXPANDED; 1900 to 26 March 2019)

We developed a subject-specific search strategy in MEDLINE and other listed databases. The search strategy was developed in consultation with the Information Specialist for the Cochrane Anaesthesia Review Group. Search strategies can be found in: [Appendix 1](#); [Appendix 2](#); [Appendix 3](#); [Appendix 4](#).

We searched the following clinical trial registers for ongoing and unpublished trials.

- World Health Organization International Clinical Trials Registry Platform ([www.who.int/ictrp/en/](http://www.who.int/ictrp/en/); on 20 June 2019)
- ClinicalTrials.gov ([www.clinicaltrials.gov/](http://www.clinicaltrials.gov/); on 7 June 2019)

#### Searching other resources

We carried out citation searching of identified included studies published since 2013 in Web of Science on 10 June 2019 ([apps.webofknowledge.com](http://apps.webofknowledge.com)). We conducted a search of grey literature using Opengrey on 20 June 2019 ([www.opengrey.eu/](http://www.opengrey.eu/)). In addition, we scanned reference lists of relevant systematic reviews which were published since 2010.

#### Data collection and analysis

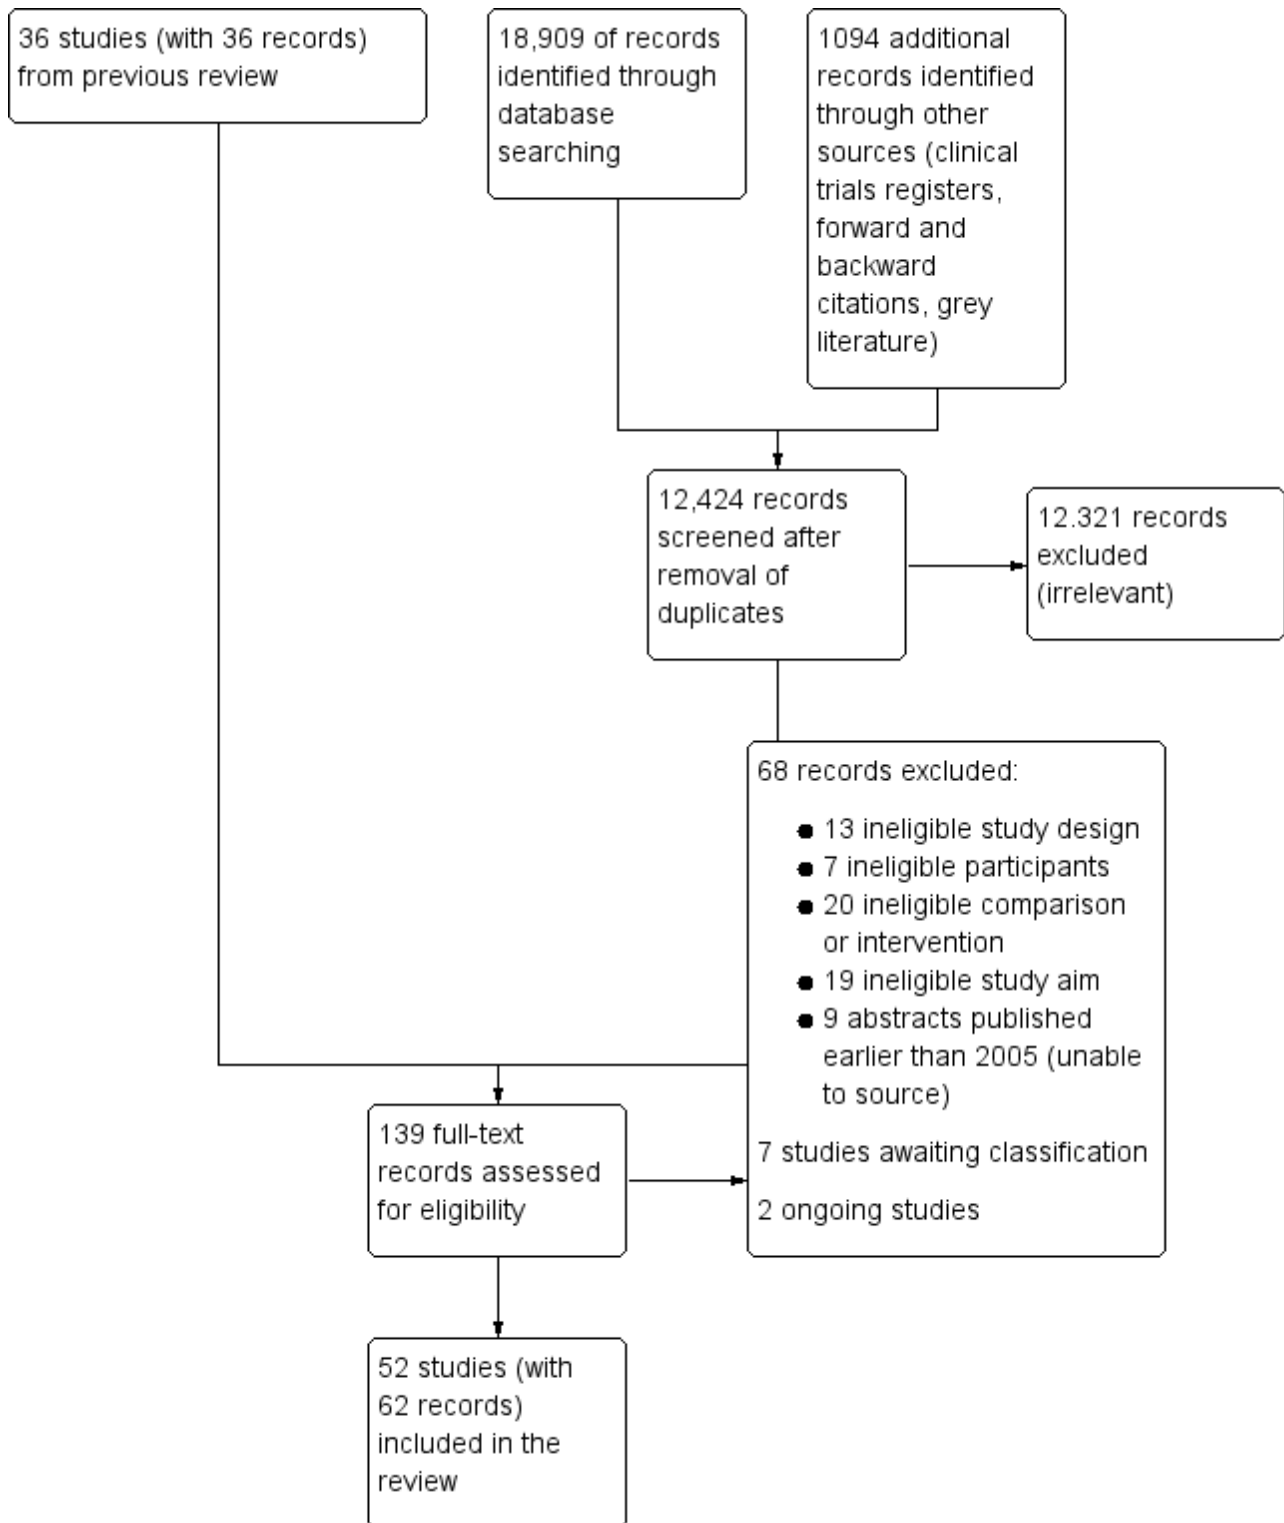

Two review authors (SL, and MP or LF) independently selected studies and extracted data from new included studies. We compared decisions at each stage. In cases of disagreement, we reassessed the respective studies to reach consensus.

#### Selection of studies

We used reference management software to collate the results of searches and to remove duplicates ([Endnote](#)). We used Covidence software to screen results of the search of titles and abstracts and identify potentially relevant studies ([Covidence 2019](#)). We sourced the full texts of all potentially relevant studies and considered whether they met the inclusion criteria (see [Criteria for considering studies for this review](#)). We reviewed abstracts at this stage and included these in the review only if they provided sufficient information and relevant results that included denominator figures for the intervention and control groups. Because of changes made to the review inclusion criteria (see [Differences between protocol and review](#)), we re-evaluated all studies previously included in the review.

We recorded the number of papers retrieved at each stage and reported this information using a PRISMA flow chart ([Figure 1](#)). We did not report details of all studies excluded during the evaluation of full-text articles; we reported in the review brief details of only closely related but excluded articles.

**Figure 1. Study flow diagram. Search conducted in March 2019.**

**Data extraction and management**

We used a data extraction form to collect information and outcome data from studies (Appendix 5). We collected the following information.

- Methods: type of study design, setting; dates of study; funding sources and study author declarations of interest.
- Participants: number randomized to each group; number of losses; number analysed in each group; baseline characteristics (age, gender, American Society of Anesthesiologists (ASA) physical status or other measure of health status; body mass

- index (BMI); weight; height; type of surgery; and duration of anaesthesia).
- Intervention: details of BIS target values; details of control group; anaesthetic agents; experience of anaesthetist.
- Outcomes: data for all reported review outcomes to include study author definitions, measurement tools and time points.

We considered the applicability of information from individual studies and generalizability of the data to our intended study population.

In multi-arm studies, we did not collect data on any groups that were not eligible for inclusion in the review.

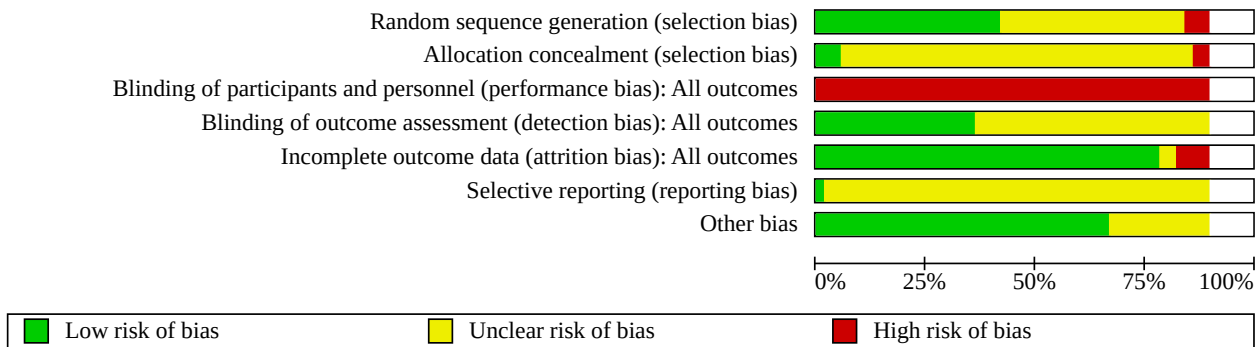

**Assessment of risk of bias in included studies**

We assessed study quality, study limitations, and the extent of potential bias using the Cochrane 'Risk of bias' tool (Higgins 2011). We considered the following domains.

- Sequence generation (selection bias).
- Allocation concealment (selection bias).
- Blinding of participants, personnel, and outcomes assessors (performance and detection bias).
- Incomplete outcome data (attrition bias).
- Selective outcome reporting (reporting bias).
- Other risks of bias.

For each domain, two review authors (SL, and MP or LF) judged whether study authors made sufficient attempts to minimize bias in their study design. We made judgements using three measures - high, low, or unclear risk of bias. We recorded this in 'Risk of bias' tables and presented summary 'Risk of bias' figures (Figure 2; Figure 3).

**Figure 2. Methodological quality graph: review authors' judgements about each methodological quality item presented as percentages across all included studies.**

**Figure 3. Methodological quality summary: review authors' judgements about each methodological quality item for each included study. Blank spaces indicate that we did not conduct 'Risk of bias' assessments because studies did not report review outcomes.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias): All outcomes	Blinding of outcome assessment (detection bias): All outcomes	Incomplete outcome data (attrition bias): All outcomes	Selective reporting (reporting bias)	Other bias

**Measures of treatment effect**

We collected dichotomous data for intraoperative awareness. We collected continuous data for recovery outcomes, which were time to eye opening, time to orientation, and time to discharge from the postanaesthesia care unit (PACU).

We reported dichotomous data as Peto odds ratios (OR) to compare groups and continuous data as a mean difference (MD). We reported 95% confidence intervals (CIs).

**Unit of analysis issues**

The review included multi-arm studies, in which more than one type of anaesthesia was included as separate study groups, or in which comparison groups included a clinical signs group and an ETAG-guided group.

For multi-arm studies that included study groups with different types of anaesthesia, we combined data for these groups for dichotomous data (occurrence of intraoperative awareness), and we selected the anaesthetic group which had the most conservative result for continuous data (recovery times). In subgroup analysis, we included each group separately according to type of anaesthetic agent.

We reported data separately for different comparison groups, and therefore there was no unit of analysis considerations for multi-arm studies that included study groups with clinical signs and ETAG-guided anaesthesia.

**Dealing with missing data**

We did not re-include missing data by using imputation methods; we used the number of analysed participants as reported by study authors. In the previous version of the review (Punjasawadwong

2014), we contacted study authors to obtain missing data; owing to time limitations in the preparation of this update, we did not contact study authors in the case of missing data.

We did not recalculate the standard deviations (SDs) for studies reporting continuous outcomes as medians with ranges or interquartile ranges (IQR). In this update, we reported data with median values in the notes section of the relevant table in [Characteristics of included studies](#).

### Assessment of heterogeneity

We assessed whether evidence of inconsistency was apparent in our results by considering heterogeneity. We assessed clinical and methodological heterogeneity by comparing similarities in our included studies between study designs, participants, interventions, and outcomes, and used the data collected from the full-text reports (as stated in [Data collection and analysis](#)). We explored clinical and methodological heterogeneity through subgroup analysis. We assessed statistical heterogeneity by calculating the  $\text{Chi}^2$  test or the  $I^2$  statistic and judged any heterogeneity above an  $I^2$  value of 50% and a  $\text{Chi}^2$  P value less than or equal to 0.05 to indicate moderate to substantial statistical heterogeneity ([Higgins 2011](#)).

In addition to looking at statistical results, we considered point estimates and overlap of CIs. If CIs overlap, then results are more consistent. However, combined studies may show a large consistent effect but with significant heterogeneity. Therefore, we planned to interpret heterogeneity with caution ([Guyatt 2011a](#)).

### Assessment of reporting biases

We attempted to source the published protocols for each of our included studies by using the results from our clinical trial register searches. We compared published protocols with published study results to assess the risk of selective reporting bias. In addition, we appraised reporting bias through visual assessment of funnel plots for outcomes for which we found more than 10 studies ([Egger 1997](#)). We only included figures of funnel plots in the review in which we identified possible reporting bias from visual inspection.

### Data synthesis

We presented a statistical summary of treatment effects in the absence of significant clinical or methodological heterogeneity. We used the statistical calculator in ReMan 5 to perform meta-analysis ([Review Manager 14](#)).

For the occurrence of intraoperative awareness, we used the Peto method to pool ORs across studies; this method accounted for the extremely rare events for this outcome. For continuous outcomes, we calculated the mean difference (MD); we used a random-effects model to account for potential variability in types of surgeries between studies ([Borenstein 2010](#)).

We calculated CIs at 95% and used a P value less than or equal to 0.05 to judge whether a result was statistically significant. We considered imprecision in the results of analyses by assessing the CI around an effects measure; a wide CI would suggest a higher level of imprecision in our results. A small number of studies may also reduce precision ([Guyatt 2011b](#)).

### Subgroup analysis and investigation of heterogeneity

In subgroup analysis, we evaluated the type of anaesthetic agent which was used in the maintenance of anaesthesia (propofol, desflurane, isoflurane, sevoflurane). We conducted subgroup analysis for outcomes in which we found more than 10 studies ([Higgins 2011](#)).

### Sensitivity analysis

We explored the potential effect of decisions made as part of the review process. In each sensitivity analysis, we compared the effect estimate with the main analysis. We reported these effect estimates only if they indicated a difference in interpretation of the effect. We performed the following sensitivity analyses.

- We excluded studies that we judged to have a high or unclear risk of selection bias (for sequence generation).
- We excluded studies that we judged to have a high risk of attrition bias because of a loss of more than 10% participants, or loss which was unbalanced between groups, or which was unexplained.

We found a large number of studies that reported intraoperative awareness with zero events in both arms. We used the Peto OR in the primary analysis of intraoperative awareness but made a post-hoc decision to evaluate the effect of these zero-event data by using alternative statistical methods. In sensitivity analysis, we used risk ratios (RR) with both a Mantel-Haenszel and Inverse Variance method; we also evaluated these methods using a fixed-effect and a random-effects model. We did not use a risk difference method, because this method is unsuitable when events are rare ([Bradburn 2007](#)).

### 'Summary of findings' table and GRADE

One review author (SL) used the GRADE system to assess the certainty of the body of evidence associated with the following outcomes ([Guyatt 2008](#)).

- Occurrence of intraoperative awareness
- Time to eye opening
- Time to orientation
- Time to discharge from the PACU

The GRADE approach appraises the certainty of a body of evidence based on the extent to which we can be confident that an estimate of effect or association reflects the item being assessed. Evaluation of the certainty of a body of evidence considers within-study risk of bias, directness of the evidence, heterogeneity of the data, precision of the effect estimates, and risk of publication bias.

We constructed 'Summary of findings' tables using GRADE profiler software for two comparisons ([gradepro.org](#)).

- BIS-guided anaesthesia versus clinical signs-guided anaesthesia
- BIS-guided anaesthesia versus ETAG-guided anaesthesia

## Summary of findings and assessment of the certainty of the evidence

### RESULTS

#### Description of studies

##### Results of the search

After the removal of duplicates from the search results, we screened 12,424 titles and abstracts, which included forward and backward citation searches, clinical trials registers and grey literature. We re-evaluated previously included studies alongside 103 articles sourced as full-text reports and, therefore, assessed eligibility of 139 articles. See [Figure 1](#).

##### Included studies

See [Characteristics of included studies](#).

We included 52 studies with 41,331 participants ([Ahmad 2003](#); [Alimian 2016](#); [Anez 2001](#); [Arbabpour 2015](#); [Assare 2002](#); [Avidan 2008](#); [Avidan 2011](#); [Başar 2003](#); [Boztuğ 2006](#); [Bresil 2013](#); [Bruhn 2005](#); [Ellerkmann 2010](#); [Fakhr 2014](#); [Gan 1997](#); [Georgakis 2000](#); [Guo 2015](#); [Ibraheim 2008](#); [Jain 2016](#); [Kabukcu 2012](#); [Kamal 2009](#); [Kamali 2017a](#); [Karaca 2014](#); [Khoshrang 2016](#); [Kim 2003](#); [Kreuer 2003](#); [Kreuer 2005](#); [Luginbuhl 2003](#); [Mashour 2012](#); [Masuda 2002](#); [Morimoto 2002](#); [Mozafari 2014](#); [Muralidhar 2008](#); [Myles 2004](#); [Nelskyla 2001](#); [Paventi 2001](#); [Payas 2013](#); [Persec 2012](#); [Puri 2003](#); [Rahul 2015](#); [Raksakietisak 2016](#); [Recart 2003](#); [Savli 2005](#); [Shafiq 2012](#); [Siampalioti 2015](#); [Song 1997](#); [Sudhakaran 2018](#); [Tufano 2000](#); [White 2004](#); [Wong 2002](#); [Zhang 2011](#); [Zhang 2016](#); [Zohar 2006](#)). Two studies were quasi-randomized ([Anez 2001](#); [Shafiq 2012](#)); the remaining studies were randomized controlled trials (RCTs). We included three studies for which we could only source the abstract and this limited the details of study characteristics that we were able to extract ([Georgakis 2000](#); [Kabukcu 2012](#); [Raksakietisak 2016](#)). We sourced the full text of all the remaining studies. We did not seek translation of five studies ([Arbabpour 2015](#); [Kim 2003](#); [Masuda 2002](#); [Morimoto 2002](#); [Savli 2005](#)), and details of study characteristics and outcome data in these studies were limited to data in the English abstract or tables within the main text.

This review includes 22 new studies ([Alimian 2016](#); [Arbabpour 2015](#); [Bresil 2013](#); [Fakhr 2014](#); [Georgakis 2000](#); [Guo 2015](#); [Jain 2016](#); [Kabukcu 2012](#); [Kamali 2017a](#); [Karaca 2014](#); [Khoshrang 2016](#); [Kim 2003](#); [Mozafari 2014](#); [Payas 2013](#); [Persec 2012](#); [Rahul 2015](#); [Raksakietisak 2016](#); [Savli 2005](#); [Shafiq 2012](#); [Siampalioti 2015](#); [Sudhakaran 2018](#); [Zhang 2016](#)). The remaining studies were previously included in [Punjasawadwong 2014](#).

##### Study population

All studies included participants undergoing surgery under general anaesthesia. In one study, participants were undergoing procedures using regional anaesthesia combined with general anaesthesia ([Ellerkmann 2010](#)).

General anaesthesia was maintained by propofol, or by sevoflurane, desflurane or isoflurane, and in one study, halothane was used ([Jain 2016](#)). Only three studies used laryngeal masks (LMA); these were during surgical procedures with a duration of less than one hour ([Anez 2001](#); [Assare 2002](#); [Zohar 2006](#)).

Five studies included more than one comparison group according to the type of anaesthetic agent ([Luginbuhl 2003](#); [Muralidhar 2008](#); [Siampalioti 2015](#); [Song 1997](#); [Tufano 2000](#)). The type of anaesthetic agents was at the discretion of the attending anaesthetists in four studies ([Avidan 2008](#); [Avidan 2011](#); [Mashour 2012](#); [Myles 2004](#)); in [Avidan 2008](#) and [Avidan 2011](#) agents were only volatile. We were uncertain of the type of anaesthetic agent in [Arbabpour 2015](#).

Three studies recruited only participants who were at high risk of intraoperative awareness ([Avidan 2008](#); [Avidan 2011](#); [Myles 2004](#)), whilst two studies specifically recruited an unselected participant group ([Mashour 2012](#); [Zhang 2011](#)). In general, we found most studies did not report whether the population group was at risk. However, in the findings of the 5th National Audit Project (NAP5) on accidental awareness during general anaesthesia ([NAP5 2014](#)), some factors may increase risk of intraoperative awareness: female gender; age (younger adults); obesity; seniority of anaesthetists (junior trainees); history of accidental awareness; out of hours operating; emergencies; type of surgery (obstetric, cardiac, thoracic, neurosurgery); and use of neuromuscular blockade. We collected information on studies that had at least one risk factor and reported this information in [Appendix 6](#). However, we did not think this information alone was sufficient to categorise these studies as having participants at high risk of awareness.

##### Study setting

All studies were conducted in a hospital setting and seven were multi-centre studies ([Avidan 2008](#); [Avidan 2011](#); [Bruhn 2005](#); [Mashour 2012](#); [Myles 2004](#); [Rahul 2015](#); [Zhang 2011](#)).

##### Interventions and comparisons

All studies included an intervention group in which a BIS monitor was used to guide anaesthesia. In six studies, this was compared with ETAG-guided anaesthesia ([Avidan 2008](#); [Avidan 2011](#); [Jain 2016](#); [Mashour 2012](#); [Muralidhar 2008](#); [Sudhakaran 2018](#)); one of these studies included comparisons with both ETAG-guided anaesthesia, and anaesthesia guided by clinical signs ([Sudhakaran 2018](#)). One study described that the control group participants had anaesthesia guided by both clinical signs and end-tidal concentration in the form of minimum alveolar concentration; (MAC) ([Shafiq 2012](#)); we categorised this study as belonging to our first comparison group (BIS versus clinical signs). The remaining studies included comparisons with only clinical signs. We could not be certain of other monitoring methods used in the included studies; our information was limited to the details reported in published reports. Therefore, it is possible that some studies in which anaesthesia was guided by clinical signs may also have been guided by ETAG. Similarly, because it was not always clearly reported, we could not be certain whether audible alarms were used for ETAG-guided anaesthesia.

The large number of participants in this review was dominated by five large studies; two of these studies compared BIS with clinical signs and in total included 7772 participants ([Myles 2004](#); [Zhang 2011](#)), and three studies compared BIS with ETAG and had 29,642 participants ([Avidan 2008](#); [Avidan 2011](#); [Mashour 2012](#)).

Most studies defined clinical signs as using parameters such as heart rate or systolic blood pressure. One study used a standardised scoring system (PRST: systolic blood pressure, heart rate, sweating and tears) to evaluate depth of anaesthesia ([Rahul 2015](#)).

BIS target values varied in each study but all were within a range of 40 to 60.

Only four studies reported the experience of the attending anaesthetist, which was described as a quote: "experienced anaesthesiologist" (Ellerkmann 2010), "supervised by a faculty anaesthetist" (Gan 1997), greater than one year (Başar 2003), and greater than five years (Wong 2002). The remaining studies did not describe the experience of the attending anaesthetist.

### Outcomes

Five studies did not report outcomes relevant to the review (Ahmad 2003; Bresil 2013; Jain 2016; Payas 2013; Raksakietisak 2016). The remaining studies reported measured at least one of the review outcomes.

For the measurement of intraoperative awareness, we noted that studies did not report a clear definition of intraoperative awareness. In addition, the time point of measurement varied between studies and included one or more measurement taken from as early as the time in the PACU to several days, and up to 30 days, after anaesthesia. In addition, the methods or tools used to collect the information were not always reported, and were described in limited terms such as 'an interview', or in more comprehensive terms (for example, by including a specific standardised questionnaire such as structured modified Brice questionnaire (Brice 1970).

### Funding

Five studies reported financial support or included study authors who had received fees (for example for consultancy work), from companies involved in the manufacture of BIS monitors (Ahmad 2003; Bruhn 2005; Gan 1997; Myles 2004; Wong 2002). Twenty-one studies were either not funded or funded from independent sources (Alimian 2016; Avidan 2008; Avidan 2011; Bresil 2013; Fakhr 2014; Kamali 2017a; Khoshrang 2016; Kreuer 2003; Kreuer 2005; Luginbuhl 2003; Mashour 2012; Mozafari 2014; Nelskyla 2001; Payas 2013; Persec 2012; Rahul 2015; Raksakietisak 2016; Recart 2003; Sudhakaran 2018; White 2004; Zohar 2006). We could not ascertain funding sources from the remaining studies.

### Excluded studies

We excluded 68 studies during full-text review and the reasons for these exclusions are described in Figure 1.

In order to improve usability of the review, we have only reported details of 19 of these 68 excluded studies in the review (Aceto 2015; Aimé 2006; Chan 2013; Chiu 2007; Hachero 2001; Kamali 2017b; Karwacki 2014; Kaval 2015; Kerssens 2009; Nitzschke 2014; Panagopoulou 2000; Quesada 2016; Radtke 2013; Rüsck 2018; Samarkandi 2004; Shahrbazi 2008; Struys 2001; Vretzakis 2005; Zhou 2018). We excluded these 19 studies because their study aims did not match the review aim. See [Characteristics of excluded studies](#).

Of these 19 studies, five studies were included in the previous version of the review (Aimé 2006; Chiu 2007; Hachero 2001; Samarkandi 2004; Struys 2001); the decision to exclude these five studies was due to a change in the review criteria (see [Differences between protocol and review](#)).

We did not include in the review studies that were excluded during previous versions of the review (Punjasawadwong 2007; Punjasawadwong 2014).

### Studies awaiting classification

Six studies are awaiting classification (Aksun 2007; Croci 2014; CTRI/2018/03/012457; Golmohammadi 2014; Jeong 2002; Qu 2011). We were unable to source the full text of two studies from current library sources and the abstracts contained insufficient information to assess eligibility (Aksun 2007; Qu 2011). Croci 2014 was published only as an abstract and, similarly this contained insufficient information to assess eligibility. We found one completed study in a clinical trial register but the clinical trial register did not include study results and therefore, we await publication of the full report (CTRI/2018/03/012457). Two studies require translation to assess eligibility (Golmohammadi 2014; Jeong 2002).

### Ongoing studies

We found two ongoing studies (Martins 2013; NCT03571945). One study is a protocol, previously included in the review as 'awaiting classification' (Martins 2013); because the status is recorded in the clinical trial register as unknown we have assumed that it is still ongoing. This study compares BIS with clinical signs in people undergoing coronary artery bypass graft. The other ongoing and multi-centre study aims to recruit 2000 participants and will compare BIS-guided anaesthesia with anaesthesia guided by ETAG in participants undergoing elective surgery lasting more than 30 minutes (NCT03571945).

### Risk of bias in included studies

See [Characteristics of included studies](#), Figure 2 and Figure 3.

We only conducted 'Risk of bias' assessments on studies that measured or reported review outcomes. Blank spaces in Figure 2 and Figure 3 indicate that these studies did not measure or report review outcomes.

### Allocation

Two quasi-randomized studies were at high risk of selection bias because of methods used for sequence generation and allocation concealment (Anez 2001; Shafiq 2012). In addition, we noted differences between the number of participants allocated to each group and differences between groups in one study which we also judged to have a high risk of bias for sequence generation (Zhang 2011).

Twenty-two studies reported insufficient detail of methods to randomize participants and we judged these studies to have an unclear risk of bias for sequence generation (Alimian 2016; Arbabpour 2015; Assare 2002; Başar 2003; Georgakis 2000; Ibraheim 2008; Kamal 2009; Kamali 2017a; Karaca 2014; Kim 2003; Masuda 2002; Morimoto 2002; Muralidhar 2008; Nelskyla 2001; Paventi 2001; Rahul 2015; Recart 2003; Savli 2005; Tufano 2000; White 2004; Zhang 2016; Zohar 2006). The remaining studies reported adequate methods to randomize participants and we judged these to have a low risk of bias for sequence generation.

Four studies reported adequate methods to conceal allocation and we judged these to have a low risk of bias (Avidan 2011; Boztuğ 2006; Gan 1997; Myles 2004). The remaining studies did not report

sufficient methods to conceal allocation to enable us to judge the risk of bias for allocation concealment.

### Blinding

Whilst some studies reported that participants were blinded to group allocation, we based our judgement for risk of performance bias according to whether relevant personnel were blinded; this was because we expected that knowledge of group assignment was unlikely to influence participants. In all studies, it was not feasible to blind anaesthetists to the two methods used to guide anaesthesia in this review. Therefore we judged all studies to have a high risk of performance bias. As well as the risk that anaesthetists may alter their methods of providing anaesthesia depending on the group to which they are allocated, this type of study has a performance bias risk related to 'learning contamination' bias. Learning contamination bias is the risk of changing clinical practice in the parallel control or unmonitored group by using the information from the BIS group (Roizen 1994).

Intraoperative awareness is a self-reported outcome; however, we did not consider the blinding of participants to influence the measurement of intraoperative awareness. We expected that most studies used an anaesthetist who interviewed the participants postoperatively (either informally or using a standardised questionnaire) and, in this review, we classed the interviewer as the outcome assessor as the terms used to ask questionnaires may be subject to bias. Nineteen studies reported that outcome assessors were blinded (Avidan 2008; Avidan 2011; Bruhn 2005; Fakhr 2014; Gan 1997; Kamali 2017a; Khoshrang 2016; Kreuer 2003; Kreuer 2005; Luginbuhl 2003; Mashour 2012; Myles 2004; Paventi 2001; Recart 2003; Siampalioti 2015; White 2004; Wong 2002; Zhang 2011; Zohar 2006). The remaining studies did not report whether outcome assessors were blinded.

### Incomplete outcome data

In four studies, we noted a loss of more than 10% participants or that the loss of participants was imbalanced between groups (Gan 1997; Mashour 2012; Morimoto 2002; Zhang 2011); we judged these studies to have a high risk of attrition bias. We could not be certain whether all participants were accounted for in two studies; therefore, we judged these studies to have an unclear risk of attrition bias (Arbabpour 2015; Fakhr 2014). The remaining studies had no apparent participant loss, or the loss of participants was fewer than 10%, and we judged these studies to have a low risk of attrition bias.

### Selective reporting

Two studies were prospectively registered with a clinical trial register (Avidan 2011; Mashour 2012). We judged Mashour 2012 to have a low risk of reporting bias because outcomes in the published report were the same as those in the clinical trial register documents. We could not be certain whether a risk of reporting bias was evident in Avidan 2011 because several outcomes listed in the clinical trial register documents were not included in the published report.

Four studies were retrospectively registered with a clinical trial register (Alimian 2016; Avidan 2008; Khoshrang 2016; Persec 2012), and we could not be certain whether registration was prospective or retrospective in one study (Siampalioti 2015); it was not feasible to use these documents to effectively assess risk of reporting bias. The

remaining studies did not report clinical trial registration or study protocol publication, and therefore, it was similarly not feasible to effectively assess risk of reporting bias.

### Other potential sources of bias

We were unable to assess risks of other sources of bias in those studies for which we did not seek translation (Arbabpour 2015; Kim 2003; Masuda 2002; Morimoto 2002; Savli 2005), or in studies that were reported only as abstracts (Georgakis 2000; Kabukcu 2012); therefore, we used an unclear judgement for other risks of bias. Similarly, we used an unclear judgement in two studies in which study characteristics were poorly reported (for example, with no baseline characteristics table) (Kamali 2017a; Tufano 2000).

We noted some important baseline imbalances between groups in three studies and we could not be certain of the influence of these imbalances on the outcome data (Avidan 2008; Persec 2012; Rahul 2015).

### Effects of interventions

See: [Summary of findings 1 Bispectral index compared to clinical signs for improving intraoperative awareness and early postoperative recovery](#); [Summary of findings 2 BIS compared to ETAG for improving intraoperative awareness and early postoperative recovery](#)

#### 1. BIS versus clinical signs

##### Occurrence of intraoperative awareness

Twenty-nine studies measured intraoperative awareness (Anez 2001; Assare 2002; Bruhn 2005; Ellerkmann 2010; Fakhr 2014; Guo 2015; Ibraheim 2008; Kabukcu 2012; Kamal 2009; Kamali 2017a; Karaca 2014; Kim 2003; Kreuer 2003; Kreuer 2005; Luginbuhl 2003; Mozafari 2014; Myles 2004; Paventi 2001; Persec 2012; Puri 2003; Rahul 2015; Recart 2003; Song 1997; Sudhakaran 2018; White 2004; Wong 2002; Zhang 2011; Zhang 2016; Zohar 2006). In two studies, data were measured but were unclearly reported or were not reported (Fakhr 2014; Paventi 2001).

Events were rare, and only five of these studies included incidences of awareness (Kamali 2017a; Mozafari 2014; Myles 2004; Puri 2003; Zhang 2011). Two of these studies were large, multi-centre trials - one included only participants at high risk of intraoperative awareness (Myles 2004), and one included an unselected population (Zhang 2011). Four of these five studies used a structured questionnaire to collect data on awareness, and one study reported that participants were interviewed (with no additional details). Two of these five studies used an adjudication process to judge whether descriptions of awareness were possible or confirmed, and we included data only for confirmed reports of awareness.

We found that BIS-guided anaesthesia may reduce the risk of intraoperative awareness in a surgical population that were at unselected or at high risk of awareness (Peto odds ratio (OR) 0.36, 95% confidence interval (CI) 0.21 to 0.60;  $I^2 = 61%$ ; 27 studies; 9765 participants; low-certainty evidence; [Analysis 1.1](#)). We used GRADE to downgrade the certainty of the evidence by two levels. We downgraded by one level for study limitations owing to the inclusion of some studies with unclear risks of bias, and in all studies, it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high

risk of performance bias throughout. We downgraded by one level for imprecision; whilst we noted a narrow CI, the effect was dominated by two large trials (with two different populations selected according to the likelihood of intraoperative awareness) and we found many studies with zero events in both arms. We conducted sensitivity analysis to explore alternative statistical models to account for zero events in both arms as well as rare events and found more conservative estimates when we used a random-effects model, thus reducing our certainty in the estimate. See [Summary of findings 1](#).

### **Recovery time to eye opening**

Twenty-seven studies measured time to eye opening ([Anez 2001](#); [Başar 2003](#); [Boztuğ 2006](#); [Bruhn 2005](#); [Ellerkmann 2010](#); [Gan 1997](#); [Georgakis 2000](#); [Ibraheim 2008](#); [Kamal 2009](#); [Karaca 2014](#); [Khoshrang 2016](#); [Kreuer 2003](#); [Kreuer 2005](#); [Masuda 2002](#); [Morimoto 2002](#); [Myles 2004](#); [Nelskyla 2001](#); [Paventi 2001](#); [Puri 2003](#); [Recart 2003](#); [Savli 2005](#); [Shafiq 2012](#); [Siampalioti 2015](#); [Tufano 2000](#); [White 2004](#); [Wong 2002](#); [Zohar 2006](#)). In two studies, time was measured but not reported ([Georgakis 2000](#); [Zohar 2006](#)). We did not combine data in analysis from studies that reported time to eye opening as median values ([Myles 2004](#); [Paventi 2001](#); [Tufano 2000](#)).

For [Siampalioti 2015](#), a multi-arm study, we included data only for participants in which sevoflurane was used for anaesthesia; the effect for these participants showed a more conservative estimate.

We found that BIS-guided anaesthesia may reduce time to eye opening by mean difference (MD) 1.78 minutes (95% CI -2.53 to -1.03 minutes;  $I^2 = 83%$ ; 22 studies; 1494 participants; low-certainty evidence; [Analysis 1.2](#)). We used GRADE to downgrade the certainty of the evidence by one level for inconsistency owing to the substantial statistical heterogeneity in this effect, and by one level for study limitations owing to the inclusion of some studies with unclear risks of bias, and in all studies, it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout. See [Summary of findings 1](#).

### **Recovery time to orientation**

Eight studies measured time to orientation ([Fakhr 2014](#); [Kamal 2009](#); [Nelskyla 2001](#); [Paventi 2001](#); [Savli 2005](#); [Song 1997](#); [White 2004](#); [Wong 2002](#)). In [Fakhr 2014](#), data were measured but not reported. We did not combine data in analysis from studies that

reported time to orientation as median values ([Paventi 2001](#)). In [Song 1997](#), data were included separately according to the type of volatile anaesthetic (sevoflurane and desflurane); we included data for participants who were given sevoflurane as this presented a more conservative finding.

We found that BIS-guided anaesthesia may reduce time to orientation by MD 3.18 minutes (95% CI -4.03 to -2.33 minutes;  $I^2 = 41%$ ; 6 studies; 273 participants; low-certainty evidence; [Analysis 1.3](#)). We used GRADE to downgrade the certainty of the evidence by one level for imprecision as the evidence was from few studies with few participants, and by one level for study limitation owing to the inclusion of some studies with unclear risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout. See [Summary of findings 1](#).

### **Time to discharge from the postanesthesia care unit (PACU)**

Seventeen studies measured time to discharge from the PACU ([Alimian 2016](#); [Anez 2001](#); [Arbabpour 2015](#); [Boztuğ 2006](#); [Bruhn 2005](#); [Fakhr 2014](#); [Gan 1997](#); [Kamal 2009](#); [Khoshrang 2016](#); [Masuda 2002](#); [Morimoto 2002](#); [Myles 2004](#); [Recart 2003](#); [Song 1997](#); [White 2004](#); [Wong 2002](#); [Zohar 2006](#)). We did not include data for one study in which time was reported as median values ([Myles 2004](#)), nor for three studies in which data were not reported or were reported unclearly ([Arbabpour 2015](#); [Fakhr 2014](#); [Khoshrang 2016](#)). In [Song 1997](#), data were included separately according to the type of volatile anaesthetic (sevoflurane and desflurane); we included data for participants who were given sevoflurane as this presented a more conservative finding.

We found that BIS-guided anaesthesia may reduce time to discharge from the PACU by MD 6.86 minutes (95% CI -11.72 to -2.00;  $I^2 = 79%$ ; 13 studies; 930 participants; low-certainty evidence; [Analysis 1.4](#)). We used GRADE to downgrade the certainty of the evidence by one level for inconsistency owing to the substantial statistical heterogeneity in this effect, and by one level for study limitations owing to the inclusion of some studies with unclear risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout. See [Summary of findings 1](#).

From visual inspection of a funnel plot for these outcome data, we noted the possibility of publication bias ([Figure 4](#)).

**Figure 4. Funnel plot of comparison: 1 BIS versus clinical sides, outcome: 1.4 Time to discharge from the PACU (minutes).**

**Subgroup analysis**

**Type of agent used to guide anaesthesia**

We did not include [Myles 2004](#) in this subgroup analysis because the type of anaesthetic was at the discretion of the attending anaesthetists, and therefore may include all types.

**Occurrence of intraoperative awareness:** the effect for propofol was consistent with our primary analysis, showing a reduction in intraoperative awareness when propofol was guided by BIS (Peto OR 0.24, 95% CI 0.10 to 0.60;  $I^2 = 0\%$ ; 10 studies; 5784 participants). The evidence for isoflurane was inconsistent and showed no evidence of a reduction in intraoperative awareness when isoflurane was guided by BIS (Peto OR 0.58, 95% CI 0.26 to 1.28;  $I^2 = 74\%$ ; 4 studies; 637 participants). None of the studies in which desflurane or sevoflurane was given reported events. [Analysis 2.1.](#)

**Recovery time to eye opening:** this subgroup analysis included both propofol and sevoflurane groups in [Siampalioti 2015](#). The effect for time to eye opening was consistent with our primary analysis, showing a reduction in time to eye opening for BIS-guided anaesthesia with: propofol (MD -2.13 minutes, 95% CI -3.82 to -0.43 minutes;  $I^2 = 89\%$ ; 8 studies; 680 participants); isoflurane (MD -2.45 minutes, 95% CI -4.80 to -0.09 minutes;  $I^2 = 73\%$ ; 3 studies; 150 participants); and sevoflurane (MD -1.52 minutes, 95% CI -2.60 to

-0.44 minutes;  $I^2 = 83\%$ ; 8 studies; 392 participants). We found no evidence of a difference in time to eye opening when desflurane was used (MD -0.51 minutes, 95% CI -1.44 to 0.42 minutes;  $I^2 = 38\%$ ; 4 studies; 322 participants). [Analysis 2.2.](#)

**Recovery time to orientation:** we did not conduct subgroup analysis for this outcome because the primary analysis included too few studies.

**Recovery time to discharge from the PACU:** this subgroup analysis included both sevoflurane and desflurane anaesthetic groups in [Song 1997](#). We noted differences between subgroups in this analysis ( $\text{Chi}^2 = 57.54$ ,  $\text{df} = 13$ ,  $P < 0.00001$ ). Whilst studies in which propofol was used showed a reduction in time to discharge from the PACU which was consistent with the primary analysis (MD -5.42 minutes, 95% CI -9.36 to -1.48 minutes;  $I^2 = 0\%$ ; 4 studies; 398 participants), we found that the evidence when volatile agents were used was inconsistent: desflurane (MD -14.76 minutes, 95% CI -29.61 to 0.09 minutes;  $I^2 = 88\%$ ; 4 studies; 272 participants); isoflurane (MD -14.00 minutes, 95% CI -34.12 to 6.12 minutes; 1 study; 60 participants); sevoflurane (MD -5.99 minutes, 95% CI -13.34 to 1.36 minutes;  $I^2 = 83\%$ ; 5 studies; 230 participants). [Analysis 2.4.](#)

## Sensitivity analysis

### *Unclear or high risk of selection bias for sequence generation*

- Occurrence of intraoperative awareness: only 14 studies included in the primary analysis had a low risk of selection bias (Bruhn 2005; Ellerkmann 2010; Guo 2015; Kabukcu 2012; Kreuer 2003; Kreuer 2005; Luginbuhl 2003; Mozafari 2014; Myles 2004; Persec 2012; Puri 2003; Song 1997; Sudhakaran 2018; Wong 2002). When we excluded the remaining studies, analysis demonstrated no evidence of an effect (Peto OR 0.60 (95% CI 0.29 to 1.23; 14 studies; 3654 participants); however, we noted that this sensitivity analysis included only three studies with event data, of which one small study had findings which were inconsistent with other studies and which we could not explain (Mozafari 2014).
- Time to eye opening: only 10 studies included in the primary analysis had a low risk of selection bias (Boztuğ 2006; Bruhn 2005; Ellerkmann 2010; Gan 1997; Khoshrang 2016; Kreuer 2003; Kreuer 2005; Puri 2003; Siampalioti 2015; Wong 2002). When the remaining studies were excluded, we found no difference in the interpretation of the effect.
- Time to orientation: only two studies included in the primary analysis had a low risk of selection bias (Song 1997; Wong 2002). When we excluded the remaining studies, we found no difference in the interpretation of the effect.
- Time to discharge from the PACU: only five studies included in the primary analysis had a low risk of selection bias (Boztuğ 2006; Bruhn 2005; Gan 1997; Song 1997; Wong 2002). When we excluded the remaining studies, we found no evidence of an effect (MD -1.62 minutes (95% CI -5.96 to 2.72); 519 participants).

### *Unclear or high risk of attrition bias*

- Occurrence of intraoperative awareness: we excluded one study with a high risk of attrition bias (Zhang 2011). This did not alter the interpretation of the effect.
- Time to eye opening: we excluded two studies with a high risk of attrition bias (Gan 1997; Morimoto 2002). This did not alter the interpretation of the effect.
- Time to orientation: no studies included in the primary analysis had an unclear or high risk of attrition bias.
- Time to discharge from the PACU: we excluded two studies with a high risk of attrition bias (Gan 1997; Morimoto 2002). This did not alter the interpretation of the effect.

### *Zero event data*

Analysis of the occurrence of intraoperative awareness included 22 studies with zero events in both arms. We evaluated alternative statistical tools and methods using the calculator in [Review Manager 14](#). We report the effect of these sensitivity analyses in [Appendix 7](#). Based on a fixed-effect model, using a RR with either Mantel-Haenszel or Inverse Variance did not alter the interpretation of the effect. Although we evaluated the effect using a random-effects model, this model is less appropriate for evidence of rare events (Higgins 2011). Based on a random-effects model, we found a more conservative estimate which indicated no evidence of a difference in intraoperative awareness when the Mantel-Haenszel method was used (RR 0.32, 95% CI 0.10 to 1.01;  $I^2 = 62%$ ), and when the Inverse Variance method was used (RR 0.32, 95% CI 0.10 to 1.00;  $I^2 = 60%$ ).

## 2. BIS versus ETAG

### *Occurrence of intraoperative awareness*

Five studies measured and reported intraoperative awareness (Avidan 2008; Avidan 2011; Mashour 2012; Muralidhar 2008; Sudhakaran 2018). This surgical population included participants who were at high risk of intraoperative awareness (Avidan 2008; Avidan 2011), who were unselected (Mashour 2012), or for whom risk of awareness was not specified (Muralidhar 2008; Sudhakaran 2018).

Events were rare and only three of these studies included incidences of awareness. Of the three studies with event data, all used a structured Brice questionnaire to collect data on awareness, and all used an adjudication process to categorise incidences of awareness as possible or definite; we included in analysis data for definite awareness.

We found no evidence of a difference in incidences of intraoperative awareness according to whether anaesthesia was guided by BIS or by ETAG (Peto OR 1.13, 95% CI 0.56 to 2.26;  $I^2 = 37%$ ; 26,572 participants; low-certainty evidence; [Analysis 3.1](#)). We used GRADE to downgrade the certainty of the evidence by one level for imprecision; despite a large number of participants, events were very rare (one per 1000 in the intervention and the comparison group) and the confidence interval for this effect was wide. In addition, we downgraded by one level for study limitations owing to the inclusion of some studies with unclear and high risks of bias, and in all studies it was not possible to blind anaesthetists to the different methods of depth of anaesthesia monitoring leading to a high risk of performance bias throughout. See [Summary of findings 2](#).

### *Recovery time to eye opening*

No studies reported time to eye opening.

### *Recovery time to orientation*

No studies reported time to orientation.

### *Time to discharge from the PACU*

One study measured and reported time to discharge from the PACU (Mashour 2012). Study authors reported a reduction in readiness for discharge from the PACU when BIS-guided anaesthesia was used, with a median interquartile range (IQR) duration of 95 minutes (64 to 138 minutes) for participants having BIS-guided anaesthesia (6076 participants) compared to a median (IQR) duration of 98 minutes (66 to 140 minutes) for participants having ETAG-guided anaesthesia (9376 participants). We used GRADE to downgrade this evidence to low certainty. We downgraded by two levels for imprecision because the evidence was from one study in which the IQR of time spent in the PACU was wide in both groups.

### *Subgroup analysis*

We did not conduct subgroup analysis for the comparison BIS versus ETAG because we found too few studies in the primary analysis.

## Sensitivity analysis

### *Unclear or high risk of selection bias for sequence generation*

Occurrence of intraoperative awareness: all studies in the primary had a low risk of selection bias (Mashour 2012).

Time to discharge from the PACU: data for this outcome were from a single study which we judged to have a low risk of selection bias (Mashour 2012).

### *Unclear or high risk of attrition bias*

Occurrence of intraoperative awareness: we excluded one study with a high risk of attrition bias (Mashour 2012). This did not alter the interpretation of the effect.

Time to discharge from the PACU: data for this outcome was from a single study which we judged to have a high risk of attrition bias (Mashour 2012).

### *Zero event data*

Analysis of the occurrence of intraoperative awareness included two studies with zero events in both arms. We evaluated alternative statistical tools and methods using the calculator in [Review Manager 14](#). We report the effect of these sensitivity analyses in [Appendix 7](#). We found that alternative statistical tools did not alter the interpretation of the effect for this outcome.

## DISCUSSION

### Summary of main results

We found 52 studies that compared bispectral index (BIS)-guided anaesthesia with either clinical signs or end-tidal anaesthetic gas (ETAG). Studies included participants undergoing any type of surgery under general anaesthesia. Three studies included only participants who were at high risk of intraoperative awareness, and two studies included only unselected participants. Whilst some studies included participants who had one or more factor that may increase the risk of intraoperative awareness (according to [NAP5 2014](#)), we did not categorise these studies as at high risk of intraoperative awareness.

We included two comparison groups in the review: BIS-guided anaesthesia compared with anaesthesia guided by clinical signs, and BIS-guided anaesthesia compared with anaesthesia guided by ETAG.

We found low-certainty evidence that BIS-guided anaesthesia compared to clinical signs may reduce the incidence of intraoperative awareness. However, incidences of awareness were rare. Incidences, when BIS was used, were only six per 1000 fewer than in the clinical signs group. We found low-certainty evidence that early recovery times may be reduced when BIS was used; the time to eye opening, to orientation, and to discharge from the PACU was shorter for all studies in which BIS was used.

For BIS-guided anaesthesia compared to ETAG-guided anaesthesia, we found no evidence of a difference in the incidence of intraoperative awareness. Again, we found few incidences of intraoperative awareness (1 per 1000 in both groups) and we judged this evidence to be low certainty. Only one study in which BIS was compared with ETAG-guided anaesthesia measured the time to discharge from the PACU, and this study reported median values

which showed a reduction in time to discharge from the PACU for BIS-guided anaesthesia (low-certainty evidence). No studies comparing BIS- to ETAG-guided anaesthesia measured or reported the time to eye opening and the time to orientation.

### Overall completeness and applicability of evidence

We identified 52 studies with 41,331 participants. All participants were undergoing surgery under general anaesthesia. Most studies did not specify whether participants were selected according to their risk of intraoperative awareness, and we noted that some characteristics of included participants and the methods used in their anaesthesia indicated at least one risk factor for awareness. These factors, identified in the most recent NAP5 audit ([NAP5 2014](#)), included female gender, obesity, type of surgery (obstetric, cardiac, thoracic, neurosurgery), and the use of neuromuscular blockade. Whilst experience of the anaesthetist may be relevant to the risk of intraoperative awareness, we found that this was poorly reported in studies, and no studies reported that attending anaesthetists in the trials had a junior level of experience.

Most studies compared BIS with clinical signs to monitor the depth of anaesthesia with only six studies comparing BIS with ETAG.

We attempted to account for differences between studies in terms of the type surgery by using a random-effects model in the analysis of the recovery time points. However, we noted a moderate to substantial statistical heterogeneity in most of our primary analyses. We expected that this was inevitable because of the broad inclusion criteria regarding type of surgery. These differences in surgery type may increase the duration of general anaesthesia and the subsequent recovery times, and we believed that this statistical heterogeneity was unavoidable in the review.

### Quality of the evidence

We used GRADE to downgrade the certainty of the evidence for all outcomes in this review to low. Whilst we found a large number of studies that compared BIS with anaesthesia guided by clinical signs, incidences of intraoperative awareness were so infrequent with most studies reporting no events in either group. We reported the effect estimate as Peto odds ratio (OR) which accounted for rare events, but when we used alternative statistical methods using random-effects models, we found more conservative estimates, thus we believed the evidence was imprecise. Similarly, although evidence comparing BIS to ETAG, included a larger number of participants, events were from only three studies and were infrequent.

We also used GRADE to downgrade the certainty of the evidence owing to study limitations. We used the 'Risk of bias' tool to assess some studies as having an unclear risk of bias, often because these studies reported no information on which to base a confident judgement. This study design prohibits blinding of the attending anaesthetists and therefore, we judged all studies to have a high risk of performance bias. We expected that some anaesthetists who were assigned a BIS monitor may continue to base their judgements of a patient's depth of anaesthesia on standard clinical practices rather than BIS, or that they may alter their standard anaesthetic practice in other ways when using the BIS monitor.

We also noted that intraoperative awareness was often not clearly defined in studies and without a precise definition we could not be certain that the incidences (or lack of incidences) were comparable

in the analyses. Similarly, the time points at which intraoperative awareness was measured (for example in the postanesthesia care unit (PACU), or on the first, second, or third postoperative day, or up to 30 days postoperatively) were not comparable, nor the methods of data collection (for example, using a simple question or using a recognised data collection tool such as the Brice questionnaire, and whether reports of awareness were evaluated for being possible or definite).

### Potential biases in the review process

We conducted a thorough search in the update and used two review authors to assess study eligibility, extract data, and assess risk of bias in included studies; therefore, we reduced potential bias in the review process.

In updating this review, we made minor changes to the review inclusion criteria. We decided to exclude studies that did not aim to address our review question. As a result of this decision, we excluded five previously included studies. As these five studies, and other similar studies identified during the search, did not address our review aims, it was not expected that this decision affected data for the relevant outcomes in the review. In addition, we re-evaluated the previous review outcomes. In order to improve the focus of the review, we reduced the number of outcomes and included only those that measured the success of anaesthesia in terms of a reduction in the risk of intraoperative awareness and an optimum early recovery; for usability, we selected only three measures of recovery (time to eye opening, time to orientation, and time to discharge from the PACU). The decision to reduce the number of outcomes may introduce bias into the review process, however, we believed that this decision improved the usability of the review.

In addition, we were unable to source all texts from current British Library sources, and we did not seek translation of some studies, and therefore the review includes six studies awaiting classification. We could not be certain whether these studies included relevant data for the review.

For the primary outcome (the occurrence of intraoperative awareness), we found many studies with zero events in both arms. We limited the choice of appropriate meta-analytic tools to those available in [Review Manager 14](#), and used Peto OR in the primary analysis. We conducted sensitivity analysis using alternative statistical methods in [Review Manager 14](#). Alternative methods, such as Bayesian meta-analysis, may offer a more robust method to account for rare events as well as studies with zero events in both arms ([Cheng 2016](#)).

### Agreements and disagreements with other studies or reviews

A recent meta-analysis conducted by Gao and colleagues ([Gao 2018](#)), combined data from the five largest studies in this review ([Avidan 2008](#); [Avidan 2011](#); [Mashour 2012](#); [Myles 2004](#); [Zhang 2011](#)). Whilst their findings demonstrated that intraoperative awareness did not appear to be associated with BIS monitoring, this result combined studies of both ETAG- and clinical signs-guided comparison groups. Similarly, the Cochrane Review by Messina and colleagues also combined both comparison groups ([Messina 2016](#)). We noted that [Messina 2016](#) gave greater emphasis to the definition of different types of awareness, and the methods by

which data were collected. As we had not specified this criteria, and the primary outcome in our review was for a broader criteria for intraoperative awareness, we subsequently included more small studies in the analysis. We do not think that the result in [Messina 2016](#) is comparable with our own findings.

In relation to recovery measures, our findings are consistent with other systematic reviews which indicate that anaesthesia guided by BIS monitoring improves early postoperative recovery with a shorter time to eye opening and to orientation demonstrated in [Chiang 2018](#) and [Oliveira 2017](#), and a reduced time in the PACU for participants undergoing ambulatory surgery in [Liu 2004](#).

## AUTHORS' CONCLUSIONS

### Implications for practice

BIS-guided anaesthesia may reduce the risk of intraoperative awareness in surgical patients at high risk or unselected for risk of awareness compared to using clinical signs as the guide for anaesthetic depth. Bispectral index (BIS)-guided anaesthesia may also reduce early recovery parameters of the time to eye opening, the time to orientation, and the time to discharge from the postanesthesia care unit (PACU). We found no evidence to indicate whether BIS-guided or end-tidal anaesthetic gas (ETAG)-guided anaesthesia affected the incidence of intraoperative awareness, and evidence from only one study comparing BIS with ETAG that indicated a shorter length of stay in the PACU with BIS-guided anaesthesia. However, we considered the certainty of evidence to be low for each of these outcomes.

### Implications for research

Despite some large multi-centre studies included in this review, the incidences of awareness are so infrequent that imprecision is inevitable. We hope that future research will continue to contribute evidence towards the evaluation of the effectiveness of BIS-monitoring to reduce incidences of intraoperative awareness. We would recommend future studies to consider the need to report clearly their definition of awareness, and to use measurement tools such as the Brice questionnaire with appropriate adjudication of whether reports of intraoperative awareness are possible or definite.

## ACKNOWLEDGEMENTS

For acknowledgements in previous versions of the review, see [Punjasawadwong 2007](#) and [Punjasawadwong 2014](#).

For this 2019 update, we would like to thank Lars H Lundström (Content Editor), Jing Xie (Statistical Editor), Michel Struys and Paul S Myles (Peer Reviewers), Stephana Cherak (Consumer Referee), Janne Vendt (Information Specialist) Jane Cracknell and Teo Quay (Managing Editors), and Andrew Smith (Co-ordinating Editor) for their help and editorial advice during the preparation of this systematic review

We would like to thank review authors for their contributions to previous versions of the review (Aram Phongchiewboon and Nuchanart Bunchungmongkoi). We would like to thank study authors who provided additional information on their studies (Dr Jan Jakobsson, Dr Tong J Gan, and Dr Paul Manberg). We would like to thank people who supported the review by searching databases or establishing search strategy terms in the previous versions of

the review (Denna N Braaksma, Ms Chompunuch Boonyawan, Anupa Shah, and Karen Hovhannisyan). We would like to thank people who provided comment on or translation of studies in the previous versions of the review (Valeria Salerno, Dr Andrea Casati, Dr Sandro Salzano, Prof Martha Delgado, Dr Cesar Carcamo, Dr Idoris Cordero, Ivan Sola, Dr Tomoki Hashimoto, Dr Simonia Vecchi). For the review published in 2007, we would like to thank

Dr Mathew Zacharias (Content Editor), Prof Nathan Pace (Statistical Editor), Dr Michel Struys and Dr Chris Pomfrett (Peer Reviewers), Dr Janet Wale (Consumer Editor), and Jane Cracknell for co-ordinating the updated review. For the review published in 2014, We would like to thank Dr Stephan C Kettner and Dr Mathew Zacharias (Content Editors), Dr Cathal Walsh (Statistical Editor), Dr Melissa Giraldo-Duque, Dr Maurizio Solca and Dr Paul Myles (Peer Reviewers).

**CHARACTERISTICS OF STUDIES**
**Characteristics of included studies [ordered by study ID]**
**Ahmad 2003**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 99</p> <p><b>Country:</b> USA</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> undergoing gynaecological laparoscopy; with written informed consent</p> <p><b>Exclusion criteria:</b> not reported</p> <p><b>Type of surgery:</b> gynaecologic laparoscopy</p> <p><b>Baseline characteristics</b></p>

**Ahmad 2003** (Continued)

**Intervention group** (BIS)

- Age, mean (SD): 35.6 ( $\pm$  8.7) years
- Weight, mean (SD): 61.2 ( $\pm$  10.5) kg
- Height, mean (SD): 164.3 ( $\pm$  5.8) cm
- ASA status I/II: 25/24
- Duration of surgery, mean (SD): 69 ( $\pm$  37) minutes

**Comparison group** (clinical signs)

- Age, mean (SD): 35.4 ( $\pm$  8.9) years
- Weight, mean (SD): 68.4 ( $\pm$  12.61) kg
- Height, mean (SD): 165.6 ( $\pm$  6.6) cm
- ASA status I/II: 28/2
- Duration of surgery, mean (SD): 67 ( $\pm$  36) minutes

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 49; losses = 0; analysed, n = 49</li> <li>• Details: induction with sevoflurane and oxygen. Sevoflurane guided by BIS (target value of 50 to 60). After removal of laparoscope from the abdomen, nitrous oxide was added to help maintain BIS value &lt; 60.</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 48; losses = 0; analysed, n = 48</li> <li>• Details: sevoflurane inhalation guided by BP and HR within 20% baseline values. After removal of laparoscope from the abdomen, nitrous oxide was added if BP or HR increased to &gt; 20% baseline values.</li> </ul> <p>Both groups: neuromuscular blocking agents to facilitate tracheal intubation and intraoperative paralysis in all participants; type of agent and dose, plus agents for reversal, was at discretion of attending anaesthetist. Sufentanil administered before induction, and given in supplemental doses for BP or HR increases &gt; 20% despite BIS value of 50 to 60 or end-tidal sevoflurane concentration of 2%. Dexmethasone given after induction as an antiemetic. Thirty minutes before end of surgery, metochlorpropamide and ephedrine were given as additional antiemetics, and ketorolac for opiate-sparing analgesia</p>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> successful fast track rate (using modified Aldrete Score, main outcome); mean concentration of sevoflurane (%); mean dose of sufentanil; mean dose of rocuronium; mean duration of phase II recovery room stay (time to discharge); pain in phase II recovery area; nausea/vomiting in phase II recovery area</p> <p><b>Outcomes relevant to the review:</b> none</p>
Notes	<p><b>Funding/declarations of interest:</b> supported in part by Aspect Medical Systems, USA</p> <p><b>Study dates:</b> not specified</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• we did not conduct 'Risk of bias' assessment because study authors reported no outcomes relevant to the review</li> </ul>

**Alimian 2016**
**Study characteristics**

Methods	RCT, parallel design
---------	----------------------

**Alimian 2016** (Continued)

Participants

**Total number of randomized participants:** 80

**Country:** Iran

**Setting:** hospital; single centre

**Inclusion criteria:** 15 to 53 years of age; scheduled for laparoscopic surgery in women's field; ASA I or II

**Exclusion criteria:** < 18 years old; history of COPD; kidney dysfunction with creatinine > 2 mg/dL or liver dysfunction; neurological diseases; difficult airway (by direct laryngoscopy or fiberoptic); history of analgesics, anticonvulsants and antidepressants; untreated hypertension; heart failure; drug allergy; undergoing emergency surgery

**Type of surgery:** laparoscopic gynaecology

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 32.37 ( $\pm$  9.07) years
- Duration of surgery, mean (SD): 128.23 ( $\pm$  54.42) minutes

Comparison group (clinical signs)

- Age, mean (SD): 30.86 ( $\pm$  8.49) years
- Duration of surgery, mean (SD): 134.34 ( $\pm$  57.82) minutes

Interventions

Intervention group (BIS)

- Randomized, n = 40; losses, n = 0; analysed, n = 40
- Details: propofol guided by BIS (Aspect Medical Systems Inc, USA), target values 45 to 60; propofol increased or decreased by 10% to keep BIS within target range. If increased BP despite increases in dose of propofol or additional fentanyl, TNG was used.

Comparison group (clinical signs)

- Randomized, n = 40; losses, n = 0; analysed, n = 40
- Details: 20% increase to propofol dosage for an increase of 20% in BP and HR, or in case of unresponsiveness fentanyl was given. If BP did not decrease TNG infusion started. If BP decreased up to 20% from baseline values, 20% to 30% of propofol was decreased.

Both groups: premedication with fentanyl and midazolam. Induction with propofol and cisatracurium. Then propofol and cisatracurium every 30 minutes and fentanyl every 40 minutes. Reversal with neostigmine and atropine.

Outcomes

**Outcomes measured/reported by study authors:** time to discharge from recovery; nausea and vomiting; pain in recovery

**Outcomes relevant to the review:** time to discharge from recovery

Notes

**Funding/declarations of interest:** funded by Research Deputy of Iran University of Medical Sciences

**Study dates:** March 2015 to October 2015

**Risk of bias**
**Bias**
**Authors' judgement**
**Support for judgement**

Random sequence generation (selection bias)

Unclear risk

Described as "triple-blinded randomized trial". However, method used to randomize participants to group is not described.

**Alimian 2016** (Continued)

Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Retrospectively registered with clinical trials register (IRCT2015122919715N2). It is not feasible to use this registration document to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Anez 2001**
**Study characteristics**

Methods	Quasi-randomized trial, parallel design
Participants	<p><b>Total number of randomized participants:</b> 40</p> <p><b>Country:</b> Spain</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> ASA status I or II; scheduled for general, vascular, or orthopaedic surgery under GA</p> <p><b>Exclusion criteria:</b> using psychotropic medication; contraindications to medications used in the study, to use of an LMA, or for whom GA is not indicated; ASA status &gt; II</p> <p><b>Type of surgery:</b> vascular (venous) or orthopaedic outpatient surgery</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 38.10 (<math>\pm</math> 14.07) years</li> <li>• Weight, mean (SD): 72.20 (<math>\pm</math> 16.73) kg</li> <li>• Height, mean (SD): 161.85 (<math>\pm</math> 9.32) cm</li> <li>• Duration of surgery, mean (SD): 43.90 (<math>\pm</math> 15.36) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 43.05 (<math>\pm</math> 15.27) years</li> <li>• Weight, mean (SD): 72.21 (<math>\pm</math> 13.96) kg</li> <li>• Height, mean (SD): 163.72 (<math>\pm</math> 10.45) cm</li> <li>• Duration of surgery, mean (SD): 39.16 (<math>\pm</math> 12.64) minutes</li> </ul>
Interventions	Intervention group (BIS)

**Bispectral index for improving intraoperative awareness and early postoperative recovery in adults (Review)**

**Anez 2001** (Continued)

- Randomized, n = 20; losses = 0; analysed, n = 20
- Details: propofol TCI guided by BIS (BIS A-2000 Aspect) target values of 40 to 60

Comparison group (clinical signs)

- Randomized, n = 20; losses = 1 (due to protocol violation); analysed, n = 19
- Details: propofol administration guided by clinical signs (loss of reflexes, and haemodynamic responses)

Both groups: premedication with midazolam. Atropine, alfentanil, propofol, rocuronium. Use of LMA.

Outcomes	<p><b>Outcomes measured/reported by study authors:</b> intraoperative awareness (assessed after full recovery from anaesthetic); propofol consumption; recovery (time to eye opening; time in the recovery room)</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness, time to eye opening</p>
Notes	<p><b>Funding/declarations of interest:</b> not reported</p> <p><b>Study dates:</b> not reported</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	The study used sequential randomization (quasi-randomization). The rationale for this 'sequence' was to avoid any contamination or influence of the 'BIS guided anaesthesia' on the 'standard anaesthesia' administered subsequently
Allocation concealment (selection bias)	High risk	Investigators did not conceal allocation
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are blinded to allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss of only one participant
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or published protocol. It is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Arbabpour 2015**
**Study characteristics**

Methods	RCT, parallel design
Participants	<b>Total number of randomized participants: 68</b>

**Bispectral index for improving intraoperative awareness and early postoperative recovery in adults (Review)**

**Arbabpour 2015** (Continued)

**Country:** Iran

**Setting:** hospital; single centre

**Inclusion criteria:** women undergoing caesarean section

**Exclusion criteria:** not specified in English abstract

**Type of surgery:** caesarean section

**Baseline characteristics not reported in English abstract**

Interventions	Intervention group (BIS) <ul style="list-style-type: none"> <li>• Randomized, n = 34; losses, n = unknown; analysed, n = unknown</li> <li>• Details: anaesthesia maintained using BIS, target values 40 to 60</li> </ul> Comparison group (clinical signs) <ul style="list-style-type: none"> <li>• Randomized, n = 34; losses, n = unknown; analysed, n = unknown</li> <li>• Details: anaesthesia maintained using haemodynamic variables</li> </ul>
Outcomes	<b>Outcomes measured/ reported by study authors:</b> record times (time to extubation, time to discharge from recovery unit); complications during recovery  <b>Outcomes relevant to the review:</b> time to discharge from the PACU (see note below)
Notes	<b>Funding/declarations of interest:</b> not reported in English abstract  <b>Study dates:</b> not reported in English abstract  <b>Notes:</b> <ul style="list-style-type: none"> <li>• study is in Persian, and we did not seek translation. We have taken information only from the English abstract</li> <li>• we were unable to include data in analysis because the number of analysed participants was not reported in the abstract</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Participants are randomly assigned; no additional details in English abstract
Allocation concealment (selection bias)	Unclear risk	Not specified in English abstract
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	It is unclear from the English abstract whether all participants were accounted for in analysis

**Arbabpour 2015** (Continued)

Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or published protocol. It is not feasible to effectively assess risk of reporting bias
Other bias	Unclear risk	We did not seek full translation of this study report, and we could not be certain whether the study included other sources of bias

**Assare 2002**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 40</p> <p><b>Country:</b> Sweden</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> ASA I or II; scheduled for elective knee arthroscopy; informed consent</p> <p><b>Exclusion criteria:</b> not reported</p> <p><b>Type of surgery:</b> elective arthroscopy (ambulatory surgery)</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 45 (<math>\pm</math> 14) years</li> <li>Weight, mean (SD): 77 (<math>\pm</math> 19) kg</li> <li>Duration of anaesthesia, mean (SD): 15 (<math>\pm</math> 5.0) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 44 (<math>\pm</math> 11) years</li> <li>Weight, mean (SD): 82 (<math>\pm</math> 12) kg</li> <li>Duration of anaesthesia, mean (SD): 17 (<math>\pm</math> 4.8) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Randomized, n = 20; losses = 0; analysed, n = 20</li> <li>Details: sevoflurane inhalation guided by BIS (Aspect 2000, BIS Algorithm 3.4, USA), target value of 60</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>Randomized, n = 20; losses = 0; analysed, n = 20</li> <li>Details: sevoflurane inhalation guided by routine clinical signs</li> </ul> <p>Both groups: premedication with cyclizine. Induction with fentanyl and propofol according to clinical need. Muscle relaxants were not used and LMA placed in all participants. For maintenance sevoflurane was combined with oxygen in nitrous oxide. Lidocaine prior to incision and with adrenaline at the start of surgery, and with fentanyl at the end of surgery. All participants were given paracetamol and lornoxicam for postoperative analgesia.</p>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> sevoflurane consumption; recovery (time to removal of laryngeal mask; time to state birth and name; time to readiness to discharge); fentanyl consumption; rescue analgesics; PONV; intraoperative awareness (postoperative interview; details of interview structure or time not reported)</p>

**Assare 2002** (Continued)

**Outcomes relevant to the Review:** intraoperative awareness; time to readiness to discharge

Notes

**Funding/declarations of interest:** not reported

**Study dates:** not reported

**Notes:**

- study authors included an additional study group (auditory evoked potential) which we did not include in the review

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not specified
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or publication of a protocol and it was not feasible to assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Avidan 2008**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 2000</p> <p><b>Country:</b> USA</p> <p><b>Setting:</b> single centre</p> <p><b>Inclusion criteria:</b> ≥ 18 years of age; scheduled for surgery under GA with isoflurane, sevoflurane or desflurane; at high risk of intraoperative awareness with at least one criterion (preoperative long-term use of anticonvulsant agents, opiates, benzodiazepines, or cocaine; cardiac ejection fraction &lt; 40%; history of anaesthesia awareness; history of difficult intubation or anticipated difficult intubation; ASA status IV or V; aortic stenosis; end-stage lung disease; marginal exercise tolerance not resulting from musculoskeletal dysfunction; pulmonary hypertension; planned open-heart surgery; daily alcohol consumption) or two minor criteria (preoperative use of beta-blockers; COPD; moderate exercise tolerance)</p>

**Avidan 2008** (Continued)

not resulting from musculoskeletal dysfunction; smoking  $\geq 2$  packs of cigarettes per day; obesity defined as BMI  $> 30$  kg/m<sup>2</sup>)

**Exclusion criteria:** the surgical procedure or positioning of the participant prevented BIS monitoring or if the surgery required a wake-up test; dementia: unable to provide informed consent; history of stroke with residual neurological deficits

**Risk of awareness:** participants at high risk for this complication (see inclusion criteria)

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 59.5 ( $\pm$  14.8) years
- Gender, M/F: 516/ 451
- Weight, mean (SD): 87.7 ( $\pm$  25.9) kg
- ASA status I/II/III/IV (out of 962 patients): 21/265/454/222

Comparison group (ETAG)

- Age, mean (SD): 59.2 ( $\pm$  14.6) years
- Gender, M/F: 523/451
- Weight, mean (SD): 87.4 ( $\pm$  26.7) kg
- ASA status I/II/III/IV (out of 972 patients): 15/252/503/202

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 1000; losses = 33 (9 had technical difficulties, 12 cancelled surgery, 8 received sedation only, 2 received total IV anaesthesia, 2 received spinal anaesthesia only) ; analysed, n = 967</li> <li>• Details: BIS guided anaesthesia (BIS Quattro Sensor, Aspect Medical Systems, USA), target value of 40 to 60, and use of an audible alarm. Anaesthesia was sevoflurane, desflurane, or isoflurane.</li> <li>• ETAG concentrations could be viewed</li> </ul> <p>Comparison group (ETAG)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 1000; losses = 26 (4 had technical difficulties, 9 cancelled surgery, 6 received only sedation, 3 received total IV anaesthesia, 4 received spinal anaesthesia only); analysed, n = 974</li> <li>• Details: anaesthesia guided by end tidal anaesthetic gas (ETAG) concentrations, with audible alarm set between 0.7 MAC and 1.3 MAC</li> </ul>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> definite intraoperative awareness and possible intraoperative awareness (assessed using Brice questionnaire at 3 time points: 24 hours after anaesthesia; between 24 hours and 72 hours; and 30 days); BIS values; ETAG concentrations</p> <p><b>Outcomes relevant to the review:</b> definite intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> study authors report that manufacturer of the BIS monitor (Aspect Medical Systems) had no role in the study design, data collection, data analysis, or manuscript preparation. No study monitors or other means of support were provided by Aspect Medical Systems. Supported by a grant from the Barnes-Jewish Hospital Foundation (to Dr. Avidan)</p> <p><b>Study dates:</b> September 2005 to October 2006.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• 1754 patients completed all three interviews, 133 patients only completed two interviews, 18 patients only completed one interview</li> <li>• this study is also known as the B-Unaware study</li> </ul>

**Risk of bias**

**Avidan 2008** (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "2000 patients underwent prerandomization electronically in blocks of 100, with 50 patients assigned to a BIS-guided protocol and 50 to an ETAG-guided protocol."
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "The anaesthesia practitioners were aware of the assignments of the patients, but the patients, the postoperative interviewers, the expert reviewers, and the statistician were not."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "The anaesthesia practitioners were aware of the assignments of the patients, but the patients, the postoperative interviewers, the expert reviewers, and the statistician were not."
Incomplete outcome data (attrition bias) All outcomes	Low risk	We noted 59 losses, but these were relatively balanced between groups, and amounted to a loss of fewer than 10%. ITT analysis was planned
Selective reporting (reporting bias)	Unclear risk	Retrospectively registered on clinical trials register (NCT00281489). It is not feasible to assess the risk of reporting bias from these reports. In addition, we noted a retrospectively published protocol (Avidan 2009)
Other bias	Unclear risk	All patients classed as high risk although a significant difference was noted between the amount of patients with a neurological pre-existing medical condition in the ETAG group and the BIS group.

Signs of inadequate anaesthesia managed by increasing concentration of sevoflurane.</p>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> mean sevoflurane exposure (aged-adjusted MAC); amount of sevoflurane used; immediate recovery times (time to open eyes on verbal command; time to motor respond to verbal command); Aldrete score at 10 minutes: bradycardia; hypotension or hypertension requiring treatment</p> <p><b>Outcomes relevant to the review:</b> time to eye opening</p>
Notes	<p><b>Funding/declarations of interest:</b> not reported</p> <p><b>Study dates:</b> not reported</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Insufficient information about the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

## Boztuğ 2006

### Study characteristics

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 50</p> <p><b>Country:</b> Turkey</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> 18 to 75 years of age; ASA I or II patients undergoing craniotomy.</p> <p><b>Exclusion criteria:</b> any medication interaction with the central nervous system (antidepressant drugs, anti-seizure drugs) or cardiopulmonary system (antihypertensive drugs, beta blockers); or a need for postoperative ventilation or other psychotropic drugs</p> <p><b>Type of surgery:</b> supratentorial craniotomy</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 45 (<math>\pm</math> 11) years</li> <li>• Gender, M/F: 13/11</li> <li>• Weight, mean (SD): 71 (<math>\pm</math> 8) kg</li> <li>• Duration of anaesthesia, mean (SD): 239 (<math>\pm</math> 30) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 50 (<math>\pm</math> 10) years</li> <li>• Gender, M/F: 11/12</li> <li>• Weight, mean (SD): 67 (<math>\pm</math> 12) kg</li> <li>• Duration of anaesthesia, mean (SD): 222 (<math>\pm</math> 32) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 25; losses = 1; analysed, n = 24</li> <li>• Details: sevoflurane guided by BIS (A-2000 EEG monitor, Aspect Medical Systems Inc, USA), target values of 40 to 60 during maintenance, and values of 60 to 70 during the last 15 minutes of surgery. If BIS value rose to 55, additional fentanyl was given.</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 25; losses = 2; analysed, n = 23</li> <li>• Details: sevoflurane inhalation guided by clinical signs (BP and HR, somatic response). If MAP increased by 20% of baseline, fentanyl was administered. For inadequate decreases in haemodynamic values, sevoflurane concentration increased by 20%</li> </ul> <p>Both groups: premedication with midazolam. Induction with thiopental and fentanyl, followed by cisatracurium to facilitate intubation. Maintenance with sevoflurane 0.8% to 1.5% with mix of oxygen/air (50%/50%). Cisatracurium administered if needed.</p>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> average end tidal concentrations of sevoflurane; recovery times (from end of surgery to first spontaneous breathing; from end of surgery to eye opening; from end of surgery to extubation; time to reach Aldrete score of 9 or 10; PACU stay); haemodynamic variables</p> <p><b>Outcomes relevant to the review:</b> duration of PACU stay</p>

**Boztuğ 2006** (Continued)

Notes

**Funding/declarations of interest:** supported by the Akdeniz University Faculty of Medicine Research Application Center

**Study dates:** not reported

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	A computer-generated sequence of number was used
Allocation concealment (selection bias)	Unclear risk	A sealed envelope technique was used; insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors did not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "3 patients were excluded from the study due to disconnection of BIS probe (2) or artefact contamination (1)." Study authors do not report missing outcome data is managed, or to which group the missing participants belonged, however number of losses is < 10%
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or published protocol. It is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Bresil 2013**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 70</p> <p><b>Country:</b> Denmark</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> both genders; ASA I and II; 1 to 65 years of age (see note below); undergoing elective ENT surgery (tonsillectomy, adenotomy, myringotomy, laryngoscopy, bronchoscopy and oesophagoscopy, myringo-tympanoplasty)</p> <p><b>Exclusion criteria:</b> patient refusal; presence of psychiatric conditions; use of psychopharmacological, antiepileptic or anti-arrhythmic medication; chronic use of opioids; intake of &gt; 21 units of alcohol per week</p> <p><b>Type of surgery:</b> elective ENT</p> <p><b>Baseline characteristics</b></p>

**Bresil 2013** (Continued)

## Intervention group (BIS)

- Weight, mean (SD): 75 ( $\pm$  15) kg
- Height, mean (SD): 172 ( $\pm$  9) cm
- Duration of anaesthesia, mean (SD): 47 ( $\pm$  30) minutes

## Comparison group (clinical signs):

- Weight, mean (SD): 77 ( $\pm$  14) kg
- Height, mean (SD): 173 ( $\pm$  10) cm
- Duration of anaesthesia, mean (SD): 50 ( $\pm$  47) minutes

## Interventions

## Intervention group (BIS):

- Randomized, n = 35; losses, n = 7 (5 received fentanyl at end of surgery; 2 were > 65 years of age); analysed (per protocol), n = 28; analysed (ITT), n = 35
- Details: propofol maintenance with BIS (Covidien, USA), target values 45 to 60, with clinicians also using clinical signs as a guide.

## Comparison group (clinical signs):

- Randomized, n = 35; losses, n = 5 (3 received fentanyl of ketobemidone at end of surgery; 2 were > 65 years of age); analysed (per protocol), n = 30; analysed (ITT), = 35
- Details: TIVA with infusion rates guided by clinical judgement. BIS monitor was not visible to anaesthetist.

Both groups: no muscle relaxants, gas anaesthetic or premedication with benzodiazepine was used. Induction with remifentanyl and propofol. Lidocaine used during laryngoscopy. Maintenance with propofol, remifentanyl.

## Outcomes

**Outcomes measured/ reported by study authors:** time to extubation; volumes of propofol and remifentanyl; hypotension, bradycardia; haemodynamic variables

**Outcomes relevant to the review:** none

## Notes

**Funding/declarations of interest:** department funding only. Study authors report no conflicts of interest

**Study dates:** January 2010 to March 2012

**Notes:**

- study included participants of all ages. However, study authors reported data separately by age group. We have included data only for participants aged 18 to 65 years of age
- study terminated early because investigators were employed in another department and not able to recruit participants
- we did not conduct 'Risk of bias' assessment because study authors reported no outcomes relevant to the review
- study is registered with clinical trial register (NCT01043952)

**Bruhn 2005**
**Study characteristics**

## Methods

RCT, parallel design

## Participants

**Total number of randomized participants:** 142

**Bruhn 2005** (Continued)

**Country:** Germany

**Setting:** multi-centre; 4 university anaesthesia departments.

**Inclusion criteria:** 18 to 80 years of age; written informed consent; undergoing minor surgery expected to last  $\geq 1$  hour

**Exclusion criteria:** a history of any disabling central nervous or cerebrovascular diseases; hypersensitivity to opioids or substance abuse; a treatment with opioids or any psychoactive medication

**Type of surgery:** minor surgery expected to last  $\geq 1$  hour

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 46.3 ( $\pm$  13.0) years
- Weight, mean (SD): 76.1 ( $\pm$  19.0) kg
- Height, mean (SD): 170.8 ( $\pm$  15.2) cm
- ASA status I/II/III: 32/38/1
- Duration of anaesthesia, mean (SD): 122.2 ( $\pm$  62.2) minutes
- Duration of surgery, mean (SD): 85.1 ( $\pm$  53.6) minutes

Comparison group (clinical signs)

- Age, mean (SD): 48.6 ( $\pm$  14.5) years
- Weight, mean (SD): 77.7 ( $\pm$  17.8) kg
- Height, mean (SD): 168.1 ( $\pm$  12.9) cm
- ASA status I/II/III: 22/45/4
- Duration of anaesthesia, mean (SD): 120.4 ( $\pm$  55.4) minutes
- Duration of surgery, mean (SD): 83.9 ( $\pm$  47.6) minutes

**Interventions**

Intervention group (BIS)

- Randomized, n = 71; losses = 0; analysed, n = 71
- Details: desflurane guided by BIS (A-2000 BIS monitor, XP sensor, Aspect Medical Systems, USA), target value of 50 during maintenance and of 60 during the last 15 minutes of surgery. If anaesthesia judged inadequate despite the BIS values, remifentanyl could be increased. Hypotension treated with IV fluid replacement, desflurane concentration reduced or IV vasopressor given at a dose chosen by the investigator. Bradycardia treated with atropine.

Comparison group (clinical signs)

- Randomized, n = 71; losses = 0; analysed, n = 71
- Details: desflurane guided by standard clinical signs. If inadequate anaesthesia, desflurane concentration was increased in steps of 0.5 vol% as necessary, then increase in remifentanyl. Hypotension and bradycardia treated as for BIS group

Both groups: premedication with midazolam. Induction with remifentanyl and propofol, cisatracurium for tracheal intubation. Maintenance with remifentanyl and desflurane. No neuromuscular blocking agents were given intraoperatively.

**Outcomes**

**Outcomes measured/reported by study authors:**

Desflurane consumption (end tidal concentrations); recovery times (time to open eyes; time to be extubated; time to stating name; time to arrive in PACU; time to discharge from the PACU); occurrence of intraoperative recall (interviewed on POD1 and POD3)

**Outcomes relevant to the review:** intraoperative awareness; time to discharge from the PACU

**Notes**

**Funding/declarations of interest:** supported by funding from Baxter, Inc., Germany

**Bruhn 2005** (Continued)

**Study dates:** not reported

**Note:**

- study included an additional group (AAI) which we did not include in the review

---

**Risk of bias**

---

Bias	Authors' judgement	Support for judgement

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "Recovery times were recorded by a blinded investigator."
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Ellerkmann 2010**

---

**Study characteristics**

---

Methods RCT, parallel design

Participants **Total number of randomized participants:** 60

**Country:** Germany

**Setting:** hospital; single centre

**Inclusion criteria:** 18 to 80 years of age; ASA status I to III; undergoing orthopaedic surgery expected to last  $\geq 1$  hour in which regional anaesthesia for intra- and postoperative pain control for surgery to the upper or lower extremity was used in combination with GA

**Exclusion criteria:** history of any disabling central nervous or cerebrovascular diseases; hypersensitivity to opioids or substance abuse; a treatment with opioids or any psychoactive medication

**Type of surgery:** minor orthopaedic surgery

**Experience of anaesthetist (in years or qualifications):** an experienced anaesthetist

**Baseline characteristics**

**Ellerkmann 2010** (Continued)

## Intervention group (BIS)

- Age, mean (SD): 50.6 ( $\pm$  15.7) years
- Gender, M/F: 9/18
- Weight, mean (SD): 82.4 ( $\pm$  15.7) kg
- Height, mean (SD): 171.5 ( $\pm$  9.7) cm
- ASA status I/II/III: 10/16/1
- Duration of anaesthesia, mean (SD): 100.0 ( $\pm$  30.7) minutes

## Comparison group (clinical signs)

- Age, mean (SD): 53.6 ( $\pm$  18.4) years
- Gender, M/F: 12/15
- Weight, mean (SD): 76.7 ( $\pm$  14.1) kg
- Height, mean (SD): 170/7 ( $\pm$  11.3) cm
- ASA status I/II/III: 10/10/7
- Duration of anaesthesia, mean (SD): 119.5 ( $\pm$  50.6) minutes

## Interventions

## Intervention group (BIS)

- Randomized, n = 30; losses = 3 (2 insufficient regional anaesthesia; 1 EEG data loss); analysed, n = 27
- Details: propofol infusion guided by BIS (A-2000 BIS monitor, Aspect Medical Systems Inc, USA), target value of 50. Hypotension treated with IV fluid replacement and finally IV vasopressor. Bradycardia treated with atropine. Additional bolus dose of propofol if sudden increase of BIS value > 65

## Comparison group (clinical signs)

- Randomized, n = 30; losses = 3 (2 insufficient regional anaesthesia; 1 EEG data loss); analysed, n = 27
- Details: propofol guided by clinical parameters (BP, HR, sweating, tear production, movement). If anaesthesia judged inadequate, propofol concentration was increased in steps as necessary. Hypotension was treated with IV fluid replacement, reduction in propofol and finally IV vasopressor. Bradycardia treated with atropine

Both groups: premedication with midazolam. Induction with remifentanyl and propofol. Cisatracurium for intubation. Maintenance with propofol and remifentanyl. No neuromuscular blocking agents were given intraoperatively. An additional bolus dose of propofol could be given in the presence of an unexpected somatic intraoperative response.

## Outcomes

**Outcomes measured/reported by study authors:** propofol consumption; remifentanyl consumption; recovery (time to eye opening; time to extubation; time to reach Aldrete scores); BIS values; intraoperative awareness (in recovery room; POD 1 and POD 3. NOTE: study authors do not report whether this was assessed using an interview, a questionnaire, or was voluntarily reported by participants)

**Outcomes relevant to the review:** intraoperative awareness; time to eye opening

## Notes

**Funding/declarations of interest:** not reported

**Study dates:** not reported

**Note:**

- study authors reported an additional study group (Entropy) which we did not include in the review

**Risk of bias**
**Bias**
**Authors' judgement**
**Support for judgement**

Random sequence generation (selection bias)

Low risk

Patients were randomized by drawing lots from a closed box

**Ellerkmann 2010** (Continued)

Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were aware of group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	Due to insufficient regional anaesthesia or EEG data loss, 3 participants in each of the BIS and standard practice groups had to be excluded from further investigation. Although this loss was 10% of participants, it was balanced between groups
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Fakhr 2014**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 68</p> <p><b>Country:</b> Iran</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> &gt; 60 years of age; ASA status I to III; scheduled for elective abdominal surgery; normal healthy patients with mild systemic disease or patients with severe systemic disease with no immediate danger of death</p> <p><b>Exclusion criteria:</b> people with psychotic disorders; dementia; previous cerebrovascular accident; head trauma; drug abuse</p> <p><b>Type of surgery:</b> abdominal surgery</p> <p><b>Baseline characteristics not reported.</b> Study authors report that there were quote: "no significant differences in age, sex, height, weight and physical status between the control and intervention groups"</p>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Randomized, n = unknown (see notes below); losses, n = unknown; analysed, n = unknown</li> <li>Details: inspiratory concentration of isoflurane increased to BIS level of 45 to 65. For hypertension or tachycardia, 50 µg IV fentanyl was given</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>Randomized, n = unknown (see notes below); losses, n = unknown; analysed, n = unknown</li> <li>Details: anaesthesia guided by blood pressure and heart rate. For hypertension or tachycardia, inspiratory concentration of isoflurane was increased or 50 µg IV fentanyl was given</li> </ul>

**Fakhr 2014** (Continued)

Both groups: induction with fentanyl, midazolam, propofol, and atracurium. Then isoflurane 1% or 2%, nitrous oxide, and oxygen. Neostigmine and atropine given at end of anaesthesia

Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> recovery times (time to extubation; time to orientation; time to transfer to PACU; time up to discharge from PACU); intraoperative awareness (on the following day; asked if any memory of the surgery room and its events; asked if they heard anything during surgery)</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness (not reported by study authors, see below); time to orientation (not reported); duration of time in PACU</p>
----------	---

**Funding/declarations of interest:** funded by the Research Council of Hamedan University of Medical Sciences. Study authors declare no conflicts of interest

**Study dates:** not reported

**Notes:**

- we unsuccessfully attempted to contact study authors to clarify the number of participants in each group and for data relating to intraoperative awareness and orientation.
- we did not include outcome data for this study in the review because we had no denominators for each group

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Block randomization used
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Assessments made by an anaesthetist who was not aware of group allocation
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Study report included the total number of randomized participants, but did not report how many were randomized to each group, and did not report number of analysed participants. Therefore, it was not possible to effectively assess risk of attrition bias
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Gan 1997**

**Gan 1997** (Continued)

Methods	RCT, multi-centre
Participants	<p><b>Total number of randomized participants:</b> 268</p> <p><b>Country:</b> USA</p> <p><b>Setting:</b> multi-centre; 4 institutions</p> <p><b>Inclusion criteria:</b> 18 to 80 years of age; ASA I to III; scheduled for general surgical procedures expected to last at least 1 hour.</p> <p><b>Exclusion criteria:</b> known neurological disorders; uncontrolled hypertension; baseline systolic BP &lt; 106 HR &lt; 55; other serious medical conditions that would interfere with cardiovascular response assessment.</p> <p><b>Type of surgery:</b> general surgical procedures ≥ 1 hour</p> <p><b>Experience of anaesthetist (in years or qualifications):</b> anaesthesia supervised by a faculty anaesthetist.</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, mean (range): 40 (37 to 43) years</li> <li>• Gender, M/F: 37/78</li> <li>• Weight (kg), mean (range): 80.0 (76.4 to 83.7) kg</li> <li>• ASA status I/II/III: 45/65/5</li> <li>• Duration of anaesthesia, mean (range): 108 (99 to 119) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Age, mean (range): 41 (39 to 43) years</li> <li>• Gender, M/F: 41/84</li> <li>• Weight (kg), mean (range): 77.5 (74.3 to 80.7) kg</li> <li>• ASA status I/II/III: 45/72/8</li> <li>• Duration of anaesthesia, mean (range): 125 (114 to 135) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = not reported; losses = not reported ; analysed, n =115</li> <li>• Details: propofol guided by BIS (A-100 EEG monitor, Aspect Medical Systems Inc.), target values of 45 to 60 during maintenance and 60 to 75 at the end of surgery. Inadequate anaesthesia or hypotension managed with increased or decreased alfentanil, respectively, if BIS was within the recommended range. Hypotension and bradycardia managed with appropriate dose reductions, adjustment to fluid states or other pharmacologic agents as needed.</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = not reported ; losses = not reported; analysed, n = 125</li> <li>• Details: propofol guided by clinical signs (increased blood pressure of greater than 20%, increased heart rate of greater than 90 beats per minutes and other somatic responses). Inadequate anaesthesia managed with increases in the doses of either alfentanil, propofol or an antihypertensive at the discretion of the anaesthetist. Hypotension and bradycardia managed with appropriate dose reductions, adjustment to fluid states or other pharmacologic agents as needed.</li> </ul> <p>Both groups: premedication with midazolam. Induction with propofol and alfentanil, then with 50% nitrous oxide. If necessary a neuromuscular blocking agent was given to facilitate tracheal intubation. After intubation or insertion of LMA, additional neuromuscular blocking agents only administered if surgically indicated.</p>

**Gan 1997** (Continued)

## Outcomes

**Outcomes measured/reported by study authors:** normalized propofol infusion rate ( $\mu\text{g}/\text{kg}/\text{hour}$ ); mean propofol used (mg); normalized alfentanil infusion rate ( $\mu\text{g}/\text{kg}/\text{min}$ ); time to open eyes (min); time to respond to command (minutes); time to be extubated; time to be eligible to discharge from the PACU; number of unwanted somatic and haemodynamic responses; intraoperative global assessment score; % of patients arrived fully oriented to the postanesthesia care unit (PACU); overall global nursing impression score

**Outcomes relevant to the review:** recovery (time to eye opening); time to be ready for discharge from the PACU

## Notes

**Funding/declarations of interest:** sponsored in part by a grant from Aspect Medical Systems (MS, USA). Some study authors received fees from Aspect Medical Systems

**Study dates:** not reported

**Notes:**

- study authors did not report number of participants randomized to each group, and did not report to which group participant losses were from; 28 participants were excluded because of protocol violations

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "The sequence of treatments was determined in blocks of 10 using a random number generator."
Allocation concealment (selection bias)	Low risk	Quote: "Assignment to the study condition was determined using sequential coded envelopes."
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "Patients were assessed continuously by a recovery room nurse who blinded to the intraoperative treatment group assignment."
Incomplete outcome data (attrition bias) All outcomes	High risk	Quote: "Twenty-eight patients were excluded from efficacy analysis due to protocol violations for various reasons." As a result, there were 125 participants in the clinical signs group and 115 participants in the BIS group.
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Country:** Egypt

**Setting:** hospital; single centre

**Inclusion criteria:** informed consent; 45 to 60 years of age; ASA I to III; scheduled for elective moderate abdominal surgical procedures; expected durations at least 2 hours.

**Exclusion criteria:** a history of any disabling central nervous or cerebrovascular disease; hypersensitivity to opioids; substance abuse; treatment with opioids or any psychoactive medication; a BMI > 40

**Type of surgery:** abdominal surgery

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 51.6 ( $\pm$  7.4) years
- Gender, M/F: 18/11
- Weight (kg), mean (SD): 87.6 ( $\pm$  8.2) kg
- Duration of anaesthesia: 111.7 ( $\pm$  14.6) minutes

Comparison group (clinical signs)

- Age, mean (SD): 52.1 ( $\pm$  5.2) years
- Gender, M/F: 20/8
- Weight (kg), mean (SD): 91.4 ( $\pm$  6.5) kg
- Duration of anaesthesia: 108.7 ( $\pm$  10.5) minutes

**Interventions**

Intervention group (BIS)

- Randomized, n = 30; losses = 1 (desaturated intra-operatively); analysed, n = 29
- Details: sevoflurane guided by BIS (Aspect Medical Systems, USA), target values of 50 to 60 during maintenance and target values of 55 to 70 at the end of surgery. Hypertension or tachycardia were managed according to BIS values. Hypertension or tachycardia occurred the treatment was dependent on the BIS index - if BIS value > 60, sevoflurane was increased, if BIS already in the target range, then fentanyl was given. If BIS value < 50, sevoflurane was decreased and patient was checked for signs of analgesia

Comparison group (clinical signs)

- Randomized, n = 30; losses = 2 (received excessive fentanyl near end of surgery); analysed, n = 28
- Details: sevoflurane or fentanyl guided by clinical signs (mean arterial blood pressure > 25 above baseline >25% above baseline or heart rate > 90 beats per minutes) or labetalol at the discretion of attending anaesthetist. For hypertension or tachycardia, sevoflurane was increased, or administration of fentanyl or labetalol

Both groups: induction with propofol and fentanyl, then atracurium. Maintenance with sevoflurane and nitrous oxide/oxygen (50%/50%), and intermittent boluses of atracurium. Hypotension treated with IV fluid replacement or decrease in sevoflurane concentration, or finally by ephedrine or phenylephrine. Bradycardia treated with reduction in sevoflurane or with atropine. Residual neuromuscular blockade was reversed with glycopyrrolate and neostigmine

**Outcomes**

**Outcomes measured/reported by study authors:** recovery times (time to eye opening; time to extubation; time to orientation; time to arrival in the PACU; time to discharge from the PACU); sevoflurane consumption; propofol and fentanyl consumption; end-tidal concentration of sevoflurane; incidence of intraoperative awareness (POD 1, POD 2, and POD 3; interviewed about any recall of events, sounds, feeling surgical instruments or dressings, or dreaming)

**Outcomes relevant to the review:** intraoperative awareness; time to orientation; time to discharge from the PACU

**Notes**

**Funding/declarations of interest:** not reported

**Kamal 2009** (Continued)

**Study dates:** January 2006 to July 2007

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Patients were randomly selected and assigned into two groups of 30 patients each. Method of randomization is not reported
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	3 participants were excluded. However, these losses were fewer than 10%
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 214</p> <p><b>Country:</b> Iran</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> scheduled for non-emergency caesarean section; gestational age of 37 to 42 weeks; lack of any systemic disorder; ASA status I or II; 15 to 45 years of age; no chronic drug abuse; no prior history of heart, liver or kidney disorder; maximum surgery duration of 60 minutes; undergoing surgery by one surgeon</p> <p><b>Exclusion criteria:</b> intubation for more than 35 seconds; pre-eclampsia or chronic hypertension; morbid obesity; ASA status &gt; II; systemic or mental disorder; duration of surgery &gt; 90 minutes</p> <p><b>Type of surgery:</b> non-emergency caesarean</p> <p><b>Baseline characteristics are not reported</b></p>
Interventions	Intervention group (BIS): <ul style="list-style-type: none"> <li>Randomized, n = 107; losses, n = 0; analysed, n = 107</li> </ul>

**Kamali 2017a** (Continued)

- Details: use of narcotics, anaesthetic gases and medications if increase in BP or HR or if BIS target value was > 60

Comparison group (clinical signs)

- Randomized, n = 107; losses, n = 0; analysed, n = 107
- Details: adjustments of narcotics, anaesthetic gases and medications for increase in BP, HR, tears in the eyes or limb movements

Both groups: induction with thiopental and succinylcholine. Maintenance with nitrous oxide/oxygen (50%/50%) and 1% isoflurane, and atracurium if required. Fentanyl given after delivery

Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> intraoperative awareness (interview and questionnaire at 12 hours and 24 hours after surgery); haemodynamic variables</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> support from Arak University of Medical Sciences. Study authors declare no conflicts of interest</p> <p><b>Study dates:</b> not specified</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not specified
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Participants were blinded to group allocation. However, it was not feasible to blind anaesthetists to group allocation.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Awareness was evaluated by a trainee anaesthetist, to ensure blinding of outcome assessors
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Retrospective clinical trial registration (ChiCTR-TRC-1200239); it is not feasible to effectively assess risk of reporting bias from this document
Other bias	Unclear risk	Study authors do not report baseline characteristics table, and we could not be certain whether characteristics were equivalent between groups

**Karaca 2014**
**Study characteristics**

Methods	RCT, parallel design
---------	----------------------

**Karaca 2014** (Continued)

## Participants

**Total number of randomized participants:** 82

**Country:** Turkey

**Setting:** hospital; single centre

**Inclusion criteria:** ASA I to II; 20 to 60 years of age; undergoing elective surgery for supratentorial mass lesions under general anaesthesia

**Exclusion criteria:** cardiac failure; renal failure; anaemia; ischaemic heart disease; liver disease; gastrointestinal system disease; diabetes mellitus; hypothalamus pituitary gland disorders; diuretic use; hypoalbuminaemia; hyperglycaemia; electrolyte imbalance; alcohol consumption; requiring hormone replacement therapy; pregnancy or lactating women; psychiatric condition

**Type of surgery:** neurosurgery

**Baseline characteristics**

## Intervention group (BIS)

- Age, mean (SD): 48.83 ( $\pm$  14.73) years
- Gender, M/F: 24/17
- BMI, mean (SD): 26.21 ( $\pm$  4.32) kg/m<sup>2</sup>
- Weight, mean (SD): 74.61 ( $\pm$  12.93) kg
- Height, mean (SD): 168.78 ( $\pm$  7.11) cm
- ASA status, mean (SD): 1.46 (0.51)

## Comparison group (clinical signs)

- Age, mean (SD): 48.17 ( $\pm$  15.78) years
- Gender, M/F: 18/23
- BMI, mean (SD): 27.10 ( $\pm$  4.33) kg/m<sup>2</sup>
- Weight, mean (SD): 74.02 ( $\pm$  11.28) kg
- Height, mean (SD): 166.05 ( $\pm$  9.21) cm
- ASA status, mean (SD): 1.49 (0.51)

## Interventions

## Intervention group (BIS)

- Randomized, n = 41; losses, n = 0; analysed, n = 41
- Details: induction with initial dose of 1 mg/kg propofol with 20 mg additional doses until BIS was < 60, then remifentanyl. Maintenance with propofol infusion initiated at 8 mg/kg/hour and continued in 40 mg doses to maintain BIS target values between 40 and 60

## Comparison group (clinical signs)

- Randomized, n = 41; losses, n = 0; analysed, n = 41
- Details: induction with 2 mg/kg propofol, then remifentanyl. Maintenance with propofol infusion started at a dose of 8 mg/kg/hour and decreased by 2 mg/kg/hour at 10-minute intervals. Adjustments made according to haemodynamic parameters to maintain MAP and HR within 20% baseline

Both groups: premedication with midazolam. Vecuronium to facilitate intubation. Maintenance with propofol, remifentanyl and use of rocuronium

## Outcomes

**Outcomes measured/ reported by study authors:** intraoperative awareness (participants were asked quote: "the last event they recalled about the surgery"; time point of assessment is not specified); recovery times (time to eye opening; time to spontaneous breathing; Aldrete scores at 20 minutes); TOF values; fluid balance; bleeding volume; consumption of propofol, remifentanyl, and rocuronium; duration of surgery; haemodynamic variables

**Outcomes relevant to the review:** intraoperative awareness; time to eye opening

**Karaca 2014** (Continued)

Notes

**Funding/declarations of interest:** not reported

**Study dates:** not reported

**Note:**

- intervention and control group received different doses of propofol for induction and maintenance

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Use of quote: "closed envelope method" for randomization; no additional details
Allocation concealment (selection bias)	Unclear risk	See above; insufficient details
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were aware of group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Khoshrang 2016**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 96</p> <p><b>Country:</b> Iran</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> 15 to 65 years of age</p> <p><b>Exclusion criteria:</b> personality disorder; neurological disorders; prior history of head trauma; drug abuse; drugs that affect the central nervous system; craniofacial anomalies; abnormal forehead; uncontrolled blood pressure (SBP &gt; 150 mmHg and DBP &gt; 105 mmHg); insulin-dependent diabetes; BMI &gt; 33; emergency operation; ASA class <math>\geq</math> II</p> <p><b>Type of surgery:</b> open renal surgery</p>

**Khoshrang 2016** (Continued)

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 41.18 ( $\pm$  12.64) years
- Gender, M/F: 31/17
- BMI, mean (SD): 24.9 ( $\pm$  3.54) kg/m<sup>2</sup>

Comparison group (clinical signs)

- Age, mean (SD): 43.64 ( $\pm$  16.46) years
- Gender, M/F: 32/16
- BMI, mean (SD): 26.24 ( $\pm$  3.8) kg/m<sup>2</sup>

Interventions	Intervention group (BIS) <ul style="list-style-type: none"> <li>• Randomized, n = 48; losses, n = 0; analysed, n = 48</li> <li>• Details: anaesthesia guided by BIS (Aspect A2000, USA), target values between 40 and 60. If BIS value increased above 60, then 20% more than initial dose of remifentanyl was given</li> </ul> Comparison group (clinical signs) <ul style="list-style-type: none"> <li>• Randomized, n = 48; losses, n = 0; analysed, n = 48</li> <li>• Details: depth of anaesthesia based on HR, BP, respiratory rate, sweating, tearing, and pupil dilation. Remifentanyl (at 20% more than initial dose) given for a 20% increase in baseline haemodynamic parameters</li> </ul> Both groups: induction with propofol, fentanyl, and then atracurium. Maintenance, propofol and remifentanyl. Nitrous oxide and oxygen used for inhalation anaesthesia with atracurium IV
Outcomes	<b>Outcomes measured/reported by study authors:</b> recovery times (time to: eye opening; verbal response to verbal stimulation; extubation; stay in the PACU); first-time to narcotic usage; total dosage of IV narcotics  <b>Outcomes relevant to the review:</b> time to eye opening; length of stay in the PACU (see notes)
Notes	<b>Funding/declarations of interest:</b> quote: "no financial relationship with any organization". Study authors report no conflicts of interest  <b>Study dates:</b> October 2014 to October 2015  <b>Notes:</b> <ul style="list-style-type: none"> <li>• length of stay in PACU is not clearly reported. In the discussion section of the study report, study authors state "except for time of discharging from recovery unit in all other cases, the BIS group took statistically significantly less time than the clinical groups"</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Study authors use block randomization
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation

**Khoshrang 2016** (Continued)

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Assessment of discharge from PACU based on Aldrete score $\geq 9$ , by an anaesthetist who was blinded to group allocation
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses
Selective reporting (reporting bias)	Unclear risk	Study was retrospectively registered with a clinical trials register (IRCT2015042111766N2). It is not feasible to use this document to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Randomized, n = 20; losses, n = 1 (participant excluded due to temperature changes that required additional treatment/clinical management); analysed, n = 19</li> <li>Details: anaesthesia maintained with BIS (A-2000; Aspect Medical System, USA), target values of 40 to 50</li> </ul> <p>Comparison group (clinical signs)</p>

**Bispectral index for improving intraoperative awareness and early postoperative recovery in adults (Review)**

**Kim 2003** (Continued)

- Randomized, n = 20; losses, n = 0; analysed, n = 20
- Details: anaesthesia maintained mainly according to SBP

Both groups: anaesthesia with propofol, fentanyl, and vecuronium. Participants were given 12 words during surgery, which they were asked if they recalled

Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> intraoperative awareness (interview on second postoperative day); consumption of propofol, fentanyl, and morphine</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> not reported in abstract</p> <p><b>Study dates:</b> not specified</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• study report is in Korean. We did not seek translation. Data have been taken from the English abstract, and tables which were reported in English. Some key paragraphs were translated using Google Translate.</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not specified
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not specify whether participants were aware of group allocation. Not feasible to blind anaesthetists from group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss of only one participant in the BIS group
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Unclear risk	We did not seek full translation of this study report, and we could not be certain whether the study included other sources of bias

**Kreuer 2003**
**Study characteristics**

Methods	RCT parallel design
---------	---------------------

**Kreuer 2003** (Continued)

Participants

**Total number of randomized participants:** 80

**Country:** Germany

**Setting:** hospital; single centre

**Inclusion criteria:** 18 to 80 years of age; ASA I to III; scheduled to undergo minor orthopaedic surgery expected to last at least one hour.

**Exclusion criteria:** disabling central nervous or cerebrovascular diseases; hypersensitivity to opioid; substance abuse; treatment with opioids or any psychoactive medication

**Type of surgery:** minor orthopaedic surgery lasted  $\geq 1$  hour

**Overall duration of anaesthesia, if reported:** 121.2 ( $\pm 40.9$ ) minutes (BIS); 108.2 ( $\pm 44.2$ ) minutes (clinical signs)

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 43.8 ( $\pm 4.2$ ) years
- Gender, M/F: 20/20
- Weight (kg), mean (SD): 78.3 ( $\pm 13.8$ ) kg
- Height (cm), mean (SD): 171.2 ( $\pm 8.1$ ) cm
- ASA status I/II/III: 12/25/3
- Duration of anaesthesia: 121.2 ( $\pm 40.9$ ) minutes

Comparison group (clinical signs)

- Age, mean (SD): 46.1 ( $\pm 14.5$ ) years
- Gender, M/F: 20/20
- Weight (kg), mean (SD): 82.7 ( $\pm 17.8$ ) kg
- Height (cm), mean (SD): 172.6 ( $\pm 7.8$ ) cm
- ASA status I/II/III: 12/24/4
- Duration of anaesthesia: 108.2 ( $\pm 44.2$ ) minutes

Interventions

Intervention group (BIS)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: propofol guided by a BIS monitor (A-2000, software version 3.2), target value at 50. Then at 15 minutes before end of surgery target BIS level changed to 60. If anaesthesia inadequate and BIS target had been achieved, the infusion rate of remifentanyl increased. Hypotension initially treated with IV fluids and finally a vasopressor IV given. Bradycardia treated with atropine.

Comparison group (clinical signs)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: TCI propofol guided by standard clinical signs. If inadequate anaesthesia, propofol, target concentration increased in steps as necessary. If this was insufficient, then infusion rate of remifentanyl increased. Hypotension treated with IV fluid, then propofol concentration reduced in steps and finally a vasopressor IV given. Bradycardia treated with atropine

Both groups: premedication with diazepam. Induction with remifentanyl and propofol, then cisatracurium to facilitate tracheal intubation. Propofol TCI and remifentanyl for maintenance. Metamizol for postoperative pain relief.

Outcomes

**Outcomes measured/reported by study authors:** normalized propofol infusion rate; normalized remifentanyl infusion rate; time to open eyes; time to be extubated; time to arrive in PACU; intraoperative awareness (study authors did not report time point or method of assessment); number of patients receiving intervention to treat intraoperative hypotension; haemodynamic variables

**Kreuer 2003** (Continued)

**Outcomes relevant to the review:** intraoperative awareness

Notes

**Funding/declarations of interest:** departmental support only

**Study dates:** not reported

**Note:**

- study authors included an additional study group (Narcotrend) which we did not include in the review

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: ".. patients were randomized by drawing lots from a closed box."
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "Recovery times and propofol consumption were recorded by a blinded investigator."
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

- Duration of anaesthesia, mean (SD): 90.5 ( $\pm$  70.3) minutes

Interventions

Intervention group (BIS propofol)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: induction and maintenance with TCI propofol and boluses of fentanyl. Propofol guided by BIS (Aspect A-2000, Aspect Medical Systems, USA),

Intervention group (BIS desflurane)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: induction with propofol and fentanyl, maintenance with desflurane and top-up doses of fentanyl. Desflurane guided by BIS, target values between 45 and 55 during surgery. Vecuronium given before increasing anaesthetic drug

Comparison group (clinical signs propofol)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: propofol using standard clinical guide (haemodynamic and vital signs criteria)

Comparison group (clinical signs desflurane)

- Randomized, n = 40; losses = 0; analysed, n = 40
- Details: desflurane using standard clinical guide (haemodynamic vital signs criteria)

All groups: premedication with midazolam or lorazepam. Intubation facilitated with vecuronium; ventilation with mix of oxygen and air. Remifentanyl at discretion of attending anaesthetist. Muscle relaxants and opioids administered according to clinical criteria

Outcomes

**Outcomes measured/reported by study authors:** intraoperative data (HR, BP etc.); anaesthetic drug use; inadequate hypnosis with potential for explicit recall (BIS > 60 for > 3 minutes; BIS > 65 for > 4 minutes); haemodynamic variables; recovery (Aldrete score; extubation times); patient satisfaction (to include nausea and vomiting)

**Outcomes relevant to the Review:** intraoperative awareness (described as quote: "explicit recall of events during anaesthesia"; time point or method of measurement was not reported)

Notes

**Funding/declarations of interest:** funding from Research Fund of the Department of Anesthesiology, University Hospital of Bern, Switzerland

**Study dates:** not reported

**Risk of bias**

**Masuda 2002** (Continued)

Outcomes **Outcomes measured/reported by study authors:** propofol infusion rate; propofol consumption; recovery (time to discharge from the PACU); intraoperative responses (definition not described in English abstract)

**Outcomes relevant to the review:** time to discharge from the PACU

Notes **Funding/declarations of interest:** unknown

**Study dates:** unknown

**Note:**

- we did not seek translation of the full-text (written in Japanese) during the review update; we collected information from the English abstract and from baseline characteristics tables in the full text

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Insufficient information
Allocation concealment (selection bias)	Unclear risk	Insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Insufficient information
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	It was uncertain whether study authors reported prospective clinical trials registration, therefore it is not feasible to assess risk of reporting bias
Other bias	Unclear risk	Insufficient information reported in English abstract to assess risks of other bias

**Morimoto 2002**

**Study characteristics**

Methods RCT, parallel design

Participants **Total number of randomized participants:** 60

**Country:** Japan

**Setting:** hospital; single centre

**Inclusion criteria:** participants undergoing various surgical procedures under sevoflurane with nitrous oxide anaesthesia; ASA I or II; surgery scheduled to last 2 to 6 hours; 18 to 70 years of age

**Morimoto 2002** (Continued)

**Exclusion criteria:** unknown

**Type of surgery:** various

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 53 ( $\pm$  12) years
- Gender, M/F: 10/11
- Weight, mean (SD): 55 ( $\pm$  8) kg
- Duration of anaesthesia, mean (SD): 274 ( $\pm$  85) minutes

Comparison group (clinical signs)

- Age, mean (SD): 55 ( $\pm$  9) years
- Gender, M/F: 11/14
- Weight, mean (SD): 61 ( $\pm$  13) kg
- Duration of anaesthesia, mean (SD): 256 ( $\pm$  72) minutes

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = unknown (see notes below); losses = unknown; analysed, n = 21</li> <li>• Details: sevoflurane guided by BIS (A 1050, version 3.4), target values of 40 to 60 during maintenance and target values of 60 to 75 at the end</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = unknown (see notes below); losses = unknown; analysed, n = 25</li> <li>• Details: sevoflurane guided by clinical signs (HR and BP)</li> </ul>

**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 40</p> <p><b>Country:</b> India</p>

**Bispectral index for improving intraoperative awareness and early postoperative recovery in adults (Review)**

**Muralidhar 2008** (Continued)

**Setting:** hospital; single centre

**Inclusion criteria:** undergoing elective CABG

**Exclusion criteria:** poor ventricular function < 40%; left ventricular aneurysms; renal or hepatic dysfunction; requiring extra corporeal circulation; preoperative or intraoperative intra-aortic balloon pump; presence of unstable angina; carotid stenosis; cerebrovascular accident; excessive alcohol intake; drug abuse

**Type of surgery:** elective off-pump CABG

**Baseline characteristics**

Intervention group (BIS isoflurane)

- Age, mean (SD): 50 ( $\pm$  6) years
- Gender, M/F: 9/1
- Weight, mean (SD): 71 ( $\pm$  5) kg

Intervention group (BIS propofol)

- Age, mean (SD): 52 ( $\pm$  7) years
- Gender, M/F: 8/2
- Weight, mean (SD): 71 ( $\pm$  6) kg

Comparison group (ETAG isoflurane)

- Age, mean (SD): 50 ( $\pm$  4) years
- Gender, M/F: 8/2
- Weight, mean (SD): 71 ( $\pm$  6) kg

Comparison group (ETAG propofol)

- Age, mean (SD): 47 ( $\pm$  5) years
- Gender, M/F: 10/0
- Weight, mean (SD): 71 ( $\pm$  4) kg

**Interventions**

Intervention group (BIS isoflurane)

- Randomized, n = 10 ; losses = 0; analysed, n = 10
- Details: maintenance with isoflurane to maintain BIS (Zipprep, Aspect Medical System, Natick, MA, USA), target value of 50 ( $\pm$  5)

Intervention group (BIS propofol)

- Randomized, n = 10 ; losses = 0; analysed, n = 10
- Details: BIS-guided propofol administration, target value of 50 ( $\pm$  5)

Comparison group (ETAG isoflurane)

- Randomized, n = 10 ; losses = 0; analysed, n = 10
- Details: no BIS-guided isoflurane anaesthesia, maintaining end tidal isoflurane 1 to 1.2%,

Comparison group (propofol - no BIS)

- Randomized, n = 10 ; losses = 0; analysed, n = 10
- Details: no BIS-guided propofol anaesthesia, propofol 6 to 8 mg/kg/hour during sternotomy and 4 to 6 mg/kg/hour during maintenance

All groups: anti-hypertensive and anti-anginal medication continued until the morning of surgery. Pre-medication with diazepam. Induction with midazolam, fentanyl and thiopentone. Pancuronium bro-

**Muralidhar 2008** (Continued)

mide for intubation. Haemodynamic parameters maintained within 20% baseline with dopamine, phenylephrine, and glyceryl trinitrate, as required. Perioperative analgesic using rectal diclofenac

Outcomes	<p><b>Outcomes measured/reported by study authors:</b> intraoperative awareness (structured interview in the ICU, 18 hours after extubation); volume of anaesthetic agents; time to extubation; length of ICU and hospital stay</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> not reported</p> <p><b>Study dates:</b> not reported</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Insufficient information regarding the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Quote: "Patients were randomly divided into four groups by a sealed envelope technique.." Insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Prospective clinical trials registration or published protocol not reported. It was not feasible to assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Myles 2004**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 2463</p> <p><b>Country:</b> Australia</p> <p><b>Setting:</b> hospital; multi-centre</p> <p><b>Inclusion criteria:</b> 18 years of age or older; scheduled for surgery under GA; at least one of risk factors for awareness, i.e. caesarean section, high-risk cardiac surgery, acute trauma with hypovolaemia, rigid bronchoscopy, significant impairment of cardiovascular status, severe end-stage lung disease, past history of awareness, unplanned awake intubation, known or suspected heavy alcohol intake, chronic benzodiazepine or opioid use, or current protease inhibitor therapy</p>

**Myles 2004** (Continued)

**Exclusion criteria:** inadequate comprehension of English language; traumatic brain injury; memory impairment; psychosis; known or suspected EEG abnormality; not expected to be available for postoperative interview

**Type of surgery:** minor (208 participants), intermediate (457 participants), major (1808 participants)

**Risk of awareness:** see inclusion criteria

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 58.1 (± 16.5) years
- Gender, M/F: 752/473
- Weight, mean (SD): 72.7 (± 17.6) kg
- ASA status I/II/III/IV/V: 111/179/542/388/5
- Duration of anaesthesia, median (IQR): 3.2 (1.5 to 4.4) hours

Comparison group (clinical signs)

- Age, mean (SD): 57.5 (± 16.9) years
- Gender, M/F: 784/454
- Weight, mean (SD): 74.2 (± 17.7) kg
- ASA status I/II/III/IV/V: 127/227/520/354/10
- Duration of anaesthesia, median (IQR): 3.1 (1.3 to 4.5) hours

**Interventions**

Intervention group (BIS)

- Randomized, n = 1248; losses = 23 (13 surgery cancelled; 6 consent withdrawn; 4 did not receive GA); analysed for intraoperative awareness, n = 1225 (modified ITT analysis to include 14 participants who did not receive BIS monitoring)
- Details: choice of anaesthetic agents was at the discretion of the attending anaesthetist. BIS-guided anaesthesia (A-2000, version 3.4, Aspect Medical Systems), a target BIS value of 40 to 60

Comparison group (clinical signs)

- Randomized, n = 1263; losses = 15 (13 surgery cancelled; 2 under age); analysed for intraoperative awareness, n = 1238 (modified ITT analysis to include 6 participants who did not receive BIS monitoring)
- Details: BIS monitors were applied to each participant but attending anaesthetists were not able to see the display. Anaesthesia guided by routine clinical management

**Outcomes**

**Outcomes measured/reported by study authors:** confirmed intraoperative awareness (interviews using a structured questionnaire at 3 time points: 2 to 6 hours after surgery; 24 to 36 hours postoperatively; and 30 days postoperatively); possible awareness; recovery times (eye opening; eligibility for discharge from the PACU); hypnotic drug administration; hypotension; anxiety and depression; patient satisfaction; major complications; 30 day mortality

**Outcomes relevant to the review:** confirmed intraoperative awareness; time in the PACU (only for participants who were transferred to the PACU); time to eye opening (only for participants who were transferred to the PACU)

**Notes**

**Funding/declarations of interest:** funded by project grants from: the Australian and New Zealand College of Anaesthetists; the Alfred Hospital Research Trust; Royal Hobart Hospital Research Foundation; the Centre for Encouragement of Philanthropy in Australia. One author (P Myles) was funded by an Australian National Health and Medical Research Council Practitioner's Fellowship. Loan of equipment and some unrestricted funding from Aspect Medical Systems, and one author (K Leslie) received support for travel and conference expenses from Aspect Medical Systems. Study sponsors had no involvement in study design, data analysis or data interpretation

**Study dates:** September 2000 to December 2002

**Myles 2004** (Continued)

**Notes:**

- we have added an associated publication to this study; Leslie 2005a was previously reported as a separate study in previous versions of the review.
- also known as B-Aware trial
- study report includes baseline characteristics according to different risk factors
- we did not include in analysis data for time to eye opening because it was reported in median (IQR) values - BIS group (for 547 participants admitted to the PACU): 9 minutes (5 to 14 minutes); clinical signs group (for 576 participants admitted to the PACU): 10 minutes (5 to 15 minutes)
- we did not include in analysis data for time to discharge from the PACU because it was reported in median (IQR) values - BIS group (for 547 participants admitted to the PACU): 63 minutes (40 to 95 minutes); clinical signs group (for 576 participants admitted to the PACU): 66 minutes (40 to 100 minutes)

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random group allocation
Allocation concealment (selection bias)	Low risk	Central allocation
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "Follow-up was undertaken by a blinded observer."
Incomplete outcome data (attrition bias) All outcomes	Low risk	40 participants were withdrawn because of cancellation of surgery, withdrawal of consent, GA was not used; or participants were under age
Selective reporting (reporting bias)	Unclear risk	Study authors do not report registration with clinical trials register or details of pre published protocol. Therefore, It is not feasible to assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Nelskyla 2001**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 62</p> <p><b>Country:</b> Finland</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> females; ASA status I or II; 18 to 50 years of age; normal body weight; scheduled for gynaecological laparoscopy</p>

**Nelskyla 2001** (Continued)

**Exclusion criteria:** procedures that involved tubal ligation

**Type of surgery:** gynaecologic laparoscopy

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 32 ( $\pm$  6) years
- Gender, M/F: all women
- Weight, mean (SD): 60 ( $\pm$  7) kg
- Height, mean (SD): 166 ( $\pm$  5) cm
- Duration of anaesthesia: 59 ( $\pm$  39) minutes

Comparison group (clinical signs)

- Age, mean (SD): 32 ( $\pm$  6) years
- Gender, M/F:
- Weight, mean (SD): 61 ( $\pm$  6) kg
- Height, mean (SD): 166 ( $\pm$  6) cm
- Duration of anaesthesia: 55 ( $\pm$  50) minutes

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 32; losses = 0; analysed, n = 32</li> <li>• Details: sevoflurane guided by BIS (Aspect version 3.21), target values of 50 to 60. If BP or HR increased to &gt; 25% above baseline and BIS was within target range, alfentanil was given</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 30; losses = 0; analysed, n = 32</li> <li>• Details: sevoflurane guided by clinical signs (BP and HR), and adjusted to 0.94%. BIS also recorded in control group, but anaesthetist blinded to the monitor. BP and HR maintained within 25% baseline by adjusting end-tidal concentration, then alfentanil if required.</li> </ul> <p>Both groups: premedication with diazepam. Then glycopyrrolate and fentanyl, induction with propofol, with rocuronium to facilitate intubation and maintained throughout anaesthesia. Manual ventilation of lungs with 50% nitrous oxide in air and 1.5% sevoflurane. Residual neuromuscular blockade reversal with neostigmine and glycopyrrolate. At the end of anaesthesia, participants were given ketoprofen</p>
Outcomes	<p><b>Outcomes measured/reported by study authors:</b> PONV; volume of anaesthetic agents; recovery times (time to extubation; spontaneous eye opening; response to commands; orientation; tolerate oral fluids; able to sit; able to walk; home readiness); postoperative analgesics; pain</p> <p><b>Outcomes relevant to the review:</b> time to spontaneous eye opening; time to orientation</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Insufficient information
Allocation concealment (selection bias)	Unclear risk	Insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to study groups
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "All recovery parameters were assessed by the same research coordinator not involved in treatment of the patient."
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Payas 2013**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 100</p> <p><b>Country:</b> Turkey</p>

**Payas 2013** (Continued)

**Setting:** hospital; single centre

**Inclusion criteria:** ASA status II to III; 30 to 65 years of age; having a cardiac problem but no previous history of cardiac surgery; scheduled for elective open cholecystectomy under GA

**Exclusion criteria:** ASA status III with decompensated heart failure or history of myocardial infarction in the last 6 months; liver failure; chronic renal insufficiency; history of neurological and psychiatric diseases; respiratory system diseases; alcohol and drug use; history of allergy

**Type of surgery:** elective open cholecystectomy

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 52.68 (± 8.70) years
- Gender, M/F: 19/31
- Weight, mean (SD): 72.28 (± 13.52) kg
- Height, mean (SD): 164.98 (± 9.11) cm
- ASA status II/III: 8/42

Comparison group (clinical signs)

- Age, mean (SD): 55.58 (± 8.24) years
- Gender, M/F: 20/30
- Weight, mean (SD): 70.54 (± 12.99) kg
- Height, mean (SD): 165.94 (± 8.68) cm
- ASA status II/III: 9/41

Interventions

Intervention group (BIS)

- Randomized, n = 50; losses, n = 0; analysed, n = 50
- Details: desflurane ETVAC adjusted using BIS (BIS XP monitor, Aspect A-2000, USA), target values at 50 to 60.

Comparison group (clinical signs)

- Randomized, n = 50; losses, n = 0; analysed, n = 50
- Details: desflurane ETVAC was titrated according to haemodynamic responses, according to a 20% change from baseline in HR and MAP values

Both groups: premedication with midazolam, induction with fentanyl, etomidate, and rocuronium for tracheal intubation and to maintain neuromuscular blockade. Maintenance with nitrous oxide/oxygen (50%/50%) and desflurane

Outcomes

**Outcomes measured/ reported by study authors:** duration of anaesthesia; total opioid dose; total dose of neuromuscular blockade; extubation duration; time to reach an Aldrete recovery score of ≥ 9; haemodynamic variables; BIS values

**Outcomes relevant to the review:** none

Notes

**Funding/declarations of interest:** study authors report quote: "Financial disclosure: N/A". Study authors report no conflicts of interest

**Study dates:** not reported

**Note:**

- we did not complete 'Risk of bias' assessment because study authors did not report outcomes relevant to the review

**Persec 2012**

**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 45</p> <p><b>Country:</b> Croatia</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> ≥ 18 years of age; ASA status II or III</p> <p><b>Exclusion criteria:</b> memory impairment; psychosis; known or suspected electroencephalograph abnormality; chronic use of psychoactive medication; surgery lasting &gt; 6 hours</p> <p><b>Type of surgery:</b> major abdominal surgery</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, median (range): 64.5 (39 to 84) years</li> <li>• Gender, M/F: 11/9</li> <li>• BMI, median (range): 26.5 (17.5 to 35) kg/m<sup>2</sup></li> <li>• ASA status, median (range): II (II to III)</li> <li>• Duration of surgery, median (range): 195 (130 to 280) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Age, median (range): 66.5 (25 to 81) years</li> <li>• Gender, M/F: 10/10</li> <li>• BMI, median (range): 25.5 (21 to 30) kg/m<sup>2</sup></li> <li>• ASA status, median (range): III (II to IV)</li> <li>• Duration of surgery, median (range): 166 (150 to 245) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = unclear (see note below); losses, n = unclear (see note below); analysed, n = 20</li> <li>• Details: BIS monitor (Aspect Medical Systems, USA), target values of 50 to 60</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = unclear (see note below); losses, n = unclear (see note below); analysed, n = 20</li> <li>• Details: BIS monitor was attached to participant but screen was blinded to anaesthetist. Participants received routine anaesthesia care</li> </ul> <p>Both groups: induction with midazolam, fentanyl, and vecuronium to facilitate tracheal intubation. For maintenance 1.5 to 2 MAC of sevoflurane, nitrous oxide in 50% oxygen, fentanyl and vecuronium</p>
Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> BIS values; haemodynamic variables; surgery time; extubation time; intraoperative recall (interview on first postoperative day); adverse events or side effects</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> no financial support and study authors report no conflicts of interest</p> <p><b>Study dates:</b> February 2011 to July 2011</p>

**Persec 2012** (Continued)

**Notes:**

- we noted a discrepancy in the reported number of participants. We have used number of participants as reported in the baseline characteristics table rather than the flow-chart. We note that 5 participants were excluded but we are uncertain to which group these participants belonged

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomization
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants are aware of group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Retrospective clinical trials registration (NCT01470898). It was not feasible to use this report to assess risk of reporting bias
Other bias	Unclear risk	Although study authors described no statistically significant differences between groups, we noted that study authors reported baseline characteristics using median values which may indicate data that is skewed. We noted that the control group had a higher median and range values for ASA status; this may indicate an important clinical difference between groups

**Puri 2003**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 30</p> <p><b>Country:</b> India</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> 18 to 70 years of age; undergoing either CAGB or valve replacement under cardiopulmonary bypass (CPB)</p> <p><b>Exclusion criteria:</b> neurological disorders; poor ventricular function; New York Heart Association grade IV; diabetes mellitus; impaired renal or hepatic function</p> <p><b>Type of surgery:</b> CAGB or valve replacement under CPB</p>

**Puri 2003** (Continued)

**Baseline characteristics**

## Intervention group (BIS)

- Age, mean (SD): 38.25 ( $\pm$  14.02) years
- Weight (kg), mean (SD): 53.17 ( $\pm$  7.92) kg
- Height (m), mean (SD): 1.65 ( $\pm$  0.10) m
- Duration of surgery (min): 295 ( $\pm$  45) minutes

## Comparison group (clinical signs)

- Age, mean (SD): 32.08 ( $\pm$  13.84) years
- Weight (kg), mean (SD): 51.17 ( $\pm$  14.33) kg
- Height (m), mean (SD): 1.64 ( $\pm$  0.10) m
- Duration of surgery (min): 285 ( $\pm$  40) minutes

**Interventions**

## Intervention group (BIS)

- Randomized, n = 14; losses = 0; analysed, n = 14
- Details: inhaled Isoflurane administration guided by BIS (Aspect A-1000, version 3.1), target values of 45 to 55 throughout procedure except last 30 minutes when titrated to 65 to 75. If hypertension or tachycardia occurred whilst the BIS range was normal then morphine 0.05 to 0.1 mg/kg was given IV, before using vasodilators or beta-blocking drugs.

## Comparison group (clinical signs)

- Randomized, n = 16; losses = 0; analysed, n = 16
- Details: inhaled Isoflurane administration guided by clinical signs. BIS monitor attached but out of viewpoint to the anaesthetist. If hypertension or tachycardia occurred whilst the BIS range was normal then morphine 0.05 to 0.1 mg/kg-1 was given IV, before using vasodilators or beta-blocking drugs.

Both groups: premedication with diazepam. Induction with morphine, midazolam and thiopental. Vecuronium to facilitate tracheal intubation. Maintenance with isoflurane, 66% nitrous oxide in oxygen, and morphine. Isoflurane discontinued once skin suturing completed

**Outcomes**

**Outcomes measured/reported by study authors:** number of haemodynamic disturbances (hypertension; tachycardia; hypotension; bradycardia); recovery endpoint (time from switching off anaesthetic vaporizer to opening eyes or response to verbal commands); time to tracheal extubation awareness (interview on first postoperative day)

**Outcomes relevant to the review:** intraoperative awareness; time to eye opening

**Notes**

**Funding/declarations of interest:** not reported

**Study dates:** not reported

**Note:** during the search in 2019, we identified an abstract by the same author team (Puri 1999) which also compared BIS with clinical signs in people undergoing CABG. The number of randomized participants in each study differed but we could not be certain whether Puri 1999 was an interim publication of [Puri 2003](#). We did not include Puri 1999 as a separate study in this review; we added this reference as an associated reference to [Puri 2003](#).

**Recart 2003**

**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 60</p> <p><b>Country:</b> USA</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> undergoing laparoscopic general surgery procedures (e.g. cholecystectomy; gastric bypass/banding; hernia repair)</p>

**Recart 2003** (Continued)

**Exclusion criteria:** history of central nervous system disease; chronic use of psychoactive medication; clinical significant cardiovascular, renal, hepatic or endocrinology disorders

**Type of surgery:** laparoscopic general surgery procedures (e.g. cholecystectomy, gastric bypass/banding, hernia repair)

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 47 (± 17) years
- Gender, M/F: 9/21
- Weight, mean (SD): 87 (± 23) kg
- Duration of anaesthesia: 125 (± 52) minutes

Comparison group (clinical signs)

- Age, mean (SD): 46 (± 15) years
- Gender, M/F: 10/20
- Weight, mean (SD): 83 (± 34) kg
- Duration of anaesthesia, mean (SD): 127 (± 38) minutes

**Interventions**

Intervention group (BIS)

- Randomized, n = 30; losses = 0; analysed, n = 30
- Details: desflurane guided by BIS (BIS TM sensor XP, Aspect Medical Systems Inc, USA), target values of 45 to 55

Comparison group (clinical signs)

- Randomized, n = 30; losses = 0; analysed, n = 30
- Details: desflurane guided by clinical signs

Both groups: premedication with midazolam. Induction with propofol and fentanyl, and rocuronium to facilitate tracheal intubation. Maintenance with desflurane 4% combined with air and oxygen, titrated in 1% to 2% increments. Fentanyl given to maintain stable haemodynamics, and labetalol as required. Residual neuromuscular block antagonized with neostigmine and glycopyrrolate.

**Outcomes**

**Outcomes measured/reported by study authors:** end-tidal concentrations of desflurane; fentanyl, rocuronium, labetalol use; recovery (time to eye opening; time to extubation; time to obey commands; time in PACU; time to reach Aldrete score of 10; time to reach fast-track score of > 12); intraoperative awareness (assessed at discharge from the PACU and at 24 hours postoperatively); pain scores; PONV

**Outcomes relevant to the review:** intraoperative awareness; recovery (time in the PACU)

**Notes**

**Funding/declarations of interest:** supported in part by an educational grant from Alaris Medical Systems; salary support from the Margaret Milam McDermot Distinguished Chair of Anesthesiology

**Study dates:** not reported

**Notes:**

- study included an additional group (auditory evoked potential) which we did not include in the review

**Risk of bias**

Participants	<p><b>Total number of randomized participants:</b> 60</p> <p><b>Country:</b> Pakistan</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> ≥ 60 years of age; ASA status I or II; no significant organ damage; requiring GA with endotracheal intubation and controlled mode ventilation; undergoing general and gynaecological surgeries expected to last 2 to 6 hours</p> <p><b>Exclusion criteria:</b> history of psychiatric illness; alcohol abuse; altered state of mind; requiring head, neck or laparoscopic surgeries</p> <p><b>Type of surgery:</b> general and gynaecological</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 64 (± 4.68) years</li> <li>• Gender, M/F: 8/22</li> <li>• BMI, mean (SD): 26.46 (± 9.88) kg/m<sup>2</sup></li> <li>• Weight, mean (SD): 66.37 (± 12.49) kg</li> <li>• Height, mean (SD): 158.38 (± 9.88) cm</li> </ul> <p>Comparison group (clinical signs/ETAG)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 62.80 (± 3.14) years</li> <li>• Gender, M/F: 8/22</li> <li>• BMI, mean (SD): 26.66 (± 3.46) kg/m<sup>2</sup></li> <li>• Weight, mean (SD): 64.24 (± 13.73) kg</li> <li>• Height, mean (SD): 157.78 (± 7.43) cm</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 30; losses, n = 0; analysed, n = 30</li> <li>• Details: isoflurane titrated using BIS target values of 45 to 55</li> </ul> <p>Comparison group (clinical signs/ETAG)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 30; losses, n = 0; analysed, n = 30</li> <li>• Details: isoflurane titrated according to routine clinical parameters (such as HR, BP, and end-tidal concentration in the form of MAC)</li> </ul> <p>Both groups: premedication with midazolam. Induction with propofol, fentanyl and atracurium to facilitate tracheal intubation. Maintenance with nitrous oxide/oxygen (60%/40%) and isoflurane, and intermittent doses of atracurium. For hypertension, adjustments made accordingly to fentanyl or muscle relaxant. Ephedrine or phenylephrine for hypotension, and glycopyrrolate for bradycardia</p>
Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> haemodynamic variables; time to eye opening; time to extubation; time to transfer to PACU; postanaesthesia recovery score</p> <p><b>Outcomes relevant to the review:</b> time to eye opening</p>
Notes	<p><b>Funding/declarations of interest:</b> not specified</p> <p><b>Study dates:</b> January 2008 to December 2008</p>

**Shafiq 2012** (Continued)

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Quasi-randomized trial using slips of paper labelled as BIS group or control group which were taken from an envelope.
Allocation concealment (selection bias)	High risk	No method used to conceal allocation
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It was not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Siampalioti 2015**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 100</p> <p><b>Country:</b> Greece</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> scheduled for elective bariatric surgery; super obese with BMI &gt; 50 kg/m<sup>2</sup>; aged 21 to 60 years of age</p> <p><b>Exclusion criteria:</b> severe cardiopulmonary disease; significant renal dysfunction; liver dysfunction; history of hyper- or hypothyroidism; serious psychiatric or neurologic disorders; recall during GA; allergy to local anaesthetics; history of substance abuse; contra-indications for placement of thoracic epidural catheter; refusal to participate</p> <p><b>Type of surgery:</b> bariatric surgery</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS - propofol)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 37 (± 9) years</li> <li>• Gender, M/F: 6/19</li> <li>• BMI, mean (SD): 55 (± 6) kg/m<sup>2</sup></li> </ul>

- Weight, mean (SD): 152 ( $\pm$  20) kg
- Height, mean (SD): 166 ( $\pm$  9) cm
- Duration of surgery, mean (SD): 176 ( $\pm$  24) minutes

Intervention group (BIS - sevoflurane)

- Age, mean (SD): 36 ( $\pm$  10) years
- Gender, M/F: 7/8
- BMI, mean (SD): 57 ( $\pm$  9) kg/m<sup>2</sup>
- Weight, mean (SD): 157 ( $\pm$  26) kg
- Height, mean (SD): 166 ( $\pm$  8) cm
- Duration of surgery, mean (SD): 187 ( $\pm$  28) minutes

Comparison group (clinical signs - propofol)

- Age, mean (SD): 36 ( $\pm$  9)
- Gender, M/F: 8/17
- BMI, mean (SD): 59 ( $\pm$  11) kg/m<sup>2</sup>
- Weight, mean (SD): 162 ( $\pm$  27) kg
- Height, mean (SD): 166 ( $\pm$  9) cm
- Duration of surgery, mean (SD): 194 ( $\pm$  27) minutes

Comparison group (clinical signs - sevoflurane)

- Age, mean (SD): 42 ( $\pm$  8) years
- Gender, M/F: 10/15
- BMI, mean (SD): 61 ( $\pm$  10) kg/m<sup>2</sup>
- Weight, mean (SD): 170 ( $\pm$  35) kg
- Height, mean (SD): 167 ( $\pm$  9) cm
- Duration of surgery, mean (SD): 192 ( $\pm$  29) minutes

Interventions

Intervention (BIS - propofol)

- Randomized, n = 25; losses, n = 0; analysed, n = 25
- Details: propofol titrated to maintain BIS (Aspect Medical Systems Inc, USA), target values between 40 to 55. Also adjusted anaesthesia according to clinical signs (HR and BP to within 15% of baseline values). For decrease in BP < 15% of baseline values, remifentanyl was given and if necessary etilefrine. For HR < 45 bpm, atropine was given

Intervention (BIS - sevoflurane)

- Randomized, n = 25; losses, n = 0; analysed, n = 25
- Details: RSI with propofol, remifentanyl and succinylcholine for tracheal intubation. Maintenance with sevoflurane (end-tidal concentration of 1% to 3%), titrated to maintain BIS (Aspect Medical Systems Inc, USA), target values between 40 to 55. Also adjusted anaesthesia according to clinical signs (HR and BP to within 15% of baseline values). Nifedipine for positive sympathetic response and HR < 70 bpm, diltiazem given for HR > 70 bpm followed by esmolol if necessary.

Comparison (clinical signs - propofol)

- Randomized, n = 25; losses, n = 0; analysed, n = 25
- Details: adjusted propofol according to clinical signs (HR and BP to within 15% of baseline values). For decrease in BP < 15% of baseline values, remifentanyl was given and if necessary etilefrine. For HR < 45 bpm, atropine was given

Comparison (clinical signs - sevoflurane)

- Randomized, n = 25; losses, n = 0; analysed, n = 25

**Siampalioti 2015** (Continued)

- Details: RSI with propofol, remifentanyl and succinylcholine for tracheal intubation. Maintenance with sevoflurane (end-tidal concentration of 1% to 3%). Sevoflurane adjusted according to clinical signs (HR and BP to within 15% of baseline values). Nifedipine for positive sympathetic response and HR < 70 bpm, diltiazem given for HR > 70 bpm followed by esmolol if necessary.

All groups: doses of all anaesthetic drugs were based on either ideal body weight or corrected body weight. Neuromuscular blockade (cisatracurium) given by continuous infusion, with reversal using neostigmine and atropine

Outcomes	<p><b>Outcomes measured/reported by study authors:</b> haemodynamic variables; recovery times (time to eye opening, time to extubation, time to reach specified recovery scores); pain</p> <p><b>Outcomes relevant to the review:</b> time to eye opening</p>
Notes	<p><b>Funding/declarations of interest:</b> funding not reported. Study authors declare no conflicts of interest</p> <p><b>Study dates:</b> not reported</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• we noted that treatment used to manage HR differed between the propofol and sevoflurane groups</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Use of a computer-generated random number table
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: ""Both the anesthesiologist performing the assessment and the patients were blinded to the general anesthetic used and the BIS monitoring"
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study is registered with a clinical trial register (NCT01279499). However, because the trial does not report a study date, and the clinical trial register has not been updated, it is not possible to assess with registration was retrospective or prospective. It is not feasible to assess the risk of reporting bias without this information
Other bias	Low risk	We identified no other sources of bias

## Sudhakaran 2018

### Study characteristics

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 68</p> <p><b>Country:</b> India</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> undergoing lumbar spine surgery; ASA I or II; both genders; 20 to 60 years of age</p> <p><b>Exclusion criteria:</b> psychiatric illness; clinically significant cardiovascular, respiratory, hepatic or renal disease; long-term drug or alcohol abuse</p> <p><b>Type of surgery:</b> lumbar spine surgery</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 42.05 (<math>\pm</math> 12.81) years</li> <li>• Gender, M/F: 13/8</li> <li>• Weight, mean (SD): 69.0 (<math>\pm</math> 10.64) kg</li> <li>• ASA status I/II: 18/3</li> <li>• Duration of anaesthesia: 113.90 (<math>\pm</math> 32.14) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 40.38 (<math>\pm</math> 13.12) years</li> <li>• Gender, M/F: 16/5</li> <li>• Weight, mean (SD): 69.81 (<math>\pm</math> 13.10) kg</li> <li>• ASA status I/II: 15/6</li> <li>• Duration of anaesthesia: 110.48 (<math>\pm</math> 30.84) minutes</li> </ul> <p>Comparison group (ETAG)</p> <ul style="list-style-type: none"> <li>• Age, mean (SD): 38.10 (<math>\pm</math> 13.47) years</li> <li>• Gender, M/F: 12/9</li> <li>• Weight, mean (SD): 65.52 (<math>\pm</math> 13.39) 13.39) kg</li> <li>• ASA status I/II: 17/4</li> <li>• Duration of anaesthesia: 108.14 (<math>\pm</math> 25.58) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 22; losses, n = 1 (protocol violation); analysed, n = 21</li> <li>• Details: administration of anaesthetic to maintain BIS (XP sensor, Aspect Medical Systems, USA), values between 45 to 55, with target value of 55</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 22; losses, n = 1 (BIS recording lost); analysed, n = 21</li> <li>• Details: adjustment to maintain haemodynamic variables within 20% baseline values. Aim to reduce desflurane as much as clinically possible without allowing for movement or intraoperative awakening</li> </ul> <p>Comparison group (ETAG)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 24; losses, n = 3 (1 BIS recording lost; 2 protocol violation); analysed, n = 21</li> </ul>

**Sudhakaran 2018** (Continued)

- Details: adjustment to maintain desflurane concentrations to achieve a target age-corrected combined MAC of 0.8 to 1. Aim for lowest value, i.e. 0.8 MAC

All groups: induction with morphine and propofol, and vecuronium. Maintenance with desflurane in nitrous oxide/oxygen (50%/50%) and vecuronium. Diclofenac and ondansetron 15 minutes before end of procedure, and bupivacaine prior to skin closure. Residual neuromuscular blockade was reversed with neostigmine and glycopyrrolate

Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> recovery times (time to emergence; time extubation; time to name recall; fast track time); postoperative analgesic requirements; intraoperative awareness (interview at 24 hours postoperatively using Modified Brice Questionnaire); PONV</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> no funding. Study authors report no conflicts of interest</p> <p><b>Study dates:</b> July 2011 to December 2012</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• possible clinical trial registration (CTRI/2018/02/011695), which we have not confirmed with the study authors</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomization
Allocation concealment (selection bias)	Unclear risk	Participants selected a sealed envelope; insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	Few losses
Selective reporting (reporting bias)	Unclear risk	Although we identified a clinical trial register report that described a similar study, we did not clarify this with the study authors and could not use this document to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

Random sequence generation (selection bias)	Unclear risk	Insufficient information about the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "".....the times at which patients were able to open their eyes,...were assessed...by a third investigator who was unaware of the monitoring group.. "

**White 2004** (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	No missing outcome data
Selective reporting (reporting bias)	Unclear risk	Prospective clinical trials registration or published protocol not reported. It was not feasible to assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Wong 2002**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 68</p> <p><b>Country:</b> Canada</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> ASA status I to III; &gt; 60 years of age; scheduled for elective orthopaedic knee or hip replacement</p> <p><b>Exclusion criteria:</b> significant cardiopulmonary diseases or other end-organ disease; depression or psychiatric disorders; dementia; previous CVA; head trauma; inadequate command of English; drugs and all alcohol abuse; preoperative baseline of MMSE score &lt; 24</p> <p><b>Type of surgery:</b> elective orthopaedic knee or hip replacement</p> <p><b>Experience of anaesthetist (in years or qualifications):</b> ≥ 5 years experience of providing anaesthetic patient care</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 71 (± 5) years</li> <li>Gender, M/F: 19/10</li> <li>Weight, mean (SD): 82 (± 15) kg</li> <li>Height, mean (SD): 169 (± 9) cm</li> <li>ASA status I/II/III: 2/24/3</li> <li>Duration of anaesthesia: 120 (± 17) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 70 (± 6) years</li> <li>Gender, M/F: 21/10</li> <li>Weight, mean (SD): 84 (± 16) kg</li> <li>Height, mean (SD): 170 (± 7) cm</li> <li>ASA status I/II/III: 3/27/1</li> <li>Duration of anaesthesia: 121 (± 17) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Randomized, n = 34; losses = 5; analysed, n = 29</li> <li>Details: administration of isoflurane and fentanyl to maintain BIS (model A1050, Aspect Medical Systems, USA), target values of 50 to 60. For hypertension or tachycardia and BIS value &gt; 60, then increase</li> </ul>

**Wong 2002** (Continued)

in isoflurane concentration until BIS was between 50 to 60. If BIS was in target range, then fentanyl was given. If BIS was < 50 then isoflurane was decreased and fentanyl or labetalol were given as required

Comparison group (clinical signs)

- Randomized, n = 34; losses = 3; analysed, n = 31
- Details: isoflurane and fentanyl adjusted to clinical practice and to provide rapid recovery. Anaesthetist was blinded to BIS monitor. For hypertension or tachycardia, attending anaesthetist had the option of increasing inspired isoflurane concentration or given fentanyl or labetalol

Both groups: induction with propofol, fentanyl and midazolam. Rocuronium to facilitate intubation. Maintenance with isoflurane and 60% to 70% nitrous oxide. Additional rocuronium if required. Reversal with neostigmine and glycopyrrolate

Outcomes	<p><b>Outcomes measured/reported by study authors:</b> end-tidal concentrations and consumption of isoflurane; recovery times (awakening; orientation; discharge from PACU); BIS values; MMSE scores; intraoperative awareness (interview 72 hours after surgery and at 14 days after surgery)</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness; time to orientation; time in PACU</p>
Notes	<p><b>Funding/declarations of interest:</b> supported in part by a grant from Aspect Medical, Newton, Massachusetts, USA</p> <p><b>Study dates:</b> not reported</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	A block randomization with concealed varying block sizes was performed with computer-generated random numbers
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: ""The Aldrete score was assessed at 15 min intervals by a research nurse blinded to the group assignment ....."
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: ""....., eight patients (three from the SP group, and five from the BIS group) were excluded from the analysis for protocol violations." The missing outcome data seem to balance across intervention group
Selective reporting (reporting bias)	Unclear risk	Prospective clinical trials registration or published protocol not reported. It was not feasible to assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Zhang 2011**
**Study characteristics**

Methods	RCT, parallel design
---------	----------------------

**Zhang 2011** (Continued)

Participants

**Total number of analysed participants:** 5309

**Country:** China

**Setting:** multi-centre; 13 hospitals

**Inclusion criteria:** over 18 years of age; without any apparent mental defects; patients scheduled for total intravenous anaesthesia (TIVA)

**Exclusion criteria:** unable to be interviewed after surgery; unable to communicate in Mandarin Chinese; undergoing awake intubation; undergoing intraoperative arousal test.

**Type of surgery:** neurosurgery; craniofacial and cervical surgery; heart surgery; gynaecologic and obstetric surgery; chest and abdominal surgery; urinary surgery; spine and limb surgery; other surgeries.

**Risk of awareness:** unselected for risk of awareness

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 46.95 ( $\pm$  14.86) years
- Gender, M/F: 1237/1656
- Weight (kg), mean (SD): 63.80 ( $\pm$  11.21) kg
- ASA status I/II/>III: 1386/1128/138

Comparison group (clinical signs)

- Age, mean (SD): 46.06 ( $\pm$  14.59) years
- Gender, M/F: 971/1309
- Weight (kg), mean (SD): 63.39 ( $\pm$  14.59) kg
- ASA status I/II/>III: 1323/834/65

Interventions

Intervention group (BIS)

- Randomized, n = not reported; losses = 11 losses (due to participants < 18 years of age, 2 participants failed to be interviewed); analysed, n = 2919
- Details: propofol guided by BIS (A-2000, Aspect Medical System, USA), target values between 40 to 60

Comparison group (clinical signs)

- Randomized, n = not reported; losses = 10 losses (due to participants < 18 years of age), 2 participants failed to be interviewed); analysed, n = 2309
- Details: no BIS-guided TIVA, BIS screen recorded but covered to the anaesthetist.

Both groups: no premedication. Initiation with midazolam, and induction and maintenance with propofol. Other types of anaesthetics (analgesics and muscle relaxants) were at the discretion of the attending anaesthetists.

Outcomes

**Outcomes measured/reported by study authors:** confirmed intraoperative awareness and possible intraoperative awareness and dreaming (using a structured questionnaire on POD 1 and POD 4)

**Outcomes relevant to the review:** confirmed intraoperative awareness

Notes

**Funding/declarations of interest:** not reported

**Study dates:** November 2008 to November 2010

**Note:**

- we could not be certain of the number of randomized participants because of discrepancies in the reporting. Study authors reported that quote: "outcome data was collected from 5309 patients". We

**Zhang 2011** (Continued)

have taken this figure to indicate the number of analysed participants. We noted additional discrepancies in the baseline characteristics table which suggested that data for all participants may not have been reported; the total number of participants according to gender and the total number of participants for ASA status are not comparable.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Despite using computer-generated random numbers, we are uncertain whether sequence generation was adequately conducted because the information of group allocation was not available in 54 cases. Furthermore, using the baseline characteristics table as a guide, there was an unequal number of participants in each group, and baseline differences between groups in gender and ASA scores which indicated the possibility of poor methods of randomization
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Participants were blinded to group allocation. However, it is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: ""Interviewers and patients were blinded to the group allocation"
Incomplete outcome data (attrition bias) All outcomes	High risk	Quote: ""Fifty-four cases were withdrawn because the information of group allocation was unavailable and another 21 patients were excluded due to age younger than 18 years old (11/10) and a further six patients were excluded because of failure to be interviewed (2/2), one patient died postoperatively, operation was cancelled in one case after anaesthesia induction."
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Zhang 2016**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 72</p> <p><b>Country:</b> China</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> severe burns; escharotomy + dermatoplasty under GA during early stages (within 7 days after burn); 18 to 65 years of age; BMI &gt; 20 kg/m<sup>2</sup> or &gt; 30 kg/m<sup>2</sup>; no history of primary hypertension</p> <p><b>Exclusion criteria:</b> preoperative heart, lung, liver, kidney and other viscera insufficiently; elective surgery; other serious complications such as MI or cerebral infarction</p>

**Zhang 2016** (Continued)

**Type of surgery:** escharotomy + dermatoplasty

**Baseline characteristics**

Intervention group (BIS)

- Age, mean (SD): 47.17 ( $\pm$  14.79) years
- Gender, M/F: 21/15
- BMI, mean (SD): 24.54 ( $\pm$  2.34) kg/m<sup>2</sup>
- APACHE II, mean (SD): 2.25 ( $\pm$  0.87)

Comparison group (clinical signs)

- Age, mean (SD): 46.92 ( $\pm$  13.81) years
- Gender, M/F: 19/17
- BMI, mean (SD): 24.56 ( $\pm$  2.61) kg/m<sup>2</sup>
- APACHE II, mean (SD): 2.03 ( $\pm$  1.06)

Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 36; losses, n = 0; analysed, n = 36</li> <li>• Details: propofol and remifentanil were adjusted to achieve BIS target values of 40 to 65</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>• Randomized, n = 36; losses, n = 0 analysed, n = 36</li> <li>• Details: anaesthesia adjusted to maintain SBP within 90 to 140 mmHg</li> </ul> <p>Both groups: atropine before surgery; induction with midazolam, etomidate, sufentanil, and rocuronium. Maintenance with propofol and remifentanil, and rocuronium</p>
Outcomes	<p><b>Outcomes measured/ reported by study authors:</b> haemodynamic variables; doses of propofol and remifentanil; recovery (time to spontaneous breathing; time to directional force; time to extubation); intraoperative awareness (time of measure and method of collection was not reported)</p> <p><b>Outcomes relevant to the review:</b> intraoperative awareness</p>
Notes	<p><b>Funding/declarations of interest:</b> funding not specified. Study authors declare no conflicts of interest</p> <p><b>Study dates:</b> August 2013 to August 2015</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• study included an additional group (Narcotrend) which we did not include in this review</li> </ul>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Participants were quote: "randomly divided"; no additional details
Allocation concealment (selection bias)	Unclear risk	Not specified
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were aware of group allocation. it is not feasible to blind anaesthetists to group allocation

**Zhang 2016** (Continued)

Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**Zohar 2006**
**Study characteristics**

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 50</p> <p><b>Country:</b> Israel</p> <p><b>Setting:</b> hospital; single centre</p> <p><b>Inclusion criteria:</b> geriatric (more than 65 years of age); undergoing short elective transurethral surgical procedures</p> <p><b>Exclusion criteria:</b> a history of unstable cardiovascular, pulmonary, hepatic, renal, neurologic, psychiatric or metabolic diseases</p> <p><b>Type of surgery:</b> short elective transurethral surgical procedures</p> <p><b>Baseline characteristics</b></p> <p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 73 (<math>\pm</math> 8) years</li> <li>Gender, M/F: 21/4</li> <li>Weight, mean (SD): 77 (<math>\pm</math> 14) kg</li> <li>Height, mean (SD): 170 (<math>\pm</math> 8) cm</li> <li>ASA status I/II/III: 2/19/4</li> <li>Duration of anaesthesia: 51 (<math>\pm</math> 24) minutes</li> </ul> <p>Comparison group (clinical signs)</p> <ul style="list-style-type: none"> <li>Age, mean (SD): 76 (<math>\pm</math> 7) years</li> <li>Gender, M/F: 22/3</li> <li>Weight, mean (SD): 76 (<math>\pm</math> 12) kg</li> <li>Height, mean (SD): 169 (<math>\pm</math> 7) cm</li> <li>ASA status I/II/III: 2/20/3</li> <li>Duration of anaesthesia: 48 (<math>\pm</math> 16) minutes</li> </ul>
Interventions	<p>Intervention group (BIS)</p> <ul style="list-style-type: none"> <li>Randomized, n = 25; losses = 0; analysed, n = 25</li> </ul>

**Zohar 2006** (Continued)

- Details: sevoflurane adjusted to maintain BIS (A-2000, Aspect Medical Systems, USA), target values of 50 to 60

Comparison group (clinical signs)

- Randomized, n = 25; losses = 0; analysed, n = 25
- Details: sevoflurane adjusted to standard clinical signs

Both groups: induction with fentanyl and propofol. Use of LMA. Maintenance with sevoflurane which was increased in response to signs of an inadequate "depth of anaesthesia" (e.g. movement in response to surgical stimulation). Rescue fentanyl given for sustained increase in respiratory rate. Muscle relaxants were not used

**Outcomes**

**Outcomes measured/reported by study authors:** anaesthetic requirement (sevoflurane MAC during maintenance (MAC/hour); amount of propofol needed at induction; amount of fentanyl needed at induction; fentanyl 'rescue' dose required); recovery times (time to spontaneous eye opening (study authors do not report data for this outcome); time to remove laryngeal mask airway (LMA) device (study authors do not report data for this outcome); time to responding to simple verbal commands; time to correctly state name, age, and personal identification number; time to achieve fast-track ability (main outcome); time from awakening from anaesthesia to achieve post anaesthesia care unit (PACU) discharge eligibility); the occurrence of any side effects; the occurrence of need for therapeutic interventions; the occurrence of intraoperative recall awareness (questioned at time of discharge from PACU); patients' satisfaction scores

**Outcomes relevant to the review:** time from awakening from anaesthesia to achieve PACU discharge eligibility; occurrence of intraoperative recall awareness; time to eye opening (not reported)

**Notes**

**Funding/declarations of interest:** quote: "no industry related funding"

**Study dates:** not reported

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Insufficient information
Allocation concealment (selection bias)	Unclear risk	Insufficient information
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study authors do not report whether participants were blinded to group allocation. It is not feasible to blind anaesthetists to group allocation
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: ""Early recovery endpoints were recorded...by a blinded observer..."
Incomplete outcome data (attrition bias) All outcomes	Low risk	No apparent losses
Selective reporting (reporting bias)	Unclear risk	Study authors did not report prospective clinical trials registration or a published protocol. Therefore, it is not feasible to effectively assess risk of reporting bias
Other bias	Low risk	We identified no other sources of bias

**AAI:** auditory-evoked potential; **AEP:** auditory evoked potential; **ASA:** American Society of Anesthesiologists; **BIS:** bispectral index; **BMI:** body mass index; **BP:** blood pressure; **bpm:** beats per minute; **CABG:** coronary artery bypass graft; **COPD:** chronic obstructive pulmonary disease; **CPB:** cardiopulmonary bypass; **CVA:** cardiovascular accident; **EEG:** electroencephalography; **ENT:** ear, nose, throat; **ETAC:** end-tidal anaesthetic concentration; **ETAG:** end-tidal anaesthetic gas; **ETVAC:** end-tidal concentration of the volatile anaesthetic; **GA:** general anaesthesia; **HR:** heart rate; **IQR:** interquartile range; **ITT:** intention to treat; **IV:** intravenous(ly); **LMA:** laryngeal mask airway; **M/F:** male/female; **MAC:** minimum alveolar concentration; **MAP:** mean arterial pressure; **MMSE:** mini mental state examination; **n:** number of participants; **N/A:** not applicable; **PACU:** postanesthesia care unit; **POD:** postoperative day; **PONV:** postoperative nausea and vomiting; **PRST:** systolic blood pressure, heart rate, sweating, tears; **PTSD:** post-traumatic stress disorder; **RCT:** randomized controlled trial; **RSI:** rapid sequence induction; **SBP:** systolic blood pressure; **SD:** standard deviation; **TBSA:** total burn surface area; **TCI:** target controlled infusion; **TIVA:** total intravenous anaesthesia; **TNG:** topical nitroglycerin; **TOF:** train-of-four

### Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
<a href="#">Aceto 2015</a>	The aim of the study was to evaluate whether BIS-guided sevoflurane may achieve a lower MAC value, and to search for a MAC threshold for preventing arousal. We excluded this study because it did not meet the review criteria
<a href="#">Aimé 2006</a>	The study was included in a previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). The aim of the study was to evaluate the economic impact of hypnosis with sevoflurane and we excluded this study because it did not meet the review criteria
<a href="#">Chan 2013</a>	The aim of the study was to evaluate the effects of BIS-guided anaesthesia on postoperative delirium and cognitive decline and we excluded this study because it did not meet the review criteria
<a href="#">Chiu 2007</a>	The study was included in a previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). The aim of the study was to evaluate the impact of the use of BIS monitoring on propofol requirements and haemodynamic stability during cardiopulmonary bypass. We excluded this study because it did not meet the review criteria
<a href="#">Hachero 2001</a>	The study was included in a previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). The aim of the study was to evaluate analgesic requirements when BIS monitoring was used. We excluded this study because it did not meet the review criteria
<a href="#">Kamali 2017b</a>	The aim of the study was to evaluate the effects of BIS-guided anaesthesia on the time of extubation in the ICU following CABG. We excluded this study because it did not meet the review criteria
<a href="#">Karwacki 2014</a>	The aim of the study was to optimise the dosage of anaesthetic agents using BIS-guided anaesthesia. We excluded this study because it did not meet the review criteria
<a href="#">Kaval 2015</a>	The aim of the study was to evaluate the effects of BIS-guided anaesthesia on the time of extubation in the ICU following CABG. We excluded this study because it did not meet the review criteria
<a href="#">Kerssens 2009</a>	The aim of the study was to evaluate the effect of BIS-guided anaesthesia on memory function and physiologic stress response to surgery. We excluded this study because it did not meet the review criteria
<a href="#">Nitzschke 2014</a>	The study was in the list of studies awaiting classification in the previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). Participants undergoing on-pump cardiac surgery. We excluded this study because it was a sequential two-arm clinical study and was not randomized
<a href="#">Panagopoulou 2000</a>	RCT, parallel design. Participants undergoing ENT procedures with anaesthesia titrated to BIS (target values 40 to 60) or by clinical signs. Study is available only as an abstract and does not include the number of participants randomized or analysed in each group. We excluded this study because we did not expect that a publication of the full text is likely, since that abstract was published in 2000.

Study	Reason for exclusion
<a href="#">Quesada 2016</a>	The study was in the list of studies awaiting classification in the previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). Participants were undergoing echobronchial ultrasound under sedation and we excluded the study because the participant group was not eligible
<a href="#">Radtke 2013</a>	The aim of the study was to evaluate the effects of BIS-guided anaesthesia on postoperative delirium in elderly people and we excluded this study because it did not meet the review criteria
<a href="#">Rüsch 2018</a>	The aim of the study was to evaluate the induction of anaesthesia guided by BIS or a weight-based manual administration for the incidence of hypotension. We excluded this study because it did not meet the review criteria
<a href="#">Samarkandi 2004</a>	The study was included in a previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). The aim of the study was to evaluate the effects of BIS monitoring on anaesthetic requirements and the need for circulatory support. We excluded this study because it did not meet the review criteria
<a href="#">Shahrbazi 2008</a>	The aim of the study was to evaluate the effect of BIS monitoring on serum cortisol levels in the people undergoing CABG. We excluded this study because it did not meet the review criteria
<a href="#">Struys 2001</a>	The study was included in a previous version of the review ( <a href="#">Punjasawadwong 2014</a> ). The study compared the use of a closed-loop system that included BIS with a manually-controlled system and we excluded this study because it did not meet the review criteria
<a href="#">Vretzakis 2005</a>	The aim of the study was to evaluate decision making processes when the value of BIS is known during anaesthesia. We excluded this study because it did not meet the review criteria
<a href="#">Zhou 2018</a>	The aim of the study was to evaluate the effect of BIS monitoring on postoperative attention network dysfunction in elderly surgical patients. We excluded this study because it did not meet the review criteria

**BIS:** bispectral index; **CABG:** coronary artery bypass graft; **ENT:** ear, nose and throat; **ICU:** intensive care unit; **MAC:** minimum alveolar concentration; **RCT:** randomized controlled trial

### Characteristics of studies awaiting classification [ordered by study ID]

#### [Aksun 2007](#)

Methods	RCT, parallel design
Participants	<b>Number of randomized participants:</b> 40 <b>Type of surgery:</b> cholecystectomy
Interventions	<ul style="list-style-type: none"> <li>• BIS-guided sevoflurane (BIS target values 40 to 60)</li> <li>• standard practice sevoflurane</li> <li>• BIS-guided desflurane (BIS target values 40 to 60)</li> <li>• standard practice desflurane</li> </ul>
Outcomes	Drug consumption; recovery times (type of recovery is not specified in English abstract)
Notes	We were unable to source the full text of this study from current library sources and the abstract contained insufficient information to assess eligibility

**Croci 2014**

Methods	RCT, parallel design
Participants	<b>Number of randomized participants:</b> 480 <b>Inclusion criteria:</b> women undergoing gynaecological laparoscopy surgery: ASA status I or II
Interventions	<ul style="list-style-type: none"> <li>• BIS-guided anaesthesia</li> <li>• Non BIS-guided anaesthesia</li> </ul>
Outcomes	PONV; desflurane consumption; cost
Notes	Study published only as an abstract. We could not be certain from the information in the abstract by what methods anaesthesia was guided in the control group

**CTRI/2018/03/012457**

Methods	RCT
Participants	<b>Estimated number of randomized participants:</b> 402 <b>Inclusion criteria:</b> ASA I and II; 15 to 65 years of age; either gender; undergoing elective surgical procedures requiring general anaesthesia <b>Exclusion criteria:</b> history of preoperative long-term use of anticonvulsant agents, opiates, benzodiazepines, cocaine or daily alcohol consumption; pre-existing renal hepatic and cardiac disease; history of difficult intubation or anticipated difficult intubation; ASA status III, IV or IV; surgical procedure or positioning of the patient prevents BIS monitoring; people with dementia; unable to provide informed consent; history of stroke with residual neurological deficits <b>Country:</b> India
Interventions	BIS-guided anaesthesia; ETAG-guided anaesthesia
Outcomes	Time to recovery; time to extubation
Notes	Completed study in clinical trials register. We await publication of full report to assess eligibility

**Golmohammadi 2014**

Methods	It is unclear if the study is an RCT
Participants	<b>Total number of randomized participants:</b> 50 <b>Inclusion criteria:</b> morbidly obese adult patients undergoing elective laparoscopic cholecystectomy
Interventions	BIS-guided isoflurane anaesthesia; and standard clinical practice
Outcomes	Isoflurane consumption; recovery (time to extubation; time to awakening)
Notes	Requires translation from Persian. We could not be certain from the English abstract whether this study was an RCT or a cohort study

### Jeong 2002

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 40</p> <p><b>Inclusion criteria:</b> scheduled for gastric resection under GA</p> <p><b>Exclusion criteria:</b> kidney or liver function abnormalities; hypertension; diabetes; surgery expected to take &lt; 150 minutes</p>
Interventions	Intervention group (BIS), n = 20; versus control group (not specified), n = 20
Outcomes	Concentrations of sevoflurane; BIS values; recovery times (time to response, time to extubation, time to reach 10 points on recovery scale, time to discharge from PACU)
Notes	Requires translation from Korean. We could not be certain from the English abstract of the control group methods to monitor depth of anaesthesia

### Qu 2011

Methods	RCT, parallel design
Participants	<p><b>Total number of randomized participants:</b> 100</p> <p><b>Inclusion criteria:</b> participants undergoing TIVA anaesthesia; no additional details</p>
Interventions	BIS-guided anaesthesia; no BIS
Outcomes	Intraoperative recall awareness
Notes	We were unable to source the full text of this study from current sources. The English abstract does not include denominator figures for each group and we require the full text in order to include this study

**ASA:** American Society of Anesthesiologists; **BIS:** bispectral index; **ETAG:** end-tidal anaesthetic gas; **GA:** general anaesthesia; **PACU:** postanaesthesia care unit; **PONV:** postoperative nausea and vomiting; **RCT:** randomized controlled trial; **TIVA:** total intravenous anaesthesia

### Characteristics of ongoing studies [ordered by study ID]

#### Martins 2013

Study name	Influence of processed EEG monitoring in the anesthetic management and its cost in off-pump coronary surgery: a research protocol
Methods	RCT
Participants	Participants undergoing CABG without CPB
Interventions	BIS visible; BIS not visible (BIS monitor is hidden and monitoring of anaesthetic depth is based on clinical signs associated with the monitoring of expiratory fraction of halogenated anaesthetic agent)
Outcomes	Anaesthetic depth; cost

**Martins 2013** (Continued)

Starting date	Unknown
Contact information	Unknown
Notes	We were unable to source the full text of this article. We have not been able to identify any completed trials for which this protocol may be associated, and therefore we assume that the study is ongoing. To populate this tables, we have used information included in the previous version of the review (Punjasawadwong 2014).

**NCT03571945**

Study name	Incidence of intraoperative awareness in Indian patient population
Methods	RCT, parallel design
Participants	<p><b>Target number of randomized participants:</b> 2000</p> <p><b>Inclusion criteria:</b> either gender; 18 to 65 years of age; ASA status I or II; GA; elective surgery with a duration of &gt; 30 minutes; consenting to follow-up</p> <p><b>Exclusion criteria:</b> uncompensated systemic co-morbidity; cardiac and neurosurgical procedures; head and neck surgery; obstetric surgery; emergency surgery; anticipated difficult airway; H/O brain injury; EEG abnormality; neuropsychiatry disorders; substance abuse (opioids, alcohol, recreational drugs, benzodiazepine); pacemakers and electronic implants; obesity (BMI &gt; 30kg/m<sup>2</sup>); adhesive allergy</p> <p><b>Setting:</b> India; multi-centre</p>
Interventions	BIS versus ETAG
Outcomes	Incidence of intraoperative awareness; BIS score; ETAG concentration; MAC concentration; recovery (time to open eyes; time to extubation); haemodynamic variables; postoperative sedation; PONV; postoperative analgesia
Starting date	10 October 2018
Contact information	Amitabh Dutta ( <a href="mailto:duttaamiatbh@yahoo.co.in">duttaamiatbh@yahoo.co.in</a> ); Nitin Sethi ( <a href="mailto:nitinsethi77@yahoo.co.in">nitinsethi77@yahoo.co.in</a> )
Notes	<b>Estimated primary completion date:</b> July 2020

**ASA:** American Society of Anesthesiologists; **BIS:** bispectral index; **BMI:** body mass index; **CABG:** coronary artery bypass graft; **CPB:** cardiopulmonary bypass; **EEG:** electroencephalography; **ETAG:** end-tidal anaesthetic gas; **GA:** general anaesthesia; **H/O:** heterotopic ossification; **MAC:** minimum alveolar concentration; **PONV:** postoperative nausea and vomiting; **RCT:** randomized controlled trial

## DATA AND ANALYSES

### Comparison 1. BIS versus clinical sides

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Occurrence of intraoperative awareness	27	9765	Peto Odds Ratio (Peto, Fixed, 95% CI)	0.36 [0.21, 0.60]

### Bispectral index for improving intraoperative awareness and early postoperative recovery in adults (Review)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.2 Time to eye opening (minutes)	22	1494	Mean Difference (IV, Random, 95% CI)	-1.78 [-2.53, -1.03]
1.3 Time to orientation (minutes)	6	273	Mean Difference (IV, Random, 95% CI)	-3.18 [-4.03, -2.33]
1.4 Time to discharge from the PACU (minutes)	13	930	Mean Difference (IV, Random, 95% CI)	-6.86 [-11.72, -2.00]

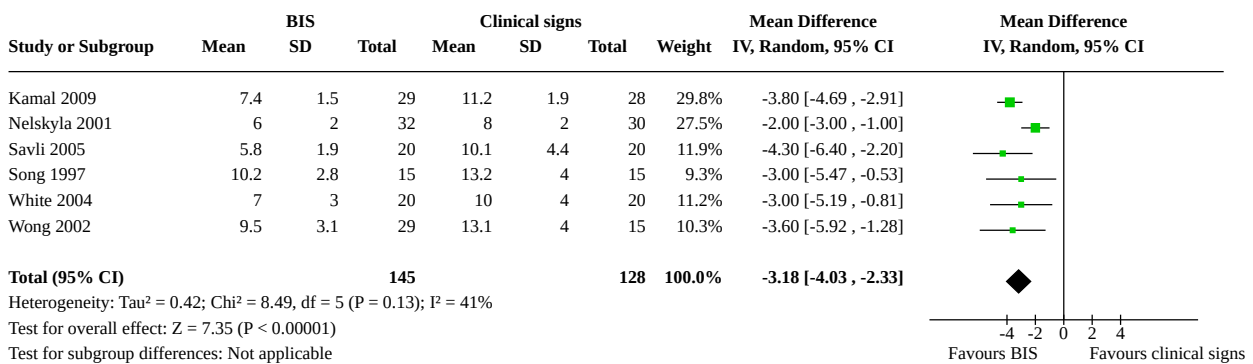

**Analysis 1.1. Comparison 1: BIS versus clinical signs, Outcome 1: Occurrence of intraoperative awareness**

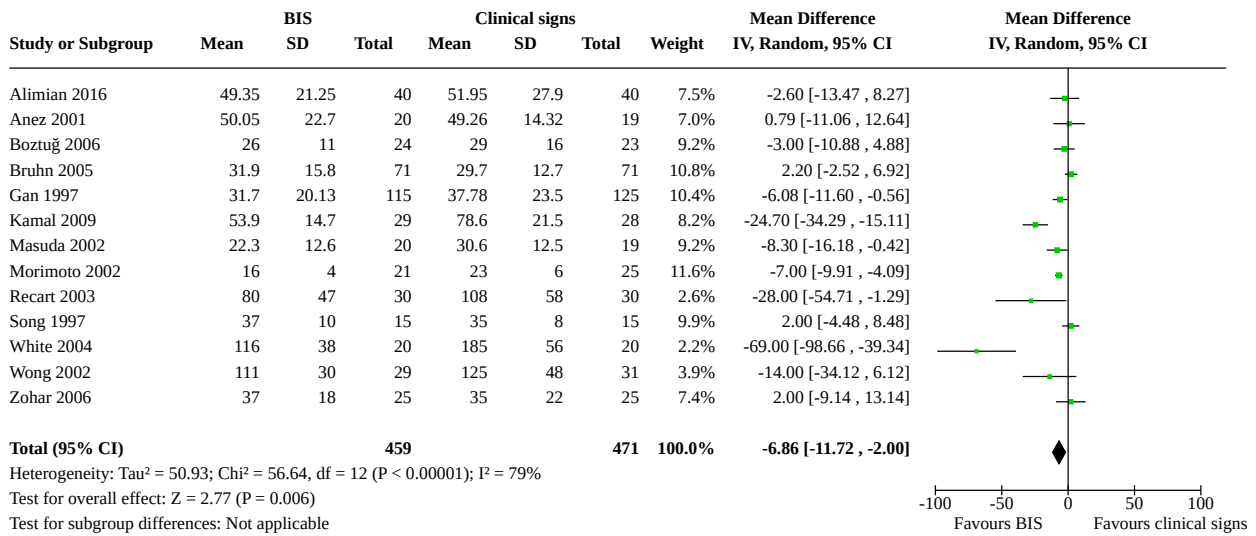

**Analysis 1.2. Comparison 1: BIS versus clinical sides, Outcome 2: Time to eye opening (minutes)**

**Analysis 1.3. Comparison 1: BIS versus clinical sides, Outcome 3: Time to orientation (minutes)**

**Analysis 1.4. Comparison 1: BIS versus clinical signs, Outcome 4: Time to discharge from the PACU (minutes)**

**Comparison 2. BIS versus clinical signs: subgroup by type of anaesthetic**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
<a href="#">2.1 Occurrence of intra-operative awareness</a>	26	7302	Peto Odds Ratio (Peto, Fixed, 95% CI)	0.40 [0.22, 0.72]

### 'Risk of bias' table

Domain	High/Low/ Unclear	Judgement
Random sequence generation (selection bias)		
Allocation concealment (selection bias)		
Blinding of participants and personnel (performance bias)		
Blinding of outcome assessors (detection bias)		
Incomplete outcome data (attrition bias)		
Selective reporting (reporting bias)		
Other bias		

### Appendix 6. Factors that increase the risk of intraoperative awareness

Factors that increase the risk of interoperative awareness (NAP5 2014)	Study ID
Female gender	Kamali 2017a; Luginbuhl 2003; Nelskyla 2001; Savli 2005; Song 1997; White 2004
Obesity	Ibraheim 2008; Siampalioti 2015
Type of surgery	Obstetric: Kamali 2017a; Luginbuhl 2003; Nelskyla 2001; Savli 2005; Song 1997; White 2004 Cardiac: Kabukcu 2012; Kim 2003; Muralidhar 2008; Puri 2003 Neurosurgery: Boztuğ 2006; Karaca 2014;
Neuromuscular blockade	Ahmad 2003; Alimian 2016; Anez 2001; Boztuğ 2006; Fakhr 2014; Georgakis 2000; Guo 2015; Ibraheim 2008; Jain 2016; Kamal 2009; Kamali 2017a; Karaca 2014; Khoshrang 2016; Kim 2003; Luginbuhl 2003; Nelskyla 2001; Paventi 2001; Payas 2013; Persec 2012; Puri 2003; Raksakietisak 2016; Re-cart 2003; Shafiq 2012; Siampalioti 2015; Song 1997; Sudhakaran 2018; Tufano 2000; White 2004; Wong 2002; Zhang 2016

## Appendix 7. Sensitivity analysis on statistical models: occurrence of intraoperative awareness

### BIS versus clinical signs

Statistical tool	Effect estimate using fixed-effect model	Effect estimate using random-effects model
Peto OR (9765 participants)	0.36, 95% CI 0.21 to 0.60; $I^2 = 61\%$	n/a
RR, M-H (9765 participants)	0.35, 95% CI 0.20 to 0.62; $I^2 = 62\%$	0.32, 95% CI 0.10 to 1.01; $I^2 = 62\%$
RR, IV (9765 participants)	0.43, 95% CI 0.23 to 0.80; $I^2 = 60\%$	0.32, 95% CI 0.10 to 1.00; $I^2 = 60\%$

### BIS versus ETAG

Statistical tool	Effect estimate using fixed-effect model	Effect estimate using random-effects model
Peto OR	1.13, 95% CI 0.56 to 2.26; $I^2 = 37\%$	n/a
RR, M-H	1.13, 95% CI 0.56 to 2.26; $I^2 = 32\%$	1.19, 95% CI 0.45 to 3.14; $I^2 = 32\%$
RR, IV	1.06, 95% CI 0.51 to 2.21; $I^2 = 31\%$	1.19, 95% CI 0.45 to 3.11; $I^2 = 31\%$

CI: confidence interval; IV: inverse variance; M-H: Mantel-Haenszel; OR: odds ratio; RR: risk ratio

### WHAT'S NEW

Date	Event	Description
2 July 2020	Amended	Number of participants for the outcome 'Time to discharge from PACU' corrected in Summary of findings table 2 and Abstract.

### HISTORY

Protocol first published: Issue 4, 2002

Review first published: Issue 4, 2007

Date	Event	Description
20 September 2019	New citation required but conclusions have not changed	We updated the review and made the following amendments. <ul style="list-style-type: none"> <li>Title: we changed the title to better reflect the review objectives.</li> <li>Review authors: we added three authors (SL, MP, LF) and removed two authors (Aram Phongchiewboon and Nutchantart Bunchungmongkoi)</li> </ul>

Date	Event	Description
		<ul style="list-style-type: none"> <li>Objectives: we changed the objectives to reflect changes to the outcomes.</li> <li>Types of interventions: we only included studies in which investigators aimed to evaluate the effectiveness of bispectral index (BIS) for its role in monitoring intraoperative depth of anaesthesia or potential improvements in early recovery times from anaesthesia.</li> <li>Types of outcome measures: we reduced the number of outcomes to improve the usability of the review. We selected outcomes that directly measured the effects of BIS-guided anaesthesia on intraoperative awareness and on early postoperative recovery, and we limited the recovery outcomes to time to: eye opening; orientation; and discharge from the postanesthesia care unit (PACU).</li> <li>Search methods and data extraction: we conducted a search for new studies. We used the same search strategies but used alternative platforms to search the databases. We used Covidence software to manage search results and an alternative data extraction template form. We edited the previous 'Risk of bias' assessments and used the standard template for these decisions.</li> <li>Data and analysis: we analysed the data as two comparisons (BIS versus clinical signs; and BIS versus end-tidal anaesthetic gas (ETAG)). We reported our methods and findings, and 'Summary of findings' tables according to these comparison groups.</li> <li>The conclusions of the review remain unchanged.</li> </ul>
20 September 2019	New search has been performed	<ul style="list-style-type: none"> <li>We conducted a search for new studies</li> <li>We excluded five studies previously included because they did not match the aim of this review. We included 22 new studies.</li> </ul>
30 June 2018	Amended	<p>We corrected a typo in 'what's new' section (the following line: 'the result of our updated review published in 2014 seems contradictory to the result in a recent review published in 2016 by Messina et al' was repeated.</p>
11 September 2017	Amended	<p>We made the following corrections to the published review:</p> <ul style="list-style-type: none"> <li>We added a new paragraph to <a href="#">Measures of treatment effect</a> "We used SMD to determine the overall effect of the BIS on requirements of the three volatile anaesthetics (desflurane, isoflurane, and sevoflurane) and expressed it as standardized mean difference of minimal alveolar concentration equivalents (MAC SMD equivalents). We interpreted the SMD as follows: 0.2 represents a small effect, 0.5 a moderate effect, and 0.8 a large effect."(<a href="#">Higgins 2011</a>)</li> <li>We changed paragraph seven, (sub heading Requirement of anaesthetics) <a href="#">Effects of interventions</a> ' to read 'The combined results for all volatile anaesthetics from 14 studies with a total of 985 participants demonstrated a significant effect of BIS monitoring in reducing the use of volatile anaesthetics, with an overall decrease of 0.65 MAC SMD equivalents (985 participants; 95% CI -1.01 to -0.28; <math>I^2 = 86%</math>) (Analysis 5.2). The requirement for sevoflurane was decreased by 0.52 MAC SMD equivalents (573 participants; 95% CI -0.87 to -0.18; <math>I^2 = 74%</math>). The MAC equivalent reduction for sevoflurane was -0.15, 95% CI (-0.25 to -0.05).The requirement for desflurane was decreased by 1.02 MAC SMD equivalents (352 participants; 95% CI -2.03 to -0.10; <math>I^2</math></li> </ul>

Date	Event	Description
		<p>= 94%). The MAC equivalent reduction for desflurane was -0.11 to 95% CI (-0.25 to -0.03).'</p> <ul style="list-style-type: none"> <li>We added a new reference (<a href="#">Messina 2016</a>)</li> <li>We added a new paragraph to <a href="#">Agreements and disagreements with other studies or reviews</a>: the result of our updated review published in 2014 seems contradictory to the result in a recent review published in 2016 by Messina et al (<a href="#">Messina 2016</a>), regarding the effect of BIS-guided anaesthesia on the risk of intraoperative recall awareness. This could be explained by the differences between the two reviews. Our review focused only on studies which were conducted in surgical patients at a high risk of intraoperative recall awareness. Whereas <a href="#">Messina 2016</a>, included studies with mixed groups of surgical patients (with or without risk of intraoperative recall awareness). Furthermore, our review performed sub-group analyses based on studies using clinical signs or ETAG as their anaesthetic guide in the standard practice group. While <a href="#">Messina 2016</a>, included all studies regardless as to whether they used clinical signs or ETAG as an anaesthetics guide in the standard practice group. The result favouring BIS monitoring for definite awareness could only be demonstrated in our sub-group analysis, where clinical signs were used as an anaesthetic guide in the standard practice group.</li> <li>In addition, we reran the search on 27 February 2017. We identified 14 new studies of interest. These 14 studies of interest are not fully incorporated into the results of the review. There are now 17 studies awaiting classification. They will be dealt with when we update the review.</li> </ul>
10 June 2014	New citation required and conclusions have changed	<ul style="list-style-type: none"> <li>The additional included studies changed the outcome and conclusion regarding intraoperative recall awareness to: "BIS-guided anaesthesia can reduce the risk of intraoperative recall in surgical patients with high risk of awareness in studies using clinical signs as a guide to anaesthetic practice. BIS-guided anaesthesia and ETAG-guided anaesthesia may be equivalent in protection against intraoperative recall awareness. In addition, anaesthesia guided by the BIS within the recommended range does improve anaesthetic delivery and postoperative recovery from relatively deep anaesthesia".</li> <li>We categorized the control or standard practice group into two subgroups: clinical signs-guided anaesthesia (CS group) and end tidal anaesthetic gas-guided anaesthesia (ETAG group).</li> <li>We have removed Mayer 2007 from the list of included studies and given the reason for exclusion of this study,</li> </ul>
10 June 2014	New search has been performed	<ul style="list-style-type: none"> <li>We re-ran the searches from May 2009 to January 2013. We found six new trials (<a href="#">Avidan 2011</a>; <a href="#">Ballard 2012</a>; <a href="#">Kabukcu 2012a</a>; <a href="#">Mashour 2012</a>; <a href="#">Qu 2011</a>; <a href="#">Zhang 2011</a>). Of those six trials, we included three randomized controlled trials in this update (<a href="#">Avidan 2011</a>; <a href="#">Mashour 2012</a>; <a href="#">Zhang 2011</a>) and excluded one trial (<a href="#">Ballard 2012</a>). Two trials (<a href="#">Kabukcu 2012a</a>; <a href="#">Qu 2011</a>) are still awaiting assessment.</li> <li>We included one study (<a href="#">Samarkandi 2004a</a>) in this updated review which previously was 'awaiting assessment'.</li> <li>In total, this updated review now contains 36 included and 19 excluded studies.</li> </ul>

Date	Event	Description
3 May 2009	New search has been performed	<ul style="list-style-type: none"> <li>We re-ran the searches from May 2007 until May 2009. We found 14 new trials (Aime 2006; Akcali 2008; Aksun 2007; Avidan 2008; Chiu 2007; Ibraheim 2008; Mayer 2007; Muralidhar 2008; Zohar 2006; Leslie 2005b; Lindholm 2008; Pavlin 2005; Schulz 2007; Vedtofte 2007). Of those 14 trials we included seven randomized controlled trials in this update (Aime 2006; Avidan 2008; Chiu 2007; Ibraheim 2008; Mayer 2007; Muralidhar 2008; Zohar 2006) and excluded six trials (Akcali 2008; Leslie 2005b; Lindholm 2008; Pavlin 2005; Schulz 2007; Vedtofte 2007); One trial (Aksun 2007) is still awaiting assessment.</li> <li>We included four studies (Boztug 2006; Bruhn 2005; Kreuer 2005; Leslie 2005a) awaiting assessment in the first publication in this updated review.</li> <li>In total, this review now contains 31 included and 17 excluded studies.</li> <li>The additional included studies did not change the conclusions of this review</li> <li>We added five new references to the additional references (Gonsowski 1995; Higgins 2008; Hozo 2005; Liu 2004; RevMan 5.0).</li> <li>One previous reference (Leslie 2005) was modified to Leslie 2005a. For studies reporting medians and ranges or interquartile ranges (IQR) (Paventi 2001; Struys 2001; Tufano 2000), we recalculated standard deviations (SD) by using the following formulas: <math>SD = IQR/1.35</math>; <math>SD = range / 4</math> (for <math>n &lt; 70</math>); or <math>SD = range/6</math> (for <math>n &gt; 70</math>). We used the Peto method for computing OR (95% CI) in this updated review. These changes did not affect the conclusions of the review. We included risk of bias and summary of findings tables in this updated version. We included a new plain language summary.</li> </ul>

## CONTRIBUTIONS OF AUTHORS

Contributions of authors in the current version of the review.

Sharon Lewis (SL), Michael Pritchard (MP), Lizzy Fawcett (LF), Yodying Punjasawadwong (YP)

Conceiving of the review: YP

Co-ordinating the review: SL

Undertaking manual searches: SL, Janne Vendt (Information Specialist, Cochrane Anaesthesia Review Group)

Screening search results: SL, MP, LF

Organizing retrieval of papers: SL, LF, MP

Screening retrieved papers against inclusion criteria: SL, LF, MP

Appraising quality of papers: SL, LF, MP

Abstracting data from papers: SL, MP, LF

Managing data for the review: SL

Entering data into Review Manager 5 (Review Manager 2014): SL, MP, LF

Analysing RevMan statistical data: SL

Interpreting data: SL, LF, MP, YP

Making statistical inferences: SL, YP

Writing the review: SL

Securing funding for the review: Cochrane Anaesthesia Review Group

Taking responsibility for reading and checking the review before submission: SL

## DECLARATIONS OF INTEREST

Sharon Lewis: none known

Michael Pritchard: none known

Lizzy Fawcett: none known

Yodying Punjasawadwong: none known

### External sources

- NIHR Cochrane Incentive Awards Scheme, 2018, UK

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

### Differences between the previous review and the updated review

- Title: we changed the title of review because it did not sufficiently describe the review objectives in relation to the primary outcome (intraoperative awareness) and the changes that we made to the outcomes (see below).
- Review authors: we added three new authors (Sharon Lewis, Michael Pritchard, and Lizzy Fawcett), and we removed two authors who did not wish to be included in the current update (Aram Phongchiewboon and Nutchanart Bunchungmongkoi).
- Objectives: we changed the objectives to reflect the changes that we made to the outcomes (see below).
- Types of studies: we specified that we did not include studies with publications that were retracted from journals. We excluded abstracts with limited information that were published prior to 2005.
- Types of interventions: we included only studies in which investigators aimed to evaluate the effectiveness of BIS for its role in monitoring intraoperative depth of anaesthesia or potential improvements in early recovery times from anaesthesia. The BIS scale is based on a measure of electrical brain activity and some studies sought to use the BIS monitor for purposes other than the objective of this review, for example to reduce the risk of postoperative cognitive dysfunction. However, in this updated review, we did not exclude studies that did not measure or report review outcomes. For clarity in this section, we specified that the review included two comparison groups.
- Types of outcome measures: we re-evaluated the previous review outcomes. In order to improve the usability, manageability, and focus of the review (Methodological Expectation of Cochrane Intervention Reviews), we reduced the number of outcomes. We removed the measure of the consumption of anaesthetics and other drugs, and the measure of cost. We believed that these proxy measures were less important considerations to the anaesthetist, whose aim is to provide a good quality anaesthetic with an appropriate depth of anaesthesia without risk of intraoperative awareness and that provides optimum early recovery. The previous review included six measurements of early recovery (time to: eye opening, response to verbal command, extubation, orientation, discharge from the PACU, and readiness to home discharge). To improve usability we included only the time to eye opening, the time to orientation, and the time to discharge from the PACU. In addition, we provided clarity on the type of data collected for the occurrence of intraoperative awareness.
- Search methods: although we used the same databases for searches, we used different search platforms which were more readily available.
- Selection of studies: we used Covidence software to (Covidence) to manage the results of the searches. We re-evaluated all studies included in previous versions of the review against the updated criteria. We noted that one study (previously called Leslie 2005a) was an associated report of [Myles 2004](#) and we merged these studies to avoid double counting participants. In addition, we excluded five studies which no longer met the review criteria ([Aimé 2006](#); [Chiu 2007](#); [Hachero 2001](#); [Samarkandi 2004](#); [Struys 2001](#)).
- Data extraction and management: we used an amended template for collecting data which was more familiar to the new review authors who were responsible for data extraction in this review. In order to improve transparency, we added additional detail to the tables in [Characteristics of included studies](#), and we created a summary table of factors that increased the risk of intraoperative

awareness ([Appendix 6](#)). We did not include a summary table of anaesthetic practices in each study; we provided this information in the [Characteristics of included studies](#).

- Assessment of risk of bias in included studies: we altered the domains in which risk of bias decisions were previously assessed, in order to use the current standard risk of bias domains. We re-evaluated risk of bias judgements in the previously included studies to ensure a consistent decision-making process for previously included and new included studies; we made judgements which were based on recommendations in [Higgins 2011](#).
- Dealing with missing data: we did not perform intention-to-treat analysis in the review. We re-evaluated the decision to re-calculate median value data because we believed that these re-calculations may not provide a true value owing to the potential of skewed data; therefore, we did not include outcome data for recovery times in analysis for three studies ([Myles 2004](#); [Paventi 2001](#); [Tufano 2000](#)).
- Assessment of reporting bias: we assessed risk of reporting bias against published protocols or clinical trial register documents, and specified that we only assessed funnel plots for risk of reporting bias for outcomes in which we had more than 10 studies.
- Subgroup analyses: we conducted subgroup analyses only on the maintenance type of anaesthesia. Rather than using subgroup analysis to distinguish between comparisons of clinical signs and ETAG, we treated these as separate comparisons in the review.
- Sensitivity analysis: we did not perform sensitivity analysis on missing data using best- and worst-case scenarios. We made a post-hoc decision to re-analyse the data for intraoperative awareness using different statistical methods; this accounted for the evidence including many studies with zero events in both arms, and the rate of rare events.
- 'Summary of findings' table and GRADE: we added detail to the Methods section to describe the use of GRADE in the review
