## ABSTRACT

### Background

This is the second update of a Cochrane review that was first published in 2009, Issue 1. Gestational trophoblastic neoplasia (GTN) is a rare but curable disease arising in the fetal chorion during pregnancy. Most women with low-risk GTN will be cured by evacuation of the uterus with or without single-agent chemotherapy. However, chemotherapy regimens vary between treatment centres worldwide and the comparable benefits and risks of these different regimens are unclear.

### Objectives

To determine the efficacy and safety of first-line chemotherapy in the treatment of low-risk GTN.

### Search methods

We electronically searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE and Embase in September 2008, February 2012, and January 2016. In addition, we searched online trial registers for protocols and ongoing trials.

### Selection criteria

For the original review, we included randomised controlled trials (RCTs), quasi-RCTs and non-RCTs that compared first-line chemotherapy for the treatment of low-risk GTN. For this updated versions of the review, we included only RCTs.

### Data collection and analysis

Two review authors independently assessed studies for inclusion and extracted data to a pre-designed data extraction form. Meta-analysis was performed using the random-effects model.

### Main results

We included seven RCTs (667 women) in this updated review. Most studies were at a low or moderate risk of bias and all compared methotrexate with actinomycin D. Three studies compared weekly intramuscular (IM) methotrexate with bi-weekly pulsed intravenous (IV) actinomycin D (393 women), one study compared five-day IM methotrexate with bi-weekly pulsed IV actinomycin D (75 women), one study compared eight-day IM methotrexate-folinic acid (MTX-FA) with five-day IV actinomycin D (49 women), and one study compared eight-day IM MTX-FA with bi-weekly pulsed IV actinomycin D. One study contributed no data.

*Moderate-certainty evidence* indicates that actinomycin D is probably more likely to lead to primary cure than methotrexate (risk ratio (RR) 0.65, 95% confidence interval (CI) 0.57 to 0.75; six trials, 577 participants;  $I^2 = 26\%$ ), and first-line methotrexate treatment is probably more likely to fail than actinomycin D treatment (RR 3.55, 95% CI 1.81 to 6.95; six trials, 577 participants;  $I^2 = 61\%$ ; *moderate-certainty evidence*)

*Low-certainty evidence* suggests that there may be little or no difference between methotrexate and actinomycin D treatment with respect to nausea (four studies, 466 women; RR 0.61, 95% CI 0.29 to 1.26) or any of the other individual side-effects reported, although data for all of these outcomes were insufficient and too inconsistent to be conclusive. *Low-certainty evidence* suggests that there may be little or no difference in the risk of severe adverse events (SAEs) between the groups overall (five studies, 515 women; RR 0.35, 95% CI 0.08 to 1.66;  $I^2 = 60\%$ ); however, the direction of effect favours methotrexate and more evidence is needed. Furthermore, evidence from subgroup analyses suggests that actinomycin D may be associated with a greater risk of SAEs than methotrexate (*low-certainty evidence*). We found no evidence on the effect of these treatments on future fertility.

### Authors' conclusions

Actinomycin D is probably more likely to achieve a primary cure in women with low-risk GTN, and less likely to result in treatment failure, than a methotrexate regimen. There may be little or no difference between the pulsed actinomycin D regimen and the methotrexate regimen with regard to side-effects. However, actinomycin D may be associated with a greater risk of severe adverse events (SAEs) than a methotrexate regimen. Higher-certainty evidence is still needed on treating low-risk GTN and the four ongoing trials are likely to make a significant contribution to this field. Given the variety of treatment regimens, findings from these trials could facilitate a network meta-analysis in the next version of this review to help women and clinicians determine the best treatment options for low-risk GTN.

## PLAIN LANGUAGE SUMMARY

### First-line treatment with anti-cancer drugs for low-risk gestational trophoblastic neoplasia

#### What is the issue?

Gestational trophoblastic neoplasia (GTN) is a rare but curable disease whereby a malignant tumour develops in the womb after a normal or molar pregnancy (where tissue develops in the womb instead of a baby). Women with GTN are classified as having low- or high-risk GTN using a specific scoring system. Virtually all women with low-risk GTN are cured by treatment with chemotherapy (anti-cancer drugs) after undergoing dilatation and curettage (D&C) of the womb. Methotrexate and actinomycin D are the two most commonly used drugs for first-line treatment of low-risk GTN, although methotrexate has been favoured in Europe and North America. Sometimes the first-line treatment fails to cure the disease or has side-effects that require it be discontinued, and a secondary treatment has to be used. If methotrexate is the first drug used, actinomycin D is usually the secondary treatment, and vice versa. We undertook this review as it was not clear which drug, if any, was more likely to cure low-risk disease in the first instance. Furthermore, it was not clear which, if any, caused more side-effects.

#### How was the review conducted?

This is an updated version of a review that was first published in 2009. Since undertaking this review, we have searched the literature three times (2008, 2012 and 2016), and have identified seven completed randomised controlled trials (RCTs) and four ongoing trials. The completed trials compared three different treatment methotrexate regimens with two different actinomycin D regimens that differed by drug dose and dosing frequency. We assessed these trials as being at low to moderate risk of bias. We extracted and pooled data where possible, grouping the studies according to the treatments compared in the studies.

#### What did we find?

Overall, and for each treatment regimen compared, the review evidence shows that actinomycin D is probably more likely to achieve a cure in the first instance than methotrexate, and less likely to fail. Side-effects were reported to be relatively mild with either treatment and the most commonly experienced side-effects among women in the studies were nausea, fatigue and anaemia. However, the evidence on side-effects and serious adverse events is uncertain. Low-certainty evidence suggests that severe adverse events may be more common with actinomycin D, particularly with the five-day regimen.

#### Conclusions

Actinomycin D is probably a more effective treatment than methotrexate but the evidence on side-effects and severe adverse effects is uncertain and more evidence is needed. More evidence is also needed on the effects of these treatments on future fertility. Four RCTs comparing methotrexate and actinomycin D regimen are currently underway and these will make an important contribution to this field.

## SUMMARY OF FINDINGS

### Summary of findings for the main comparison.

#### Actinomycin D compared with methotrexate (MTX) for low-risk gestational trophoblastic neoplasia (GTN)

**Patient or population:** women with low-risk GTN

**Settings:** outpatient or hospital

**Intervention:** actinomycin D (Act D)

**Comparison:** MTX

Outcomes	Illustrative Assumed risk* (Act D)	Illustrative Corresponding risk (MTX)	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
<b>Primary cure (remission)</b>	824 per 1000	536 per 1000 (470 to 618)	<b>RR 0.65</b> (0.57 to 0.75)	577 women (6 studies)	⊕⊕⊕⊖ <b>moderate</b> <sup>1</sup>	Act D is probably more likely to achieve a primary cure than MTX.  55% of the data came from trials of weekly IM MTX, which may be less effective than the 5- or 8-day MTX regimens.
<b>Failure of first-line therapy</b>	154 per 1000	547 per 1000 (279 to 1000)	<b>RR 3.55</b> (1.81 to 6.95)	577 women (6 studies)	⊕⊕⊕⊖ <b>moderate</b> <sup>1</sup>	Act D as a first-line treatment is probably less likely to fail than MTX.  59% of the data came from trials of weekly IM MTX, which may be less effective than the 5- or 8-day MTX regimens.
<b>Severe adverse events (≥ grade 3)</b>	142 per 1000	50 per 1000 (11 to 235)	<b>RR 0.35</b> (0.08 to 1.66)	515 women (5 studies)	⊕⊕⊕⊖ <b>low</b> <sup>1,2</sup>	There may be little or no difference between interventions overall. However, the point estimate and subgroup analyses favoured MTX. SAEs occurred in 3 out of 6 studies, but one study did not contribute to the meta-analysis due to insufficient data.
<b>Nausea</b>	462 per 1000	282 per 1000 (134 to 582)	<b>RR 0.61</b> (0.29 to 1.26)	466 women (4 studies)	⊕⊕⊕⊖ <b>moderate</b> <sup>1</sup>	There is probably little or no difference between MTX and Act D for nausea.
<b>Alopecia</b>	Subtotals only				⊕⊕⊕⊖	Data on alopecia were not pooled due to substantial subgroup differences. However, in general the evidence

suggested that there may be little or no difference between MTX and Act D regimens with regard to alopecia, except for the five-day Act D regimen, which may be more frequently associated with alopecia than the 8-day MTX regimen.

low<sup>1,2</sup>

\*The basis for the **assumed risk** is the mean control group risk across studies. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**CI:** Confidence interval; **RR:** Risk Ratio

GRADE Working Group grades of evidence

**High quality:** Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** We are very uncertain about the estimate.

IM = intramuscular; SAE = severe adverse effects

<sup>1</sup> Downgraded for clinical or statistical inconsistency

<sup>2</sup> Downgraded for imprecision

## BACKGROUND

This is an updated version of this original review first published in the Cochrane Database of Systematic Reviews, 2009, Issue 1, and re-published as an update in 2012, Issue 7.

### Description of the condition

Gestational trophoblastic disease (GTD) is a rare disease of pregnancy arising in the fetal chorion. It encompasses five main clinicopathologic forms: hydatidiform mole (complete and partial), invasive mole, choriocarcinoma, placental site trophoblastic tumour (PSTT) and epithelioid trophoblastic tumour (ETT). The term gestational trophoblastic neoplasia (GTN) refers only to the invasive and malignant forms of GTD i.e. invasive mole, choriocarcinoma, PSTT and ETT. GTN may develop after a molar or non-molar pregnancy, irrespective of the site and gestational age, as a consequence of autonomous overgrowth of one of the three cell layers of the trophoblast.

The incidence of GTD varies between different regions of the world, with higher rates reported in Indonesia (around 10 per 1000 pregnancies), Mexico (4.6 per 1000) and Japan (two per 1000) and lower rates reported in North America and Europe (less than one per 1000); however, rates differ according to whether studies are population-based or hospital-based and may vary between areas within the same country (Lee 2009). Newer data from North America and Asia suggest that rates of GTD are declining (Lee 2009). The aetiology of GTD is poorly understood; a previous molar pregnancy and advanced or very young maternal age are associated with an increased risk of GTD; however, other factors including ethnicity, poor nutrition, viral infections and environmental factors may play a role (Lee 2009).

Complete moles (CMs) usually arise as a consequence of duplication of the haploid sperm following fertilisation of an 'empty' ovum, and are therefore diploid and androgenic in origin, with no evidence of fetal tissue. Partial moles (PMs) are typically triploid in origin with two sets of paternal haploid and one set of maternal haploid genes (Fisher 2009). In most cases, moles resolve spontaneously following one or more uterine evacuations without a need for chemotherapy, however, in approximately 16% of CMs and 0.5% of PMs the disease persists and chemotherapy is required (Seckl 2009). Molar transformation to GTN results in an enlarging uterine mass that may invade locally, metastasise to other sites (most ominously, the liver or brain), and lead to death if left untreated. The most common clinical manifestations of post-molar GTN are vaginal bleeding, uterine and ovarian enlargement, and raised human chorionic gonadotrophin (hCG) levels (Lurain 2010).

Moles are considered to have undergone transformation to GTN if four or more hCG values indicate a plateau over a period of at least three weeks, if there is a rise in at least three consecutive hCG values by at least 10% over a two-week period, if hCG values are raised six months after evacuation, or if there is a histological diagnosis of choriocarcinoma (Kohorn 2009). Urine hCG levels may be helpful in predicting malignant transformation (Alazzam 2011). There is limited evidence that Vitamin A prophylaxis may reduce the risk of malignant transformation (Andrijono 2010).

Various staging and scoring systems have been developed over the years (Bagshawe 1976; Hammond 1973; Nagan 2002; WHO

1983). The system described by Bagshawe 1976 formed the basis of the World Health Organization (WHO) Prognostic scoring System (WHO 1983) that included age, antecedent pregnancy, interval since antecedent pregnancy, hCG level, ABO blood group, largest tumour site(s) of metastases, site of metastases, and previous chemotherapy. This system was subsequently modified and adapted by the International Federation of Gynecology and Obstetrics (FIGO) (see Table 1; Table 2) (Nagan 2002; FIGO 2009). The modified WHO-FIGO system differs from the WHO system in that the ABO blood group risk factor has been eliminated and the risk factor of liver metastases has been upgraded from two to four. A score of six or less defines 'low-risk' due to the merging of the old intermediate risk group (previously described by scores of five and six) with the existing low-risk category (score zero to four). A score of seven or more defines 'high-risk'.

Low-risk GTN includes invasive moles and choriocarcinomas that receive a low-risk score. Once the uterus has been evacuated (preferably by suction curettage to minimise the chance of uterine perforation) and a diagnosis of low-risk GTN has been made, either histologically or following serial hCG measurements, treatment with single-agent chemotherapy is usually commenced. FIGO criteria for commencing chemotherapy after evacuation are as follows (Mangili 2014):

- weekly hCG rising (more than a 10% increase over the previous weekly value) for at least three consecutive measurements for a period of at least three weeks (day 0, 7, and 14);
- weekly hCG plateauing (less than a 10% change over the previous weekly value) for at least four consecutive measurements for a period of at least three weeks (day 0, 7, 14, and 21);
- persistence of hCG more than six months after evacuation;
- histological diagnosis of choriocarcinoma.

Other criteria that may be used include a serum hCG greater than 20,000 IU/L more than four weeks after evacuation, because of the risk of uterine perforation and severe haemorrhage (Seckl 2010).

### Description of the intervention

There are many effective chemotherapeutic regimens used worldwide for the treatment of low-risk GTN, mostly involving methotrexate and actinomycin D. The first report of methotrexate therapy for GTN was in 1956 (Hertz 1956). By 1971, methotrexate had been reported in conjunction with folinic acid as "rescue" from the severe marrow and gestational toxicities seen with high-dose methotrexate given alone (Bagshawe 1976) and actinomycin D had been reported as a drug of choice for initial therapy (Goldstein 1972).

The most commonly used first-line regimens for treating low-risk GTN are as follows.

- Methotrexate eight-day regimen (1 mg/kg intramuscular (IM), days one, three, five and seven) with folinic acid rescue (days two, four six and eight), repeated every 14 to 16 days (Bagshawe 1989; McNeish 2002); also known as the Charing Cross or Modified Bagshawe regimen.
- Low-dose (30 to 50 mg/m<sup>2</sup>) IM methotrexate, repeated weekly (Homesley 1988; Homesley 1990).

- Five-day low-dose methotrexate (intravenous (IV) or IM); maximum of 25 mg/m<sup>2</sup> daily for five days, repeated every 14 days (Roberts 1996; Soper 1994).
- Pulsed IV actinomycin D (1.25 mg/m<sup>2</sup> to a maximum 2 mg single dose), repeated every 14 days (Osborne 2011; Petrilli 1980; Schlaerth 1984; Twiggs 1983).
- Five-day actinomycin D (0.5 mg IV), repeated every 14 days (Kohorn 1996; Osathanondh 1975).

Other regimens that have been described are included in Table 3. Most women with low-risk GTN will be cured by chemotherapy regardless of the regimen used; however, reported primary remission rates vary and up to 40% per cent of affected women may require additional drug therapy to effect a cure (Homesley 1988; Khan 2003; Lurain 1995; McNeish 2002; Soper 1994). In an analysis of 359 women with low-risk GTN treated between 1979 and 2006 at the Brewer Trophoblastic Center (Chicago), approximately 80% of women were cured with first-line single-agent therapy (mainly methotrexate), an additional 10% responded to sequential single-agent therapy and approximately 10% needed multi-agent therapy (Lurain 2011).

Due to the chemosensitive nature of this disease and its low prevalence, the choice of treatment regimen depends more on geographic location and clinician's experience/preference than high-quality evidence relating to the relative efficacy and side-effects of the various regimens. In Europe and North America, there has been a preference for the five-day or eight-day methotrexate regimens. On these regimens, women are usually hospitalised for the first cycle due to concerns regarding potential haemorrhage from arteriovenous malformations, and cycles are usually continued for at least three weeks once hCG is normal.

Historically, five-day actinomycin D has been associated with severe alopecia and nausea; therefore, in many centres, it is reserved as salvage therapy in cases of methotrexate resistance or toxicity. However, pulsed actinomycin D every 14 days is reported to be effective, with minimal side-effects, when used as salvage therapy (Covens 2006), and as effective as weekly methotrexate when used as first-line therapy (Petrilli 1987; Schlaerth 1984; Twiggs 1983). In addition, the pulsed actinomycin D regimen has potential advantages over the other regimens in terms of convenience and cost.

Drug resistance and toxic side-effects leading to discontinuation and switching to an alternative regimen may occur with either drug. Predictors of resistance to single-agent treatment in low-risk GTN include non-molar antecedent pregnancy, a histological diagnosis of choriocarcinoma (Hammond 1973; Lurain 1995), higher pre-treatment hCG levels (McGrath 2010; Yarandi 2008) and higher risk scores (Osborne 2011).

### Why it is important to do this review

We embarked on this systematic review and meta-analysis because various treatment regimens are used for the first-line treatment of low-risk GTN, yet the comparative benefits and risks of these regimens were unclear.

## OBJECTIVES

To assess the efficacy and safety of the various first-line chemotherapy regimens in the treatment of women with low-risk GTN.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

Randomised controlled trials (RCTs) comparing first-line chemotherapy regimens for the treatment of low-risk gestational trophoblastic neoplasia (GTN).

#### Types of participants

##### Inclusions

All women with low-risk GTN (as defined by any of the known risk-scoring systems), who received primary chemotherapy. Studies that did not provide complete information about the risk-scoring system, or that did not distinguish a low-risk group were excluded from the review.

##### Exclusions

Women with high-risk GTN, placental site trophoblastic tumour (PSTT) or epithelial trophoblastic tumour (ETT).

#### Types of interventions

Any chemotherapeutic agent used in the first-line treatment of GTN (e.g. methotrexate, actinomycin D, fluorouracil, etoposide) in any dose, duration, frequency and setting.

#### Types of outcome measures

##### Primary outcomes

- Primary cure (remission)
- Failure of first-line therapy
- Overall survival (OS)
- Death due to toxicity
- Death due to disease

##### Secondary outcomes

- Mean number of courses or time to first-line cure
- Mean number of courses or time to first-line failure (failure was defined as change in regimen due to drug resistance or toxicity, or surgery for drug resistance)
- Quality of life (QoL), measured by a validated scale
- Secondary tumours due to chemotherapy
- Toxicity due to chemotherapy

Grades of toxicity were extracted according to CTCAE 2010: (a) haematological (anaemia, neutropenia, abnormal liver function); (b) gastrointestinal (pain, nausea, vomiting); (c) genitourinary (vaginal bleeding); (d) skin (stomatitis, mucositis, alopecia, allergy); (e) neurological (peripheral and central); (f) respiratory (pain, shortness of breath, pleural effusion).

## Search methods for identification of studies

### Electronic searches

The original search included, Cochrane Central Register of Controlled Trials (CENTRAL, 2008, Issue 3), Ovid MEDLINE (1950 to 2008) and Embase (1980 to 2008) in September 2008. For the previous review update, we re-ran these database searches to February 2012.

For this update we extended the searches to January 2016.

CENTRAL (December 2015, Issue 12)  
 MEDLINE Ovid (2012 to Jan Week 01 2016)  
 Embase Ovid (2012 to 2016 week 03)

The search strategy was broad and we adapted the key words in the strategies in the databases listed in [Searching other resources](#), as appropriate. We considered papers in all languages. For the original search strategies see [Appendix 1](#) and for the 2012 update see [Appendix 2](#).

### Searching other resources

In addition to electronic searches, for this update we searched the following for ongoing trials: [www.ClinicalTrials.gov](http://www.ClinicalTrials.gov) and the International Clinical Trials Registry Platform search portal (<http://apps.who.int/trialsearch/>). We searched reference lists of identified studies for additional articles.

## Data collection and analysis

### Selection of studies

Two review authors independently selected articles on the basis of title and/or abstract for full-text scrutiny (Mo'iad Alazzam (MA) and John Tidy (JT) for the original review; MA and Theresa Lawrie (TL) for the updates). We excluded those studies that clearly did not meet the inclusion criteria and obtained the full text of the others. For the original review, MA and JT independently assessed each article to determine whether it met the review eligibility criteria. MA and TL did this for the updates. We resolved difference by discussion between the two review authors or by involving a third review author.

### Data extraction and management

For the original review, MA and JT independently extracted data using a pre-designed data extraction form; for the updates, MA and TL performed this using an Excel spreadsheet. We included the following information from each study.

- Design: description of randomisation method, blinding, number of study centres, study duration and number of study withdrawals.
- Participants: number, mean age, mean risk score.
- Intervention; name of chemotherapy agents used, dose, route of administration and schedule.
- Outcomes: Where possible data was extracted to allow intention-to-treat (ITT) analysis. For dichotomous outcomes (e.g. primary cure, adverse events, and number of patients who relapsed or died), we abstracted the number of patients in each treatment arm who experienced the outcome of interest, in order to estimate a risk ratio (RR). For continuous outcomes (e.g. quality of life (QoL) measures and duration of treatment), we

extracted the arithmetic mean and standard deviation (SD) of the outcome of interest in each treatment arm. For dichotomous and continuous data, we abstracted the number of patients assessed at the endpoint. If reported, we extracted median and range data too. We noted any scoring systems (e.g. FIGO, WHO, National Cancer Institute (NCI)) used.

- Outcomes: Where possible we extracted data to allow intention-to-treat (ITT) analysis. For dichotomous outcomes (e.g. primary cure, adverse events, and number of patients who relapsed or died), we abstracted the number of patients in each treatment arm who experienced the outcome of interest, in order to estimate the RR. For continuous outcomes (e.g. QoL measures and duration of treatment), we extracted the arithmetic mean and SD of the outcome of interest in each treatment arm. For dichotomous and continuous data, we abstracted the number of patients assessed at the endpoint. If reported, we extracted median and range data too. We noted any scoring systems (e.g. FIGO, WHO, NCI) used.

Where the data were insufficient or missing from a trial, we attempted to contact trial investigators for more information. We resolved differences between the review authors by discussion or by referral to a third review author.

### Assessment of risk of bias in included studies

We assessed the risk of bias of included studies according to the guidelines in the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2011](#)) including the following.

- Selection bias (random sequence generation and allocation concealment).
- Detection bias (blinding of outcome assessment).
- Attrition bias (incomplete outcome data, loss to follow-up).
- Reporting bias (selective reporting of outcomes).
- Other possible sources of bias.

For more details of 'Risk of bias' assessment, see [Appendix 3](#).

### Measures of treatment effect

We used the following measures of the effect of treatment.

- For dichotomous outcomes, we present results as summary RR with 95% confidence intervals (CI).
- For continuous outcomes, we present results as the mean difference (MD) between treatment arms with the associated SD.

### Dealing with missing data

We attempted to extract data on the outcomes only among participants who were assessed at endpoint. We did not impute missing outcome data for the primary outcome. If data were missing or only imputed data were reported, we contacted trial authors to request data on the outcomes only among the participants who were assessed.

### Assessment of heterogeneity

We assessed heterogeneity between studies by visual inspection of forest plots and by measuring the statistical variation between combined studies using the  $I^2$  statistic ([Deeks 2001](#); [Higgins 2003](#)). In addition, we applied random-effects modelling (REM) to all pooled-effect estimates. When heterogeneity was found, we tried

to determine the potential reasons for it by examining individual study characteristics.

### Assessment of reporting biases

As the largest meta-analysis included only five studies we did not assess funnel plots.

### Data synthesis

We grouped studies into those comparing similar chemotherapy regimens. Within these groups we performed meta-analyses if there were sufficient trials using the [RevMan 2014](#) software.

- For dichotomous outcomes, we calculated the RR for each study and pooled these data.
- For continuous outcomes, we calculated the MD between the treatment arms at the end of follow-up and pooled these data provided outcomes were measured in a similar way between trials.
- Random-effects method was used for all meta-analyses ([DerSimonian 1986](#)).

### Grading of the evidence

We created a 'Summary of findings' table in [RevMan 2014](#) using the GRADE approach ([GRADEpro GDT 2015](#)). For assessments of the overall quality of evidence for each outcome that included pooled data, we downgraded the evidence from 'high quality' by one level for serious (or by two for very serious) study limitations (risk of bias), indirectness of evidence, serious inconsistency, imprecision of effect estimates or potential publication bias.

### Subgroup analysis and investigation of heterogeneity

In the protocol and for the original review, we did not perform subgroup analyses, but grouped studies into individual comparisons based on the comparative interventions and regimens tested. For the revised review, we compared interventions, subgrouping trials by regimen. Therefore, for trials comparing methotrexate with actinomycin D, we considered the following subgroups where possible.

1. Weekly IM methotrexate versus bi-weekly pulsed IV actinomycin D.
2. Five-day IM methotrexate versus bi-weekly pulsed IV actinomycin D.
3. Eight-day IM methotrexate-folinic acid (MTX-FA) versus five-day IV actinomycin D.
4. Five-day IM methotrexate versus five-day IV actinomycin D.
5. Eight-day IM MTX-FA versus bi-weekly pulsed IV actinomycin D.
6. Weekly IM methotrexate versus five-day pulsed actinomycin D.

Although we did not pre-specify subgroup analyses, we analysed these 'subgroups' in the original review, where possible, as individual comparisons.

### Sensitivity analysis

We performed sensitivity analysis to assess the robustness of the meta-analyses by comparing the results using all trials and then excluding trials of lower methodological quality or those considered to be at a higher risk of bias.

## RESULTS

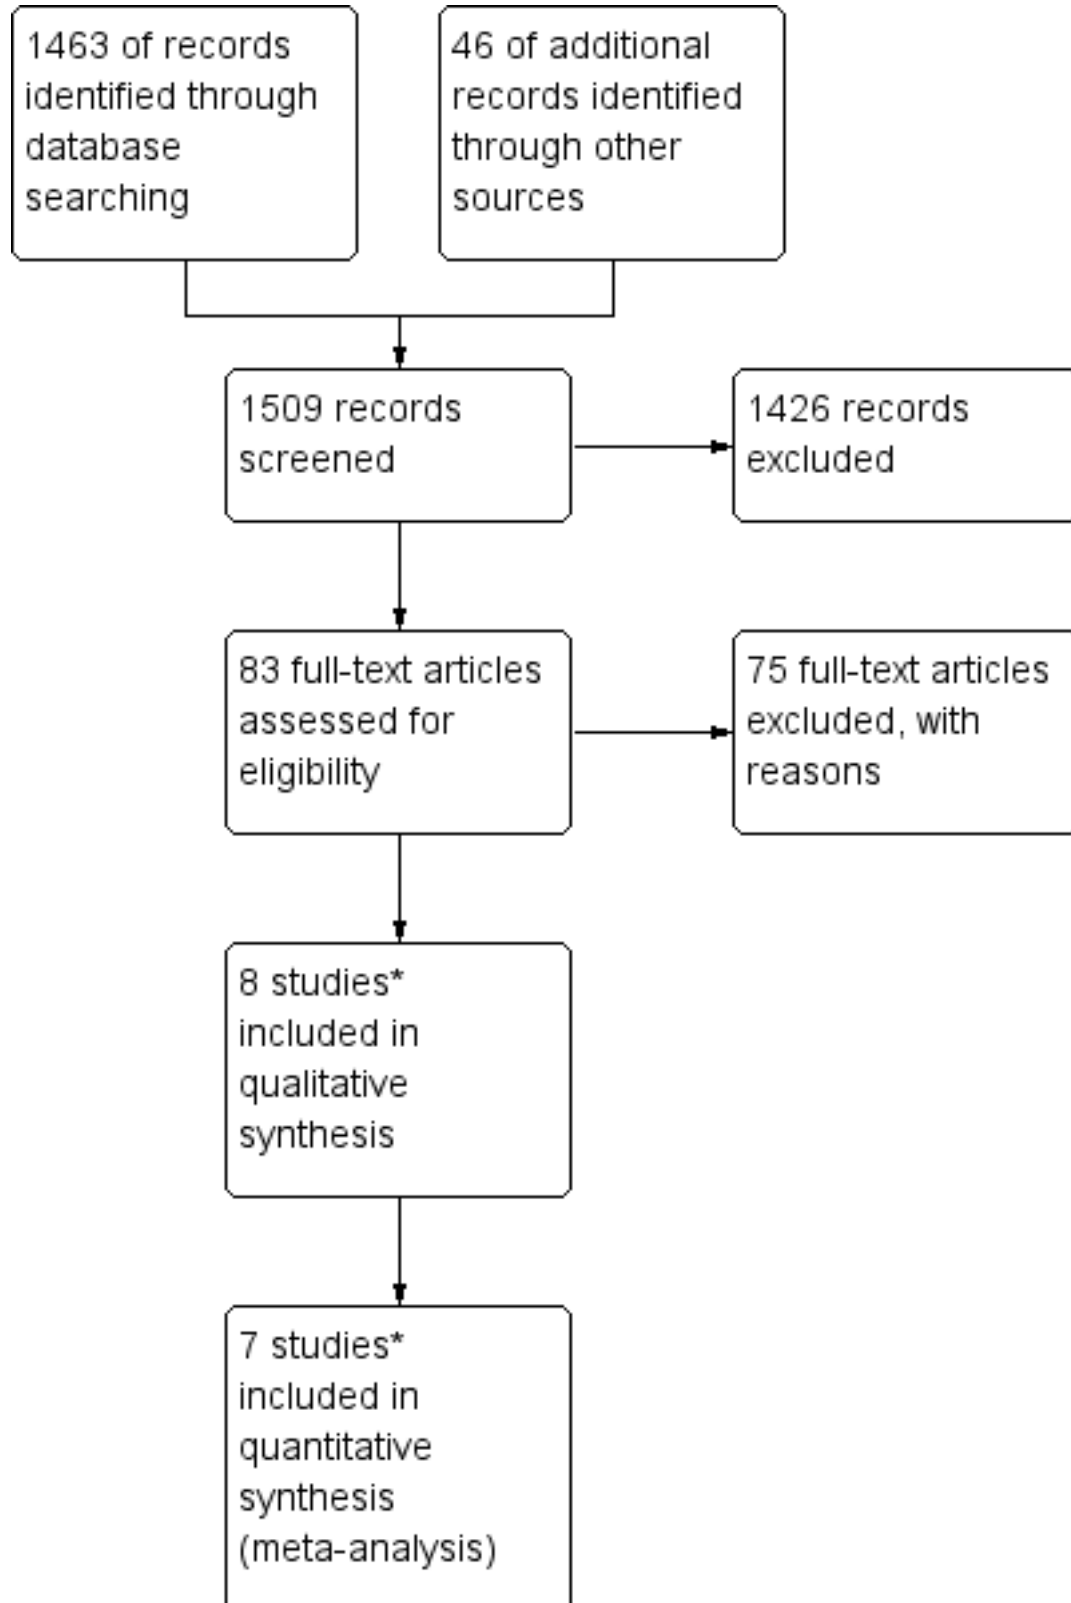

### Description of studies

See [Characteristics of included studies](#); [Characteristics of excluded studies](#)

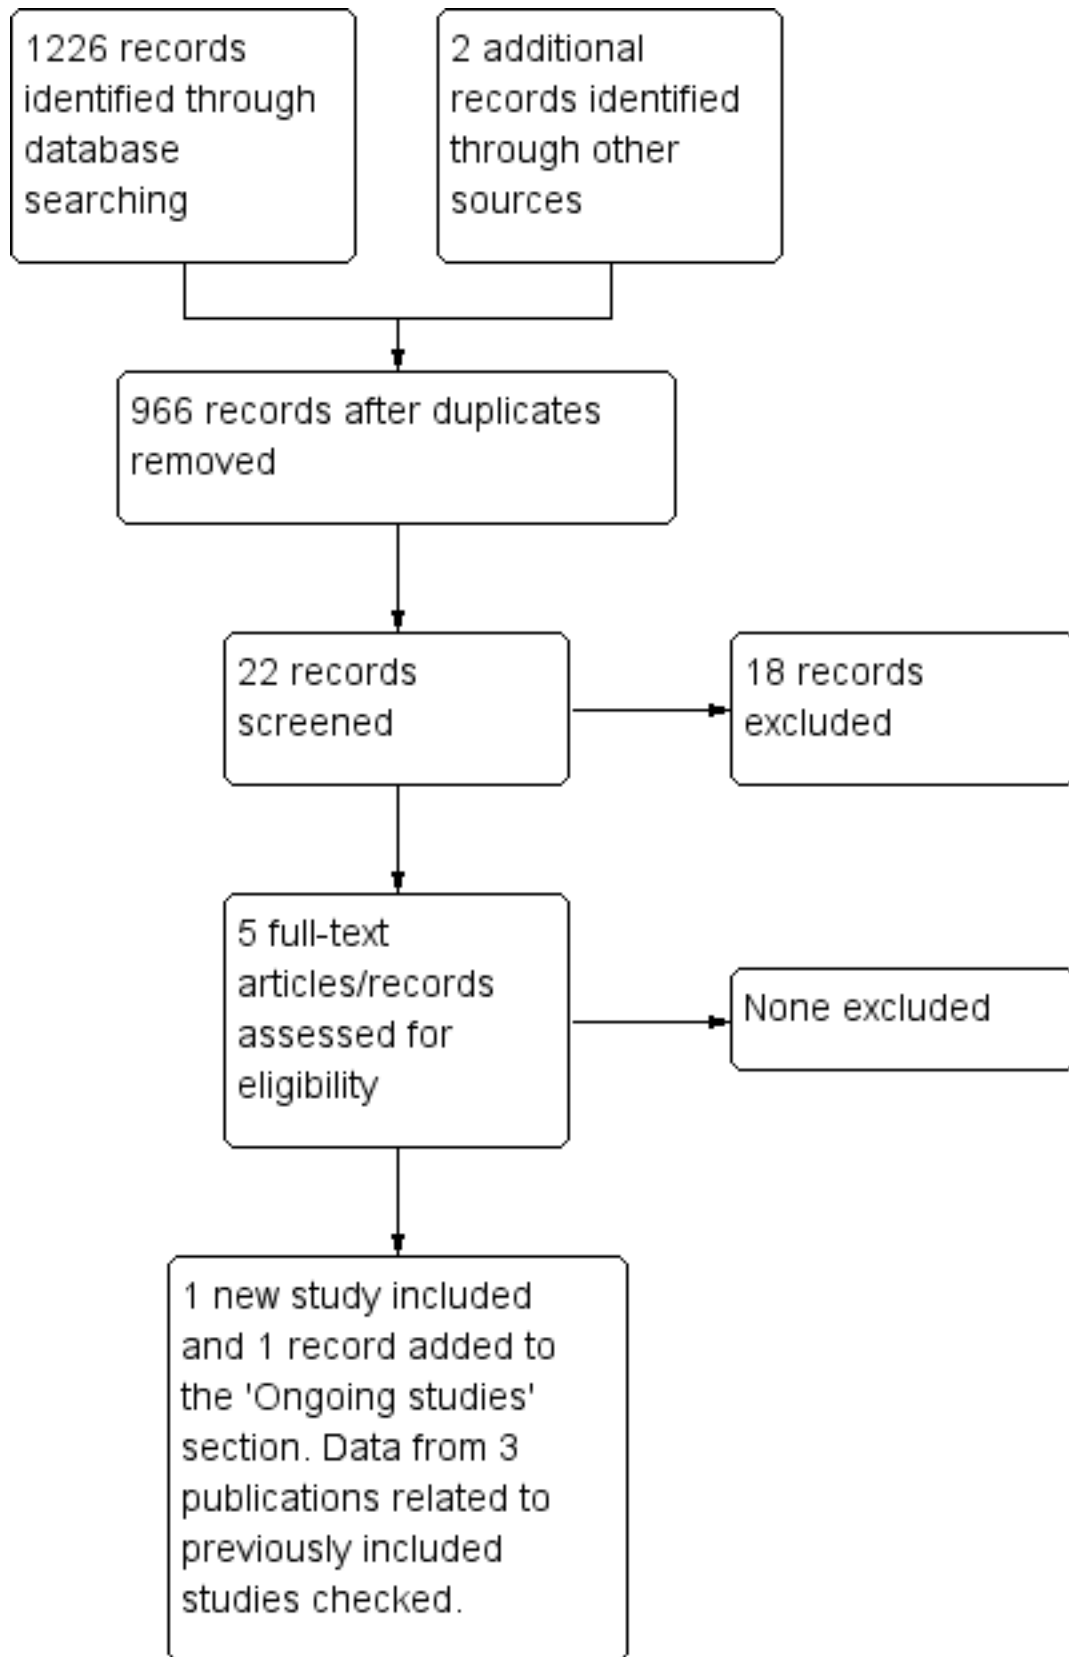

### Results of the search

For the original review, we identified 14 potentially eligible studies and, of these, we included eight studies and excluded six (see [Figure 1](#)). The original version of the review included four non-randomised studies (NRS). For the first update published in May 2012, which restricted studies to RCTs, only four of the originally included studies met the revised inclusion criteria ([Gilani 2005](#); [Lertkhachonsuk 2009](#); [Osborne 2011](#); [Yarandi 2008](#)). One new study ([Mousavi 2012](#)) was included and (see [Figure 2](#)), three records relating to the previously included studies ([Lertkhachonsuk 2009a](#); [Osborne 2011a](#); [Rahimi-Moghaddam 2004](#)) and one ongoing study ([GOG 0275](#)) were added. Thus, the previous version of this review included data from five RCTs (with eight references).

**Figure 1. Study flow diagram of the original 2009 review** \*The original 2009 review Included four non-RCTs (Abrao 2008; Kohorn 1996; Smith 1982; Wong 1985) in the qualitative and three (Abrao 2008 not included) in the quantitative meta-analysis). These non-RCTs were excluded in the updated review.

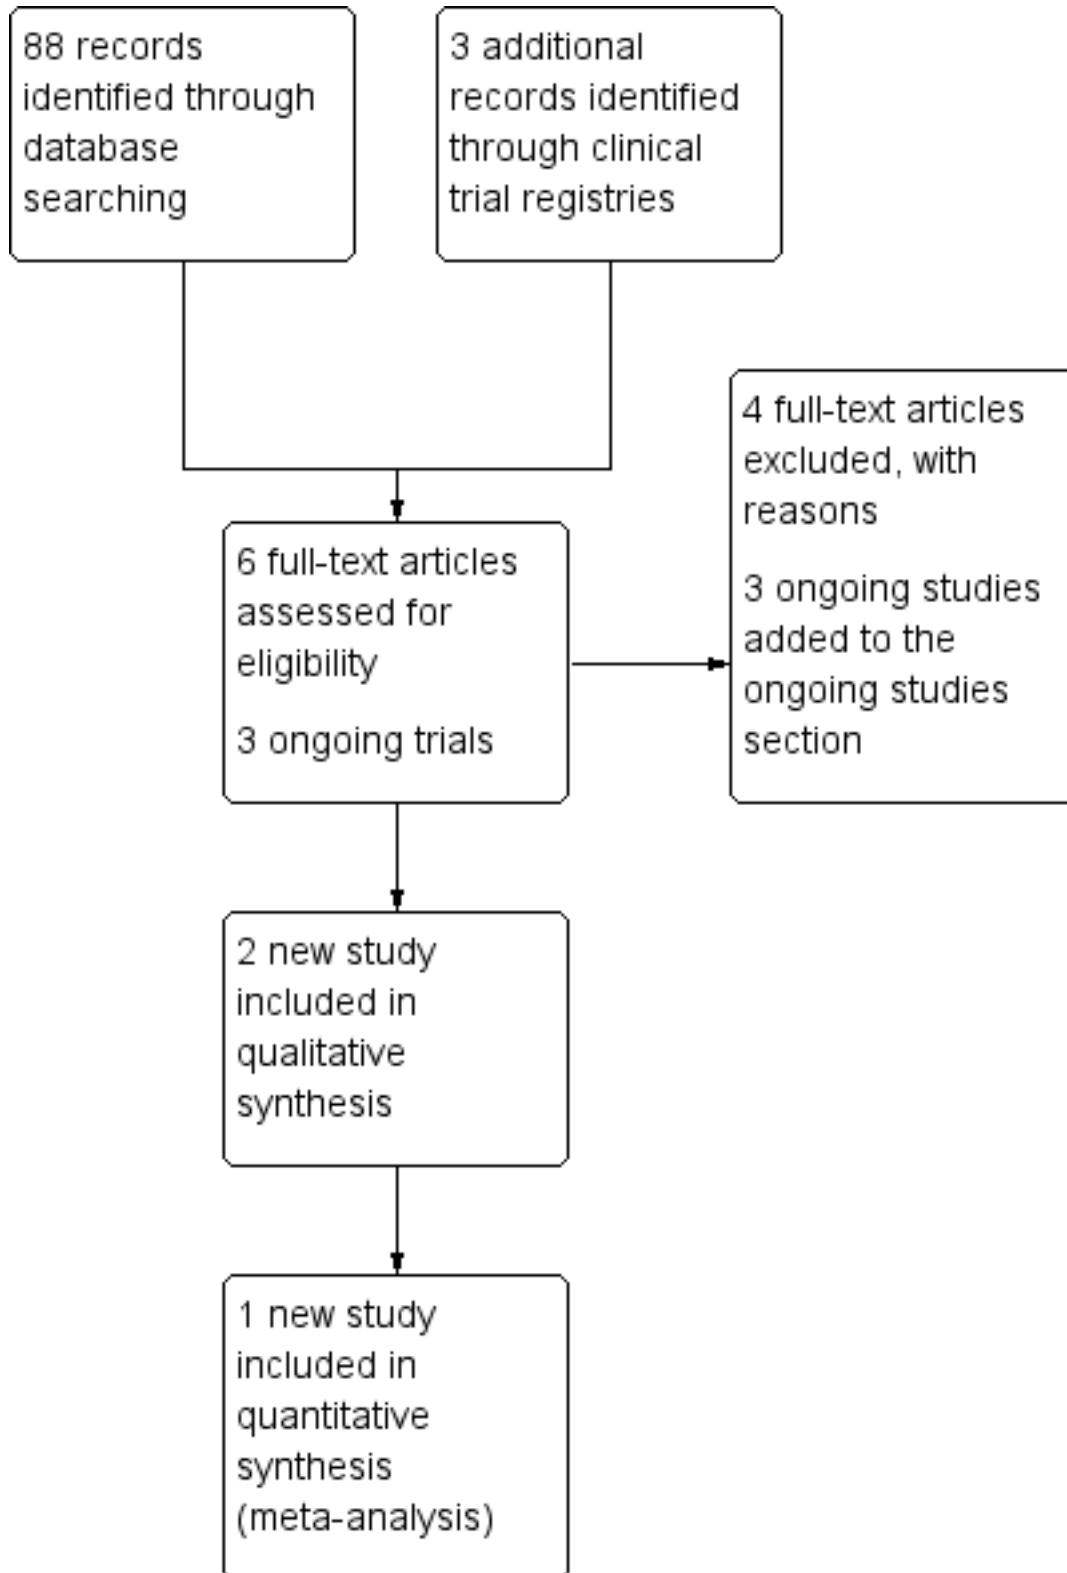

**Figure 2. Study flow diagram of the updated search conducted from January 2010 to February 2012.**

For this 2016 version of the review, the updated search identified 88 records from which we identified six potentially eligible new studies. After full-text retrieval of these records, two met the inclusion criteria (Figure 3). One was published as a conference

abstract (Yarandi 2015), the other was published in Farsi (Shobeiri 2014). For the latter, at the time of writing we had been unable to obtain the published manuscript from the investigators.

**Figure 3. Study flow diagram for the updated search conducted from Feb 2012 to January 2016.**

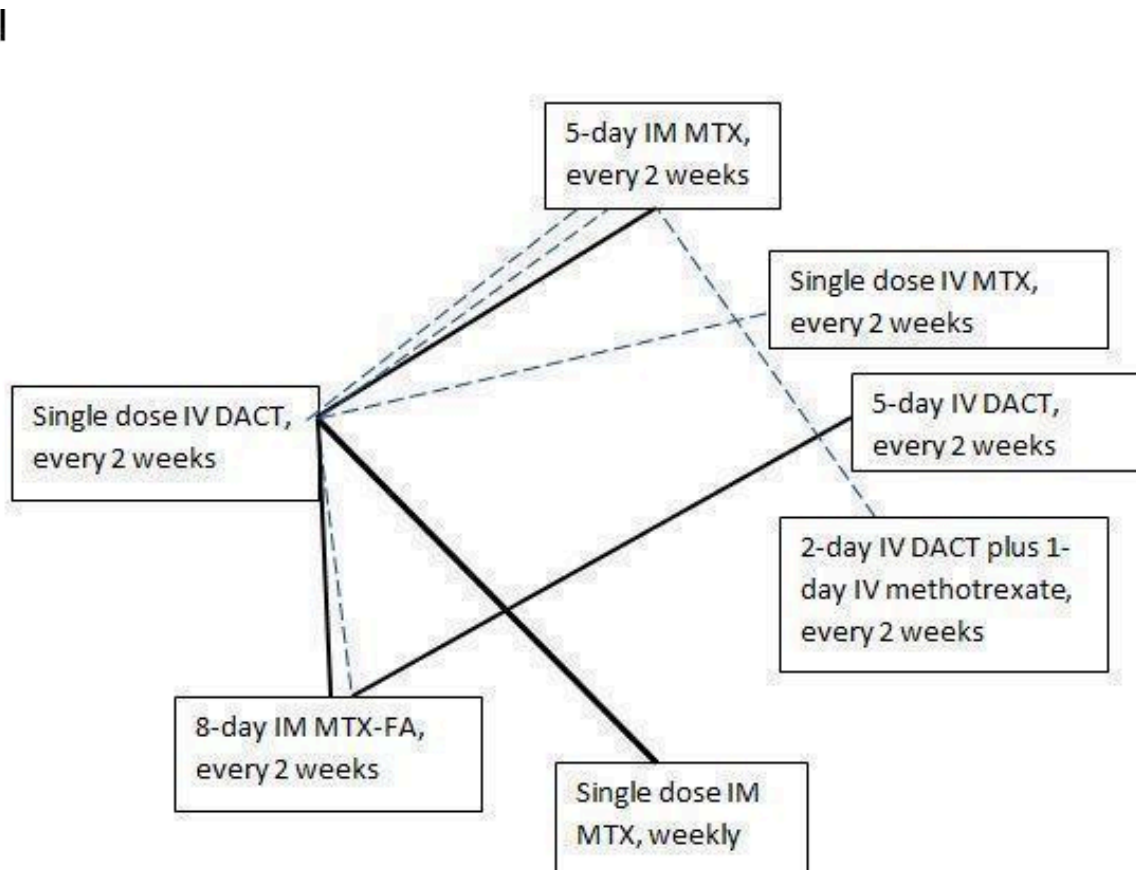

We identified three additional ongoing trials (CTRI/2012/11/003120; IRCT2015012519567N1; NCT01823315) from an updated search of clinical trial registries.

**Included studies**

The seven included RCTs enrolled a total of 667 women with low-risk gestational trophoblastic neoplasia (GTN). Low-risk GTN was defined by either the earlier WHO/FIGO 2000 scoring system (Gilani 2005; Lertkhachonsuk 2009), or the modified WHO scoring system

(Table 2; Mousavi 2012; Shobeiri 2014; Yarandi 2008). One study (Osborne 2011) defined low-risk GTN as a score of less than or equal to four for women recruited before June 2002, and as less than or equal to six for women recruited from July 2002 and February 2007, following modification of the WHO scoring system. Shobeiri 2014 only included FIGO stage I disease. Another study in the form of a conference abstract only did not state how low-risk GTN was defined (Yarandi 2015). The included RCTs evaluated the following comparisons (see Figure 4).

**Figure 4. Chemotherapy treatment comparisons of included RCTs (solid lines) and ongoing RCTs (dotted lines)**

**1. Weekly IM methotrexate versus bi-weekly pulsed IV actinomycin D**

Three trials (Gilani 2005; Osborne 2011; Yarandi 2008) compared a weekly IM methotrexate regimen with fortnightly pulsed IV actinomycin D. All three trials used the same protocol of treatment (weekly IM methotrexate at 30 mg/m<sup>2</sup> versus bi-weekly pulsed IV actinomycin D at 1.25 mg/m<sup>2</sup>). Gilani 2005 (46 women) and Yarandi 2008 (131 women) randomised participants in a methotrexate:actinomycin D ratio of 1.5:1 for 'economic reasons'; all participants were evaluated. Osborne 2011 randomised 240 participants in a 1:1 ratio, of whom 214 were analysed.

**2. Five-day IM methotrexate versus bi-weekly pulsed IV actinomycin D**

Mousavi 2012 randomised 75 participants in a ratio of 1:2 to receive five-day methotrexate (0.4 mg/kg daily IM) or actinomycin D (1.25 mg/m<sup>2</sup> IV bolus) respectively, repeated every 14 days until normal human chorionic gonadotrophin (hCG) levels were obtained. All participants were evaluated. Yarandi 2015 also evaluated this comparison in 62 women; however, only a conference abstract for this study was available, which did not describe how many participants were allocated to each treatment group and we were unable to obtain this information from the authors. Therefore, Yarandi 2015 contributed no data to this updated review.

### 3. Eight-day IM methotrexate-folinic acid versus five-day IV actinomycin D

Lertkhachonsuk 2009 randomised 49 participants to receive either five-day actinomycin D (10 mcg/kg; N = 22) or eight-day methotrexate-folinic acid (MTX-FA) (methotrexate 1 mg/kg, alternate days and folinic acid 0.1 mg/kg alternate days; N = 27). Two participants in each group were not evaluable for the primary outcome.

### 4. Eight-day IM methotrexate-folinic acid versus bi-weekly pulsed IV actinomycin D

Shobeiri 2014 randomised 64 participants to receive either eight-day IM methotrexate-folinic acid (methotrexate 1 mg/kg, alternate days and folinic acid 0.1 mg/kg alternate days; N = 32) or bi-weekly pulsed IV actinomycin D (1.25 mg/m<sup>2</sup> IV; N = 32).

Women were followed up in all trials for one year after last treatment. See [Characteristics of included studies](#) for further details.

#### Ongoing studies

As at 28 March 2016, there were four ongoing RCTs as follows.

- [GOG 0275](#): Eight-day IM methotrexate-folinic acid or five-day methotrexate versus bi-weekly pulsed IV actinomycin D
- [CTRI/2012/11/003120](#): One-day methotrexate infusion versus bi-weekly pulsed IV actinomycin D
- [IRCT2015012519567N1](#): Five-day IV methotrexate versus bi-weekly pulsed IV actinomycin D
- [NCT01823315](#): Five-day IM methotrexate versus IV methotrexate/actinomycin D combined

For more details of the ongoing studies, see [Characteristics of ongoing studies](#) and [Figure 4](#).

#### Excluded studies

For the original review, we excluded six studies ([Berkowitz 1979](#); [Gleeson 1993](#); [Matsui 1998](#); [Matsui 2005](#); [Petrilli 1980](#); [Roberts 1996](#)). All these studies were non-RCTs, excluded mainly due to a high risk of bias. ([Characteristics of excluded studies](#)).

For the 2012 updated review, we excluded a further four non-RCTs, that had been classified as 'included' in the original review (see [Differences between protocol and review](#)), on the basis that they were not RCTs. These non-randomised studies evaluated the following comparisons.

#### 1. Eight-day methotrexate-folinic acid versus five-day methotrexate

[Smith 1982](#) and [Wong 1985](#) compared eight-day MTX-FA with the five-day methotrexate regimen. Both studies used the same

treatment protocol (methotrexate at 1 mg/kg days one, three, five and seven and folinic acid at 0.1 mg/kg days two, four, six and eight; OR methotrexate 0.4 mg/kg on days one to five). Ninety-seven participants received MTX-FA and 72 participants received five-day methotrexate. Remission rates in [Wong 1985](#) were 82% versus 79%, respectively; and 82% versus 72% in [Smith 1982](#).

#### 2. 'Pulsed' actinomycin D versus five-day actinomycin D

[Kohorn 1996](#) compared pulsed actinomycin D (1.25 mg/m<sup>2</sup>; N = 18) with the five-day actinomycin D (12 mcg/kg; N = 43). Complete response was achieved in 14 out of 18 (77%) and 38/43 (88%) respectively, with a mean number of 4.6 (SD 5.4) versus 2.7 (SD 1.3) courses. Toxicity was reported as 'minimal' in both groups with no further details.

#### 3. Five-day methotrexate versus five-day actinomycin D versus combination of both

[Abrao 2008](#) compared three different regimens; five-day methotrexate (20 mg/m<sup>2</sup>, N = 42), five-day actinomycin D (12 mcg/kg, N = 42) and the combination of five-day methotrexate and actinomycin D (methotrexate 20 mg/day and actinomycin D 500 mcg/kg, N = 24). Remission rates were 69%, 61% and 79%, respectively. Adverse effects occurred most frequently in the combined treatment group (62.5%) and least frequently in the actinomycin D group.

For the 2016 update, we excluded four NRS, including one comparative study that evaluated three treatments as follows.

#### 4. Eight-day methotrexate-folinic acid versus five-day actinomycin D versus five-day etoposide

In [Baptista 2012](#), 60 women with low-risk gestational trophoblastic neoplasia (LRGTN) (risk score ≤ 6) were assigned to methotrexate (50 mg/day/IM) alternating with folinic acid rescue for eight days (n = 20), five-day actinomycin D (12 mcg/kg/IV) (n = 20) or etoposide (100 mg/m<sup>2</sup>/IV) (n = 20). Complete responses were 50%, 90% and 100% for methotrexate, actinomycin D and etoposide, respectively. MTX was associated with the least toxicity and alopecia was the most common side-effect caused by etoposide (occurred in 95% of women).

#### Risk of bias in included studies

The 'Risk of bias' assessment of included studies is graphically represented in [Figure 5](#). In general, we considered [Lertkhachonsuk 2009](#) and [Osborne 2011](#) to be at low risk of bias and the other studies to be at moderate risk of bias due to a lack of clarity about study methods.

**Figure 5. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding (performance bias and detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias
Gilani 2005	?	?	?	+	+	?
Lertkhachonsuk 2009	+	?	?	+	?	+
Mousavi 2012	?	?	?	+	+	+
Osborne 2011	+	+	?	+	+	+
Shobeiri 2014	?	?	?	?	?	?
Yarandi 2008	?	?	?	+	+	?
Yarandi 2015	?	?	?	?	?	?

**Allocation**

The method of randomisation was described in only two trials: [Lertkhachonsuk 2009](#) (random number tables) and [Osborne 2011](#) (central randomisation). Only one trial described allocation concealment ([Osborne 2011](#)).

**Blinding**

Neither patients nor physicians were blind to the allocated treatment in [Osborne 2011](#). Blinding was not described in most of the other studies. The [Shobeiri 2014](#) abstract states that this study was 'single-blind', however, in the absence of any details we judged

the risk of bias for this study (as for the studies) to be unclear for blinding.

**Incomplete outcome data**

Loss to follow-up was low (less than 20% for all assessable outcomes) in one trial ([Lertkhachonsuk 2009](#)) and balanced between treatment arms. Four trials reported complete follow-up ([Gilani 2005](#); [Mousavi 2012](#); [Osborne 2011](#); [Yarandi 2008](#)) and for two trials ([Shobeiri 2014](#); [Yarandi 2015](#)), there was insufficient information on follow-up to pass judgement.

## Selective reporting

Protocols were only available for two of the seven trials (Osborne 2011; Shobeiri 2014). Five studies reported expected outcomes. Toxicity and adverse effects were insufficiently reported in Gilani 2005 but were described as 'minimal'. For Shobeiri 2014 and Yarandi 2015 there was insufficient information in the abstract reports to pass judgement on reporting bias.

## Other potential sources of bias

It is not clear why the data from Gilani 2005 and Yarandi 2008 were not combined by the investigators, since these trials were conducted in consecutive years by the same investigators, compared the same interventions, and applied the same methodology. For this reason, we performed sensitivity analyses, by excluding the Gilani 2005 data in case these data were duplicated in Yarandi 2008. For Shobeiri 2014, and Yarandi 2015 there was insufficient information to pass judgement on other potential sources of bias.

## Effects of interventions

See: [Summary of findings for the main comparison](#)

One trial (Yarandi 2015) contributed no data to this update. Therefore, six RCTs evaluated 581 women who were randomly allocated to receive methotrexate or actinomycin D for low-risk GTN.

### 1. Methotrexate versus Actinomycin D

#### 1.1 Primary cure (remission)

Irrespective of the type of regimen used, actinomycin D is probably more likely to lead to a primary cure than methotrexate in women with low-risk GTN (risk ratio (RR) 0.65, 95% confidence interval (CI) 0.57 to 0.75; six trials, 577 participants;  $I^2 = 26%$ ; *moderate-certainty evidence*, downgraded due clinical inconsistency; [Analysis 1.1](#)).

Due to concerns related to [Other potential sources of bias](#), we performed sensitivity analysis, excluding Gilani 2005, and obtained similar results (RR 0.66, 95% CI 0.57 to 0.77).

Tests for subgroup differences indicated no heterogeneity between treatment subgroups for this outcome ( $I^2 = 0%$ ).

#### 1.2 Failure of first-line therapy

First-line chemotherapy is probably more likely to fail with methotrexate regimen than with actinomycin D regimen (RR 3.55, 95% CI 1.81 to 6.95; six trials, 577 participants;  $I^2 = 61%$ ; [Analysis 1.2](#); *moderate-certainty evidence*, downgraded due inconsistency). As in [Analysis 1.1](#), a sensitivity analysis, excluding Gilani 2005, produced similar results.

Tests for subgroup differences indicated no heterogeneity between treatment subgroups for this outcome ( $I^2 = 0%$ ). The Lertkhachonsuk 2009 data included six women in the methotrexate-folinic acid (MTX-FA) group who were changed to second-line therapy due to chemotoxicity. When we excluded these women, the results were similar.

#### 1.3 Chemotherapy cycles to primary cure

The combined data for this outcome was substantially heterogeneous and findings differed according to treatment

subgroups ( $I^2 = 75.6%$ ,  $P$  value = 0.04), therefore, we present these results as subtotals only.

For the subgroup of trials comparing weekly IM methotrexate versus bi-weekly pulsed IV actinomycin D, fewer cycles of actinomycin D were needed to effect a primary cure (two trials, 346 participants; mean difference (MD) 3.04, 95% CI 0.93 to 5.14; [Analysis 1.3](#)). There was substantial heterogeneity between the two trials included in this subgroup ( $I^2 = 92%$ ).

The other subgroups included only one trial for this outcome ([Analysis 1.3](#)).

Mousavi 2012 reported that significantly fewer cycles were necessary in the five-day IM methotrexate group than in the pulsed IV actinomycin D group, however, this trial included secondary treatment cycles in these data.

In Lertkhachonsuk 2009, there was no clear difference between the eight-day MTX-FA group and the five-day IV actinomycin D group with regard to the number of cycles.

#### 1.4 to 1.14 Adverse effects

The most commonly occurring side-effects in both groups were nausea, fatigue (constitutional) and anaemia. Findings indicate that there may be little or no difference between a methotrexate and actinomycin D regimen, overall or for subgroup analyses, in the following side-effects and adverse events.

- Nausea (four trials, 466 participants; RR 0.61, 95% CI 0.29 to 1.26; [Analysis 1.4](#);  $I^2 = 80%$ ).
- Vomiting (three trials, 420 participants; RR 0.75, 95% CI 0.32 to 1.73; [Analysis 1.5](#);  $I^2 = 64%$ ).
- Diarrhoea (three trials, 419 participants; RR 1.43, 95% CI 0.85 to 2.41; [Analysis 1.6](#);  $I^2 = 0%$ ).
- Fatigue (constitutional) (three trials, 420 participants; RR 1.00, 95% CI 0.84 to 1.19; [Analysis 1.7](#);  $I^2 = 0%$ ).
- Neutropenia (four trials, 469 participants; RR 0.83, 95% CI 0.48 to 1.45; [Analysis 1.11](#)  $I^2 = 4%$ ).
- Thrombocytopenia (three trials, 338 participants; RR 0.76, 95% CI 0.16 to 3.55; [Analysis 1.12](#);  $I^2 = 65%$ ).
- Anaemia (one trial, 214 participants; [Analysis 1.13](#)).
- Hepatotoxicity (two trials, 263 participants; RR 2.57, 95% CI 0.39 to 16.88; [Analysis 1.14](#)).
- Haemoptysis (two trials, 206 participants; RR 0.99, 95% CI 0.30 to 3.31; [Analysis 1.15](#)).

This evidence is mostly of low certainty.

#### Other adverse effects

Three studies reported alopecia. There was no significant difference in the rate of women experiencing alopecia in the two studies that compared methotrexate (weekly or five-day IM) with pulsed IV actinomycin D (206 participants; RR 0.91, 95% CI 0.43 to 1.90;  $I^2 = 0%$ ; [Analysis 1.8](#)). However, in the one study that compared eight-day IM MTX-FA with five-day IV actinomycin D (Lertkhachonsuk 2009), significantly more women in the actinomycin D group experienced alopecia (49 participants; RR 0.03, 95% CI 0.00 to 0.53; [Analysis 1.8](#)). These findings suggest a dose-response relationship for actinomycin D and alopecia, and we

did not pool these heterogeneous subgroup data (Test for subgroup differences:  $P$  value = 0.05;  $I^2$  = 65.7%).

Similarly, mucositis occurred more frequently in the five-day IV actinomycin D group than the eight-day MTX-FA treatment group of [Lertkhachonsuk 2009](#). These data differed from the only other study reporting this outcome and in which the interventions had similar effects on mucositis ([Osborne 2011](#)). Tests for subgroup differences suggest that the effects of these different regimens on the risk of mucositis differ ( $P$  value = 0.02;  $I^2$  = 81%), therefore, we did not pool these data ([Analysis 1.9](#)).

Dermatological adverse effects (including rash or alopecia) occurred more frequently in the actinomycin D group, in the one study reporting this combined outcome ([Osborne 2011](#); RR 0.52, 95% CI 0.29 to 0.93; [Analysis 1.10](#)). However, these adverse effects were all [CTCAE 2010](#) grade one, except for one grade two effect in the methotrexate group.

Severe adverse events (SAEs; [CTCAE 2010](#) or Gynecologic Oncology Group (GOG)  $\geq$  grade 3) were experienced by participants of two out of the five studies ([Lertkhachonsuk 2009](#); [Osborne 2011](#)). All reported SAEs were grade three except for two women in the actinomycin D group of the [Osborne 2011](#) study who experienced grade four haematological SAEs. The evidence overall suggests that there may be little or no difference between the methotrexate and actinomycin D groups for SAEs; however, the evidence is of a low certainty due to imprecision and inconsistency (five trials, 515 participants; RR 0.35, 95% 0.08 to 1.66; [Analysis 1.16](#);  $I^2$  = 60%). Five-day actinomycin D may be associated with a higher risk of SAEs than the eight-day MTX-FA regimen (low-certainty evidence).

Six women in the [Lertkhachonsuk 2009](#) study and one woman in the [Shobeiri 2014](#) had the allocated treatment (MTX-FA) discontinued due to hepatotoxicity. No other incidents of treatment discontinuation were reported. No deaths occurred in any of the trials.

Reproductive data were scarce: only [Yarandi 2008](#) reports that "no ovarian failure" occurred.

## DISCUSSION

### Summary of main results

See [Summary of findings for the main comparison](#).

Seven RCTs were included and six trials evaluating 577 women contributed data. All trials compared methotrexate with actinomycin D. Moderate-certainty evidence indicates that actinomycin D is probably more likely to be associated with a higher primary cure rate than methotrexate, irrespective of the treatment regimen compared, and less likely to be associated with first-line treatment failure.

Side-effects were reported to be mild ([CTCAE 2010](#) or GOG grade one to two) or minimal in three trials. Low-certainty evidence suggests that there may be little or no difference in various side-effects. However, the five-day actinomycin D regimen may cause more alopecia and mucositis than the eight-day methotrexate-folinic acid regimen (MTX-FA).

Overall, it is uncertain whether there is a difference in the risk of severe adverse events (SAEs) between actinomycin D and

methotrexate regimens. However, low-certainty evidence suggests that the five-day actinomycin D regimen may be more likely to be associated with SAEs than the eight-day MTX-FA regimen.

### Overall completeness and applicability of evidence

The evidence indicates that actinomycin D is probably better than methotrexate in achieving a primary cure in women with low-risk GTN. However, three out of seven included trials used a weekly IM dose of methotrexate and it has been argued that this regimen is not as effective as the five- or eight-day regimens ([Aghajanian 2011](#)). Hence, the ongoing research comparing pulsed actinomycin D with more intensive methotrexate regimens ([CTRI/2012/11/003120](#); [GOG 0275](#); [IRCT2015012519567N1](#)) is likely to have an important impact on our confidence in this evidence.

Although most included studies reported minimal side-effects and the evidence indicated that there may be little or no difference in side-effect outcomes, the relative side-effect profiles of the two drugs is still uncertain. This is largely because interventions and data were frequently heterogeneous. Furthermore, in the two studies with data on SAEs (mainly grade three) ([Lertkhachonsuk 2009](#); [Osborne 2011](#)), data were scarce; however, more SAEs occurred in the actinomycin D group. As side-effects and SAEs play an important role in treatment choice, more evidence on the relative side-effects is necessary. However, since the efficacy of actinomycin D does not appear to be adversely affected by the lower, pulsed bi-weekly dosage, which appears to be associated with fewer side-effects than the five-day regimen, pulsed actinomycin D may compare favourably in terms of relative side-effects to the five- and eight-day methotrexate regimens. This was shown in the one small included study ([Mousavi 2012](#)) in which no significant differences were found between these two groups in terms of side-effects, and no SAEs occurred. Thus, the ongoing trials are likely to make an important contribution to the body of evidence on SAEs and side-effects.

These results may not be applicable to women with WHO risk scores of five to six and/or those with histologically-confirmed choriocarcinoma. [Yarandi 2008](#) excluded women with histologically-confirmed choriocarcinoma from their trial, and [Osborne 2011](#) found that these higher scoring, low-risk lesions (previously classified as intermediate risk) were significantly less likely to respond to either drug as single-agent therapy. In the latter study, the primary response rate for these higher scoring lesions was 9% and 42% for methotrexate and actinomycin D, respectively. This needs further investigation.

Women undergoing treatment for low-risk GTN may wish to bear children in the future. Follow-up in the included studies was continued for one year after the last treatment cycle and only one mentioned ovarian failure as a potential adverse outcome ([Yarandi 2008](#)). Reproductive data should be included in future studies of treatment for low-risk GTN.

As health economics play an increasingly important role in determining treatment guidelines, particularly where several different treatment regimens result in similar cure rates and similar/low rate of side-effects, the relative cost of treatment and treatment failure needs to be examined. Unfortunately, this was beyond the scope of this review but may be considered for the next update.

## Quality of the evidence

The quality of evidence ranges from low to moderate certainty, with evidence most frequently being downgraded due to clinical or statistical inconsistency and/or imprecision. For more details see [Summary of findings for the main comparison](#).

## Potential biases in the review process

To our knowledge there were no potential biases in the review process. We included all the relevant randomised controlled trials (RCTs) identified by the search. Where there were concerns regarding the quality of included trials, we contacted the investigators, and performed sensitivity analyses. We were unable to obtain the full [Shobeiri 2014](#) manuscript for this 2016 update but still hope to do so and, once translated, to include more data from this study in the next update.

## Agreements and disagreements with other studies or reviews

The largest contributing subgroup of trials used the weekly methotrexate regimen. This regimen has been criticised as being less effective than the more commonly used methotrexate treatment regimens, namely the five- or eight-day regimens ([Aghajanian 2011](#)). However, efficacy data on the various methotrexate regimens have come mainly from retrospective ([Bagshawe 1989](#); [McNeish 2002](#); [Soper 1994](#)) and case-control studies ([Smith 1982](#); [Wong 1985](#)), which may be subject to high levels of bias; furthermore, there have been no RCTs comparing the weekly methotrexate regimen with the five- and eight-day regimens ([Figure 4](#)). Given the wide range of methotrexate and actinomycin D regimens evaluated, and the uncertainty with regard to which regimen is optimal, it would seem appropriate to conduct a network meta-analysis for the next update of this review, when we should be able to include the data from current ongoing studies.

## AUTHORS' CONCLUSIONS

### Implications for practice

Actinomycin D treatment is probably more likely to achieve a primary cure in women with gestational trophoblastic neoplasia (GTN) and less likely to result in treatment failure compared with methotrexate. The evidence on side-effects and severe adverse events (SAEs) is uncertain; however, actinomycin D may be

associated with more SAEs, particularly when given as a five-day regimen.

## Implications for research

The ongoing trials ([CTRI/2012/11/003120](#); [GOG 0275](#); [IRCT2015012519567N1](#); [NCT01823315](#)), projected to include 878 participants altogether should provide the crucial, missing, information on the comparable effects of the more commonly used methotrexate regimens with actinomycin D. In addition, [NCT01823315](#) may provide useful evidence on a combination regimen. For further information, see [Characteristics of ongoing studies](#).

More research is needed to determine whether higher-scoring, low-risk lesions (scores of five/six) are best treated with single-agent therapy, and what the impact of the respective interventions is, if any, on future reproduction.

## ACKNOWLEDGEMENTS

We thank the following people:

- Jo Morrison, Clare Jess, Gail Quinn, and Jane Hayes at the Cochrane Gynaecological, Neuro, and Orphan Cancer Review Group in Bath for their advice and support throughout the review process;
- Jo Platt for conducting the updated 2016 search and sifting the initial results;
- Alison Little (Sheffield University) and Anne Oestmann (Cochrane Gynaecological Cancer Collaborative Review Group) for their assistance in developing the search strategy process and literature search for the original review; and
- The authors of [Lertkhachonsuk 2009](#) and [Yarandi 2008](#) for providing additional data.
- The 2012 review update received methodological and statistical support as part of the 10/4001/12 NIHR Cochrane Programme Grant Scheme - Optimising care, diagnosis and treatment pathways to ensure cost effectiveness and best practice in gynaecological cancer: improving evidence for the NHS.
- This project was supported by the National Institute for Health Research, via Cochrane Infrastructure funding to the Cochrane Gynaecological, Neuro-oncology and Orphan Cancer Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health.

**CHARACTERISTICS OF STUDIES**
**Characteristics of included studies [ordered by study ID]**
**Gilani 2005**

Methods	Single-centre RCT (Iran). Study duration: 2001 to 2003.
Participants	Low-risk GTN. Number randomised: 46. Number evaluable:46. Randomisation ratio of 1.5 MTX:1 Act D applied due to economic limitations.
Interventions	Group1: MTX, IM, 30 mg/m <sup>2</sup> repeated every week. Group2: ACT, IV, 1.25 mg/m <sup>2</sup> repeated every 2 weeks.
Outcomes	Efficacy: remission rate, number of cycles to remission, duration of treatment, need for second-line chemotherapy. Adverse effects: nausea.
Notes	Risk scoring: WHO/FIGO 2000. Non-response defined as < 10% decrease in BhCG over 3 weeks, more than 20% rise in BhCG over 2 consecutive weeks or the appearance of new metastatic disease. Remission defined as hCG < 5 IU/L. One additional cycle was given after remission.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Sequence generation not reported.
Allocation concealment (selection bias)	Unclear risk	Allocation concealment not reported.

**Gilani 2005** (Continued)

Blinding (performance bias and detection bias) All outcomes	Unclear risk	Blinding not reported.
Incomplete outcome data (attrition bias) All outcomes	Low risk	100% of participants analysed.
Selective reporting (reporting bias)	Low risk	All pre-specified outcomes reported. Toxicity not reported in detail but said to be 'minimal' in both groups.
Other bias	Unclear risk	This trial has the same authors, location and protocol as <a href="#">Yarandi 2008</a> , with consecutive enrolment dates, yet the later <a href="#">Yarandi 2008</a> study does not refer to <a href="#">Gilani 2005</a> . It is not clear why. Attempts to clarify this with Dr Yarandi have been unsuccessful.

**Lertkhachonsuk 2009**

Methods	Single-centre RCT (Thailand).  Study duration: 1994 to 2005.  Follow-up: 1 year.
Participants	Low-risk GTN (FIGO stage 1).  Number randomised: 49.  Number evaluable: 45.
Interventions	Group 1: Act D IV 10 µg/kg/day (D1 to D5) repeated every two weeks.  Group 2: MTX-FA: MTX IM 1 mg/kg/day (days 1, 3, 5, 7) and MTX-FA IM 0.1 mg/kg/day (days 2, 4, 6, 8), repeated every two weeks.
Outcomes	Efficacy: remission rate, number of cycles to remission, need for second-line chemotherapy.  Adverse effects: liver toxicity, neutropenia, skin pigmentation, alopecia and mucositis.
Notes	Risk scoring: FIGO.  Two participants in each arm of treatment were lost to follow-up and were excluded from the analysis in the reporting article.  Six participants in the MTX-FA group were switched to Act D due to rising levels of liver enzymes. The investigators excluded these participants from analyses of remission rates (i.e. not ITT analyses), however we have added these data back. ITT analysis gives a remission rate of 14/25 in the MTX group, not 14/19 as reported.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Used table of random numbers.

**Lertkhachonsuk 2009** (Continued)

Allocation concealment (selection bias)	Unclear risk	Allocation concealment not reported.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Blinding not reported.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Four lost to follow-up, two in each group. Therefore 92% analysed : 20/22 (91%) of 5-day Act D arm and 25/27 (92.6%) of the MTX-FA arm.
Selective reporting (reporting bias)	Unclear risk	Not ITT analysis. Six women in MTX-FA who were switched to Act D due to hepatotoxicity were excluded from final analysis; therefore remission rate was reported as 14/19 instead of 14/25.
Other bias	Low risk	No evidence of other bias.

**Mousavi 2012**

Methods	RCT conducted in Iran; randomisation ratio not stated but appears to be 1 MTX:2 Act D Accrual dates: Jan 2008 to Dec 2010 Follow-up: 1 year	
Participants	75 women with FIGO stage I-III; modified WHO risk scores $\leq 6$ ; ; a rise in hCG of $> 10\%$ in the 3 weeks post-termination of pregnancy or a hCG plateau of 4 weeks. Exclusion criteria were prior CT or hysterectomy.	
Interventions	Group 1: 5-day IM MTX (0.4 mg/kg) repeated every two weeks vs. Group 2: bi-weekly IV Act D (1.25 mg/m <sup>2</sup> bolus)	
Outcomes	Primary remission; need for second-line CT; duration of treatment; toxicity	
Notes	Non-response defined as a BhCG plateau or rising BhCG titres for 2 consecutive weeks. No major adverse events were reported in either group (classified according to the GOG grading system). Baseline characteristic similar. Mucositis not reported.	

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	'Randomised'; no other details provided.
Allocation concealment (selection bias)	Unclear risk	Not described.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Not described.
Incomplete outcome data (attrition bias)	Low risk	No loss to follow-up.

**Mousavi 2012** (Continued)

## All outcomes

Selective reporting (reporting bias)	Low risk	All pre-specified and expected outcomes were reported.
Other bias	Low risk	None evident. Baseline characteristic similar.

**Osborne 2011**

Methods	Multicentre RCT (US, Japan, Canada and South Africa) with central randomisation through the GOG Centre. Clinical trial registration ID: NCT00003702  Study duration: 1999 to 2007.  Follow-up: 1 year.	
Participants	Low-risk GTN (see notes).  Number randomised: 240.  Number ineligible: 24.  Number evaluable: 216.	
Interventions	Group 1 = MTX, IM, 30 mg/m <sup>2</sup> , weekly.  Group 2 = ACT, IV, 1.25 mg/m <sup>2</sup> , every two weeks.	
Outcomes	Primary: CR defined as a normal hCG sustained over four weekly measurements.  Secondary: number of CT cycles to remission, treatment failure/need for second-line CT.  Adverse effects.	
Notes	Baseline characteristics were similar between the two groups. Risk scoring: WHO/FIGO 2000.  WHO risk score 0 to 4 was used between June 1999 to June 2002, then modified score 0 to 6 was used from July 2002 to February 2007. Twenty-seven women had WHO scores of 0 (balanced between groups) which may have inflated the CR rate.  Two women did not receive their allocated treatment, therefore, they were included in ITT analysis but not in analysis of toxicity. Twenty-four women deemed ineligible: 13 did not meet the entry criteria for persistent disease, 4 did not have GTN, 4 had inadequate documentation of the disease and 3 had a centrally re-calculated risk WHO risk score > 6.  Non-response (NR) defined as any set of three consecutive assay results that declined by < 10%. Eleven NR women (5 MTX and 6 Act D) continued to receive their allocated treatment and went on to achieve CR.  No women had to have allocated treatment terminated because of toxicity.  Alopecia coded as dermatological toxicity.  11 women continued on the allocated regimen after being assessed as non-responders and attained CR. If these women had been included in the analyses of CR the percentage of responders would have been 63% for MTX and 79% for Act D (compared with 53% and 70% respectively).	

**Risk of bias**

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

**Osborne 2011** (Continued)

Random sequence generation (selection bias)	Low risk	Computer-generated random sequence.
Allocation concealment (selection bias)	Low risk	Central randomisation and allocation of treatment.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Neither participants nor treatment providers were blinded.
Incomplete outcome data (attrition bias) All outcomes	Low risk	90% of participants were analysed : 107/120 (89%) of weekly MTX arm and 108/120 (90%) of "pulsed" ACT D arm.
Selective reporting (reporting bias)	Low risk	All pre-specified and expected outcomes reported. Analysis by ITT.
Other bias	Low risk	No evidence of other bias.

**Shobeiri 2014**

Methods	Randomised single-blind trial conducted in Iran with recruitment between 2011 and 2013. Clinical trial registration ID: IRCT201105236563N1	
Participants	<p>Women with untreated low-risk GTN (LRGTN) stage I and (WHO) prognostic scoring of 6 or less.</p> <p>Inclusion criteria: women with a plateau or increase in serum BhCG level or persistent elevation above the normal B-hCG value 16 weeks after molar (complete or incomplete) evacuation . Plateau BhCG level is defined as 10% or less change in BhCG titre at least over 3 weeks (4 values in days 1, 7, 14, 21) and rising BhCG titre is defined as greater than 10% increase in BhCG titre at least over 2 weeks (3 values in days 1, 7, 14) .</p> <p>Exclusion criteria: histologically-confirmed choriocarcinoma or placental site trophoblastic tumour (PSTT), did not agree to have effective contraception for the duration of the study, metastasis, FIGO prognostic score of 7 or more, willing to continue breast feeding, presence of other malignancies with disease free duration less than 5 years, contraindication for protocols of chemotherapy due to previous cancer treatment, prior chemotherapy or hysterectomy for GTN</p> <p>Number eligible: 64</p> <p>Number evaluable: 64</p>	
Interventions	<p>Group 1: Act D, IV, 1.25 mg/m<sup>2</sup> repeated every 2 weeks.</p> <p>Group 2: MTX 1 mg/kg per day on days 1, 3, 5, and 7 IM with IM Folinic Acid 0.1 mL/kg per day on days 2, 4, 6, and 8.</p>	
Outcomes	<p>Primary: CR</p> <p>Secondary: adverse events</p>	
Notes	Info and data extracted from published English abstract only as the published paper could not be obtained for translation. Emailed for more details on the 28/3/16	

**Risk of bias**

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

**Shobeiri 2014** (Continued)

Random sequence generation (selection bias)	Unclear risk	'randomly assigned' - sequence generation not described
Allocation concealment (selection bias)	Unclear risk	Not described
Blinding (performance bias and detection bias) All outcomes	Unclear risk	'single-blind' but no details provided
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Few data available in conference abstract only
Selective reporting (reporting bias)	Unclear risk	Published abstract gave data on response to treatment but was insufficient for other outcomes
Other bias	Unclear risk	Insufficient details in published abstract to make a judgement

**Yarandi 2008**

Methods	<p>Single-centre RCT (Iran).</p> <p>Study duration: 09/2003 to 09/2006.</p> <p>Follow-up: 1 year.</p>
Participants	<p>Low-risk GTN.</p> <p>Number eligible:131.</p> <p>Number evaluable:131.</p> <p>Participants randomised into two groups: group 1 = 81 and group 2 = 50 (randomisation ratio of 1.5 MTX:1 Act D applied). Reasons given for this were economic limitations.</p> <p>Excluded patients with choriocarcinoma.</p>
Interventions	<p>Group 1: MTX, IM, 30 mg/m<sup>2</sup> repeated every week.</p> <p>Group 2: Act D, IV, 1.25 mg/m<sup>2</sup> repeated every 2 weeks.</p>
Outcomes	<p>Efficacy: remission rate, number of cycles to remission, duration of treatment, need for second-line chemotherapy.</p> <p>Adverse effects: nausea.</p>
Notes	<p>Risk scoring: FIGO 2000.</p> <p>Six women ( 4 in group 1 and 2 in group 2) did not complete their first-line chemotherapy, but were considered in the ITT analysis.</p>

**Risk of bias**

Random sequence generation (selection bias)	Unclear risk	Sequence generation not described.
Allocation concealment (selection bias)	Unclear risk	Allocation concealment not described.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Blinding not described.
Incomplete outcome data (attrition bias) All outcomes	Low risk	100% of randomised participants were analysed.
Selective reporting (reporting bias)	Low risk	All pre-specified and expected outcomes were reported. Analysis was by ITT.
Other bias	Unclear risk	See 'Risk of bias' comment for <a href="#">Gilani 2005</a> .

**Yarandi 2015**

Methods	Single-centre RCT (Iran)
Participants	62 women with LRGTN
Interventions	Group 1: 5-day MTX (0.4 mg/kg IM) (25 mg max) Group 2: bi-weekly Act D (1.25 mg/m <sup>2</sup> IV bolus) (2mg max)
Outcomes	Primary: primary remission, resistance to chemotherapy
Notes	<p>Conference abstract only.</p> <p>Numbers randomised to each arm was not stated in the abstract, therefore data could not be extracted/included in the review.</p> <p>Results were reported as follows: "Complete remission after receiving first-line chemotherapy was achieved in 79% of all cases, 80% of Act-D and 78.1% of MTX group (P value = 0.86) 20% of Act-D and 21.9% of MTX cases showed resistance to the first chemotherapy, of which 16.7% and 15.6% respectively responded completely to the second-line mono therapy. 3.3% of Act-D and 6.,3% of MTX group needed multiple drug therapy (P value = 0.86) Side-effects were not significantly different in both groups." Baseline characteristics were reported to be similar viz. BhCG level, uterine mass size, lung metastasis, antecedent pregnancy and the duration from diagnosis to treatment.</p> <p>Authors were emailed for info but the email bounced back.</p>

**Yarandi 2015** (Continued)

Blinding (performance bias and detection bias) All outcomes	Unclear risk	Blinding not described.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Insufficient information in conference abstract
Selective reporting (reporting bias)	Unclear risk	Insufficient information; no study protocol identified
Other bias	Unclear risk	Insufficient information in conference abstract. Attempts to contact study investigators (F Yarandi) were unsuccessful.

Abbreviations: Act D = Actinomycin D or Dactinomycin; BhCG = beta human chorionic gonadotrophin; CR = Complete response; CT = chemotherapy; FIGO = International Federation of Gynecology and Obstetrics; GOG = Gynecologic Oncology Group; GTN = Gestational trophoblastic neoplasia; IM = intramuscular; ITT = Intention-to-treat; IV = intravenous; LRGTN = low-risk gestational trophoblastic neoplasia; MTX = Methotrexate; MTX-FA = methotrexate-folinic acid; RCT = randomised controlled trial; WHO = World Health Organization

**Characteristics of excluded studies** [ordered by study ID]

Study	Reason for exclusion
<a href="#">Abrao 2008</a>	Not an RCT. In this case-control study, 108 women were treated with 5-day MTX (42 women) or 5-day Act D (42 women) or MTX/Act D combined (24 women). The combined intervention was stopped due to high rates of toxicity.
<a href="#">Baptista 2012</a>	Not an RCT. In this prospective study conducted in Brazil, 60 women with LRGTN (risk score $\leq 6$ ) were assigned to MTX (50 mg/day/IM) alternating with folinic acid rescue for 8 days (N = 20), 5-day Act D (12 mcg/kg/IV) (n = 20) and etoposide (100 mg/m <sup>2</sup> /IV) (n = 20). Alopecia was the most common side-effect caused by etoposide (occurred in 95% of women).
<a href="#">Berkowitz 1979</a>	Not an RCT. The study may have high-risk patients.  It was not clear if patients were balanced for demographic variables.  It was not clear if all patients between 1976 to 1978 were treated with MTX @ 6 mg/kg or if the decision to use this dose was left to attending physician.
<a href="#">Berkowitz 2014</a>	A review of the management in GTN.
<a href="#">Gilani 2013</a>	A cohort study of 66 women treated with MTX.
<a href="#">Gleeson 1993</a>	Not an RCT. High risk of selection bias " the choice of treatment was at the discretion of the attending oncologist".  Follow-up period not clear.
<a href="#">Kar 2015</a>	A conference abstract of a cohort study of 50 women with GTD.
<a href="#">Kohorn 1996</a>	Not an RCT. In this case-control study, women were treated with a 5-day Act D regimen (43 women) or a pulsed Act D regimen (18 women).
<a href="#">Matsui 1998</a>	High risk of selection bias; patients were not matched for the potential confounding variables in the different treatment groups.  Included in subsequent publication.

Study	Reason for exclusion
Matsui 2005	High risk of selection bias; study did not provide information about patient characteristics and if they were matched for the potential confounding variables in the different treatment groups.
Petrilli 1980	High risk of selection bias: study did not provide information about the characteristics of patients and if they were matched for potential confounding variables in the treatment groups.
Roberts 1996	Case series rather than case-control study; 61 patients received MTX, 4 ACT and 5 MACT. Risk of selection bias; patients were not matched for the potential confounding variables.
Smith 1982	Not an RCT. In this case-control study, 39 women received MTX and 29 women received MTX-FA.
Wong 1985	Not an RCT. In this case-control study, 33 women received MTX and 68 women received MTX-FA.

Act D = actinomycin D; GTD = gestational trophoblastic disease; GTN = gestational trophoblastic neoplasia; IM = intramuscular; IV = intravenous; LRGTN = low-risk gestational trophoblastic neoplasia; MTX = methotrexate; MTX-FA = methotrexate-folinic acid; RCT = randomised controlled trial

### Characteristics of ongoing studies [ordered by study ID]

#### CTRI/2012/11/003120

Trial name or title	Randomised trial of pulsed actinomycin D versus MTX infusion in low risk gestational trophoblastic neoplasia
Methods	Open-label, randomised parallel arm trial in India, fixed block randomisation, sequentially numbered, sealed, opaque envelopes 5-year follow-up
Participants	150 women with abnormal BhCG regression following any type of pregnancy (molar, term, abortion, ectopic), i.e. <ul style="list-style-type: none"> <li>• hCG plateau for 4 consecutive values over 3 weeks</li> <li>• hCG rise of &gt; 10% for 3 values over 2 weeks</li> <li>• hCG persistence 6 months after molar pregnancy evacuation</li> </ul> FIGO score ≤ 6
Interventions	Arm 1: MTX 300 mg/m <sup>2</sup> in 500 mL of normal saline given as an IV infusion over six hours followed by folinic acid 15 mg PO every 6 hours for four doses starting 24 hours after the start of MTX infusion. The same is repeated every two weeks until the hCG becomes normal. Arm 2: ACT D 1.25 mg/m <sup>2</sup> slow IV push and the same repeated every two weeks until the hCG becomes normal
Outcomes	Primary: Primary remission rate, CR Secondary: Time to cure, number of cycles required for CR, toxicity and side-effects, cost of treatment
Starting date	19-11-2012. Estimated completion date 2017
Contact information	Dr Anitha Thomas. Department of Obstetrics and Gynecology Unit 1 Christian Medical College Vellore, Tamil Nadu, India Vellore. TAMIL NADU

Notes

**GOG 0275**

Trial name or title	Methotrexate or actinomycin D in treating patients with low-risk gestational trophoblastic neoplasia (NCT01535053)
Methods	Multicentre phase III RCT; open-label
Participants	384 women with LRGTN
Interventions	Arm I: MTX IM on days 1, 3, 5, and 7 and leucovorin calcium PO on days 2, 4, 6, and 8 OR MTX IV on days 1 to 5.  Arm II: Act D IV over 15 minutes on day 1.  Cycles repeated every 14 days for up to 13 courses in the absence of disease progression or unacceptable toxicity. Women receive 3 courses after hCG < (< 5 mIU/mL
Outcomes	Primary: CR rate  Secondary: post-protocol surgery; post-protocol multi-agent treatment; severe adverse events; QoL
Starting date	January 2012. Estimated completion August 2016
Contact information	Dr Julian Schink  Robert H. Lurie Cancer Center, Northwestern University, Chicago, Illinois, United States, 60611  Ph: 312-472-4684
Notes	Investigators emailed 28/3/16

**IRCT2015012519567N1**

Trial name or title	Comparison of pulsed actinomycin versus 5-day methotrexate for the treatment of low-risk gestational trophoblastic disease in patients
Methods	Randomised single-blind trial in Iran
Participants	44 women with WHO risk score 0-6
Interventions	Arm 1: Actinomycin 1.25 mg/m <sup>2</sup> every 14 days IV (maximum dose 2 mg)  Arm 2: MTX 5-day (0.4 mg/kg IV) (25 mg max)
Outcomes	Primary: BhCG
Starting date	21-3-2011. Estimated completion date 20-3-2015
Contact information	Dr Abbaslou: fabbaslou@yahoo.com; mirzalib@sina.tums.ac.ir

**IRCT2015012519567N1** (Continued)

Notes Investigators emailed 28/3/16 to enquire about completion (no response received)

**NCT01823315**

Trial name or title	Methotrexate single-dose treatment and methotrexate/actinomycin-D single-dose treatment in low-risk gestational trophoblastic neoplasia (GTN-01)
Methods	Open-label RCT in China; 3-year follow-up
Participants	300 women with LRGTN
Interventions	<p>Arm 1: MTX 0.4 mg/(kg·day) IM on days 1-5. If BhCG level can not drop to 1/10 of the origin level during the following 3 weeks, additional course is administered at 2-week intervals, after the first normal hCG value has been recorded.</p> <p>Arm 2: Act D 0.6 mg/m<sup>2</sup>, IV on day 1,2; MTX 100 mg/m<sup>2</sup>, IV, on day1 (after Act D); MTX 200 mg/m<sup>2</sup>, IV, on day 1 (after MTX, 500 mL NS &gt; 4 hours) If BhCG level does not drop to 1/10 of the origin level during the following 3 weeks, additional courses are administered at 2-week intervals, with one additional cycle after the first normal hCG value has been recorded.</p>
Outcomes	<p>Primary: adverse events; progression-free survival, CR and treatment failure</p> <p>Secondary: resumption of menstruation, pregnancy rate, delivery rate of live-born babies, abnormal pregnancy (stillbirth, neonatal deaths, miscarriage, terminations, ectopic and molar pregnancies)</p>
Starting date	December 2012. Estimated completion date December 2017
Contact information	<p>Dr Danhui Weng</p> <p>Tongji Hospital, Wuhan, Hubei, China, 430030</p>
Notes	

Act D = Actinomycin D; BhCG = beta human chorionic gonadotrophin; CR = Complete response; CT = chemotherapy; FIGO = International Federation of Gynecology and Obstetrics; IM = intramuscular; IV = intravenous; LRGTN = low-risk gestational trophoblastic neoplasia; MTX = Methotrexate; NS = normal saline; PO = by mouth; QoL = quality of life; RCT = randomised controlled trial; WHO = World Health Organization

**DATA AND ANALYSES**
**Comparison 1. Methotrexate vs. Actinomycin D**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Primary cure (remission)	6	577	Risk Ratio (M-H, Random, 95% CI)	0.65 [0.57, 0.75]

**Analysis 1.16. Comparison 1 Methotrexate vs. Actinomycin D, Outcome 16 Severe adverse events (≥G3).**

**ADDITIONAL TABLES**

**Table 1. FIGO anatomical staging \***

Stage I	Disease confined to the uterus
Stage II	GTN extends outside of the uterus, but is limited to the genital structures (adnexae, vagina, broad ligament)
Stage III	GTN extends to the lungs with or without known genital tract involvement
Stage IV	All other metastatic sites

\*FIGO 2009

GTN:

**Table 2. Modified WHO Prognostic Scoring System as adapted by FIGO for GTN**

Scores	0	1	2	4
Age (years)	< 40	≥ 40	–	–
Antecedent pregnancy	mole	abortion	term	–
Interval months from index pregnancy	< 4	4–6	7–12	> 12
Pretreatment serum hCG (IU/L)	< 10 <sup>3</sup>	10 <sup>3</sup> to 10 <sup>4</sup>	10 <sup>4</sup> to 10 <sup>5</sup>	> 10 <sup>5</sup>
Largest tumour size (including uterus)	< 3	3cm to 4 cm	≥ 5 cm	–
Site of metastases	lung	spleen, kidney	gastrointestinal	liver, brain
Number of metastases	–	1 to 4	5 to 8	> 8
Previous failed chemotherapy	–	–	single drug	≥ 2 drugs

*To stage and allot a risk factor score, a patient's diagnosis is allocated to a stage as represented by a Roman numeral I, II, III, and IV. This is then separated by a colon from the sum of all the actual risk factor scores expressed in Arabic numerals, i.e., stage II:4, stage IV:9. This stage and score will be allotted for each patient.(FIGO 2009). A score ≤ 6 indicates low-risk; > 6 indicates high-risk.*

hCG = human chorionic gonadotrophin; IU = International Units

**Table 3. Other first-line chemotherapy regimens described**

Drug	Study	Comment
Intravenous (IV) methotrexate (100, 150, or 300 mg/m <sup>2</sup> ) with folinic acid rescue 24 hours later, repeated weekly	<a href="#">Bagshawe 1976</a>	The original Bagshawe regimen.
Bolus (100 mg/m <sup>2</sup> IV or IM) and 12-hour continuous methotrexate infusion (200 mg/m <sup>2</sup> ) with folinic acid rescue 24 hours later, repeated fortnightly	<a href="#">Garrett 2002</a>	
Combined 5-day methotrexate (day 1 to 5) and 5-day actinomycin D (day 15 to 19), repeated every 28 days	<a href="#">Abrao 2008</a> ; <a href="#">Smith 1975</a> ; <a href="#">Rose 1989</a>	Associated with a high incidence of toxicity.

**Table 3. Other first-line chemotherapy regimens described** (Continued)

High-dose methotrexate (600 mg/m <sup>2</sup> )	<a href="#">Elit 1994</a>	Did not effect a higher cure than other methotrexate regimens.
Etoposide (oral and parenteral)	<a href="#">Hitchins 1988; Wong 1984; Wong 1986; Baptistista 2012</a>	Reported to be highly effective but not widely used for low-risk GTN due to the high risk of side-effects, particularly alopecia.
Fluorouracil	<a href="#">Sung 1984; Song 1998</a>	Used in China for several decades, mainly because of its low cost, but is not favoured elsewhere.
Intra-lesional methotrexate infusion	<a href="#">Su 2001</a>	Not favoured in Europe or North America.
Chinese preparations	<a href="#">Wang 1998</a>	Not favoured in Europe or North America.

GTN = gestational trophoblastic neoplasia

### Appendix 3. Risk of bias assessment for included studies

We assessed the risk of bias of included RCTs in accordance with guidelines in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011) as follows.

#### Randomisation

The method of randomisation was noted on the data extraction form. We assessed the randomisation as:

- low risk of bias: e.g. a computer-generated random sequence or a table of random numbers;
- high risk of bias: e.g. date of birth, clinic id-number or surname;
- unclear risk of bias: e.g. details not reported.

#### Allocation concealment

We assessed the concealment of allocation sequence from treatment providers and participants as:

- low risk of bias: e.g. where the allocation sequence could not be foretold;
- high risk of bias: e.g. the computer-generated random sequence was displayed so treatment providers could see which arm of the trial the next participant was assigned to, or kept in a sealed opaque envelope;
- unclear risk of bias: allocation concealment not reported.

#### Blinding

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judged that the lack of blinding would be unlikely to affect results. We assessed blinding separately for different outcomes or classes of outcomes and assessed the methods as:

- low, high or unclear risk of bias for participants;
- low, high or unclear risk of bias for personnel.

### Incomplete outcome data

We recorded the proportion of participants whose outcomes were not reported at the end of the study and we noted if loss to follow-up was not reported.

We assessed methods as:

- low risk of bias, if fewer than 20% of patients were lost to follow-up and reasons for loss to follow-up were similar in both treatment arms;
- high risk of bias, if more than 20% of patients were lost to follow-up or reasons for loss to follow-up differed between the treatment arms;
- unclear risk of bias if loss to follow-up was not reported.

### Selective reporting

We assessed the methods of outcome reporting as:

- low risk of bias (where it is clear that all of the study's pre-specified outcomes and all expected outcomes of interest have been reported);
- high risk of bias (where not all the study's pre-specified outcomes were reported; one or more reported primary outcomes were not pre-specified; outcomes of interest were reported incompletely and so could not be used; study fails to include results of a key outcome that would have been expected to have been reported);
- unclear risk of bias.

### Other bias

We described for each included study any important concerns we had about other possible sources of bias. We assessed whether each study was free of other problems that could put it at risk of bias and assessed the risk as follows:

- low risk of other bias;
- high risk of other bias;
- unclear whether there is risk of other bias.

## WHAT'S NEW

Date	Event	Description
30 September 2019	Review declared as stable	Most recent search 29 April 2019. No potentially relevant new studies identified. The conclusions of this Cochrane Review are therefore still considered up to date for this topic. No new studies expected in this topic area.

## HISTORY

Protocol first published: Issue 2, 2008

Review first published: Issue 1, 2009

Date	Event	Description
30 March 2016	New citation required but conclusions have not changed	Two additional studies included ( <a href="#">Shobeiri 2014</a> ; <a href="#">Yarandi 2015</a> ), four additional studies excluded
18 January 2016	New search has been performed	New search conducted 18 January 2016
28 March 2012	New citation required and conclusions have changed	Five records were identified from the updated search: one new study was included ( <a href="#">Mousavi 2012</a> ); three records were added to previously included studies ( <a href="#">Lertkhachonsuk 2009a</a> ; <a href="#">Rahimi-Moghaddam 2004</a> ; <a href="#">Osborne 2011a</a> ); one record was added to 'Ongoing studies' section ( <a href="#">GOG 0275</a> ).

Date	Event	Description
		Previously included non-RCTs ( <a href="#">Abrao 2008</a> ; <a href="#">Kohorn 1996</a> ; <a href="#">Smith 1982</a> ; <a href="#">Wong 1985</a> ) were excluded.  Conclusions updated.
14 February 2012	New search has been performed	Electronic database search updated rendering 964 records after de-duplication.
27 January 2008	New citation required and major changes	Substantive amendment

## CONTRIBUTIONS OF AUTHORS

Mo'iad Alazzam: protocol development, methodological quality assessment, retrieval of papers, data extraction, data analysis and writing the review.

John Tidy: protocol development, methodological quality assessment, data extraction and revision of the review. Barry Hancock: content expert and revision of the review.

Ray Osborne: content expert, contributed to writing discussion and revision of the review.

Tess Lawrie: co-ordination of the review updates, methodological quality assessment, retrieval of papers, data extraction, data analysis and updating the review.

## DECLARATIONS OF INTEREST

Ray Osborne was a primary investigator of a study that has been included in this review ([Osborne 2011](#)). He was not involved in the consideration or assessment of this study for inclusion.

## SOURCES OF SUPPORT

### Internal sources

- Sheffield Teaching Hospitals NHS Trust, UK.

### External sources

- 10/4001/12 National Institute for Health Research (NIHR) Cochrane Programme Grant Scheme, UK., UK.

This review received methodological and statistical support as part of the 10/4001/12 NIHR Cochrane Programme Grant Scheme - Optimising care, diagnosis and treatment pathways to ensure cost effectiveness and best practice in gynaecological cancer: improving evidence for the NHS.

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In the protocol and the original 2009 review, we included non-randomised studies (NRS) as well as RCTs. For the updated and revised review, we included only RCTs.

## INDEX TERMS

### Medical Subject Headings (MeSH)

Antineoplastic Agents [\*administration & dosage] [adverse effects]; Case-Control Studies; Cohort Studies; Dactinomycin [\*administration & dosage] [adverse effects]; Drug Administration Schedule; Gestational Trophoblastic Disease [\*drug therapy]; Leucovorin [administration & dosage]; Methotrexate [\*administration & dosage] [adverse effects]; Randomized Controlled Trials as Topic; Risk; Vitamin B Complex [administration & dosage]

### MeSH check words

Female; Humans; Pregnancy
