Abstract

A set of novel Kv7.2/7.3 (KCNQ2/3) channel blockers was synthesized to address several liabilities of the known compounds XE991 (metabolic instability and CYP inhibition) and the clinical compound DMP 543 (acid instability, insolubility, and lipophilicity). Using the anthrone scaffold of the prior channel blockers, alternative heteroarylmethyl substituents were installed via enolate alkylation reactions. Incorporation of a pyridazine and a fluorinated pyridine gave an analog (compound 18, JDP-107) with a promising combination of potency ($IC_{50} = 0.16 \mu M$ in a Kv7.2 thallium flux assay), efficacy in a Kv7.2/7.3 patch clamp assay, and drug-like properties.

Keywords

Kv7 blocker; voltage-gated potassium channel; schizophrenia; DMP 543; JDP-107

New and more efficacious treatments for schizophrenia are greatly needed, and this need has not yet been diminished by enormous investments in the clinical investigation of new drug

Supplementary data

Synthetic protocols, assay protocols, and select compound characterization data.

A preliminary version of this manuscript was submitted to the preprint server ChemRxiv.³⁴ C.D.W. is an owner of WaveFront Biosciences and ION Biosciences, manufacturers of the Panoptic plate reader and thallium-sensitive dyes used for the thallium flux assays described in this manuscript.

targets.¹⁻³ One approach to schizophrenia drug discovery involves the repurposing of compounds that have at least demonstrated safety in clinical trials.⁴ With this in mind, our interest in the chemical modification and redesign of bioactive natural and unnatural scaffolds led us to reexamine blockers of specific voltage-gated potassium channels of the family Kv7 (KCNQ). These are expressed in the nervous system, and two subtypes, KCNQ2 and KCNQ3, combine to form heteromeric channels that regulate the excitability of neurons via the so-called M-current.⁵ Previously, certain compounds possessing a rigid carbo- or heterocyclic core with two pendant Lewis basic sites were demonstrated to enhance the release of acetylcholine (ACh) in neuronal tissue and were under clinical investigation as cognitive enhancers for the treatment of dementia.⁶⁻¹¹ Linopirdine (**1**)^{6,12-14} was well-tolerated but ineffective as a cognitive enhancer in a phase 3 trial with Alzheimer's patients.¹⁵ Subsequent work led to the characterization of these compounds as blockers of Kv7 (KCNQ) potassium channels that control neuronal M-currents.¹⁶⁻²⁰ More recently, a patent by Ghasemzadeh reported that the KCNQ2/3 channel blockers XE991 (**2**)⁷ and DMP 543 (**3**),^{10,11} a compound also previously in clinical trials, could reverse the effects of phencyclidine (PCP) in a mouse model of schizophrenia, as measured by prepulse inhibition, social interaction time, and forced delayed alternation task.²¹ The patent also claimed that such compounds could be used to attenuate the negative symptoms of schizophrenia or treat drug addiction. Very recently, Shi and Xie reported that XE991 acts as a neuroprotective agent in a mouse model of Parkinson's disease.²² These findings prompted us to reexamine the use of KCNQ2/3 channel blockers for the potential treatment of neurological disorders, and to identify novel compounds with improved properties.

Beginning with patent applications first submitted in the 1980s,²³ researchers at DuPont Pharmaceuticals disclosed examples of scaffolds with α,α -bispyridylmethyl substituents as neuronal ACh releasers for potential use as cognitive enhancers (compounds **1** to **4**, Figure 1). With dozens of analogs previously disclosed in patents and publications, the pharmacophore for this compound class is now well established, with a rigid central scaffold flanked by two pendant hydrogen bond accepting moieties. Linopirdine and XE991 suffer from a lack of metabolic stability due to pyridine *N*-oxidation, which can be ameliorated by fluorination at the 2-position of the pyridine (DMP 543).¹⁰ Two more recent examples of KCNQ2 blockers are UCL2077^{24,25} and ML252,²⁶ at least one of which suffers from low metabolic stability.²⁶ Based on the promising safety profile reported for linopirdine in the clinic,¹⁵ and the potency and stability of DMP 543,¹⁰ we focused our efforts on identifying novel anthrone-based KCNQ2/3 blockers that may have improved properties. In particular, DMP 543 has several liabilities, including low aqueous solubility (6 μ M) and a lack of stability under acidic conditions.^{27,28} Herein are described our efforts at addressing these issues with novel analogs (Figure 1, bottom).

The acidic instability of DMP 543 is likely due to a S_NAr mechanism whereby the pyridine is reversibly protonated prior to attack by water at the 2-position, followed by elimination of fluoride.²⁸ We reasoned that replacement of the 2-fluoro pyridine substituents with 2-trifluoromethyl (**5**) or 3,5-difluoro (**6**) could provide compounds that maintained KCNQ2/3 channel blocking activity and stability to pyridine *N*-oxidation while greatly improving stability under acidic conditions. We also reasoned that improved solubility may be feasible

without compromising metabolic stability by using alternative heterocycles. A 4-pyrimidine analog of XE991 was reported, but it was more than tenfold less potent ($EC_{50} = 4.4$ vs 0.4 μM), and possessed less than 1% of the efficacy of XE991 in an assay measuring ACh release.⁷ Extensive SAR studies have indicated that heteroatoms at the termini of both side chains are required for ACh release activity,^{6,7,14} and we hypothesized that the pyridazine analog **7** could act as a hydrogen-bond acceptor and perhaps maintain potency and efficacy. We would expect it to have improved metabolic stability relative to XE991, improved solubility and acid stability relative to DMP 543,²⁹ and a decreased volume of distribution, as suggested by its calculated logP (ClogP) that is 3 units lower than DMP 543 (2.9 versus 5.9), using ChemAxon MarvinSketch v.18.3. The 2-methylpyridine **8** was prepared as a control compound to compare in particular with the 2-trifluoromethyl analog **5**. Calculated pKa values of **5** to **8** suggest that they could all potentially undergo salt formation with HCl (not possible with DMP 543), which could lead to improved kinetic solubilities and thus potentially improved oral bioavailabilities.

Analogs **5–8** were synthesized by the alkylation of the anthrone scaffold with mesylate electrophiles, as reported by Pesti for the synthesis of DMP 543.³⁰ To provide suitable controls, we also synthesized DMP 543 itself. A representative synthesis is given in Scheme 1 for **6**; synthetic details for the preparation of the other compounds is provided in the Supplemental data. Pyridine carboxylic acid **9** was converted to a mixed anhydride, then reduced with NaBH_4 to yield alcohol **10**, which was converted to the benzylic mesylate **11**. The alkylation of anthrone with **11** to yield the final compound **6** was investigated by varying the base, additive, and solvent (Table 1). Initial optimization attempts explored different counterions for the *tert*-butoxide base with lithium and potassium *tert*-butoxide (entries 1–3) both giving similarly low yields even upon further heating. These reactions also showed the formation of monalkylated anthrone **13** by LC-MS as a prominent byproduct. Addition of 18-crown-6 ether (entry 4) to $\text{KO}t\text{-Bu}$ did not improve the yield. Increasing amounts of NaI (entries 5 and 6) gave only a slight improvement in yield over entry 1. The use of NaH as the base (entry 7) was shown to significantly improve the conversion and yield of the second alkylation, as measured by remaining **13** after completion of the reaction.

Compounds **5–8** were tested for their ability to block currents at a concentration of 1.5 μM in tsA201 cells expressing $\text{Kv}7.2/7.3$, using a manual patch clamp protocol. The inhibition values for these preliminary screens are summarized in Table 2, along with XE 991 and DMP 543. Compounds **6** and **8** were the only novel compounds of the initial group that showed significant inhibition of $\text{Kv}7.2/7.3$ channel currents. **6** ($65 \pm 9\%$ inhibition) showed superior efficacy to DMP 543 ($31 \pm 13\%$), and was comparable to the best-in-class compound XE991 ($81 \pm 6\%$), at a concentration of 1.5 μM . Representative current traces are given for XE991, DMP 543 and **6** in Figure 2.

Prior to in vitro metabolic stability studies, we measured the ability of our compounds to inhibit cytochromes P450 (CYPs), specifically the subtype 3A4 most associated with drug metabolism (Table 2). Using high concentrations (50 μM), all compounds inhibited CYP 3A4 to a significant degree, which is not surprising given the presence of pendant heterocycles in each compound capable of coordinating to heme iron centers. The

bispyridazine **7** showed the lowest level of inhibition (28%), which is not unexpected given that it is a less basic heterocycle and a weaker metal ligand.

To attempt to avoid the liability of CYP inhibition that could introduce drug-drug interactions upon clinical use, we considered the preparation of unsymmetrically alkylated anthrones. The pharmacophore for these channel blockers (ACh releasers) is well established to possess two pendant hydrogen bond acceptors, but we wished to determine if Kv7.2/7.3 could be effectively blocked by compounds possessing one stronger and one weaker hydrogen bond acceptor. Wilkerson reported that compounds in the oxindole series (e.g., linopirdine) can be highly efficacious acetylcholine release enhancers with one of the 4-pyridinylmethyl substituents replaced with an aliphatic ester or nitrile.⁶ We reasoned that a compound containing one pyridazine could maintain efficacy and resistance to metabolic *N*-oxide formation, while potentially attenuating CYP inhibition. Such a compound is also expected to possess improved solubility and decreased volume of distribution relative to DMP 543, which is likely a desirable clinical profile if brain penetrance can be maintained.

The synthesis of the pyridine-pyridazine **18** (JDP-107) is outlined in Scheme 2. Pyridazine-4-carboxylic acid (**14**) was converted to the methyl ester **15**, then reduced with NaBH₄ to generate alcohol **16**. Anthrone (**12**) was sequentially alkylated with mesylate **11**, then the mesylate **17** generated in situ from **16**, thus generating the desired analog **18**.

Next, the compounds were tested in a thallium flux assay using HEK 293 cells expressing Kv7.2 or hERG channels (Table 2).³¹ Compounds with sub-micromolar potencies showed similar maximal inhibition of Kv7.2, including XE991. DMP 543 was the most potent compound tested, with IC₅₀ = 0.048 μM, very similar to XE991 (0.055 μM). The bis-trifluoromethylpyridine analog **5** was ~100-fold less potent in the Kv7.2 assay, and showed minimal inhibition in the patch clamp KCNQ2/3 assay. The bis-pyridazine **7** also showed only moderate inhibition of Kv7.2 (IC₅₀ = 10 μM). The bis-methylpyridine analog **8** showed better potency in the Kv7.2 assay (IC₅₀ = 0.54 μM). Pleasingly, the bis-(3,5-difluoropyridine) **6** showed good inhibition of Kv7.2 (IC₅₀ = 0.20 μM) to go with its promising electrophysiology results. Comparable inhibition was also measured with the mixed pyridine/pyridazine analog JDP-107 (**18**) (Figure 3, IC₅₀ = 0.18 μM), within approximately 3-fold the potency of DMP 543. This confirmed our hypothesis that effective inhibition may be obtained with one more basic and one less basic moiety which presumably act as H-bond acceptors within the channel. **18** also showed only minimal inhibition of the hERG channel, with no inhibition observed at 1 μM and an IC₅₀ > 30 μM. **6** showed a significantly higher level of hERG inhibition, with IC₅₀ = 12 μM. Importantly, **18** was also the most efficacious of the new analogs in the Kv7.2/7.3 patch clamp assay, with a maximal inhibition of 73 ± 7%, significantly better than DMP 543 (31%).

The success of the inhibitors **6** and **18** prompted us to profile their drug-like properties in comparison to DMP 543 (Table 3). Both DMP 543 and **18** inhibit CYP 3A4 substantially at a concentration of 10 μM, which could make for possible drug-drug interactions in human subjects. Both compounds also show decent liver microsomal stability, with DMP 543 showing the better stability after a 1 h incubation (97% vs 84% remaining). To compare the

acid stability of compounds, DMP 543, **6**, and **18** were subjected to strongly acidic conditions (CH₃CN/0.2N aq. HCl). Compounds **6** and **18** showed no degradation, and DMP 543 showed some degradation (83% remaining after 24 h), based on HPLC analysis.

To estimate the potential for our compounds to be safe CNS-active compounds, we used Pfizer's CNS multiparameter optimization desirability tool (CNS MPO), a freely available spreadsheet.³² For each molecule, ClogP, ClogD, total polar surface area (tPSA), molecular weight, number of hydrogen-bond donors, and calculated pKa were determined and input into the spreadsheet to determine the CNS MPO scores. ClogP, ClogD, and pKa were calculated with ChemAxon MarvinSketch v.18.3, and tPSA was calculated with ChemDraw Prime v.16.0. The clinical compound DMP 543 possesses a score of 3.6 out of a possible 6, with 6 being the score for compounds with the most desirable properties for CNS drug development. The attenuated lipophilicity of **18** gave it an improved score of 4.0. However, there was not a substantial increase in kinetic aqueous solubility with the addition of a pyridazine to the scaffold (22 μM for DMP 543 vs 28 μM for **18**). Both DMP 543 and **18** showed low cytotoxicity with hepG2 cells using the CellTiter-Glo® assay, with **18** showing no measurable cytotoxicity.

Finally, DMP 543, **6**, and **18** were submitted to the Psychoactive Drug Screening Program for off-target screening against a panel of mostly GPCRs, using competitive radioligand binding assays.³³ JDP-107 showed >30% inhibition of 5 of 40 targets (mostly GPCRs); K_is were measured to be >10 μM for the D3 and σ1 receptors. We conclude that at this stage, it has a clean receptor off-target binding profile for *in vivo* CNS studies.

We have determined that the anthrone scaffold of Kv7 inhibitors can tolerate replacements of pendant pyridine moieties with alternative heterocycles, and that such compounds could have an improved range of properties more suitable for *in vivo* and clinical studies. Specifically, we identified the pyridazine-containing analog **18** (JDP-107) that possesses comparable potency to DMP 543 in a Kv7.2 assay, superior efficacy in the Kv7.2/7.3 patch clamp assay, superior acid stability, and attenuated lipophilicity, though solubility and CYP inhibition continue to be liabilities of this compound class. We anticipate that these liabilities could be addressed in future compounds via alternative heterocycles and/or the judicious incorporation of pyridazine substituents.

3	LiO <i>t</i> -Bu	–	THF/90 °C ^d	12 ^c
4	KO <i>t</i> -Bu	18-crown-6 (2.4 eq.)	THF/60 °C	3 ^b
5	LiO <i>t</i> -Bu	Nal (1.5 eq.)	THF/60 °C	7 ^c
6	LiO <i>t</i> -Bu	Nal (2.0 eq.)	THF/60 °C	21 ^c
7	NaH	–	THF/60 °C	46 ^{b,c}

^aGeneral conditions: (0.055 mmol) and base (0.132 mmol) were mixed in THF (4.0 mL). The anthrone/base solution was added to a solution of the mesylate (0.110 mmol) and NaI (varying equivalents) in THF (4.0 mL), which had been heated at 50°C for 3 h prior to addition. The reactions were then stirred at 60°C for 12–16 h.

^bIsolated yield.

^cYield measured by ¹H NMR using pentachloroethane as internal standard.

^dReaction run in sealed tube in an oil bath heated to 90°C.

Table 2.K⁺ channel and CYP 3A4 inhibition data^a

compound	Kv7.2/7.3 patch clamp inhib. ^b (@1.5 μ M)	Kv7.2 flux IC ₅₀ (μ M) ^c	hERG flux IC ₅₀ (μ M) ^d	CYP3A4 inhib. ^e (@50 μ M)
XE991 (2)	81 \pm 6%	0.055	>32	NT
DMP 543 (3)	31 \pm 13%	0.048	32	82%
5	6%	5.6	inactive	95%
6	65 \pm 9%	0.20	12	97%
7	12%	10	inactive	28%
8	33%	0.54	inactive	92%
JDP-107 (18)	73 \pm 7%	0.16	>32	N.T.

^aSee Supplementary data for assay protocols. N.T. = not tested.^bPatch clamp assay using tsA201 cells expressing Kv7.2/7.3. For active compounds, means are provided for n=4 or 5, \pm SEM.^cWith HEK 293 cells expressing Kv7.2 channels.^dWith HEK 293 cells expressing hERG channels.^eCYP 3A4 activities were determined using the Vivid CYP450 screening kit (Life Technologies, Carlsberg, CA, USA) according to the manufacturer's instructions.

Table 3.Comparison of XE991, DMP 543, 6, and JDP-107 (18)^a

	XE991	DMP 543	6	JDP-107 (18)
Kv7.2/7.3 patch clamp inhib. (@ 1.5 pM) ^b	81%	31%	65%	73%
