ABSTRACT

Background

Endometriosis is a common gynaecological condition affecting approximately 10% of women of reproductive age (Ozkan 2008). Common symptoms are dysmenorrhoea, pelvic pain, infertility or a pelvic mass. Diagnosis by laparoscopy or laparotomy enables identification of the location, extent and severity of the disease. Surgery may include removal (excision) or destruction (ablation) of endometriotic tissue, division of adhesions and removal of endometriotic cysts. Laparoscopic excision or ablation of endometriosis has been shown to be effective in the management of pain in mild to moderate endometriosis. Adjunctive medical treatment pre or post-operatively may prolong the symptom-free interval.

Objectives

To determine the effectiveness of medical therapies for hormonal suppression before or after surgery for endometriosis for improving painful symptoms, reducing disease recurrence and increasing pregnancy rates.

Search methods

We searched the Cochrane Menstrual Disorders and Subfertility Group Trials Register (searched Sept 2010), the Cochrane Central Register of Controlled Trials (CENTRAL) in *The Cochrane Library* (Sept 2010), MEDLINE (January 1966 to September 2010), EMBASE (January 1985 to September 2010) and reference lists of articles.

Selection criteria

Trials were included if they were randomised controlled trials comparing medical therapies for hormonal suppression before or after or before and after, surgery for endometriosis.

Data collection and analysis

Data extraction and assessment of risk of bias were performed independently by two authors. Where possible, data were combined using relative risk (RR), standardised mean difference or mean difference and 95% confidence intervals (CI).

Main results

Sixteen trials were included. Two trials of pre-surgical medical therapy showed no evidence of benefit compared to surgery alone. There was no evidence of benefit for post-surgical hormonal suppression of endometriosis compared to surgery alone for the outcomes of pain, disease recurrence or pregnancy rates (RR 0.84, 95% CI 0.59 to 1.18). There were no trials identified in the search that compared hormonal suppression of endometriosis before and after surgery with surgery alone. One trial found no evidence that pre-surgical hormonal suppression was different from post-surgical hormonal suppression for the outcome of pain. Another single trial comparing post-

Pre and post-operative medical therapy for endometriosis surgery (Review)

surgical medical therapy with both pre and post-surgery found no difference in the outcomes of American Fertility Society (AFS) scores and pregnancy rate.

Authors' conclusions

There is no evidence of benefit associated with post surgical medical therapy and insufficient evidence to determine whether there is a benefit from pre-surgical medical therapy with regard to the outcomes evaluated.

PLAIN LANGUAGE SUMMARY**There is no evidence that hormonal suppression either before or after surgery for endometriosis is associated with a benefit**

Endometriosis is caused by the lining of the uterus (endometrium) spreading outside the uterus. It can cause pelvic pain, painful periods and infertility. Common treatments are hormonal suppression with medical therapy to reduce the size of endometrial implants or laparoscopic surgery (where small incisions are made in the abdomen) to remove visible areas of endometriosis. There is no evidence that hormonal suppression either before or after surgery is associated with a benefit compared with surgery alone.

(Synopsis prepared by Cochrane Menstrual Disorders and Subfertility Group)

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Post surgical medical therapies compared to No treatment or placebo for infertility associated with endometriosis

Post surgical medical therapies compared to No treatment or placebo for infertility associated with endometriosis

Patient or population: patients with infertility associated with endometriosis
Intervention: Post surgical medical therapies
Comparison: No treatment or placebo

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	No treatment or placebo	Post surgical medical therapies				
Pregnancy	246 per 1000	207 per 1000 (145 to 290)	RR 0.84 (0.59 to 1.18)	420 (8 studies)	⊕⊕⊕⊕ low ^{1,2}	

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio;

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹ Allocation concealment was not adequately explained in six of eight trials, there was no evidence of blinding in five trials and four trials did not explain incomplete outcome data

² Only some of the trial participants were seeking treatment for fertility- numbers unclear

Summary of findings 2. Pre and post operative medical therapies versus placebo for endometriosis

Pre and post operative medical therapies versus placebo for endometriosis

Patient or population: patients with infertility associated with endometriosis
Intervention: Post surgical medical therapies
Comparison: Pre and post-surgical medical therapy with GnRH_a

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Pre and post-surgical medical therapy with GnRH _a	Post surgical medical therapies				
Pregnancy Rate	500 per 1000	0 per 1000 (0 to 0)	RR 0 (0 to 0)	25 (1 study)	⊕⊕⊕⊕ low ¹	

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio;

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹ Description of randomisation , allocation concealment and blinding not adequate.

Summary of findings 3. Pre-surgical medical therapy compared to no medical therapy for endometriosis surgery

Pre-surgical medical therapy compared to no medical therapy for endometriosis surgery

Patient or population: patients with endometriosis surgery

Intervention: Pre-surgical medical therapy

Comparison: no medical therapy

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	no medical therapy	Pre-surgical medical therapy				
Recurrence - AFS Score - Total AFS		The mean Recurrence - AFS Score - Total AFS in the intervention groups was 9.6 lower (11.42 to 7.78 lower)		80 (1 study)	⊕⊕⊕⊕ low ^{1,2}	

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval;

BACKGROUND

Description of the condition

Endometriosis is a common gynaecological condition which affects women during their reproductive years. Endometriosis occurs when endometrial tissue, which usually grows in the uterus (normal), is found in other parts of the body, for example the ovaries, fallopian tubes and pelvis. A range of symptoms are evident and women most commonly present with dysmenorrhoea (painful periods), pelvic pain, infertility or a pelvic mass. Endometriosis also responds to hormonal changes associated with the menstrual cycle and cyclical growth of endometriotic implants or cysts is thought to be associated with pelvic pain and the development of adhesions (scar tissue). Estimates of the prevalence of endometriosis amongst women vary but a recent article (Ozkan 2008) reported a prevalence of 0.5% to 5% in fertile women and 25% to 40% in a subfertile population, with the peak incidence between 30 and 45 years of age (Guzick 1989). Endometriosis may be asymptomatic (no symptoms) or associated with chronic pelvic pain and subfertility (Cook 1991).

The 'gold standard' for the diagnosis of endometriosis is visualisation of endometriosis lesions or cysts during a surgical procedure, either laparoscopy or laparotomy. The extent of the disease can be graded according to a scale developed by the American Fertility Society (AFS 1985), although there is no direct correlation between the severity of the disease and the severity of the symptoms experienced (Vercellini 1996). Concern over the reproducibility of the scoring system resulted in the publication of a new scoring system in 1997 by the American Society of Reproductive Medicine (ASRM 1997).

Description of the intervention

Current treatments that are available for endometriosis include both surgery and medical therapy. Surgical therapy can be performed concurrently with diagnostic surgery and may involve the destruction of endometriotic tissue (ablation), division of adhesions (scar tissue) or removal of endometriotic cysts. In advanced endometriosis (AFS stage III or IV), laparoscopic surgery to remove (excise) visible endometrial implants, divide adhesions (scar tissue) or surgically interrupt neural pathways is the treatment of choice (Muzii 1996; Proctor 1999; Rana 1996). This is because large (> 3 cm) lesions respond poorly to medical therapy and hormonal suppression does not influence the extent of the adhesions which are often associated with large lesions (Shaw 1992).

Medical therapies for systemic hormonal suppression of endometriosis include danazol (a synthetic testosterone hormone derivative), gonadotrophin releasing hormone analogues (GnRHAs), progestogens, gestrinone and the oral contraceptive pill. These therapies may be effective for relief of pain associated with endometriosis but they also decrease fertility. Both danazol and GnRHAs are associated with side effects related to hyperandrogenism (increased hair growth and a deepening of the voice) and hypoestrogenism (such as hot flushes and vaginitis), respectively, and should only be used for periods of up to six months. Recurrence of endometriosis symptoms and disease is common after the cessation of medical therapy (Barbieri 1990).

How the intervention might work

Over recent years there has been interest in combining medical and surgical therapy in an attempt to reduce recurrence of endometriosis. The pre-operative use of GnRHAs may decrease the extent of endometriosis and the size of endometriomas (ovarian endometriosis) making complete removal of endometriosis easier during laparoscopic surgery and increasing subsequent pregnancy rates (Hemmings 1998; Donnez 1987). However possible disadvantages of pre-operative medical therapy, especially with danazol or GnRHAs, are the adverse effects associated with these medications (for example hot flushes or vaginal dryness), which may influence women's willingness to use the therapy and result only in a delay of surgery. Post-operative medical therapy appears to be an effective treatment of microscopic endometriosis which may not have been evident to the surgeon. It induces suppression of lesions that can not be surgically removed and reduces the risk of recurrence of endometriosis as a result of surgery (Kettel 1989; Thomas 1992).

Why it is important to do this review

Although the combination of surgery and medical therapy would appear to be beneficial, it is necessary to evaluate the benefits and consider the harms prior to this strategy being recommended. This review aims to evaluate the use of medical therapy before or after, or before and after, surgery for endometriosis.

OBJECTIVES

To determine the effectiveness of medical therapies for hormonal suppression before or after or before and after surgery for endometriosis for improving painful symptoms, reducing disease recurrence and increasing pregnancy rates.

METHODS

Criteria for considering studies for this review

Types of studies

All randomised controlled trials of the use of medical hormonal suppression therapies used:

- pre-surgery for endometriosis compared with surgery alone or placebo prior to surgery for the treatment of endometriosis;
- post-surgery for endometriosis compared with surgery alone or surgery and placebo;
- pre and post-surgery for endometriosis compared with surgery alone or surgery and placebo;
- pre-surgery for endometriosis compared with medical therapies used post-surgery for endometriosis.

Types of participants

The study population included women of reproductive age who were undergoing surgery for endometriosis. The diagnosis of endometriosis could have been made provisionally by clinical examination and confirmed during the surgery, or could have been confirmed endometriosis where women were undergoing second or subsequent surgery. They would have further medical treatment either before or after surgery. Studies in the hospital care setting were considered.

Types of interventions

All systemic medical treatments for the hormonal suppression of endometriosis including GnRHAs, danazol, progestogens, gestrinone or the oral contraceptive pill (or combinations of these) administered before surgery, after surgery or before and after surgery for endometriosis compared to medical treatment after surgery, before surgery, no medical treatment, or placebo were studied. The use of medical therapy was considered at any dosage and for a period of at least three months duration before or after surgery. Only agents used with the aim of hormonal suppression were included. Medical treatment with analgesics, anti-inflammatory drugs or antibiotics were excluded. Alternative, dietary or complementary therapeutic strategies were also excluded. Modulation of the immune system via pentoxifylline treatment is considered in a separate systematic review (Lv 2009). All surgical procedures for the treatment of endometriosis that conserve the pelvic organs (such as ovarian cystectomy, drainage of endometriosis, excision or ablation of endometriosis) were included.

Types of outcome measures

The effectiveness of the use and timing of medical therapy as an adjunct to surgery for endometriosis was compared to surgery alone (no medical treatment or placebo) and was assessed by the following outcome measures where the data were available.

Primary outcomes

- Painful symptoms of endometriosis as measured by a visual analogue scale (VAS) of pain, other validated scales or dichotomous outcomes
- Recurrence of disease as evidenced by rAFS (revised American Fertility Society) or rASRM scores at second look laparoscopy
- Pregnancy rate per woman (measured by either urinary human chorionic gonadotrophin (HCG) levels or foetal heart detected by ultrasound)

Secondary outcomes

- Ease of surgery, duration of surgery, post-operative complications
- Levels of satisfaction of women participants
- Adverse effects (proportion of women with one or more reported adverse effects associated with medical treatment)

Search methods for identification of studies

Reports that described or might have described randomised controlled trials of hormonal suppression in the treatment of endometriosis before or after surgery were obtained using the following search strategy.

Electronic searches

(1) We searched the Menstrual Disorders and Subfertility Group Specialised Register of controlled trials (10 September 2003) for any trials of hormonal suppression in the treatment of endometriosis before or after surgery. The Cochrane Menstrual Disorders and Subfertility Group Specialised Register is based on regular searches of CENTRAL, MEDLINE, EMBASE, CINAHL and PsycINFO, the handsearching of 20 relevant journals and conference proceedings, and searches of several key grey literature

sources. A full description is given in the Group's module on *The Cochrane Library*.

(2) The following electronic databases were searched using Ovid software: MEDLINE (1966 to September 2010) ([Appendix 1](#)); EMBASE (1980 to September 2010) ([Appendix 3](#)); CINAHL (1982 to September 2010); Biological Abstracts (1980 to September 2010); PsycINFO (1872 to September 2010).

The search strategy was developed for MEDLINE Ovid and adapted for use on the other Ovid databases listed above.

(3) We searched the Cochrane Central Register of Controlled Trials (CENTRAL) on *The Cochrane Library* (20 September 2010) in all fields using the search terms listed in [Appendix 2](#).

(4) We searched controlled trials.com for ongoing and recently completed trials.

Searching other resources

(5) We searched the reference lists and bibliographies of all relevant articles to identify additional trials for inclusion in this review.

(6) We sent letters to experts within the field, pharmaceutical companies producing the products being reviewed and authors of unpublished abstracts to identify unpublished trials of medical therapy before or after surgery for endometriosis.

Data collection and analysis

Selection of studies

The selection of trials for inclusion in the latest update of the review was performed by the two review authors (YC and SF) after employing the search strategy previously described. The titles and abstracts were screened and studies that were clearly ineligible were discarded but we aimed to be overly inclusive rather than risk losing relevant studies. Copies of the full articles were obtained. Both review authors then independently assessed whether the studies met the inclusion criteria. Disagreements were resolved by discussion. Further information was sought from the authors where papers contained insufficient information to make a decision about eligibility.

Data extraction and management

Included trials were analysed for the following methodological details.

- (1) Duration, timing and location of the study.
- (2) Inclusion and exclusion criteria for the trial.
- (3) Number of patients randomised, excluded or lost to follow up.
- (4) Whether a power calculation was done.
- (5) Source of funding for the trial.

This information is presented in the [Characteristics of included studies](#) table, which describes the included studies and provides a context for discussing the reliability of results.

Characteristics of the study participants

- (1) Method of diagnosis of endometriosis
- (2) Severity of endometriosis (rAFS scores)

- (3) Severity of painful symptoms associated with endometriosis (pain scales)
- (4) Age and parity of study participants
- (5) General demographic characteristics of study participants

Interventions used

- (1) Type of medical treatment used, dosage, duration of treatment, mode of administration
- (2) Type of control or placebo used
- (3) Timing of medical treatment (before or after surgery, or before and after surgery)

Outcomes

- (1) Methods used to measure recurrence of disease (rAFS or rASRM scores at second look laparoscopy)
- (2) Methods used to measure pain relief achieved by treatment (e.g. VAS pain scores, other validated pain scores, dichotomous outcomes)
- (3) Pregnancy rate per woman during follow up
- (4) Methods used to measure adverse effects (including post-operative complications) and types of adverse effects reported
- (5) Methods used to measure ease of surgery, duration of surgery
- (6) Length of follow up and timing of outcome measurement relative to timing of treatment
- (7) Methods used to measure levels of satisfaction of the women participants

Assessment of risk of bias in included studies

For the studies included in this review, assessment of risk of bias was conducted by two review authors using the Cochrane risk of bias assessment tool (Higgins 2009). We assessed six domains for each included study: sequence generation, allocation concealment, blinding of outcome assessor, completeness of outcome data, risk of selective outcome reporting and risk of other potential sources of bias.

For this systematic review we assessed risk of bias according to the following criteria.

- Adequate sequence generation: use of a random number table, use of a computerised system, central randomisation by statistical coordinating centre, randomisation by an independent service using minimisation technique, permuted block allocation or Zelan technique were considered adequate. If the paper merely stated 'randomised' or 'randomly allocated' with no further information this was assessed as being unclear.
- Allocation concealment: centralised allocation including access by telephone call or fax, or pharmacy controlled randomisation, using sequentially numbered, sealed opaque envelopes were considered adequate. Where there was no mention of allocation concealment methods, this domain was assessed as unclear.
- Blinding: for these treatments, even when blinding of patients and clinicians to treatment allocation was part of the trial protocol, the adverse effects of medical therapies make it difficult for blinding to be maintained. Therefore we have focused on whether the outcome assessment was blinded. Unless the trial was specifically described as double blind, or there was a statement about blinding in the methods section of the paper, it was assumed that blinding of patients, clinical staff and outcome assessors did not occur.

- Outcome data: outcome data were considered complete if all patients randomised were included in the analysis of the outcome(s).
- Selective outcome reporting: a trial was assessed as being at low risk of bias due to selective outcome reporting if the outcomes of interest described in the methods section were systematically reported in the results section. Where reported outcomes did not include those outcomes specified or expected in trials of treatments for endometriosis, this domain was assessed as unclear.
- Other bias: imbalance in potentially important prognostic factors between the treatment groups at baseline, or the use of a co-intervention in only one group (for example analgesics) were examples of potential sources of bias that were noted.

Additional information on trial methodology or original trial data was sought from the principal authors of trials which appeared to meet the eligibility criteria but were unclear in aspects of methodology or outcomes, or where the data were in a form unsuitable for meta-analysis.

Measures of treatment effect

This review used both positive and negative outcome measures. This was taken into account when the meta-analysis was interpreted. For example with regard to the outcome of pain, a positive treatment effect was associated with a reduction in pain scores indicated by a WMD less than zero. However with regard to pregnancy rates, which was a desirable outcome in the treatment of subfertility, a positive treatment effect was associated with an increase in pregnancy rate indicated by a relative risk (RR) greater than one. The data were entered so that in positive outcomes (for example pregnancy) points to the left of the 'line of no effect' favoured the control, and in the negative outcomes (for example pain) points to the left of the 'line of no effect' favoured treatment.

When neither continuous nor dichotomous data suitable for the calculation of mean difference, standardised mean difference or relative risk could be extracted from a trial, any available data were reported descriptively in additional data Table 1. It is expected that the data for outcomes of pain are skewed rather than normally distributed. Any skewness was described in the results section.

Unit of analysis issues

The primary analysis was per woman randomised to treatment. Reported data that was based on a different unit of analysis (for example per endometrioma cyst) were not included in the meta-analysis but were to be summarised in an additional table.

Dealing with missing data

Data were analysed on an intention-to-treat basis, where possible, and attempts were made to contact authors to obtain missing data. Where studies reported data by type of medical therapy, these treatment groups were combined and compared to placebo or no treatment using mean difference and the standard deviation for continuous outcomes. Where the mean and standard deviation for the combined groups was not reported this was estimated using the formulae described in Table 7.7a in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2009).

Assessment of heterogeneity

A fixed-effect analysis was used unless the number of trials in a meta-analysis was greater than three. It was planned that heterogeneity among the results of different studies would be examined by inspecting the scatter in the data points and the overlap in their confidence intervals and, more formally, by checking the results of the Chi² test and the I² statistic.

Data synthesis

Statistical analysis was performed in accordance with the guidelines for statistical analysis developed by the Cochrane Menstrual Disorders and Subfertility Group.

Where possible, the outcomes were pooled statistically. For dichotomous data (for example proportion of patients with pain recurrence at 12 months), results for each study were expressed as a relative risk (RR) with 95% confidence intervals (CI) and combined for meta-analysis with RevMan software using the Peto-modified Mantel-Haenszel method.

For continuous outcomes (for example multidimensional pain scores) means and standard deviations for each group were combined in the meta-analysis and shown as a mean difference (MD) or standardised mean difference (SMD) and 95% confidence interval (CI).

Subgroup analysis and investigation of heterogeneity

A priori, it was planned to look at the possible contribution of differences in trial design, medical treatment used, timing of treatment, dosage, mode of administration and duration of treatment to any heterogeneity identified. Sensitivity analysis based on these criteria was planned to investigate the robustness of the data.

Sensitivity analysis

Sensitivity analysis was conducted where there were sufficient trials included, in order to determine whether the conclusions were robust that is whether conclusions would have differed if the inclusion of trials was restricted to those with low risk of bias.

RESULTS

Description of studies

Results of the search

The original search identified 11 trials that met the inclusion criteria (Audebert 1998; Batioglu 1997; Bianchi 1999; Busacca 2001; Donnez 1994; Hornstein 1997; Loverro 2001; Muzii 2000; Parazzini 1994; Telimaa 1987; Vercellini 1999). The updated search (in September 2010) identified a further six trials which met the inclusion criteria (Loverro 2008; Sesti 2007; Shaw 2001; Shawki 2002; Tsai 2004; Yang 2006). One trial (Shawki 2002) was published only as an abstract, with insufficient information available to include it in this review. Attempts to contact the author to obtain additional information have been unsuccessful. This study is listed under studies awaiting classification. Five new trials have been included in the updated review.

Of the 16 trials now included in this review, eight were conducted in Italy (Bianchi 1999; Busacca 2001; Loverro 2001; Loverro 2008; Muzii 2000; Parazzini 1994; Sesti 2007; Vercellini 1999) and one

study was conducted in each of Belgium (Donnez 1994), China (Yang 2006), Finland (Telimaa 1987), France (Audebert 1998), Taiwan (Tsai 2004), Turkey (Batioglu 1997), UK/Republic of Ireland (Shaw 2001) and USA (Hornstein 1997). A total of 1410 women with endometriosis were randomly allocated to medical treatments which included gonadotrophin releasing hormone analogues (goserelin, leuprorelin, nafarelin, triptorelin), danazol, progestogen (gestrinone), and the combined oral contraceptive pill.

Included studies

Pre-surgical medical therapy

Two trials compared pre-surgical medical therapy for endometriosis to surgery alone (no medical therapy) (Donnez 1994; Shaw 2001).

Donnez 1994 included 80 women with infertility who were < 35 years of age with laparoscopically confirmed ovarian endometriotic cysts which were drained and flushed out laparoscopically. The patients were then randomised to receive a subcutaneous goserelin implant four-weekly for 12 weeks or no treatment. Twelve weeks after the first-look laparoscopy, another laparoscopy was performed during which a biopsy was done, endometriosis and the cyst wall vaporised. AFS scoring was done by the same two observers.

Shaw 2001 randomised 48 women aged 18 to 50 years who had been referred for management of symptoms or infertility due to endometrioma. After the cysts were aspirated women received either goserelin four-weekly for three months or no medical treatment. Following an ultrasound measurement of the residual cysts women underwent definitive excision and were then followed for a further six months. Outcomes included size of endometrioma pre-surgery, proportion who had complete excision of cysts, AFS scores and recurrence of cysts at six months.

Post-surgical medical therapy versus placebo or no treatment

Twelve studies assessed post-surgical medical therapy for endometriosis. Five of these compared post-operative medical therapy to placebo (Hornstein 1997; Loverro 2008; Parazzini 1994; Sesti 2007; Telimaa 1987) and in the remaining seven trials the control group received surgery alone with no medical therapy (Bianchi 1999; Busacca 2001; Loverro 2001; Muzii 2000; Tsai 2004; Vercellini 1999; Yang 2006).

Three different medical therapies were compared with placebo, in five trials (Hornstein 1997; Loverro 2008; Parazzini 1994; Sesti 2007; Telimaa 1987) and seven trials in this group compared post-operative medical therapy with either GNRHa, danazol, progestogen or oral contraceptive pills to no post-operative medical treatment (Bianchi 1999; Busacca 2001; Loverro 2001; Muzii 2000; Tsai 2004; Vercellini 1999; Yang 2006).

Hornstein 1997 and Parazzini 1994 both compared intranasal nafarelin (400 uG/day) with placebo over a period of six months and three months, respectively. Loverro 2008 randomised 60 women with a mean age of 28.6 years to three months of a post-operative triptorelin depot or placebo and followed them for five years to evaluate persistence of pain, recurrence of endometrioma and pregnancy. In a large trial in Rome, Sesti 2007 randomly allocated 234 women with endometriosis to post-operative medical treatment with GNRHa (either triptorelin or leuprorelin), continuous estrogen/progestin (OCP), dietary therapy

(vitamins, minerals, lactic ferments and fish oil) or placebo and evaluated pain (dysmenorrhoea, non-menstrual pelvic pain and dyspareunia) and quality of life. Data from the two hormonal suppression arms were combined and compared to placebo in the meta-analysis. The other placebo controlled trial of post-surgical medical therapy ([Telimaa 1987](#)) had two treatment arms, medroxyprogesterone acetate (MPA) 100 mg/day taken orally for six months (n = 17) and danazol 600 mg/day (200 mg tds) for six months (n = 18), and a placebo arm (n = 16). Data have been reported separately for each group compared to placebo in [Table 1](#). In the meta-analysis of the subgroup of 22 patients in this trial desiring pregnancy, data from the medical therapy groups have been combined.

In [Bianchi 1999](#), post-surgical danazol, 600 mg/day for three months, was compared with surgery alone in 53 women. [Busacca 2001](#), [Loverro 2001](#) and [Vercellini 1999](#) compared post-surgical GnRH α (leuprolide, triptorelin and goserelin respectively), administered subcutaneously every four weeks for a period of 12 weeks, with surgery alone in groups of 89, 62 and 210 women with endometriosis respectively. [Tsai 2004](#) randomly allocated 15 women to post-operative treatment with either GNRHa (leuprolide, n = 8) or danazol (n = 7) and the remaining 30 to no post-operative medical treatment prior to controlled ovarian hyperstimulation with clomiphene followed by intrauterine insemination or in vitro fertilisation. In China, [Yang 2006](#) compared post-operative treatment with traditional Chinese medicine, gestrinone or no treatment in 52 women and reported the pregnancy rate and recurrence of endometriosis with a nine and 30 months follow up.

[Muzii 2000](#) compared surgery plus six months of therapy with low-dose cyclical oral contraceptives to surgery alone.

Pre-surgical medical therapy compared with post-surgical medical therapy

One study compared pre-surgical medical therapy with post-surgical medical therapy. [Audebert 1998](#) compared medical therapy with intranasal nafarelin administered for six months before surgery with intranasal nafarelin administered for six months after surgery. Outcomes of pain, AFS scores and ease of surgery were assessed.

Post-surgical medical therapy compared with pre and post-surgical medical therapy

One study compared medical therapy pre and post-surgery with medical therapy post-surgery. [Batioglu 1997](#) compared medical therapy with triptorelin commenced post-surgery to medical therapy with triptorelin started in the luteal phase of the menstrual cycle pre-surgery and continued after surgery. The duration and dose of medical therapy was the same in both groups; the difference between the groups was the time that medical therapy started relative to surgery.

Risk of bias in included studies

Only one of the 16 trials included in this review could be considered as at low risk of bias ([Parazzini 1994](#)) (see [Figure 1](#)). Details of the risk of bias assessments are summarised under the headings below.

Figure 1. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding (performance bias and detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

Allocation

Out of the 16 included studies, nine used computer generated randomisation (Bianchi 1999; Busacca 2001; Loverro 2008; Muzii 2000; Parazzini 1994; Sesti 2007; Shaw 2001; Tsai 2004; Vercellini 1999), one used randomisation tables (Donnez 1994) and one used odd and even numbers (Batioglu 1997). These studies were assessed as at low risk of bias for this domain. The remainder of studies did not state their method of randomisation (Audebert 1998; Hornstein 1997; Loverro 2001; Telimaa 1987; Yang 2006) and were therefore assessed as unclear for this domain.

Two studies reported adequate allocation concealment using telephone allocation (Parazzini 1994; Vercellini 1999). Sesti 2007 allocated patients by using serially numbered opaque, sealed envelopes whilst Tsai 2004 allocated patients according to list "unknown to physicians". These four studies were therefore assessed as being at low risk of bias. The remainder of the included studies did not describe their allocation methods and were therefore assessed as unclear.

Blinding

Four studies were double blinded (Audebert 1998; Hornstein 1997; Parazzini 1994; Telimaa 1987). In Loverro 2008 patients were blinded to treatment allocation and placebo injections were used. The trial by Sesti 2007 stated that "neither the patients nor the surgeons were aware of the regimen prescribed during the evaluation of improvement of endometriosis-related pelvic pain and health related quality of life during the study period". However in this study patients received either placebo, GNRHa, oral contraceptive pills or dietary therapy so it is considered likely that maintaining blinding to treatment would have been difficult.

One study was open label (Vercellini 1999). Blinding was not described in the remaining studies. In all the studies included in this review the adverse effects of the medication may have alerted the investigators and the participants to the type of medical intervention.

Incomplete outcome data

Outcome data were incomplete in one study (Tsai 2004) with four women (27%) withdrawing from one group, which may have introduced a bias. A further six studies were assessed as being at

unclear risk of bias for this domain (Loverro 2001; Loverro 2008; Sesti 2007; Shaw 2001; Vercellini 1999; Yang 2006). The remaining studies were assessed as being at low risk of bias for this domain, five had no post-randomisation losses (Batioglu 1997; Bianchi 1999; Busacca 2001; Donnez 1994; Parazzini 1994) and three trials had few post-randomisation losses (Audebert 1998: 3%; Muzii 2000: 4%; Telimaa 1987: 2%). One trial (Hornstein 1997) had a 15% post-randomisation loss, approximately equal in the medical therapy and placebo groups.

Pregnancy is a desired outcome for some of the women included in these trials. Seven studies looked at pregnancy rates as an outcome measure. In Batioglu 1997, Parazzini 1994 and Telimaa 1987 pregnancy rates 12 months after treatment commenced were reported as an outcome for all participants in the trials; losses to follow up were small (0%, 9% and 2% respectively). Busacca 2001 and Loverro 2001 reported pregnancy rates after 18 months follow up in a subgroup of participants (30% and 40 % of participants respectively). Busacca 2001 reported no losses to follow up in the group desiring pregnancy and Loverro 2001 did not state whether there were any losses to follow up. In Vercellini 1999 pregnancy outcomes were reported in a subgroup of 152 women desiring fertility (56% of participants) after two years of follow up; losses to follow up in these groups were very small.

Other potential sources of bias

Five reports declared pharmaceutical support for their studies (Audebert 1998; Hornstein 1997; Parazzini 1994; Shaw 2001; Vercellini 1999) while Donnez 1994 had independent funding from Fonds de la Recherche Scientifique and Yang 2006 received funding from the Natural Science Foundation. The remainder did not describe any form of funding or support.

One trial (Tsai 2004), which was described as a randomised controlled trial, reported that patients were "randomly selected to receive" post-operative medical treatment prior to ovarian stimulation over a period of 13 years (1988 to 2001). During this time period there have been significant advancements in endoscopic technology. It is unclear whether this resulted in any bias in the results of the study.

Two studies (Batioglu 1997; Shaw 2001) reported differences between the groups at baseline with regard to disease severity,

which may have introduced a bias into the results from these studies. [Loverro 2001](#) and [Muzii 2000](#) did not report the characteristics of each group at baseline.

Effects of interventions

See: [Summary of findings for the main comparison](#) Post surgical medical therapies compared to No treatment or placebo for infertility associated with endometriosis; [Summary of findings 2](#) Pre and post operative medical therapies versus placebo for endometriosis; [Summary of findings 3](#) Pre-surgical medical therapy compared to no medical therapy for endometriosis surgery; [Summary of findings 4](#) Post-surgical medical therapy compared to placebo or no treatment for endometriosis; [Summary of findings 5](#) Pre-surgical compared to Post-surgical medical therapy for endometriosis surgery; [Summary of findings 6](#) Post-surgical medical therapy compared to Pre and post-surgical medical therapy with GnRHa for endometriosis surgery

Pre-surgical medical therapy

([Analysis 1.1](#); [Table 1](#))

Disease recurrence

Both trials used AFS scores as the outcome measure in comparing medical treatment pre-surgery with surgery alone. [Donnez 1994](#) showed a statistically significant reduction in endometrioma cyst size ([Table 1](#)), total AFS scores and implant AFS scores favouring the goserelin treated group but there was no statistically significant difference between the groups with regard to adhesion AFS scores ([Analysis 1.1](#)).

[Shaw 2001](#) found a decrease in endometrioma size and a decreased recurrence rate in the goserelin group with no difference in mean total AFS scores post-treatment (but no estimate of precision was stated so these data were not included in the meta-analysis: the raw data only are presented in [Table 1](#)).

These two trials showed that pre-operative GnRH agonist treatment decreased the size of endometrial cysts, although the clinical significance of this is unknown; however these trials were assessed as being at significant risk of bias and showed conflicting AFS results.

Based on these two trials there is insufficient evidence to conclude that pre-surgical medical therapy was better than surgery alone.

Post-surgical medical therapy versus placebo or no treatment

Pain

([Analysis 2.1](#); [Analysis 2.2](#); [Table 1](#))

The outcome of pain was reported in 10 trials ([Bianchi 1999](#); [Busacca 2001](#); [Hornstein 1997](#); [Loverro 2001](#); [Loverro 2008](#); [Parazzini 1994](#); [Muzii 2000](#); [Sesti 2007](#); [Telimaa 1987](#); [Vercellini 1999](#)).

Meta-analysis was possible for the continuous outcome, mean VAS score of pelvic pain at 12 months, for two studies ([Parazzini 1994](#); [Sesti 2007](#)) and the pooled estimate showed a statistically significant reduction in pelvic pain at 12 months (SMD -0.96, 95% CI -1.23 to -0.68) favouring medical therapy compared to placebo. However these studies show inconsistent effects and considerable statistical heterogeneity ($I^2 = 94%$, $P < 0.0001$). A third study ([Telimaa](#)

[1987](#)) reported pain after 12 months using a four-point scale and presented mean scores without estimates of precision. The paper stated that there was a "significant difference between both danazol and placebo and MPA and placebo favouring medical therapy". It was not possible to include these data in the meta-analysis but the estimates are recorded in [Table 1](#).

[Sesti 2007](#) also reported the outcomes of dysmenorrhoea and deep dyspareunia. When the groups receiving medical therapy were combined there was a statistically significant difference favouring medical therapy over placebo for both dysmenorrhoea and dyspareunia (Analysis 2.1.2; Analysis 2.1.3). In the trial by [Hornstein 1997](#) the change in pain score from baseline to 12 months after surgery was presented and showed no statistically significant difference between medical therapy and placebo (Analysis 2.1.4).

Pain recurrence was measured during the first year after surgical treatment and reported in [Bianchi 1999](#); [Loverro 2001](#) and [Vercellini 1999](#). The pooled estimate from these three trials showed no statistically significant difference between medical therapy and surgery alone (RR 0.76, 95% CI 0.52 to 1.10) ([Analysis 2.2.1](#)).

Pain recurrence during the second year after surgery was reported in three trials ([Busacca 2001](#); [Muzii 2000](#); [Vercellini 2003](#)) and the pooled estimate also showed no statistically significant difference between medical therapy after surgery and surgery alone (RR 0.70, 95% CI 0.47 to 1.03) ([Analysis 2.2.2](#)).

Five years after treatment, a single study ([Loverro 2008](#)) found no statistically significant difference in pain persistence or recurrence between medical therapy and placebo ([Analysis 2.2.3](#)).

Disease recurrence

The only study in this group to report AFS scores for disease recurrence was [Telimaa 1987](#). After 12 months, a second-look laparoscopy showed a statistically significant reduction in AFS scores from baseline in all three groups: MPA, danazol and placebo. When each active treatment group was compared to placebo, there was a statistically significant mean difference favouring MPA, but the difference between danazol and placebo was not statistically significant ([Table 1](#)) and the combined mean AFS score for both medical therapies was not statistically significantly different from placebo ([Analysis 2.3](#)).

Disease or symptom recurrence, evaluated by gynaecological examination or ultrasonography, was measured at two time points: one year and two years after surgery. There was no statistically significant difference in disease recurrence at one year ([Bianchi 1999](#); [Busacca 2001](#)) between surgery plus medical therapy and surgery alone (RR 0.76, 95% CI 0.30 to 1.90) ([Analysis 2.4.1](#)) and no difference at two years in the one study ([Tsai 2004](#)) that reported this outcome ([Analysis 2.4.2](#)).

Pregnancy

Pregnancy was a desired outcome in some of the patients in eight studies ([Bianchi 1999](#); [Busacca 2001](#); [Loverro 2001](#); [Loverro 2008](#); [Parazzini 1994](#); [Telimaa 1987](#); [Vercellini 1999](#); [Yang 2006](#)). There was no difference between surgery plus medical therapy and either surgery plus placebo or no treatment with regard to pregnancy rate following treatment (RR 0.84, 95% CI 0.59 to 1.18) ([Analysis 2.5](#)).

Patient satisfaction

Only one study reported the outcome of patients satisfaction. [Telimaa 1987](#) reported an increase in patient satisfaction in both active treatment groups, which was statistically significantly greater compared to the placebo group but there was no difference between the danazol and MPA groups for either of these outcomes ([Table 1](#)).

Pre-surgical medical therapy compared with post-surgical medical therapy

([Analysis 3.1](#); [Table 1](#))

In the single study in this comparison ([Audebert 1998](#)) there was no statistically significant difference between the groups for the outcome of pain ([Analysis 3.1](#)).

The trial reported that the pre-operative nafarelin group had statistically significantly lower global AFS scores, adhesion scores and 'endometriosis scores' compared to the post-operative nafarelin group, but data were presented in a form that was not suitable for inclusion in a forest plot so these data are recorded in [Table 1](#).

Surgery was described as 'easy' in a higher proportion of the pre-operative nafarelin group compared to the post-operative nafarelin group, but no indication of any statistical significance was given.

Post-surgical medical therapy compared with pre and post-surgical medical therapy

In this small study ([Batioglu 1997](#)) (n = 25) no statistically significant differences were found between the groups with respect to the outcomes of recurrence (total AFS scores, implant AFS scores, adhesion AFS scores) ([Analysis 4.1](#)) and pregnancy rate ([Analysis 4.2](#)).

Adverse effects

The adverse effects data were summarised in a 'Table of adverse drug effects' in the additional tables section ([Table 2](#)). Adverse effects were described in some trials but data were not presented in a way that allowed any quantitative analysis.

Sensitivity analysis

Planned sensitivity analysis was not undertaken because only one of the 16 trials was assessed as being at low risk of bias.

DISCUSSION

Summary of main results

(1) There is insufficient evidence to support the view that medical therapy for hormonal suppression of endometriosis prior to surgery is more effective than surgery alone. Two studies compared pre-surgical medical therapy with surgery alone. AFS scores were significantly improved in the medical treatment group in one study and not in the other. Meta-analysis of the data from these studies was not possible. Medical therapy may or may not be associated with better outcomes for the patients.

(2) Post-surgical hormonal suppression of endometriosis compared to surgery alone (either no medical therapy or placebo) showed some reduction in pain after 12 months but results were

inconsistent and pain recurrence in both groups indicated that there was no evidence of a benefit for pain beyond 12 months. There was no evidence of benefit for the outcomes of disease recurrence (AFS scores) or pregnancy (RR 0.84, 95% CI 0.59 to 1.18).

(3) There were no trials identified from the search that compared hormonal suppression of endometriosis before and after surgery with surgery alone.

(4) There was no significant difference between pre-surgery hormonal suppression and post-surgery hormonal suppression for the outcome of pain in the one trial identified. This trial reported a statistically significant reduction in recurrence at six months as measured by AFS scores but ease of surgery was reported only as a descriptive summary so any difference between the groups can not be quantified from the information given in the report of this trial.

(5) There was insufficient evidence to support the view that medical therapy for hormonal suppression of endometriosis pre and post-surgery was more effective than medical therapy post-surgery only.

In summary, the use of medical treatment after surgery was not associated with a long-term statistically significant difference in pain from endometriosis. When used prior to surgery, medical therapy was shown to decrease cyst size but the effect on AFS scores was conflicting. There is no evidence that medical therapy pre or post-surgery improves pregnancy rates. No conclusions can be drawn with respect to the outcomes of facilitating surgery, duration of surgery, post-operative complications or levels of satisfaction of women participants from the trials included in this review. Adverse effects were described but not quantified, so no direct comparisons between the included trials were possible.

Quality of the evidence

A strength of this review is that all of the included studies involved women with laparoscopically diagnosed endometriosis and laparoscopic assessment of the extent of the endometriosis. Weaknesses of this review are that the included studies were small and many were at risk of bias. There was a spread of different times at which a range of different outcomes were measured, which does not allow for studies to be combined in a meta-analysis. Only one study used a quality of life measure as an outcome ([Sesti 2007](#)) although this may well be the outcome of most interest to women with endometriosis.

There were some methodological issues in the trials included in this review. Of the 16 reports of randomised controlled trials, 11 described the randomisation process used but only four reported adequate allocation concealment. Four of the 16 studies were double blinded and in two studies the outcome assessors were blinded to the intervention status. The side effects associated with medical therapies for endometriosis are such that maintaining blinding of participants and investigators is likely to have been difficult in these trials.

AUTHORS' CONCLUSIONS

Implications for practice

There is no evidence from the studies identified to conclude that hormonal suppression in association with surgery for endometriosis is associated with a significant benefit with regard to any of the outcomes identified. From two studies of pre-surgical

medical therapy there is no evidence that pre-surgical medical therapy is better than surgery alone. There was no evidence that post-surgical medical therapy was associated with a benefit compared to surgery alone.

Implications for research

Research done to assess the effects of medical treatment pre or post-surgery for endometriosis is associated with many difficulties. Not many women will consent to undergo second-look laparoscopy to assess the results of previous treatment modalities. Hence, recruiting large numbers of participants for randomised trials is difficult. Maintaining blinding is also difficult due to the adverse effects associated with hormonal suppression, which would be obvious to both the patient and investigator. Blinded outcome assessment is possible and desirable. Women with subfertility due to endometriosis may also not accept treatment that may improve pain and other symptoms but reduces or delays their chance of conceiving.

Despite these difficulties, it would be valuable to have well designed, adequately powered and well conducted trials to determine if there is a significant benefit in adjunctive medical therapy before or after surgery for endometriosis. Consistency in the methods of assessing outcomes, with respect to pain and the extent of endometriosis from AFS scores, would also facilitate meta-analysis of data across trials. Data to quantify the number and degree of adverse events experienced as a result of medical therapy would enable better assessment of the comparative benefits and harms of medical treatment.

ACKNOWLEDGEMENTS

We would like to thank the Menstrual Disorders and Subfertility Group (MDSG) in Auckland, New Zealand, for their help, advice and support during the preparation of the original review. For the current update of the review we would like to thank Marian Showell (Trials Search Coordinator) who updated the searches.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Audebert 1998

Methods	Location: France No. of centres: multi centre Recruitment period: December 1990 to March 1993
Participants	Inclusion criteria: < 40 years, stage III-IV endometriosis, pelvic pain, dysmenorrhoea or dyspareunia Exclusion criteria: > 40 years, hormonal treatment for endometriosis within 3/12 (including OCP, progestins), significant medical illness e.g. liver, heart, renal disease, abnormal PAP smear, pregnancy, surgery for endometriosis within 6/12 No. randomised: 55 No. analysed: 53
Interventions	Gr A (n=28) Pre-surgery medical treatment with nafarelin nasal 400 uG daily x 6/12 Gr B (n=25) Post-surgery medical treatment with nafarelin nasal 400 uG daily x 6/12
Outcomes	Pain: dysmenorrhoea, dyspareunia, pelvic pain, pelvic tenderness, pelvic induration AFS scores: global, adhesions, endometriosis Ease of surgery
Notes	Power calculation: NS Funding: Syntex Pharmaceuticals International for supply of Nafarelin, grant for trial

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"randomised" no details of method of sequence generation provided
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	Low risk	double blinded
Incomplete outcome data (attrition bias) All outcomes	Low risk	all randomised patients included in analysis
Selective reporting (reporting bias)	Low risk	important outcomes - AFS scores, recurrence, surgical difficulty reported
Other bias	Low risk	groups appear comparable at baseline

Batioglu 1997

Methods	Location: Ankara Turkey No. of Centres: 1
---------	--

Batioglu 1997 (Continued)

Recruitment period: NS

Participants	Inclusion criteria: ovarian endometriomas >3cm unilateral/bilateral No. randomised: 25 No. analysed: 25
Interventions	Post-surgery medical treatment with triptorelin 3.75 mg IM x 4 weekly for 6 months (n = 13) versus Pre-surgery and post-surgery treatment with triptorelin 3.75 mg IM x 4 weekly for 6 months (n = 12)
Outcomes	AFS scores at 6 months Pregnancy rate at 1 year follow up
Notes	Power calculation: NS Funding: NS

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	"randomly allocated into one of the treatment groups, odd numbers in the first group and even numbers in the second"
Allocation concealment (selection bias)	High risk	no allocation concealment
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Low risk	pregnancy rate reported for all randomised patients
Selective reporting (reporting bias)	Unclear risk	mean AFS scores reported per endometrioma not per patient, pregnancy rate
Other bias	Unclear risk	there were differences between the groups at baseline with regard to mean adhesion scores

Bianchi 1999

Methods	No. of centres: 1 Location: University of Milan, Italy Recruitment period: July 1994 to October 1996
Participants	Inclusion criteria: < 40 yrs Exclusion criteria: medical or surgical treatment for endometriosis, concurrent disease that might affect fertility or cause pelvic pain, women without pain symptoms, women not seeking pregnancy, liver or endocrine disease No. randomised: 77 No. analysed: 77
Interventions	Post-surgical medical therapy 1. Danazol oral 600 mg daily x 3/12 (n = 36)

Pre and post-operative medical therapy for endometriosis surgery (Review)

Bianchi 1999 (Continued)

2. No treatment (n = 41)

Outcomes	Pain recurrence AFS scores Pregnancy rates Adverse events of medication
Notes	Power calculation: NS Funding: NS

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomization was done according to a computer generated list"
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Low risk	all randomised patients included in analysis
Selective reporting (reporting bias)	Low risk	important outcomes - pregnancy rate and recurrence of endometriosis pain, adverse effects reported
Other bias	Low risk	groups appear comparable at baseline

Busacca 2001

Methods	Location: University of Milan, Italy No. of centres: 1 Recruitment period: July 1997 to December 1999
Participants	Inclusion criteria: < 40 yrs, laparoscopic diagnosis of endometriosis stage III-IV Exclusion criteria: previous medical or surgical therapy for endometriosis, other diseases that might affect fertility or cause pelvic pain; liver, endocrine or neoplastic disease No. randomised: 89 No. analysed: 89
Interventions	Post-surgical medical therapy Gr A (n=44): leuprolide acetate SC 3.5 mg 4 weekly x 3 doses Gr B (n=45): no treatment
Outcomes	Pain: pelvic pain recurrence at 18/12 AFS scores: objective disease recurrence Cumulative pregnancy rates at 18/12
Notes	Power calculation: yes

Busacca 2001 (Continued)

Funding: NS

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomization was performed according to a computer generated list unknown to the physicians"
Allocation concealment (selection bias)	Unclear risk	not described
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Low risk	all randomised patients included in the analysis
Selective reporting (reporting bias)	Low risk	important outcomes of pregnancy and recurrence of endometriosis and pain reported
Other bias	Low risk	groups appear comparable at baseline

Donnez 1994

Methods	No. of centres: 1 Location: Catholic University of Louvain, Belgium Recruitment period: January 1990 to December 1990
Participants	Inclusion criteria: age < 35 yrs, infertility, laparoscopic confirmed ovarian endometriotic cysts (AFS moderate n = 41, AFS severe n = 39) Exclusion criteria: none No. randomised: 80 No. analysed: 80
Interventions	Medical therapy pre-surgery 1. Goserelin S/C 4 weekly x 4 (n = 40) 2. No therapy (n = 40)
Outcomes	AFS scores: total, implants, adhesions, moderate, severe scores Ovarian cyst diameter Degree of active endometriosis as determined histologically from ovarian cyst wall biopsy
Notes	Power calculation: NS Funding: Fonds de la Recherche Scientifique

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomised according to official randomisation tables"

Donnez 1994 (Continued)

Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo used
Incomplete outcome data (attrition bias) All outcomes	Low risk	all randomised patients included in outcome assessment
Selective reporting (reporting bias)	Unclear risk	AFS scores at second look laparoscopy - no pregnancy data reported
Other bias	Low risk	groups appear comparable at baseline

Hornstein 1997

Methods	No. of centres: 13 Location: 13 clinics (North America) Recruitment period: not stated
Participants	Inclusion criteria: age 18-47, normal menstrual cycles of 24-36 days, clinical pelvic pain, dysmenorrhoea, dyspareunia Exclusion criteria: received medical therapy for endometriosis within 3 months, abnormal bone density, significant medical illness, laboratory abnormalities, pregnancy and lactation No. randomised: 109 No. analysed: 93 7 in nafarelin group and 8 in placebo group withdrew after 90 days of therapy 1 in placebo group excluded because missed 5 days of medication
Interventions	Post-surgery medical therapy 1. Nafarelin nasal 400 uG daily x 6/12 (n = 49) 2. Placebo (n = 44)
Outcomes	Pain Physician scores for tenderness and induration on physical examination at end of treatment and 6/12 after treatment
Notes	Power calculation: NS Funding: Syntex laboratory, California

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"multicenter, prospective, randomized, double-blind study" method of sequence generation not described
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	Low risk	"double blind" but authors acknowledge difficulty of maintaining blinding with this treatment

Hornstein 1997 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	7 and 8 patients were excluded from analyses of treatment and placebo groups because they withdrew before completing 90 days of therapy. Remaining 93 patients included in analysis even though 39 and 43 patients from treatment and placebo groups terminated the study early
Selective reporting (reporting bias)	Low risk	primary outcome was time to requiring alternative treatment; pain & recurrence also reported
Other bias	Low risk	groups appear comparable at baseline

Loverro 2001

Methods	No. of centres: 1 Location: Bari, Italy Recruitment period: January 1996 to January 1997
Participants	Inclusion criteria: AFS score III-IV Exclusion criteria: NS No. randomised: 62 No. analysed: 62?
Interventions	Post-surgery medical therapy 1. Triptorelin SC 3.75 mg every 4 weeks x 3 months (n = 33) 2. No treatment (n = 29)
Outcomes	Pain Pregnancy rates
Notes	Power calculation: NS Funding: NS Pregnancy outcomes and pain recurrence were only expressed as percentages in each group so numbers calculated were rounded up to the nearest whole number

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"prospective and randomized" - no details of method of sequence generation
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo used
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	not stated how many women are included in the outcomes - only percentages reported.
Selective reporting (reporting bias)	Low risk	important outcomes - time to relapse (pelvic pain) and pregnancy reported

Loverro 2001 (Continued)

Other bias	Unclear risk	no information on comparability of groups at baseline given
------------	--------------	---

Loverro 2008

Methods	Location: Italy No. of centres: one Recruitment period: January 1998 to January 1999
Participants	Inclusion criteria: women of reproductive age with stage III - IV endometriosis, associated with chronic pelvic pain, adnexial mass or infertility, who had undergone complete laparoscopic excision, had rAFS score > 15 and no previous hormonal treatment Exclusion criteria: No. randomised: 60 No. analysed: 54
Interventions	Post-operative triptorelin versus placebo Gr A (n=29): triptorelin 3.75 mg depot monthly on day 20 of cycle for 3 months Gr B (n=25): placebo monthly on day 20 of cycle for 3 months
Outcomes	Pain persistence, pregnancy
Notes	Power calculation: NS Funding: NS Email sent to contact author Feb 2010 requesting further information - no reply received

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"using a computer generated randomization table"
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	Low risk	patients were blinded to treatment allocation. placebo injections used
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	1 and 5 patients lost to follow up from triptorelin and no treatment groups respectively. Possibility of bias
Selective reporting (reporting bias)	Low risk	pain, relapse and pregnancy reported (for those who desired pregnancy)
Other bias	Low risk	groups appear similar at baseline

Muzii 2000

Methods	Location: University departments, Rome, Italy
---------	---

Muzii 2000 (Continued)

No. of centres: 2

Recruitment period: January 1994 to June 1997

Participants	Inclusion criteria: 20-35 yrs, moderate to severe dysmenorrhoea and/or chronic pelvic pain, not desiring fertility Exclusion criteria: treatment for endometriosis in previous 6 months No. randomised: 70 No. analysed: 68
Interventions	Post-surgical medical therapy Gr A (n=35): cyclic monophasic oral contraceptive pill (ethinyl estradiol 0.03 mg, gestodene 0.075 mg) for 21 days with 7 pill free days x 6/12 Gr B (n=35): no treatment
Outcomes	Recurrence of pain and time to recurrence Recurrence of cysts
Notes	Power calculation: yes Funding: NS. Drugs supplied by Population Council

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomly allocated to one of two management arms on the basis of a computer generated sequence"
Allocation concealment (selection bias)	Unclear risk	not described
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Low risk	two post-randomisation withdrawals. Unlikely to have introduced a bias
Selective reporting (reporting bias)	Low risk	important outcomes reported - recurrence of endometriosis, pain, AFS scores. Patients not desiring pregnancy
Other bias	Unclear risk	no information of the baseline characteristics of the groups reported

Parazzini 1994

Methods	Location: University centres in Italy No. of centres: 6 Recruitment period: January 1990 to July 1991
Participants	Inclusion criteria: age < 38 yrs, normal medical examination, unexplained infertility for at least 1 year, with/without chronic pelvic pain, endometriosis stage III-IV, partners with normal sperm analysis and post-coital tests Exclusion criteria: previous laparoscopic/clinical diagnosis of endometriosis, other diseases that might cause infertility or pelvic pain, previous treatment for endometriosis or infertility No. randomised: 75

Pre and post-operative medical therapy for endometriosis surgery (Review)

Parazzini 1994 (Continued)

No. analysed: 75 (pregnancy rates), 68 (pain scores)

Interventions	Post-surgical medical therapy Gr A (n=36): nafarelin nasal 400 µg daily x 3/12 Gr B (n=39): placebo
Outcomes	Pain (multidimensional and 10-point linear scale) score at 12 months Pregnancy rates Adverse drug outcome (amenorrhoea)
Notes	Power calculation: yes (post-hoc?) Funding: Recordati Milan provided nafarelin

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"computer generated randomization list"
Allocation concealment (selection bias)	Low risk	assigned by telephone call 7 days from surgery
Blinding (performance bias and detection bias) All outcomes	Low risk	double blind but authors acknowledge that adverse effects of treatment make maintaining blinding difficult
Incomplete outcome data (attrition bias) All outcomes	Low risk	no losses to follow up, all randomised patients included in analyses
Selective reporting (reporting bias)	Low risk	pregnancy rate and pelvic pain reported
Other bias	Low risk	groups appear comparable at baseline

Sesti 2007

Methods	Location: Rome, Italy No. of centres: one Recruitment period: January 1999 to May 2005
Participants	Inclusion criteria: women of reproductive age <40, with endometriosis related symptoms (dysmenorrhoea, pelvic pain, deep dyspareunia), laparoscopic diagnosis of St III -IV endometriosis, desiring pregnancy, nulliparous Exclusion criteria: concurrent disease, such as cancer or pelvic inflammatory disease, previous surgery for endometriosis, contraindications to estrogens/progestins No. randomised: 234 No. analysed: 222
Interventions	Gr A (n=115): placebo for 6 months Gr B (n=119): post-operative medical or dietary therapy patients in group B received either <ul style="list-style-type: none"> • triptorelin or leuprorelin 3.75 mg depot monthly for 6 months (n=42)

Sesti 2007 (Continued)

- continuous low dose monophasic oral contraceptives for 6 months, (ethinylestradiol 0.03 mg + gestoden 0.75 mg) (n=40)
- dietary therapy for 6 months (vitamins, mineral salts, lactic ferments and omega 3 and omega 6 fatty acids together with individually tailored diet) (n=37)

Outcomes	Pelvic pain
Notes	Power calculation: yes Funding: NS

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomized according to a computer generated randomization sequence"
Allocation concealment (selection bias)	Low risk	allocated by serially numbered opaque sealed envelopes
Blinding (performance bias and detection bias) All outcomes	Unclear risk	"neither the surgeons nor the patients were aware of the regimen prescribed during the study period". However placebo not described and it seems unlikely that blinding of patients could be maintained when treatments are either SC, oral medication or diet plus supplements
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	5 and 3 lost to follow up from placebo and GNRHa groups and reasons given. 2 lost to follow up from each of OCP and diet groups but reasons not given. 222 evaluated
Selective reporting (reporting bias)	Unclear risk	pain and health related quality of life reported. No pregnancy outcome in a group of women desiring pregnancy
Other bias	Low risk	groups appear comparable at baseline

Shaw 2001

Methods	Location: UK and Republic of Ireland No. of centres: 7 Recruitment period: not stated
Participants	Inclusion criteria: 18-50 year old women referred for symptom management or infertility Exclusion criteria: cervical intraepithelial neoplasia (CIN) No. randomised: 48 No. analysed: 40
Interventions	Pre-operative goserelin versus no treatment Gr A (n=21): goserelin 3.6 mg SC monthly for 3 months pre-operatively Gr B (n=27): no medical therapy
Outcomes	Change in endometrioma size, recurrence, pregnancy
Notes	Power calculation: yes Funding: Astra Zeneca, Macclesfield, UK

Risk of bias
Pre and post-operative medical therapy for endometriosis surgery (Review)

Shaw 2001 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	participants were stratified by endometrioma size and "randomly allocated using computer generated randomization lists"
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	33%(7) and 41% (11) of patients in Gr A & B withdrew from trial before surgery. Reasons given but are different in each group. 4 withdrawals from goserelin group pre surgery due to serious AE - migraine/headache/hot flushes, groin pain, muscle cramps, pain iliac fossa/sciatica. However all patients are included in outcome evaluation provided there is >1 post baseline measurement of endometrioma, but these numbers are not stated
Selective reporting (reporting bias)	Low risk	primary outcome is change in size of endometrioma, range of other outcomes including ease of surgery and pregnancy reported
Other bias	Unclear risk	some differences between the groups at baseline in mean endometrioma size. Difficulty in recruiting patients made trial underpowered, with different numbers in each group

Telimaa 1987

Methods	Location: University of Oulu, Finland No. of centres: 1 Recruitment period: not stated
Participants	Inclusion criteria: advanced endometriosis Exclusion criteria: NS No. randomised: 60 No. analysed: 51 (pain), 59 (pregnancy)
Interventions	Post-surgical medical therapy Gr A (n = 20): danazol oral 600 mg daily x 180 days Gr B (n = 20): MPA 100 mg daily x 180 days Gr C (n=20): placebo
Outcomes	Pain scores AFS scores Pregnancy rates Patient satisfaction Adverse drug reactions: weight gain, breakthrough bleeding, acne
Notes	Power calculation: NS Funding: Research and Science Foundation Farnos Ltd, Turku; Cultural Foundation of Keski-Pohjanmaa, Finland; Farnos Group, Turku, Finland supplied drugs

Risk of bias

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

Pre and post-operative medical therapy for endometriosis surgery (Review)

Telimaa 1987 (Continued)

Random sequence generation (selection bias)	Unclear risk	"randomized" no information on method of sequence generation
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	Low risk	double blind
Incomplete outcome data (attrition bias) All outcomes	Low risk	Numbers and reasons for post randomisation exclusions similar in each group. 3,2,3 excluded in groups A,B & C due to pregnancy. 1 adverse event in placebo group
Selective reporting (reporting bias)	Low risk	important outcomes of pregnancy recurrence and pain reported
Other bias	Low risk	groups appear comparable at baseline and authors state that" no other medication was used during the trial"

Tsai 2004

Methods	Location: Taiwan No. of centres: one Recruitment period: June 1988 to December 2001
Participants	Inclusion criteria: women of reproductive age with infertility and stage III or IV endometriosis planning to undergo controlled ovarian hyperstimulation and intrauterine insemination or in vitro fertilisation and embryo transfer. All had surgery for endometriosis - either laparotomy or laparoscopy for cystectomy, adhesiolysis, ablation of endometriosis Exclusion criteria: NS No. randomised: 45 No. analysed: 41
Interventions	Post-operative medical therapy (either danazol or GNRH analogue) Gr A (n=15): either 3 months 400 mg danazol orally, twice daily for 3 months or 3.75 mg leuprolide acetate depot SC every 28 days for 3 months Gr B (n= 30): no post-operative medical treatment
Outcomes	Pregnancy rate, recurrence
Notes	Power calculation: NS Funding: NS

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"simple randomisation with a computer generated list unknown to physicians"
Allocation concealment (selection bias)	Low risk	list "unknown to physicians"

Tsai 2004 (Continued)

Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	High risk	4 lost to follow up from Gr A (27%)
Selective reporting (reporting bias)	Low risk	pregnancy and recurrence reported
Other bias	Unclear risk	13 years of recruitment - ? associated changes in surgical techniques over this time

Vercellini 1999

Methods	Location: Italy No. of centres: 19 Recruitment period: February 1992 to June 1994
Participants	Inclusion criteria: pre-menopausal, endometriosis score ≥ 4 points, chronic pelvic pain Exclusion criteria: NS No. randomised: 269 No. analysed: 210
Interventions	Post-surgical medical therapy Gr A (n= 133): goserelin SC 3.6 mg every 4 weeks x 6 months Gr B (n=134): no treatment
Outcomes	Pain recurrence Pregnancy rates
Notes	Power calculation: Yes Funding: Zeneca Pharmaceuticals provided drugs and financial support

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"randomised in a proportion of 1:1 ... in accordance with a computer-generated randomisation sequence"
Allocation concealment (selection bias)	Low risk	centralised randomisation, allocation obtained by phone call
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	269 patients randomised, 2 excluded because case record forms not completed, 26 & 31 patients (22%) withdrew from treatment and control groups respectively for reasons other than symptom recurrence or were excluded due to major protocol violations. Reasons for exclusion similar in each group- may have introduced bias

Vercellini 1999 (Continued)

Selective reporting (re-reporting bias)	Low risk	important outcomes of recurrence, dysmenorrhoea and pregnancy reported
Other bias	Low risk	groups appear comparable at baseline

Yang 2006

Methods	Location: Harbin, China No. of centres: one Recruitment period: March 2002 to March 2004	
Participants	Inclusion criteria: women with stage 3 endometriosis who had undergone conservative or semi-conservative surgery, with normal renal function and blood count, aged 23 to 42 Exclusion criteria: history of hypertension, heart disease, diabetes mellitus, had undergone hormone therapy in 6 months prior to surgery No. randomised: 52 No. analysed: unclear	
Interventions	Post-operative Gr A (n=20): yiweining (YWN) 200 ml orally twice daily, for 3 months, starting on 7th post-operative day Gr B (n=19): gestrinone 2.5 mg twice weekly, SC? for 3-6 months, starting on 7th post-operative day Gr C (n=13): control - no treatment	
Outcomes	Pregnancy, recurrence of endometriosis, adverse effects	
Notes	Power calculation: not stated Funding: Fund of National Science of Heilongjiang Province Email sent to corresponding author requesting additional information April 2010 - mailbox not found	

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"randomly divided" - no details of method of sequence generation given
Allocation concealment (selection bias)	Unclear risk	not mentioned
Blinding (performance bias and detection bias) All outcomes	High risk	not mentioned, no placebo used
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	not clear how many of the randomised patients are included in the outcomes (% only given)
Selective reporting (re-reporting bias)	Unclear risk	pregnancy and recurrence reported - no details as criteria for measuring these
Other bias	Low risk	groups are similar in age and type of surgery at baseline

NS = not stated

IM = intramuscular
 SC = subcutaneous

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Morgante 1999	This trial was excluded because all the patient received triptorelin for 6 months post-surgery before randomisation to danazol or no treatment.
Schindler 1998	This is a prospective multi centre phase three study published in German. Preliminary translation suggests however that treatment was not randomly assigned.
Vercellini 2003	This is a pilot study using the levonorgestrel-releasing intrauterine system for treatment of endometriosis post-surgery. This is a locally effective hormonal suppressive therapy and has low systemic effects.
Ylanen 2003	This is a dose finding study with no comparison of treatment modality with placebo or no treatment.

Characteristics of studies awaiting assessment [ordered by study ID]

[Shawki 2002](#)

Methods	Location: Egypt Recruitment: February 1999 to March 2000
Participants	68 women with stage I or II endometriosis, subfertility, failed clomiphene citrate stimulation, known tubal patency and partner with fertile semen analysis
Interventions	Post-operative goserelin 3.6 mg injection every 28 days for 6 months versus no medical therapy, followed by 3 months of no treatment. If no pregnancy occurs then 2 cycles of clomiphene citrate stimulation follow
Outcomes	Pregnancy rate (spontaneous or following stimulation)
Notes	Published abstract only. Outcomes expressed as percentage only, no details of randomisation, allocation concealment, withdrawals, duration of follow up. Emailed author requesting more information (February and March 2010). No reply received

DATA AND ANALYSES

Comparison 1. Pre-surgical medical therapy versus no medical therapy

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Recurrence - AFS Score	1		Mean Difference (IV, Fixed, 95% CI)	Totals not selected
1.1 Total AFS	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.2 Implant AFS	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.3 Adhesion AFS	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]

Analysis 1.1. Comparison 1 Pre-surgical medical therapy versus no medical therapy, Outcome 1 Recurrence - AFS Score.

Study or subgroup	Treatment		Control		Mean Difference Fixed, 95% CI	Mean Difference Fixed, 95% CI
	N	Mean(SD)	N	Mean(SD)		
1.1.1 Total AFS						
Donnez 1994	40	34.5 (4.1)	40	44.1 (4.2)		-9.6[-11.42,-7.78]
1.1.2 Implant AFS						
Donnez 1994	40	18.8 (4.7)	40	27.5 (4.3)		-8.7[-10.67,-6.73]
1.1.3 Adhesion AFS						
Donnez 1994	40	15.7 (5.7)	40	16.6 (5.8)		-0.9[-3.42,1.62]

Favours treatment -20 -10 0 10 20 Favours control

Comparison 2. Post-surgical medical therapy versus placebo or no treatment

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Pain (VAS)	3		Std. Mean Difference (IV, Fixed, 95% CI)	Subtotals only
1.1 Pelvic pain at 12 months	2	240	Std. Mean Difference (IV, Fixed, 95% CI)	-0.96 [-1.23, -0.68]
1.2 Dysmenorrhoea at 12 months	1	187	Std. Mean Difference (IV, Fixed, 95% CI)	-0.58 [-0.87, -0.28]
1.3 Deep Dyspareunia at 12 months	1	187	Std. Mean Difference (IV, Fixed, 95% CI)	-0.33 [-0.62, -0.03]
1.4 Change in pelvic pain score at 12 months	1	93	Std. Mean Difference (IV, Fixed, 95% CI)	-0.15 [-0.56, 0.26]
2 Pain (dichotomous)	6		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
2.1 Pain recurrence <= 12 months	3	332	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.52, 1.10]
2.2 Pain recurrence 13-24 months	3	312	Risk Ratio (M-H, Fixed, 95% CI)	0.70 [0.47, 1.03]
2.3 pain persistence/recurrence 5 years	1	54	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.53, 1.66]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
3 Recurrence - AFS Score	1		Mean Difference (IV, Fixed, 95% CI)	Totals not selected
3.1 Total AFS score (12 months)	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
4 Disease/symptom recurrence	3		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
4.1 Disease/symptoms recurrence at 12 months	2	166	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.30, 1.90]
4.2 Disease/symptoms recurrence at 24 months	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.22 [0.01, 3.75]
5 Pregnancy	8	420	Risk Ratio (M-H, Fixed, 95% CI)	0.84 [0.59, 1.18]

Analysis 2.1. Comparison 2 Post-surgical medical therapy versus placebo or no treatment, Outcome 1 Pain (VAS).

Analysis 2.2. Comparison 2 Post-surgical medical therapy versus placebo or no treatment, Outcome 2 Pain (dichotomous).

Analysis 2.3. Comparison 2 Post-surgical medical therapy versus placebo or no treatment, Outcome 3 Recurrence - AFS Score.

Analysis 2.4. Comparison 2 Post-surgical medical therapy versus placebo or no treatment, Outcome 4 Disease/symptom recurrence.

Analysis 2.5. Comparison 2 Post-surgical medical therapy versus placebo or no treatment, Outcome 5 Pregnancy.

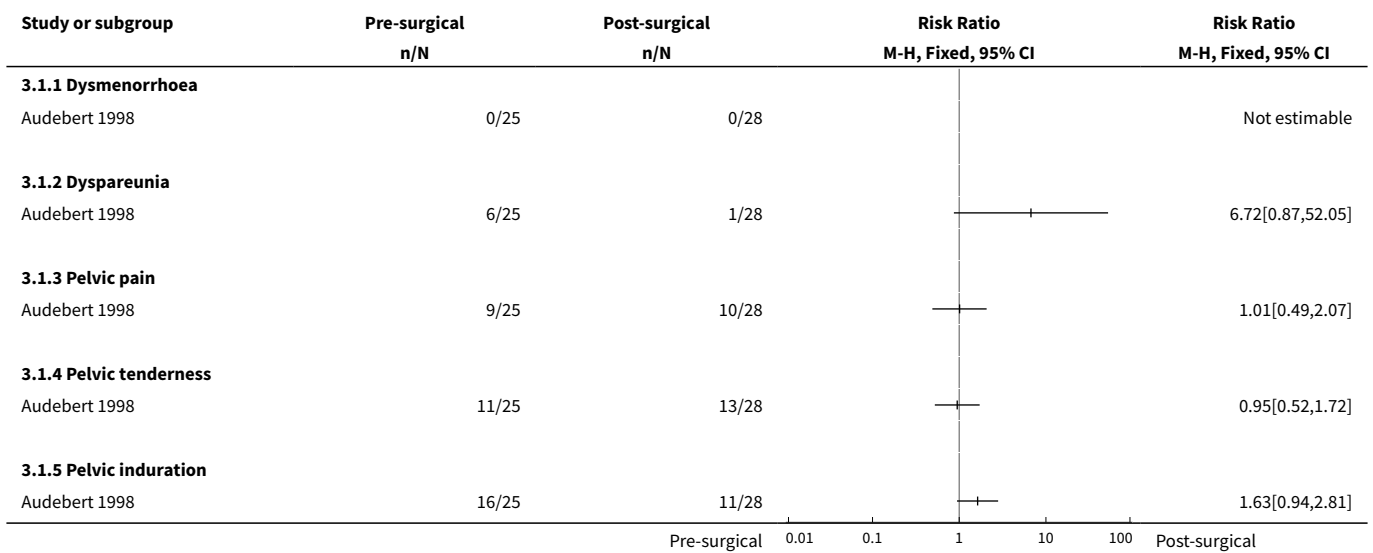

Comparison 3. Pre-surgical versus post-surgical medical therapy

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Pain (Dichotomous)	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
1.1 Dysmenorrhoea	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.2 Dyspareunia	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.3 Pelvic pain	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.4 Pelvic tenderness	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.5 Pelvic induration	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]

Analysis 3.1. Comparison 3 Pre-surgical versus post-surgical medical therapy, Outcome 1 Pain (Dichotomous).

Comparison 4. Post-surgical medical therapy versus pre and post-surgical medical therapy with GnRHa

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Recurrence - AFS Score	1		Mean Difference (IV, Fixed, 95% CI)	Totals not selected
1.1 Total AFS score	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.2 Implant AFS score	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.3 Adhesion AFS score	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
2 Pregnancy Rate	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

Analysis 4.1. Comparison 4 Post-surgical medical therapy versus pre and post-surgical medical therapy with GnRHa, Outcome 1 Recurrence - AFS Score.

Analysis 4.2. Comparison 4 Post-surgical medical therapy versus pre and post-surgical medical therapy with GnRHa, Outcome 2 Pregnancy Rate.

ADDITIONAL TABLES

Table 1. Descriptive data for trials not included in the meta-analysis

Study ID	Comparison	Outcome	n	Conclusion
Donnez 1994	pre-surgical Gn-RHa (goserelin) versus no medical therapy	mean endometrioma size	40/40	favouring goserelin mean difference -1.81cm (95% CI -2.05 to 1.57)
Shaw 2001	pre-surgical Gn-RHa (goserelin) versus no medical treatment	change in endometrioma size	21/27	favouring goserelin adj mean difference -1.25 cm (95% CI -2.42 to -0.08)
Shaw 2001		complete excision of cyst	21/27	no difference 13/21 (72%) and 16/27 (73%) had cysts completely excised at surgery
Shaw 2001		recurrence of residual cysts at 6 months	21/27	favours goserelin 2/21 (10%) and 4/27 (15%) had recurrence of residual cysts
Shaw 2001		mean rAFS scores	21/27	no difference 41.7, 42.5 (no SD given)

Table 1. Descriptive data for trials not included in the meta-analysis (Continued)

Telimaa 1987	MPA versus placebo	pain	17/8	pain scores after 12 months assessed with 4 point scales; MPA 1.8; Placebo 4.4 "significant difference"
Telimaa 1987	danazol versus placebo	pain	18/8	pain scores after 12 months assessed with 4 point scales; danazol 2.5; placebo 4.4, "significant difference"
Telimaa 1987	MPA versus placebo	patient satisfaction	17/8	patient satisfaction achieved in MPA 84% vs placebo 24%
Telimaa 1987	danazol versus placebo	patient satisfaction	18/8	patient satisfaction achieved in danazol 84% vs placebo 24%
Tsai 2004	post-surgical leuprolide/danazol versus no treatment	cumulative pregnancy rate at 12 months after clomiphene stimulation in both groups	15/30	no difference 56.7% and 54.5%
Yang 2006	post-surgical gestrinone versus no medical treatment	disease recurrence at 6-30 months	19/13	favours medical treatment 1/19 and 4/13 (p<0.05)
Audebert 1998	pre-surgical versus post-surgical GnRHa (nafarelin)	AFS scores	25/28	total AFS score after 6 months was 0 and 6 in pre and post groups respectively (p= 0.007); no SD or SE given and not calculable.
Audebert 1998		AFS scores	25/28	adhesion AFS score after 6 months was 0 and 2 in pre and post groups respectively (p= 0.007), no SD or SE given and not calculable.
Audebert 1998		AFS scores	25/28	implant AFS score after 6 months was 0 and 4 in pre and post groups respectively (p= 0.05), no SD or SE given and not calculable.
Audebert 1998		ease of surgery	25/28	surgery was easy in 56% of patients with GnRHa treatment pre-surgery (Grp II) compared to 35.7% in the post-surgery group (Grp I)

Table 2. Table of adverse drug effects

Trial ID	Adverse Drug Effects	Withdrawals-ADE
Audebert 1998	Side effects were reported with equal frequency in both groups and were consistent with those published by other investigators	2 withdrawals after randomisation from hot flushes and headaches
Batioglu 1997	Not described	None
Bianchi 1999	Hyperandrogenism 16.7%, weight gain ≥3kg 8.3%	None
Busacca 2001	Most experienced menopausal symptoms, all became amenorrhoeic	1 withdrawal from unacceptable side effects

Table 2. Table of adverse drug effects (Continued)

Donnez 1994	Not described	None
Hornstein 1997	Not described	Not due to ADE
Loverro 2001	Not described	None
Loverro 2008	Not described	None
Muzii 2000	Not described	Not due to ADE
Parazzini 1994	Amenorrhoea in all actively treated, none in placebo group	None
Sesti 2007	Menopausal symptoms, spotting, bloating, weight gain and headache reported but "well tolerated"	4 withdrew from hormonal suppression group due to AE
Shaw 2001	Hot flushes (62%), headaches (29%), dysmenorrhoea (14%) in goserelin group and 33% had dysmenorrhoea in no treatment group	4 withdrew from goserelin gp due to serious AE (1 treated to treatment)
Telimaa 1987- Danazol and Telimaa 1987-MPA	Weight increase MPA 1.9±1.3kg, danazol 3.4±2.3kg, placebo 0.4±2.6kg; breakthrough bleeding at 6/12: MPA 65%, danazol 56%, placebo 6%; acne at 6/12: danazol 56%, placebo 6%	Not due to ADE
Tsai 2004	Not described	Reasons for withdrawals not given
Vercellini 1999	Not described	None
Yang 2006	Not described	None

WHAT'S NEW

Date	Event	Description
2 May 2011	Amended	Summary of findings tables added

HISTORY

Protocol first published: Issue 2, 2002

Review first published: Issue 3, 2004

Date	Event	Description
20 September 2010	New search has been performed	Substantive update September 2010 - 5 new trials included. Risk of bias assessment on all included studies. Minor changes to the objectives - hypotheses deleted
7 November 2008	Amended	Converted to new review format.
26 May 2004	New citation required and conclusions have changed	Substantive amendment

CONTRIBUTIONS OF AUTHORS

Christine Yap: took the lead in writing the protocol, developed objectives, selection criteria, methods, background, results and discussion. Sue Furness: contributed to the background, search strategy, data extraction, risk of bias, analysis, results and discussion of the review and this update.

Cindy Farquhar: initiated and conceptualised the protocol, assisted in resolution of issues raised during the preparation of the original review, contributed to the updated review.

Ying Cheong: contributed to the data extraction, risk of bias, analysis, results and discussion of the updated review.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Clarifications to the original protocol

We consider that levonorgestrel-releasing intrauterine devices do not meet the inclusion requirement for systemic hormonal suppression and we therefore excluded the trial by [Vercellini 2003](#).

Quality assessment of included studies has been updated as 'Assessment of risk of bias of included studies' in line with the latest version of the Cochrane Handbook ([Higgins 2009](#)). Additional headings available in RevMan 5 have been utilised to make the structure of the Methods, Results and Discussion sections of the review clearer.

It was planned to undertake sensitivity analysis in this update to investigate whether the conclusions would differ if analysis was restricted to trials with low risk of bias.

Pentoxifylline is a medical therapy for endometriosis which is evaluated in a separate systematic review ([Lv 2009](#)).

Minor changes were made to the format of the objectives of this review - the hypotheses were deleted from the updated review.

INDEX TERMS

Medical Subject Headings (MeSH)

Chemotherapy, Adjuvant; Endometriosis [*drug therapy] [surgery]; Hormones [*therapeutic use]; Postoperative Period; Preoperative Care; Randomized Controlled Trials as Topic

MeSH check words
