Quercetin and polycystic ovary syndrome, current evidence and future directions: a systematic review

Fatemeh Pourteymour Fard Tabrizi¹, Fatemeh Hajizadeh-Sharafabad¹, Maryam Vaezi^{2,3}, Hamed Jafari-Vayghan⁴, Mohammad Alizadeh^{5,6*} and Vahid Maleki^{1,5,6*}

Abstract

Polycystic ovary syndrome (PCOS) is a polygenic endocrine disorder and the most common gynecological endocrinopathy among reproductive-aged women. Current remedies are often used only to control its signs and symptoms, while they are not thoroughly able to prevent complications. Quercetin is an herbal bioactive flavonoid commonly used for the treatment of metabolic and inflammatory disorders. Thus, this systematic review was conducted to evaluate the efficacy of quercetin supplementation in subjects with PCOS. Databases until March 2019 were searched. All human clinical trials and animal models evaluating the effects of quercetin on PCOS women were included. Out of 253 articles identified in our search, 8 eligible articles (5 animal studies and 3 clinical trials) were reviewed. The majority of studies supported the beneficial effects of quercetin on the ovarian histomorphology, folliculogenesis, and luteinisation processes. The effects of quercetin on reducing the levels of testosterone, luteinizing hormone (LH), and insulin resistance were also reported. Although quercetin improved dyslipidemia, no significant effect was reported for weight loss. It is suggested that the benefits of quercetin may be more closely related to antioxidant and anti-inflammatory features of quercetin rather than weight-reducing effects. Therefore, this review article provides evidence that quercetin could be considered as a potential agent to attenuate PCOS complications. However, due to the paucity of high-quality clinical trials, further studies are needed.

Keywords: Polycystic ovary syndrome, Quercetin, Insulin resistance, Inflammation, Oxidative stress

Introduction

Polycystic ovary syndrome (PCOS), as a polygenic endocrine disorder, is the most common gynecological endocrinopathy, which is estimated to affect 2–20% of reproductive-aged women [1]. Common physiological manifestations of this syndrome include ovarian enlargement, hyperandrogenism, androgenic alopecia, hirsutism, acne, menstrual irregularity, anovulation or oligo-amenorrhea, miscarriage, and infertility [2]. PCOS-related symptoms also impair the quality of life through affecting psychiatric aspects of patient's life [3]. Women with PCOS exhibit an increased incidence

of several chronic diseases including obesity, dyslipidemia, hypertension, heart disease, and type 2 diabetes mellitus (T2DM) [4–6]. It is documented that both obese and lean women with PCOS mostly exhibit insulin resistance, a major risk factor for the development of metabolic abnormalities such as impaired glucose tolerance (IGT) and T2DM [7, 8]. According to recent studies, oxidative stress is demonstrated as another contributing factor in the development of PCOS and its corresponding symptoms such as increased androgen production and infertility [9]. Although the definite etiology of PCOS remains unclear, complex interactions between genetic, behavioral, and environmental factors play critical roles in the development of PCOS and subsequent therapeutic options [10]. Current remedies are often used only to control its signs and symptoms, while they are not thoroughly able to prevent complications. Therefore, natural

products became a topic of interest for the management of PCOS and its complications [11]. Herbal plants are extensively used to prevent chronic diseases due to their polyphenolic compounds, multi-targeted effectiveness, and low toxicity [12]. Quercetin is an herbal bioactive flavonoid with radical scavenging and antioxidant properties, which is extensively used for the treatment of metabolic and inflammatory disorders [13]. Fruits and vegetables, particularly onions, apples, berries, citrus, red grapes, nuts, seeds, and tea, are a good source of quercetin [14]. Several pharmacological studies revealed that, Quercetin supplements are effective in the regulation of redox status [15], reducing inflammation [16], protecting cardiovascular system [17], inhibiting platelet aggregation [18], relaxing vessels smooth muscles [19], and preventing LDL oxidation [20], hypertension [21], cancer development [22, 23] and diabetes [24]. It is postulated that hypoglycemic effect of the quercetin is related to insulin signal transduction, such as enhanced protein expression, and tyrosine phosphorylation of insulin receptor (IR), several insulin receptor substrates (IRSs) and glucose transporters (GLUTs) [25]. Moreover, quercetin exerts the insulin-sensitizing effect by promoting the proliferation of pancreatic β -cells and enhancing glucose metabolism and insulin secretion [26]. Oxidative stress is considered as a potential stimulant of PCOS, and serum levels of antioxidants are reduced in patients with PCOS. Therefore, the use of anti-oxidative agents in the management of PCOS has attracted a lot of attention [27, 28]. Quercetin could be considered as an anti-oxidative agent due to its ability to inhibit xanthine oxidase through reducing the generation of free radicals, modifying antioxidants and inhibiting lipid peroxidation [29].

The current study aimed to systematically summarize the scientific literature regarding therapeutic effects of quercetin on PCOS, as the most common endocrinopathy in reproductive-aged women.

Methods

Search strategy

Literature search was conducted in PubMed, Scopus, Embase, ProQuest and Google Scholar electronic databases using the keywords “quercetin” [Title/Abstract] AND “polycystic ovary syndrome” [Title/Abstract] OR “PCOS” [Title/Abstract] OR “sclerocystic ovary syndrome” [Title/Abstract] OR “dysmetabolic Syndrome” [Title/Abstract]. Reference lists and related records were also reviewed. The search was limited to English language papers published until March 2019. Guideline of the Preferred Reporting for Systematic Reviews (PRISMA) was used for designing this systematic review.

Eligibility criteria

We included all human clinical trials, as well as animal studies, and published in English-language journals. In-vitro models, reviews studies, non-English-language articles and those with no access to the full text were excluded.

Data extraction

The titles and abstracts of the eligible papers were independently screened by two researchers. Studies were excluded if they could not meet the criteria. To extract data, eligible articles were evaluated based on an aim checklist, research question, and inclusion/exclusion criteria. Then, the quality of the included studies was assessed by a third reviewer. In case of any disagreements, a third author was consulted.

Results

Selected articles

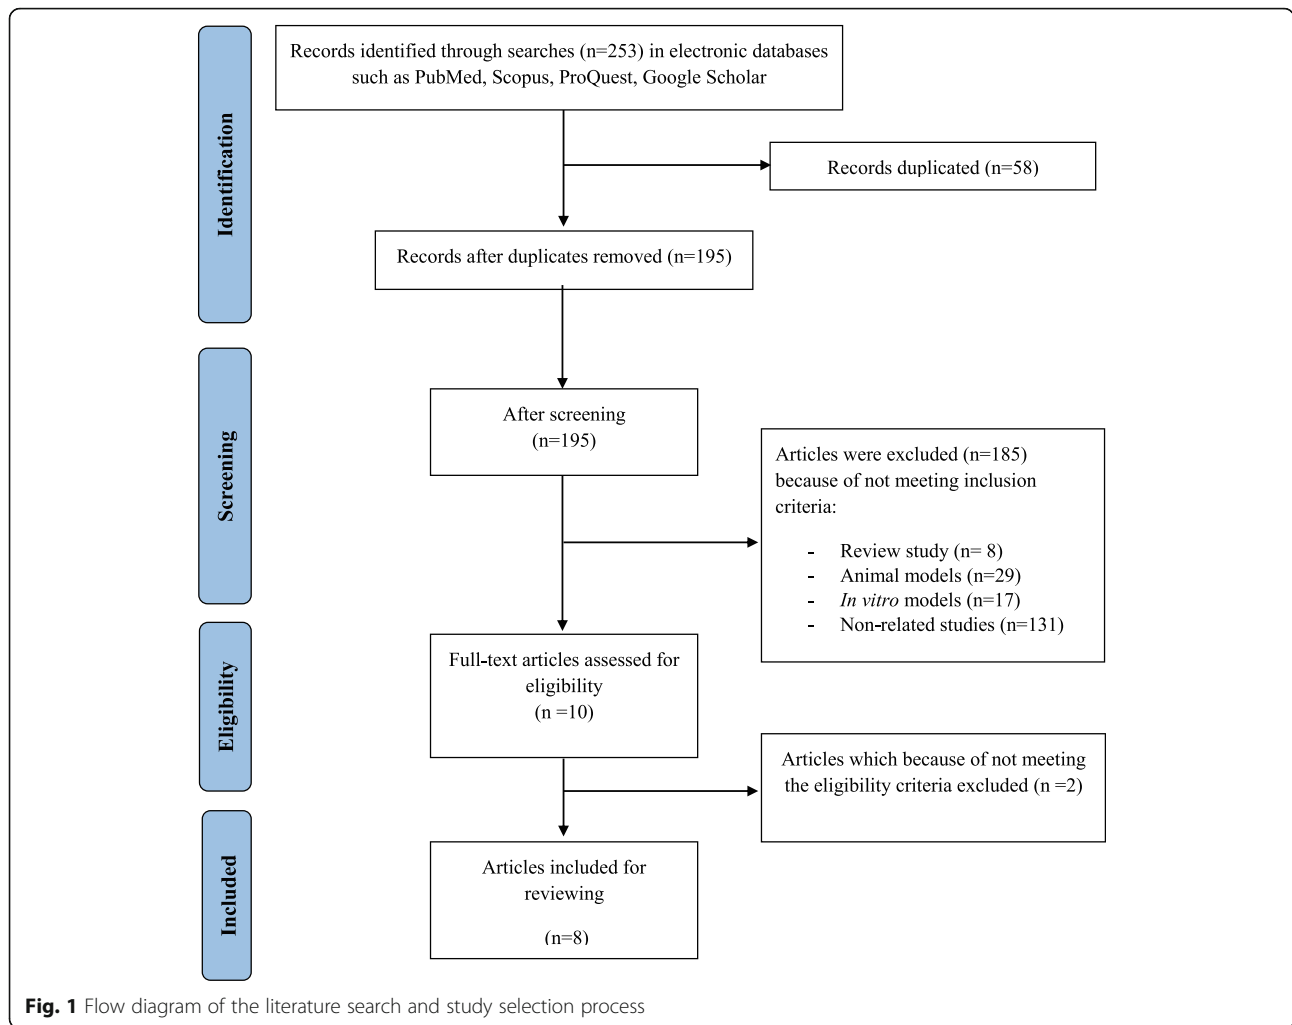

Figure 1 presents a flow diagram of the study selection. Totally, 253 articles were retrieved, 58 of which were duplicates resulting in 195 non-duplicated publications. One hundred eighty five articles could not meet our inclusion criteria and were excluded. Also, two articles were excluded due to not meeting the eligibility criteria. Finally, only 8 full-text articles were consistent with the purpose of this study and were reviewed (Table 1).

Quercetin and weight changes in PCOS

In these studies, the presence of PCOS is a contributing factor in the increased incidence of weight gain and overweight. Two of 5 animal studies reported that administration of Quercetin prevented weight gain and caused significant decrease in body weight in PCOS rats [30, 34]. Other animal studies [31–33] as well as 3 human trials [35–37] showed insignificant changes in weight, waist circumference and BMI among intervention groups compared to control groups.

Quercetin and ovarian histomorphology in PCOS

Five of eight studies used histological analysis including ovarian morphology, weight and diameter, and reported a significant improvement in ovarian morphology, folliculogenesis, and luteinisation after treatment with quercetin [30–34, 37]. Jahan et al. [31] reported a significant decrease in ovarian diameter and cystic follicle diameter in quercetin-treated PCOS subjects. Also, treatment with quercetin normalized the thickness of theca and granulosa layer. Overall, these studies found that treatment with quercetin increase normal follicles in ovaries, restore the anatomy of normal ovary, and improve the histology of the uterus, which are comparable to metformin [31–34].

Quercetin and reproductive hormones in PCOS

Six of eight studies examined the effects of quercetin on the reproductive hormones in PCOS subjects [31, 33–37]. It is reported that administration of quercetin improved the estrous cyclicity of the PCOS subjects [30, 31]. Hong Y et al. [34] showed that quercetin at a dose of 25 mg/kg body weight decreased the activity of steroidogenic enzymes (3 β -HSD and/or 17 β -HSD), in rat model with PCOS. Moreover, quercetin could regulate steroidogenesis through reducing testosterone levels and improving progesterone and estradiol levels [31]. The reducing effects of quercetin administration on testosterone, LH, and estradiol levels in PCOS subjects were also reported by five other studies [31, 33–36]. Findings from two human studies showed that quercetin supplementation in women with PCOS slightly improved testosterone and LH level, but the effects on sex hormone binding globulin (SHBG) was marginal [35, 36]. Hirsutism, a condition of unwanted hair growth in PCOS due to excess androgens, was evaluated by two of eight studies [31, 33]; however, all the included studies confirmed that quercetin treatment could

successfully improve subsiding hirsutism. Two studies showed that administration of quercetin led to decreased expression of CYP17A1 gene which is responsible for the activity of 17 α -hydroxylase, a key enzyme for androgen synthesis [31, 33].

Quercetin and metabolic profile in PCOS

Seven of eight studies evaluated the potential effects of quercetin on the metabolic profile in PCOS subjects [30, 32–37]. Hong et al. [34] reported that quercetin intake at a dose of 25 mg/kg resulted in a reduction of plasma glucose levels in PCOS rats. Other studies assessed the changes in the insulin and glucose levels, as well as homeostasis model assessment of insulin resistance (HOMA-IR) values following quercetin intake [30, 32, 33, 35, 37]. They reported that quercetin intake caused significant decrease in these values and improved insulin resistance in PCOS cases. Daily consumption of 1000 mg quercetin for 12 weeks reduced insulin resistance and fasting levels of insulin and glucose as well as plasma concentration and gene expression of resistin in overweight

Abbreviations: ADIPORs Adiponectin Receptors, AMPK AMP-activated protein kinase, BMI Body mass index, CYP17A1 Cytochrome P450 17A1, CAT Catalase, DHEA Dehydroepiandrosterone, Era Oestrogen receptor α , FBG Fasting blood glucose, GK Glucokinase, GLUT4 Glucose transporter 4, GPX Glutathione peroxidase, HDL High-density lipoprotein, HK Hexokinase, HMW High molecular weight, HOMA-IR Homeostasis model of assessment-insulin resistance, IL-6 Interleukin 6, IR Insulin resistance, LDL Low-density lipoprotein, LH Luteinizing hormone, NF- κ B Nuclear factor kappa-light-chain-enhancer of activated B cells, PCOS Polycystic ovary syndrome, PI3K Phosphatidylinositol 3-kinase, ROS Reactive oxygen species, SHBG Sex hormone binding globulin, SOD Super oxide dismutase, TBARS Thiobarbituric acid reactive substances, VLDL Very low-density lipoprotein

or obese women with PCOS; however, these changes were not statistically significant after controlling the potential confounders [36]. It is shown that adiponectin regulates the reproductive system by blocking the secretion of LH and GnRH [38]. Rezvan et al. [35] showed that oral quercetin supplementation increases the serum levels of total adiponectin by 5.56% and high-molecular-weight (HMW) adiponectin by 3.9% in PCOS women as compared to placebo. They showed the efficient role of quercetin in improving the adiponectin-mediated insulin resistance and hormonal profile of women with PCOS. In another study, quercetin supplementation up-regulated transcript expression levels of adiponectin receptors (ADIPOR1, ADIPOR2) [37]. Furthermore, they reported that quercetin increases the levels of AMP-activated protein kinase (AMPK) by 12.3% compared to the control group. AMPK enhances the regulation of glucose transporter 4 (GLUT4) as a key sensor of energy, and therefore induces glucose uptake. Treatment with quercetin for 30 days significantly increased the activity of liver hexokinase (HK) and glucokinase (GK) to a normal level in the uterus of PCOS subjects compared to the untreated group [34]. Moreover, the treatment increased the gene expression of estrogen receptor alpha (ER α) and GLUT4 up to 5 and 4.4 folds, respectively.

Quercetin and dyslipidemia in PCOS

Two of 8 studies investigated lipid profile following quercetin supplementation in PCOS subjects. They reported that treatment with quercetin produce a significant reduction in serum levels of TC, TG, LDL-C, and very low density lipoprotein (VLDL) and a significant increase in HDL-C levels compared to the control group [31, 33].

Quercetin and oxidative stress and inflammation in PCOS

Effectiveness of quercetin on oxidative stress and inflammation in PCOS were assessed in three out of 8 studies [30, 31, 34]. Administration of quercetin inhibited the expression of inflammation-related genes including the nicotinamide adenine dinucleotide phosphate oxidase subunit (p22phox), oxidized low-density lipoprotein (OX-LDL), and Toll-like receptor 4 (TLR-4), in ovarian tissue of PCOS subjects [30]. Quercetin also decreased the messenger RNA (mRNA) and protein levels of p22phox, OX-LDL, and TLR-4. Besides, quercetin significantly reduced the blood levels of interleukin 1 β (IL-1 β), interleukin-6 (IL-6), and tumor necrosis factor α (TNF- α). Also, the granulosa cell nuclear translocation of NF- κ B was significantly reduced following quercetin administration in the insulin-resistant PCOS subjects. Neisy et al. indicated that the decrease in insulin resistance as a result of quercetin intake in the PCOS group might be associated with its anti-inflammatory properties such as inhibitory effects on TNF- α [32]. Total protein content and the levels of catalase (CAT), superoxide

dismutase (SOD), peroxidase (POD), and glutathione reductase (GR) in ovarian tissue of PCOS subjects were extremely lower than the control [31]. Quercetin treatment reversed these values near to baseline levels. The levels of thiobarbituric acid reactive substances (TBARS), as surrogate marker of lipid peroxidation, were significantly higher in PCOS women than control. Following quercetin administration, TBARS level was decreased in PCOS subjects. Quercetin also significantly increased the activity of SOD, CAT, and glutathione peroxidase (GPX) in the PCOS group [34].

Discussion

The current systematic review suggests that quercetin possesses an intrinsic potential to correct hormonal disturbances and subsequent metabolic disorders occurred in PCOS. The ovarian follicles of patients with PCOS are large, with a thickened theca cell layer and a degenerated granulosa cell progressed to form cysts [33, 39]. Evidence suggests that the effects of quercetin on the improvement of ovarian histological and histomorphological analysis are similar to or higher than metformin. Animal models suggest beneficial effects of quercetin on folliculogenesis and luteinisation processes through improved ovarian tissue along with the prominent decrease of atretic and cystic follicles, improvement of hirsutism, marked an increase in normal follicles with different stages and vascularization of the thecal layer [31–33]. More luteal together with an increase in the thickness of ovarian granulosa cells were also reported following quercetin administration; however, the changes in the ovaries weight were not statistically significant [30].

Histological changes of the ovarian follicles seem to be mediated by elevated levels of androgens and disrupted folliculogenesis resulting from an irregular estrous cycle [40]. Quercetin decreased testosterone levels and reversed the low levels of estradiol and progesterone to near-normal levels [31]. Studies also reported the existence of more corpora lutea accounting for the restoration of the estrous cycle [31, 41]. It is in line with the reduced activities of 3 β -hydroxysteroid dehydrogenase and 17 β -hydroxysteroid dehydrogenase and the modified concentrations of testosterone and estradiol, as well as ovary structure following administration of quercetin [34].

Indeed, the evidence suggests that quercetin is able to counteract the mechanisms of androgen biosynthesis related to LH [31, 33]. The increased levels of LH in PCOS, which are due to the impaired hypothalamic-pituitary axis, stimulate PI3K/Akt pathway leading to the over expression of ovarian CYP17A1 gene together with 17- α hydroxylase enzyme levels, which catalyze the conversion of progesterone to androgens [31, 42, 43]. Two studies reported that the lowering effects of quercetin on the levels of testosterone and LH are linked to resistin, as a possible agent in the

steroidogenesis [36]. The potential mediators by which resistin elevates steroidogenesis include LH receptor, steroidogenic acute regulatory protein, and insulin receptor [44]. Resistin not only stimulates the synthesis of androgens by increasing theca cells thickness and 17 α -hydroxylase activity [45], but also potentiates the activities of 3 β -hydroxysteroid dehydrogenase and 17 β -hydroxysteroid dehydrogenases accompanied with the increased release of androgens [46]. Resistin, along with LH, also up-regulate gene expression of insulin receptor leading to overproduction of androgens [44]. It was found that quercetin effectively ameliorates serum levels of testosterone and LH through reducing resistin levels [36]. In summary, Fig. 2 indicates the possible mechanisms of the quercetin potential roles on hormonal status in ovarian cells. Hyperandrogenaemia may lead to PCOS-related excessive weight gain and insulin resistance [47]. Moreover, chronic inflammation and oxidative stress, as two hallmarks of PCOS, are closely related in PCOS women and cause impaired insulin action and hyperinsulinemia [48, 49] leading to anovulation [50]. Although quercetin could not make significant changes in body weight in PCOS subjects [31, 33, 34], there is evidence suggesting the ability of quercetin to redistribute fat mass [51]. Quercetin has also exhibited a potential capacity to sensitize insulin receptors attributed to its antioxidant and anti-inflammatory features. The overproduction of ROS derived from NADPH oxidation in PCOS condition leads to higher levels of oxidized LDL (ox-LDL) [52]. The interaction between ox-LDL and Toll-like receptor 4 (TLR4)

activates NF- κ B path way resulting in elevated expression of pro-inflammatory cytokines including IL-1 β , IL-6, and TNF- α which induce insulin resistance [30, 53]. Wang et al. [30] showed that quercetin suppresses the expression of NADPH oxidase subunit p22phox, ox-LDL, and TLR-4 and thereby inhibit TLR-4-NF- κ B signaling pathway leading to reduced insulin resistance.

In addition, investigations demonstrated that increasing the levels of antioxidant enzymes such as SOD, CAT, POD, GR, GSHPX, and NADPH oxidase by quercetin, are the other protective effects of quercetin against oxidative stress [31, 34]. Since the oxidative stress is positively related to testosterone levels, insulin resistance, ovarian mesenchyme hyperplasia, and infertility [54, 55]; quercetin may be considered as a potential agent to attenuate PCOS complications. Another possible mechanism by which quercetin reduces insulin resistance is mediated by its beneficial effect on the dominant adipokine regulating insulin resistance named adiponectin [37]. AdipoR1 and AdipoR2 are the prominent receptors of adiponectin which interact with the substrate and activate several signaling cascades such as AMP-activated protein kinase (AMPK) to regulate glucose and fatty acid metabolism [56]. Rezvan et al. [37] indicated that quercetin up-regulates gene expression of *ADIPOR1* and *ADIPOR2* along with a marked increment in AMPK levels in patients with PCOS.

In another study by Khorshidi et al. [36] FBG, insulin, and HOMA-IR were improved after supplementation with quercetin; however, the differences between quercetin and

Fig. 2 Possible mechanisms of the quercetin potential roles on hormonal status in ovarian cells. Abbreviations: IRS; Insulin Receptor Substrate, PI3K; Phosphoinositide 3-kinase, AKT; Protein kinase B, P450scc; Cholesterol side-chain cleavage enzyme, CYP17A1; Cytochrome P450 Family 17 Subfamily A Member 1, 3 β HSD; 3 β -Hydroxysteroid dehydrogenase, 17 β HSD; 17 β -Hydroxysteroid dehydrogenase, DHEA; Dehydroepiandrosterone

placebo groups were not significant. The authors attributed the glycaemia-mimic effect of quercetin to resistin, which showed a significant decrease in the quercetin group [36]. Resistin diminishes the phosphorylation of AMPK and Akt pathways and decreases the production of IRS-1 as well as tyrosine phosphorylation of IRS-1, leading to increased insulin resistance [57, 58]. Resistin promoter has several binding sites for sterol regulatory element-binding protein 1c and CCAAT enhancer-binding protein alpha (C/EBPα), which bind to resistin promoter and overexpress resistin gene [59].

Quercetin potentially decreases resistin through down-regulating gene expression of C/EBPα [60]. Several indirect mechanisms have been suggested for quercetin to counteract insulin resistance [32]. Lower activity of GK coupled with the increased rate of HK activity observed in PCOS indicates that liver cells in IR state potentiate the activity of HK to compensate decreased GK activity and improve glucose metabolism in the liver [32, 61]. Quercetin increased the activity of both enzymes along with the expression of GLUT4 and reversed lowered activity of GK in PCOSrat liver [32].

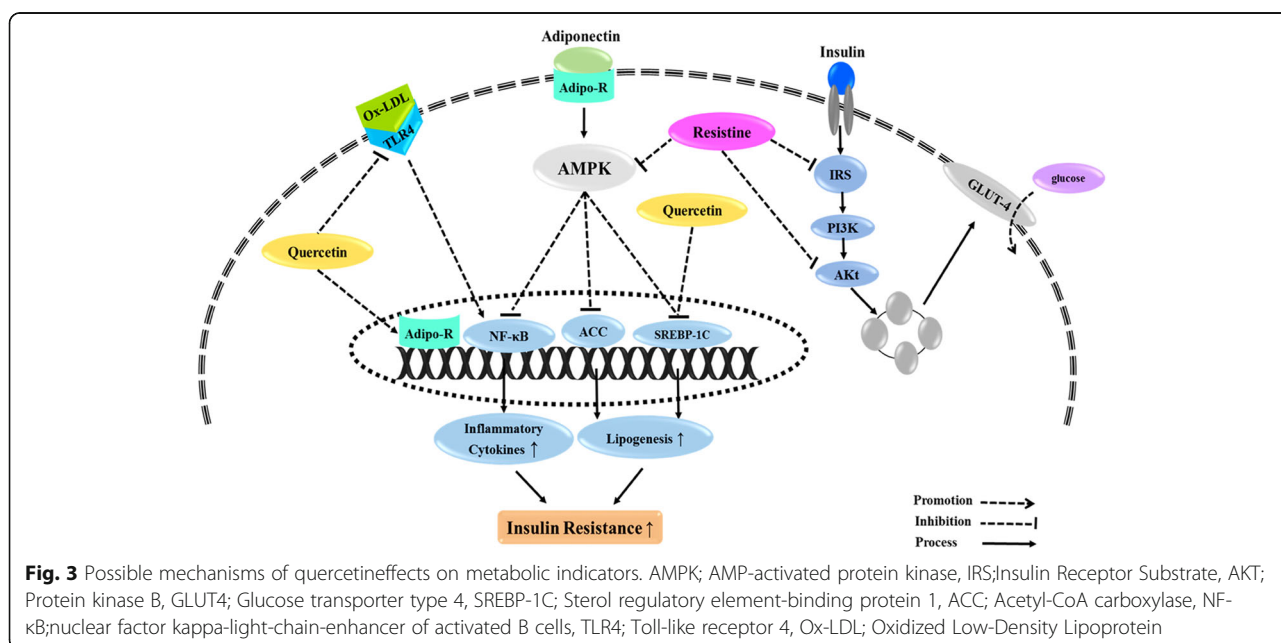

Dyslipidemia, as a common metabolic disorder in PCOS, appears to occur due to the hormonal imbalance and insulin resistance [62, 63]. Although the available evidence suggests a highly significant improvement in lipid profile following quercetin administration, more studies are required to confirm these beneficial effects. Based on these studies, anti-hyperlipidemic potential of quercetin can be attributed to its capacity in correcting hyperinsulinemia and hyperandrogenemia [31, 33]. In general, the possible mechanisms of quercetin effects on metabolic indicators are summarized in Fig. 3.

Knowledge gaps and future directions

None of the included studies measured blood concentrations of quercetin to determine its bioavailability. Dose-dependent experiments are also recommended to evaluate the therapeutic effects of quercetin in the management of PCOS complications following each dose, and to determine the optimum dose of quercetin in which the need for metformin is reduced. Since body composition can directly affect hormone levels, glycemic status, and lipid profile, further studies are needed to address the effect of quercetin on body composition. Although insulin resistance is one of the common events in PCOS, only a few studies have examined the impact of quercetin on insulin resistance and the involved mechanisms. Therefore, future well-designed studies with longer duration are warranted to reach conclusive results about quercetin consumption in women with PCOS.

Conclusion

The current evidence indicates that supplementation with quercetin effectively ameliorate hyperandrogenaemia and irregular estrous and consequently, improve the folliculogenesis and luteinisation processes. However, there are not enough studies to make robust conclusions. While data on the impact of quercetin on metabolic profiles is relatively scarce, there is evidence that quercetin may be able to counteract PCOS complications by improving insulin resistance and chronic inflammation. Mechanisms by which quercetin suppress insulin resistance include reducing testosterone, LH and resistin levels and increasing adiponectin activity.

Publisher’s Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
