ABSTRACT

Background

Social skills programmes (SSP) are treatment strategies aimed at enhancing the social performance and reducing the distress and difficulty experienced by people with a diagnosis of schizophrenia and can be incorporated as part of the rehabilitation package for people with schizophrenia.

Objectives

The primary objective is to investigate the effects of social skills training programmes, compared to standard care, for people with schizophrenia.

Search methods

We searched the Cochrane Schizophrenia Group's Trials Register (November 2006 and December 2011) which is based on regular searches of CINAHL, BIOSIS, AMED, EMBASE, PubMed, MEDLINE, PsycINFO, and registries of clinical trials. We inspected references of all identified studies for further trials.

A further search for studies has been conducted by the Cochrane Schizophrenia Group in 2015, 37 citations have been found and are currently being assessed by review authors.

Selection criteria

We included all relevant randomised controlled trials for social skills programmes versus standard care involving people with serious mental illnesses.

Data collection and analysis

We extracted data independently. For dichotomous data we calculated risk ratios (RRs) and their 95% confidence intervals (CI) on an intention-to-treat basis. For continuous data, we calculated mean differences (MD) and 95% CIs.

Main results

We included 13 randomised trials (975 participants). These evaluated social skills programmes versus standard care, or discussion group. We found evidence in favour of social skills programmes compared to standard care on all measures of social functioning. We also found that rates of relapse and rehospitalisation were lower for social skills compared to standard care (relapse: 2 RCTs, n = 263, RR 0.52 CI 0.34 to 0.79, *very low quality evidence*), (rehospitalisation: 1 RCT, n = 143, RR 0.53 CI 0.30 to 0.93, *very low quality evidence*) and participants' mental

Social skills programmes for schizophrenia (Review)

state results (1 RCT, n = 91, MD -4.01 CI -7.52 to -0.50, *very low quality evidence*) were better in the group receiving social skill programmes. Global state was measured in one trial by numbers not experiencing a clinical improvement, results favoured social skills (1 RCT, n = 67, RR 0.29 CI 0.12 to 0.68, *very low quality evidence*). Quality of life was also improved in the social skills programme compared to standard care (1 RCT, n = 112, MD -7.60 CI -12.18 to -3.02, *very low quality evidence*). However, when social skills programmes were compared to a discussion group control, we found no significant differences in the participants social functioning, relapse rates, mental state or quality of life, again the quality of evidence for these outcomes was *very low*.

Authors' conclusions

Compared to standard care, social skills training may improve the social skills of people with schizophrenia and reduce relapse rates, but at present, the evidence is very limited with data rated as very low quality. When social skills training was compared to discussion there was no difference on patients outcomes. Cultural differences might limit the applicability of the current results, as most reported studies were conducted in China. Whether social skills training can improve social functioning of people with schizophrenia in different settings remains unclear and should be investigated in a large multi-centre randomised controlled trial.

PLAIN LANGUAGE SUMMARY

Social skills programmes for people with schizophrenia

Social skills programmes (SSP) use behavioural therapy and techniques for teaching individuals to communicate their emotions and requests. This means they are more likely to achieve their goals, meet their needs for relationships and for independent living as well as getting on with other people and socially adjusting. Social skills programmes involve 'model learning' (role playing) which was introduced to improve general 'molecular' skills (eye contact, fluency of speech, gestures) and 'molar' skills (managing negative emotions, giving positive feedback). Social skills programmes enhance social performance and reduce the distress and difficulty experienced by people with schizophrenia. Social skills programmes can be incorporated as part of a rehabilitation package for people with schizophrenia.

The main objective of this review is to investigate the effectiveness of social skills programmes, compared to standard care or discussion groups, for people with schizophrenia. Based on searches carried out in 2006 and 2011, this review includes 13 trials with a total of 975 participants. Authors chose seven main outcomes of interest, all data for these outcomes were rated to be very low quality. The review found significant differences in favour of social skills programmes compared to standard care on all measures of social functioning. Rates of relapse were lower for social skills compared to standard care and there was a significant difference in favour of social skills on people's mental state. Quality of life was also improved in the social skills programme compared to standard care. However, when social skills programmes were compared to discussion groups, there were no significant differences in people's social functioning, relapse rates, mental state or quality of life.

Compared to standard care, social skills programmes may improve the social skills of people with schizophrenia and reduce relapse rates. However, at the moment evidence is very limited with data only of very low quality available. Cultural differences might also limit the relevance of current results, as most reported studies were conducted in China. Whether social skills programmes or training can improve the social functioning of people with schizophrenia in different settings remains unclear and should be further investigated in a large multi-centre randomised controlled trial.

Ben Gray, Senior Peer Researcher, McPin Foundation.<http://mcpin.org/>

SUMMARY OF FINDINGS

Summary of findings for the main comparison. SOCIAL SKILLS versus STANDARD CARE for schizophrenia

SOCIAL SKILLS versus STANDARD CARE for schizophrenia

Patient or population: patients with schizophrenia

Settings:

Intervention: SOCIAL SKILLS versus STANDARD CARE

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Control	SOCIAL SKILLS versus STANDARD CARE				
Social functioning Various scales Follow-up: 8-52 weeks	See comment	See comment	Not estimable	585 (4 studies)	⊕⊕⊕⊕ very low ^{1,2,3,4}	The four RCTs that provided data for this comparison used different scales to measure social functioning and so data were not pooled for this comparison.
Relapse Follow-up: 6-12 months	351 per 1000	183 per 1000 (119 to 277)	RR 0.52 (0.34 to 0.79)	263 (2 studies)	⊕⊕⊕⊕ very low ^{4,6,7}	
Rehospitalisation Follow-up: 12 months	366 per 1000	194 per 1000 (110 to 340)	RR 0.53 (0.3 to 0.93)	143 (1 study)	⊕⊕⊕⊕ very low ^{4,8}	
Mental state: general symptoms (BPRS) Follow-up: 12 weeks		The mean mental state: general symptoms in the intervention groups was 4.01 lower (7.52 to 0.50 lower)		91 (1 study)	⊕⊕⊕⊕ very low ^{4,8}	
Global state: not clinically improved. CGI Follow-up: 6 months	529 per 1000	153 per 1000 (63 to 360)	RR 0.29 (0.12 to 0.68)	67 (1 study)	⊕⊕⊕⊕ very low ^{4,5}	

<p>General functioning MRSS Follow-up: 8 weeks</p>	<p>The mean General functioning: average endpoint score (various scales) - MRSS in the intervention groups was 10.6 lower (17.47 to 3.73 lower)</p>	<p>112 (1 study)</p>	<p>⊕○○○ very low 4,5</p>
<p>Quality of life GWB. Scale from: 10 to 40. Follow-up: 8 weeks</p>	<p>The mean Quality of life in the intervention groups was 7.6 lower (12.18 to 3.02 lower)</p>	<p>112 (1 study)</p>	<p>⊕○○○ very low 4,5</p>

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio;

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

1 Risk of bias: very serious. Only one of the trials had adequate sequence generation. Allocation concealment was unclear in all trials and none were blinded. Two trials addressed incomplete data adequately and three were free from selective reporting. It was unclear in all trials whether they were free from other biases.

2 Inconsistency: serious. See comment.

3 Imprecision: very serious. Data were not combined, but for each single study the 95% confidence intervals around the pooled effect estimate are very wide.

4 Publication bias: strongly suspected. Less than five studies provided data for this outcome.

5 Risk of bias: very serious. The RCT that provided data for this outcome did not have adequate sequence generation, allocation concealment and blinding. It was unclear whether there were other biases.

6 Risk of bias: very serious. Neither of the two RCTs were blinded, and it was unclear in both if there was adequate allocation concealment. Only one had adequate sequence generation and one addressed incomplete data adequately. It was unclear in both if they were free from other biases.

7 Inconsistency: serious. There was moderate heterogeneity for this outcome. This may be explained by differences in type of social skills training. [Ma 2003](#) included sessions on medication and symptom management as well as social skills, whereas in [Saren 2004](#) the focus was on interpersonal interaction.

8 Risk of bias: very serious. The RCT that provided data for this outcome had unclear allocation concealment and was not blinded. It was unclear if it was free from other biases.

Summary of findings 2. SOCIAL SKILLS versus DISCUSSION CONTROL for schizophrenia

SOCIAL SKILLS versus DISCUSSION CONTROL for schizophrenia

Patient or population: patients with schizophrenia

Settings:

Intervention: SOCIAL SKILLS versus DISCUSSION CONTROL

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Control	SOCIAL SKILLS versus DISCUSSION CONTROL

Relapse Follow-up: 6 months	111 per 1000	235 per 1000 (49 to 1000)	RR 2.12 (0.44 to 10.1)	35 (1 study)	⊕○○○ very low ^{2,3,4}	
Global state GAS Follow-up: 6 months		The mean Global state: average endpoint score in the intervention groups was 4.5 higher (1.2 lower to 10.2 higher)		63 (1 study)	⊕○○○ very low ^{2,3,5}	
Mental state: general symptoms Follow-up: 6 months		The mean mental state: general symptoms in the intervention groups was 0.22 higher (4.05 lower to 4.49 higher)		99 (2 studies)	⊕○○○ very low ^{1,3,4}	
Quality of life QLS Follow-up: 6 months		The mean Quality of life: average endpoint score in the intervention groups was 3.7 higher (6.47 lower to 13.87 higher)		63 (1 study)	⊕○○○ very low ^{2,3,5}	

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio;

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

- 1 Risk of bias: serious. Only one of the RCTs had adequate sequence generation and allocation concealment, neither were blinded nor addressed incomplete data adequately. Only one was free from selective reporting it was unclear if either was free from selective reporting.
- 2 Imprecision: serious. The 95% confidence intervals are very wide and include both significant benefit and harm of the intervention.
- 3 Publication bias: strongly suspected. Less than three studies provided data for this outcome.
- 4 Risk of bias: serious. The RCT that provided data for this outcome was not blinded. It was unclear whether incomplete data were adequately addressed and whether it was free from other biases.
- 5 Risk of bias: very serious. The RCT that provided data fro this outcome was not blinded, did not adequately address incomplete data and was not free from selective reporting. It was unclear if the sequence generation and allocation concealment was adequate and whether it was free from other biases.

BACKGROUND

Description of the condition

Schizophrenia can occur as a single episode of illness. By far the greater proportion of sufferers, however, have remission and relapses; for up to 41% of those who develop schizophrenia it becomes a chronic and often disabling illness (Prudo 1987). Antipsychotic medications are commonly used for management of symptoms. However, the conclusions reached by meta-analytical methods are that treatment with antipsychotic medication 'should be combined and coordinated with other interventions involving the patient's family, and social psychological and psychotherapeutic support' (MSPI 1997). These treatments are subsumed under the general term 'rehabilitation'.

Preceding the movement of care into the community, the rehabilitation process was mostly provided by the large psychiatric hospitals in which sufferers often spent many years (Wing 1961; Wing 1970). This pattern of care has now changed (Hume 1995). During the 1980s many psychiatric hospitals were closed, community-based services were developed, and psychiatric units in general hospitals were established. Currently, few chronically mentally ill people spend longer than a few weeks per year in hospital. The rest of their care takes place in the community. Up to 75% of people with chronic schizophrenia are maintained in the community in the United Kingdom - chronic in this case is defined as lasting more than 2.5 years (Davies 1990). Relative to other chronic illnesses, the personal and economic costs of schizophrenia are considerable (Knapp 1994). It is therefore important to offer rehabilitation treatments that are both clinically effective and cost-effective.

Description of the intervention

As a part of the rehabilitation package for people with schizophrenia, social skills programmes (SSP) aim to utilise behaviour therapy principles and techniques for teaching individuals to communicate their emotions and requests, so they are more likely to achieve their goals and meet their needs for relationships and roles required for independent living and social competence (Kopelowicz 2006).

SSP involves 'model learning' (role playing) which was introduced to improve general 'molecular' skills (eye contact, fluency of speech, gestures, etc) and 'molar' skills (managing negative affects, giving positive feedback, etc.) (Brenner 1994). A problem-solving model was later incorporated and rehabilitation topics that are particularly relevant for people with schizophrenia were introduced (Lieberman 1993). The application of these modules appears far more effective than control conditions, particularly in terms of generalisation of skills and social adjustment (Marder 1996; Wallace 1998).

How the intervention might work

Learning-based procedures used in SSP include identifying the problems and setting the goals in collaboration with the client. Through role play or behavioural rehearsal, participants demonstrate the required skills and positive or corrective feedback is given to them accordingly. By social modelling and behavioural practice, participants observe and repeat the skills until the communications reach a level of quality tantamount to success in the real-life situation. Homework assignments are then given to

motivate participants to implement these communications in real-life situations.

Why it is important to do this review

This review focuses on social skills programmes, which are some of the most established psychosocial treatments for schizophrenia (Lieberman 1986; Lieberman 1986a) but vary in use across the world. Essentially, social skills programmes are treatment strategies aimed at enhancing the social performance and reducing the distress and difficulty experienced by people with a diagnosis of schizophrenia. Few reviews exist (Kopelowicz 2006) and none are maintained.

OBJECTIVES

To investigate the effects of social skills training programmes, compared to standard care, for people with schizophrenia.

METHODS

Criteria for considering studies for this review

Types of studies

All relevant randomised controlled trials. If a trial had been described as 'double blind' but implied randomisation, we planned to include such trials in a sensitivity analysis. If their inclusion did not result in a substantive difference, they would have remained in the analyses. If their inclusion did result in statistically significant differences, we would not have added the data from these lower quality studies to the results of the better trials, but presented such data within a subcategory. We excluded quasi-randomised studies, such as those allocating by alternate days of the week. Where people were given additional treatments within a social skills trial, we only included data if the adjunct treatment was evenly distributed between groups and it was only the social skills programme that was randomised.

Types of participants

Adults, however defined, with schizophrenia or related disorders, including schizophreniform disorder, schizoaffective disorder and delusional disorder, again, by any means of diagnosis.

We were interested in making sure that information is as relevant to the current care of people with schizophrenia as possible so proposed to clearly highlight the current clinical state (acute, early post-acute, partial remission, remission) as well as the stage (prodromal, first episode, early illness, persistent) and as to whether the studies primarily focused on people with particular problems (for example, negative symptoms, treatment-resistant illnesses).

Types of interventions

1. Social skills training programmes

Defined as any structured psychosocial intervention, whether group or individual, aimed at enhancing the social performance and reducing the distress and difficulty in social situations. The key components are; i. a careful behavioural-based assessment of a range of social and interpersonal skills; ii. An importance placed on both verbal and non-verbal communication; as well as the individual's ability to; i. perceive and process relevant social cues; and ii. to respond to and provide appropriate social reinforcement.

This approach has the goal of building up individual behavioural elements into complex behaviours. The aim is to develop more effective social communication. There is considerable emphasis not just on clinic-based interventions (including modelling, role-play and social reinforcement) but also the setting of homework tasks and the applicability of the treatment.

Programmes where social skills training are a component part of a more complex rehabilitation intervention were excluded, as were token economies, life skills programmes and other similar milieu-based interventions which may include an element of social skills training in a broader programme.

Programmes of five sessions and less are considered as 'brief', and six or more as 'long'. Place of residence is defined as either 'hospital' or 'community' for the purposes of this review. For example, if people are in hospital at time of attending a day-hospital based programme they are considered to be receiving 'hospital-based' care. If, on the other hand, they attend the day hospital from home then they are considered to be receiving 'community-based' care. Trained staff are those personnel who hold a professionally recognised health care qualification.

2. The control treatment

Defined as standard care without a dedicated programme of the type described above.

Types of outcome measures

If possible we divided outcomes into short term (less than six months), medium term (seven to 12 months) and long term (over one year).

Primary outcomes

1. Social functioning

No clinically important change in general social functioning

2. Relapse

3. Mental state

No clinically important change in general mental state

Secondary outcomes

1. Social functioning

- 1.2 Average endpoint general social skills score
- 1.3 Average change in general social skills scores
- 1.4 No clinically important change in specific social skills
- 1.5 Average endpoint specific social skills score
- 1.6 Average change in specific social skills scores

2. Global state

- 2.1 No clinically important change in global state (as defined by individual studies)
- 2.2 Average endpoint global state score
- 2.3 Average change in global state scores

3. Service outcomes

- 3.1 Hospitalisation
- 3.2 Time to hospitalisation

4. Mental state (with particular reference to the positive and negative symptoms of schizophrenia)

- 4.1 Average endpoint general mental state score
- 4.2 Average change in general mental state scores
- 4.3 No clinically important change in specific symptoms (positive symptoms of schizophrenia, negative symptoms of schizophrenia, depression, mania)
- 4.4 Average endpoint specific symptom score
- 4.5 Average change in specific symptom scores

5. General functioning

- 5.1 No clinically important change in general functioning
- 5.2 Average endpoint general functioning score
- 5.3 Average change in general functioning scores
- 5.4 Employed

6. Behaviour

- 6.1 No clinically important change in general behaviour
- 6.2 Average endpoint general behaviour score
- 6.3 Average change in general behaviour scores
- 6.4 No clinically important change in specific aspects of behaviour
- 6.5 Average endpoint specific aspects of behaviour
- 6.6 Average change in specific aspects of behaviour

7. Adverse effects - general and specific

- 7.1 Clinically important general adverse effects
- 7.2 Average endpoint general adverse effect score
- 7.3 Average change in general adverse effect scores
- 7.4 Clinically important specific adverse effects
- 7.5 Average endpoint specific adverse effects
- 7.6 Average change in specific adverse effects
- 7.7 Death - suicide and natural causes

8. Engagement with services

9. Satisfaction with treatment

- 9.1 Leaving the studies early
- 9.2 Recipient of care not satisfied with treatment
- 9.3 Recipient of care average satisfaction score
- 9.4 Recipient of care average change in satisfaction scores
- 9.5 Carer not satisfied with treatment
- 9.6 Carer average satisfaction score
- 9.7 Carer average change in satisfaction scores

10. Quality of life

- 10.1 No clinically important change in quality of life
- 10.2 Average endpoint quality of life score
- 10.3 Average change in quality of life scores
- 10.4 No clinically important change in specific aspects of quality of life
- 10.5 Average endpoint specific aspects of quality of life
- 10.6 Average change in specific aspects of quality of life

11. Economic outcomes

- 11.1 Direct costs
- 11.2 Indirect costs

12. 'Summary of findings' table

We used the GRADE approach to interpret findings ([Schünemann 2008](#)) and used GRADE profiler ([GRADE 2004](#)) to import data from RevMan 5 ([Review Manager 2008](#)) to create 'Summary

of findings' tables. These tables provide outcome-specific information concerning the overall quality of evidence from each included study in the comparison, the magnitude of effect of the interventions examined, and the sum of available data on all outcomes was rated as important to patient-care and decision making. We selected the following main outcomes for inclusion in the [Summary of findings for the main comparison](#) and [Summary of findings 2](#):

1. Social functioning - Clinically significant response on social skills - as defined by each of the studies

2. Clinical response

- Clinically significant response in global state - as defined by each of the studies
- Healthy days

3. Service utilisation outcomes

- Hospital admission
- Days in hospital

4. Adverse effect - Any important adverse event

5. Quality of life - Improved to an important extent

Search methods for identification of studies

Electronic searches

1. Cochrane Schizophrenia Group's Trials Register

The Trials Search Co-ordinator (TSC) searched the Cochrane Schizophrenia Group's Register of Trials (November 2006, December 21, 2011) using the following search strategy:

```
((social* OR personal*) AND (skill* OR program* OR training*))
in Title, Abstract and Indexing Terms Fields of REFERENCE
and (social skill* OR social support* OR sociotherapy* OR
socioenvironmental* OR interpersonal*) in Intervention Field of
STUDY
```

The Cochrane Schizophrenia Group's Register of Trials is compiled by systematic searches of major resources (including AMED, BIOSIS, CINAHL, EMBASE, MEDLINE, PsycINFO, PubMed, and registries of clinical trials) and their monthly updates, handsearches, grey literature, and conference proceedings (see [Group Module](#)). There is no language, date, document type, or publication status limitations for inclusion of records into the register.

Searching other resources

1. Reference searching

We inspected references of all identified studies for further relevant studies.

2. Personal contact

We contacted the first author of each included study for information regarding unpublished trials.

Data collection and analysis

Selection of studies

Review authors Muhammad Okba Al Marhi (MOA), (Mohamad Alsabbag (MA) and Muhammad Jawoosh (MJ) independently inspected citations from the November 2006 search and identified

relevant abstracts. A random 20% sample was independently re-inspected by Muhammad Qutayba Almerie (MQA) to ensure reliability. Where disputes arose, the full report was acquired for more detailed scrutiny. Full reports of the abstracts meeting the review criteria were obtained and inspected by MOA and MS. Again, a random 20% of reports were re-inspected by MQA in order to ensure reliable selection.

For the June 2010 search, review authors Nicola Maaya (NM) and Hanna Bergman (HB) independently inspected citations, and identified and inspected relevant abstracts. A random 20% sample was independently re-inspected by Karla Soares Weiser (KSW) to ensure reliability. Full reports were obtained and inspected by NM and HB and a random 20% of reports were re-inspected by KSW. Where it was not possible to resolve disagreement by discussion, we attempted to contact the authors of the study for clarification.

Data extraction and management

1. Extraction

For the November 2006 search, review authors MOA, MA and MJ extracted data from included studies. Where further clarification was needed, the authors' of trials were contacted to provide missing data. Any disagreements were discussed and the decisions documented.

For the June 2012 search, review author NM extracted data from all included studies. In addition, to ensure reliability, HB independently extracted data from a random sample of these studies, comprising 10% of the total. Again, any disagreement was discussed, decisions documented and, if necessary, authors of studies were contacted for clarification. With remaining problems KSW helped clarify issues and these final decisions were documented. Data presented only in graphs and figures were extracted whenever possible, but included only if two review authors independently had the same result. Attempts were made to contact authors through an open-ended request in order to obtain missing information or for clarification whenever necessary. If studies were multi-centre, where possible, we extracted data relevant to each component centre separately. The data from the Chinese papers were extracted by a speaker of that language (JX); but these Chinese language studies were not re-inspected by review authors.

2. Management

2.1 Forms

Data were extracted onto standard, simple forms.

2.2 Scale-derived data

We included continuous data from rating scales only if:

- the psychometric properties of the measuring instrument have been described in a peer-reviewed journal ([Marshall 2000](#)); and
- the measuring instrument had not been written or modified by one of the trialists for that particular trial.

Ideally, the measuring instrument should either be i. a self-report or ii. completed by an independent rater or relative (not the therapist). We realise that this is not often reported clearly, in [Description of studies](#) we have noted if this is the case or not.

2.3 Endpoint versus change data

There are advantages of both endpoint and change data. Change data can remove a component of between-person variability from the analysis. On the other hand, calculation of change needs two assessments (baseline and endpoint), which can be difficult in unstable and difficult to measure conditions such as schizophrenia. We decided primarily to use endpoint data, and only use change data if the former were not available. Endpoint and change data were combined in the analysis as we used mean differences (MD) rather than standardised mean differences (SMD) throughout (Higgins 2009, Chapter 9.4.5.2).

2.4 Skewed data

Continuous data on clinical and social outcomes are often not normally distributed. To avoid the pitfall of applying parametric tests to non-parametric data, we aimed to apply the following standards to all data before inclusion: a) standard deviations (SDs) and means were reported in the paper or obtainable from the authors; b) when a scale starts from the finite number zero, the SD, when multiplied by two, is less than the mean (as otherwise the mean is unlikely to be an appropriate measure of the centre of the distribution, (Altman 1996); c) if a scale started from a positive value (such as the Positive and Negative Syndrome Scale (PANSS, Kay 1986), which can have values from 30 to 210), the calculation described above was modified to take the scale starting point into account. In these cases skew is present if $2SD > (S - S_{min})$, where S is the mean score and S_{min} is the minimum score. Endpoint scores on scales often have a finite start and end point and these rules can be applied; however, we did not find any skewed endpoint data. When continuous data are presented on a scale that includes a possibility of negative values (such as change data), it is difficult to tell whether data are skewed or not. Skewed data from studies of less than 200 participants would have been entered as other data within the data and analyses section rather than into a statistical analysis. Skewed data pose less of a problem when looking at means if the sample size is large and would have been entered into statistical syntheses.

2.5 Common measure

To facilitate comparison between trials, if necessary we converted variables that can be reported in different metrics, such as days in hospital (mean days per year, per week or per month) to a common metric (e.g. mean days per month).

2.6 Conversion of continuous to binary

Where possible, efforts were made to convert outcome measures to dichotomous data. This was done by identifying cut-off points on rating scales and dividing participants accordingly into 'clinically improved' or 'not clinically improved'. It is generally assumed that if there is a 50% reduction in a scale-derived score such as the Brief Psychiatric Rating Scale (BPRS, Overall 1962) or the PANSS (Kay 1986), this can be considered as a clinically significant response (Leucht 2005; Leucht 2005a). If data based on these thresholds were not available, we used the primary cut-off presented by the original authors.

2.7 Direction of graphs

Where possible, we entered data in such a way that the area to the left of the line of no effect indicates a favourable outcome for social skills training.

Assessment of risk of bias in included studies

Again review authors NM and HB worked independently to assess risk of bias by using criteria described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2009) to assess trial quality. This set of criteria is based on evidence of associations between overestimate of effect and high risk of bias of the article such as sequence generation, allocation concealment, blinding, incomplete outcome data and selective reporting.

If the raters disagreed, the final rating was made by consensus, with the involvement of another member of the review group. Where inadequate details of randomisation and other characteristics of trials were provided, we contacted authors of the studies in order to obtain further information. Non-concurrence in quality assessment was reported, but if disputes arose as to which category a trial is to be allocated, again, resolution was made by discussion.

The level of risk of bias is noted in both the text of the review and in the [Summary of findings for the main comparison](#) and [Summary of findings 2](#).

Measures of treatment effect

1. Binary data

For binary outcomes we calculated a standard estimation of the risk ratio (RR) and its 95% confidence interval (CI). It has been shown that RR is more intuitive (Boissel 1999) than odds ratios and that odds ratios tend to be interpreted as RR by clinicians (Deeks 2000). For statistically significant results we had planned to calculate the number needed to treat to provide benefit /to induce harm statistic (NNTB/H), and its 95% confidence interval (CI) using Visual Rx (<http://www.nntonline.net/>) taking account of the event rate in the control group. This, however, has been superseded by [Summary of findings for the main comparison](#) and [Summary of findings 2](#), and the calculations therein.

2. Continuous data

For continuous outcomes we estimated the mean difference (MD) between groups. We preferred not to calculate effect size measures (standardised mean difference (SMD)). However, if scales of very considerable similarity were used, we presumed there was a small difference in measurement, and we calculated effect size and transformed the effect back to the units of one or more of the specific instruments.

Unit of analysis issues

1. Cluster trials

Studies increasingly employ 'cluster randomisation' (such as randomisation by clinician or practice) but analysis and pooling of clustered data poses problems. Firstly, authors often fail to account for intra-class correlation in clustered studies, leading to a 'unit of analysis' error (Divine 1992) whereby P values are spuriously low, confidence intervals unduly narrow and statistical significance overestimated. This causes type I errors (Bland 1997; Gulliford 1999).

We did not have any data from cluster trials. Had there been data from these types of trials, and where clustering was not accounted for in primary studies, we would have presented data in a table, with a (*) symbol to indicate the presence of a probable unit of analysis error and contacted first authors of studies to obtain

intra-class correlation coefficients (ICCs) for their clustered data and adjusted for this by using accepted methods (Gulliford 1999). If clustering had been incorporated into the analysis of primary studies, we would have presented these data as if from a non-cluster randomised study, but adjusted the data for the clustering effect.

We have sought statistical advice and have been advised that the binary data as presented in a report should be divided by a 'design effect'. This is calculated using the mean number of participants per cluster (m) and the ICC [Design effect = $1 + (m-1) \times \text{ICC}$] (Donner 2002). If the ICC had not been reported, it would have been assumed to be 0.1 (Ukoumunne 1999).

If cluster studies have been appropriately analysed taking into account ICCs and relevant data documented in the report, synthesis with other studies would have been possible using the generic inverse variance technique.

2. Cross-over trials

A major concern of cross-over trials is the carry-over effect. It occurs if an effect (e.g. pharmacological, physiological or psychological) of the treatment in the first phase is carried over to the second phase. As a consequence, on entry to the second phase the participants can differ systematically from their initial state despite a wash-out phase. For the same reason cross-over trials are not appropriate if the condition of interest is unstable (Elbourne 2002). As both effects are very likely in severe mental illness, we would have only used data of the first phase of cross-over studies.

3. Studies with multiple treatment groups

Where a study involved more than two treatment arms, if relevant, the additional treatment arms were presented in comparisons. If data were binary these were simply added and combined within the two-by-two table. If data were continuous we combined data following the formula in section 7.7.3.8 (Combining groups) of the Cochrane Handbook for Systematic Reviews of Interventions. Where the additional treatment arms were not relevant, these data were not reproduced.

Dealing with missing data

1. Overall loss of credibility

At some degree of loss of follow-up, data must lose credibility (Xia 2009). We chose that, for any particular outcome, should more than 50% of data be unaccounted for, we would not reproduce these data or use them within analyses. If, however, more than 50% of those in one arm of a study were lost, but the total loss was less than 50%, we addressed this within the 'Summary of findings' table/s by down-rating quality. Finally, we also downgraded quality within the 'Summary of findings' table/s where loss was 25% to 50% in total.

2. Binary

In the case where attrition for a binary outcome was between 0% and 50%, we presented data for the total number of participants randomised for studies that used an intention-to-treat (ITT) analysis; where studies did not use an ITT analysis, we presented completer-only data.

3. Continuous

3.1 Attrition

In the case where attrition for a continuous outcome was between 0% and 50% and completer-only data were reported, we reproduced these.

3.2 Standard deviations

If standard deviations (SDs) were not reported, we first tried to obtain the missing values from the authors. If not available, where there are missing measures of variance for continuous data, but an exact standard error (SE) and confidence intervals available for group means, and either P value or T value available for differences in mean, we can calculate them according to the rules described in the *Handbook* (Higgins 2011): When only the SE is reported, SDs are calculated by the formula $\text{SD} = \text{SE} \times \text{square root}(n)$. Chapters 7.7.3 and 16.1.3 of the *Handbook* (Higgins 2011) present detailed formulae for estimating SDs from P values, T or F values, confidence intervals, ranges or other statistics. If these formulae do not apply, we can calculate the SDs according to a validated imputation method which is based on the SDs of the other included studies (Furukawa 2006). Although some of these imputation strategies can introduce error, the alternative would be to exclude a given study's outcome and thus to lose information. We planned to examine the validity of the imputations in a sensitivity analysis excluding imputed values.

3.3 Last observation carried forward

We anticipated that in some studies the method of last observation carried forward (LOCF) would be employed within the study report. As with all methods of imputation to deal with missing data, LOCF introduces uncertainty about the reliability of the results (Leucht 2007). Therefore, if LOCF data had been used in the trial, if less than 50% of the data had been assumed, we planned to reproduce these data and indicate that they were the product of LOCF assumptions.

Assessment of heterogeneity

1. Clinical heterogeneity

We considered all included studies initially, without seeing comparison data, to judge clinical heterogeneity. We simply inspected all studies for clearly outlying people or situations which we had not predicted would arise. When such situations or participant groups arose, these were fully discussed.

2. Methodological heterogeneity

We considered all included studies initially, without seeing comparison data, to judge methodological heterogeneity. We simply inspected all studies for clearly outlying methods which we had not predicted would arise. When such methodological outliers arose, these were fully discussed.

3. Statistical heterogeneity

3.1 Visual inspection

We visually inspected graphs to investigate the possibility of statistical heterogeneity.

3.2 Employing the I^2 statistic

Heterogeneity between studies was investigated by considering the I^2 method alongside the Chi^2 'P' value. The I^2 provides an

estimate of the percentage of inconsistency thought to be due to chance (Higgins 2003). The importance of the observed value of I^2 depends on i. magnitude and direction of effects and ii. strength of evidence for heterogeneity (e.g. 'P' value from χ^2 test, or a confidence interval for I^2). an I^2 estimate greater than or equal to around 50% accompanied by a statistically significant χ^2 statistic was interpreted as evidence of substantial levels of heterogeneity (Section 9.5.2 - Higgins 2009). When substantial levels of heterogeneity were found in the primary outcome, we explored reasons for heterogeneity ([Subgroup analysis and investigation of heterogeneity](#)).

Assessment of reporting biases

Reporting biases arise when the dissemination of research findings is influenced by the nature and direction of results (Egger 1997). These are described in Section 10 of the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2009). We are aware that funnel plots may be useful in investigating reporting biases but are of limited power to detect small-study effects. As we did not have more than 10 studies providing data for outcomes, we did not need to use funnel plots. If future versions of this review do require funnel plots, we will seek statistical advice in their interpretation.

Data synthesis

We understand that there is no closed argument for preference for use of fixed-effect or random-effects models. The random-effects method incorporates an assumption that the different studies are estimating different, yet related, intervention effects. This often seems to be true to us and the random-effects model takes into account differences between studies even if there is no statistically significant heterogeneity. There is, however, a disadvantage to the random-effects model. It puts added weight onto small studies which often are the most biased ones. Depending on the direction of effect these studies can either inflate or deflate the effect size. Therefore, we chose the fixed-effect model for all analyses. The reader is, however, able to choose to inspect the data using the random-effects model.

Subgroup analysis and investigation of heterogeneity

1. Subgroup analyses - only primary outcomes

We planned to perform subgroup analyses to assess the impact of the following possible sources of heterogeneity for any of the social

skills training programmes: brief versus long programmes, clinical state, stage or problem. However, there were not enough data to undertake these analyses.

2. Investigation of heterogeneity

If inconsistency was high, this was reported. First, we investigated whether data had been entered correctly. Second, if data were correct, the graph was visually inspected and outlying studies were successively removed to see if heterogeneity was restored. For this review we decided that should this occur with data contributing to the summary finding of no more than around 10% of the total weighting, data were presented. If not, data were not pooled and issues discussed. We know of no supporting research for this 10% cut-off but are investigating use of [prediction intervals](#) as an alternative to this unsatisfactory state.

When unanticipated clinical or methodological heterogeneity was obvious we simply stated hypotheses regarding these for future reviews or versions of this review. We did not anticipate undertaking analyses relating to these.

Sensitivity analysis

We also planned to conduct sensitivity analyses for the main outcomes for trials with the implication of randomisation, assumptions made for lost binary data, trials with high risk of bias, imputed values and fixed-effect versus random-effects models. However, all of the outcomes had less than 10 trials that reported data.

RESULTS

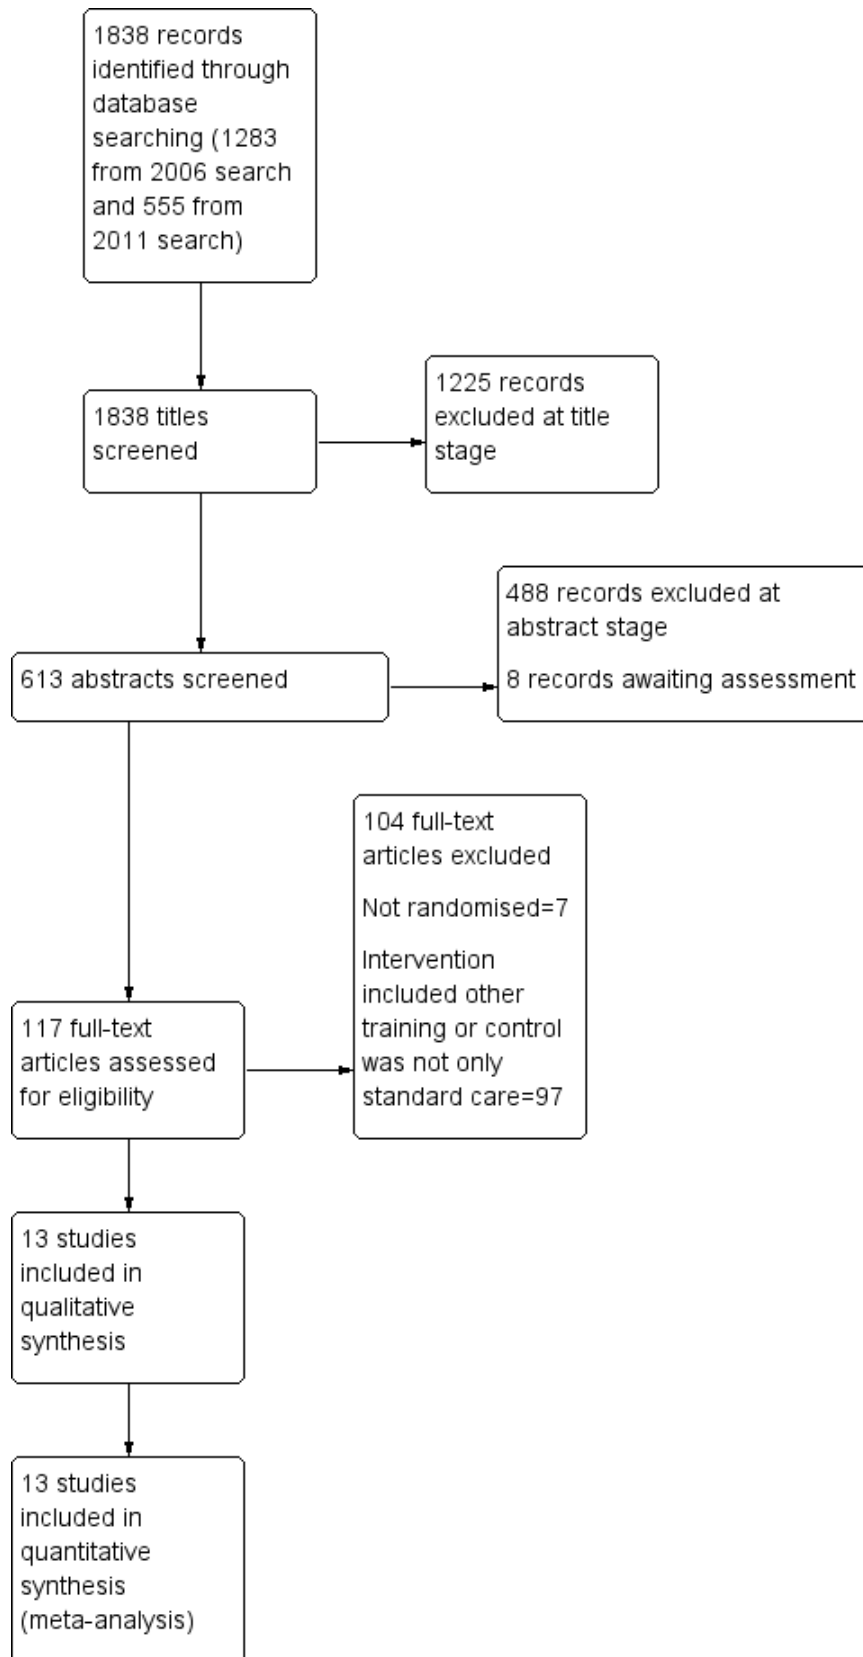

Description of studies

Please see [Characteristics of included studies](#), [Characteristics of excluded studies](#), and [Characteristics of ongoing studies](#).

Results of the search

The November 2006 search identified 1283 references and a search in December 2011 identified a further 555 references. Agreement about which reports may have been randomised was 100%. See also [Figure 1](#).

Figure 1. Study flow diagram.

Included studies

The current review includes 17 reports describing 13 studies involving 975 participants.

1. Methods

All studies were stated to be randomised. [Dobson 1995](#), [Hayes 1995](#), [Huang 2005](#) and [Ng 2006](#) all stated that the assessors were blinded to the participant's treatment allocation; it was unclear in [Potelunas 1982](#) whether all raters were blinded. In [Tsang 2001](#), the raters were blinded, but it was unclear whether the participants were. [Chien 2003](#), [Cui 2004](#), [Kopelowicz 1998](#), [Lu 2004](#), [Ma 2003](#), [Mayang 1990](#) and [Saren 2004](#) did not report that blinding was attempted. For further details please see sections below on Allocation and Blinding in [Risk of bias in included studies](#).

2. Duration

Five trials were undertaken for no longer than three months: [Chien 2003](#) four weeks; [Cui 2004](#) 12 weeks; [Kopelowicz 1998](#) three months, [Lu 2004](#) eight weeks; [Mayang 1990](#) four sessions with a four-week follow-up (it did not report the frequency of the sessions); and [Potelunas 1982](#) six weeks. Seven trials were longer than three months: [Dobson 1995](#) involved nine weeks of training with three months of follow-up for all participants, although the follow-up period lasted up to one year for the social skills group; [Hayes 1995](#) lasted for 18 weeks, but had an additional period of six months where the patients received decreasing frequency of training; the duration of [Huang 2005](#) was six months; [Ma 2003](#) had eight weeks of intervention and 26 weeks follow-up; [Ng 2006](#) was eight weeks with a six-month follow-up; [Saren 2004](#) was 10 weeks with 12 months follow-up; and [Tsang 2001](#) was 10 weeks with a three-month follow-up period.

3. Participants

All participants were people with a chronic mental illness, mostly with schizophrenia and schizoaffective disorders. One of the studies randomised only men ([Cui 2004](#)) and two studies randomised only women ([Mayang 1990](#) and [Potelunas 1982](#)); the others included both sexes. Data on mean age were available from seven trials. The average age was between 33 and 48 years. [Ma 2003](#) did not report any demographic information about the participants.

All studies included patients with schizophrenia and schizoaffective psychoses. Three studies used the Diagnostic and Statistical Manual of Mental Disorders, fourth edition (DSM-IV) criteria, one used the third edition (DSM-III), two used the third version of the Chinese Classification of Mental Disorders (CCMD-III), three used the second version (CCMD-II), and four studies did not report the diagnostic criteria.

4. Setting

Nine studies used a hospital setting ([Chien 2003](#); [Cui 2004](#); [Dobson 1995](#); [Huang 2005](#); [Kopelowicz 1998](#); [Lu 2004](#); [Mayang 1990](#); [Ng 2006](#); [Tsang 2001](#)); in four studies ([Hayes 1995](#); [Ma 2003](#); [Potelunas 1982](#); [Saren 2004](#)) the participants were outpatients. Three of the included trials were conducted in USA, five in China, one in Taiwan, two in Hong Kong, one in Canada and one in Australia.

5. Interventions

5.1 Experimental treatment

In [Chien 2003](#), the social skills training focused on conversation and assertiveness skills. Participants attended a one-hour session twice a week for four weeks. In [Dobson 1995](#), the focus was on communication and assertiveness for four one-hour sessions per week over a nine-week period.

The social skills training programme used in [Cui 2004](#) was the UCLA Social and independent Living Skills programme, which includes: i) general social interpersonal skills training, using video demonstration, role play and discussion; ii) educating patients of the purpose and function of antipsychotic medication; iii) medication management; iv) how to recognise a drug adverse effect; v) opportunity to discuss issues relating to drug therapy. The training lasted 90 to 120 minutes per session, and there were three sessions per week for 12 weeks.

[Ma 2003](#) also used the UCLA Social and independent Living Skills programme as the social skills training (90 to 120 minutes per session, one session a week for eight weeks) and [Kopelowicz 1998](#) used an adapted version, which was translated into Spanish (participants attended three months of training four days a week, although the length of each session was not reported).

The social skills training in [Hayes 1995](#) emphasised interpersonal skills, social problem solving, positive time use skills, generalisation enhancement techniques, and used instructions, modelling, behaviour rehearsal, feedback, and structured homework. The training consisted of 36 sessions of 75 minutes over 18 weeks, followed by a six-month period in which patients received decreasing frequency of training.

The social skills training in [Huang 2005](#) was delivered in groups of eight to nine people, and each session was two hours per weeks for 24 weeks. The social skills group also received routine drug therapy, recreational activities and work in the wards, which was the standard care for all patients.

In [Lu 2004](#), the training included targeted problem solving training to improve patients' attention and planning skills with the aim of gradually improving patient's social function. Training was 60 minutes per session and two sessions per week for eight weeks.

In [Mayang 1990](#) and [Ng 2006](#), the social skills training focused on problem solving skills (receiving skills, processing skills and sending skills) and involved instructions, modelling, feedback, role playing, social reinforcement. The training consisted of four sessions of 45 minutes of training in [Mayang 1990](#) and 30 to 32 hours of treatment within eight weeks in [Ng 2006](#).

In [Potelunas 1982](#), the social skills training consisted of four one-hour sessions over four weeks of videotaped presentation of eight problem situations, videotaped modelling, behaviour rehearsal, coaching and feedback, which occurred within a work adjustment programme.

In [Saren 2004](#), the training focused on making eye contact, facial expressions, tone of voice, language fluency, posture and gestures and overall enthusiasm. Training was provided in groups of between 10 to 12 people, for 60 to 90 minutes per session, three sessions per week for 10 weeks. In [Tsang 2001](#), social skills training

also consisted of basic social skills (facial expression, gestures etc.) and basic social survival skills (personal appearance, tidiness), but also included core work-related skills. In this study there were two intervention groups: one received social skills training plus follow-up support, which consisted of contact with group members and the trainer; the other group received only the social skills training and no follow-up support. The training consisted of 10 weekly group sessions lasting one and a half to two hours, with approximately six to eight people in each group.

5.2 Control treatment

In five of the studies (Chien 2003; Cui 2004; Huang 2005; Kopelowicz 1998; Tsang 2001), the comparison treatment was standard psychiatric care. However, three of the studies (Dobson 1995; Hayes 1995; Ng 2006) used a discussion group as the control treatment to control for any confounding effects that arise from interacting with the therapist during social skills training. Dobson 1995 used a social milieu, which consisted of structured activities including supportive discussion groups, exercise groups and activity groups, and occurred at same time of day and same length of time as social skills training group. Hayes 1995 used a discussion group condition, which focused on interpersonal relations and purposeful use of time using open ended questions, paraphrasing, reflecting, and summarising the participants' comments to promote self-disclosure. In Ng 2006, the control treatment was supportive group discussion with topics that included practical tips on money management and information on application for social security allowances, with special attention paid to avoid discussions on interpersonal skills issues and use of behavioural techniques. Two studies (Mayang 1990 and Potelunas 1982) had both standard care and a discussion group as their control treatments. In Mayang 1990, the interaction group condition consisted of non-treatment interaction with trainers, and in Potelunas 1982, the discussion control was four one-hour sessions over four weeks of videotaped presentation and discussion of eight problem situations.

7. Outcomes scales

7.1 Social functioning

i) Disabilities Assessment Schedule - DAS (WHO 1988)

This scale covers six domains: cognition – understanding and communicating; mobility; self-care – hygiene, dressing, eating and staying alone; interacting with other people; life activities – domestic responsibilities, leisure, work and school; participation – joining in community activities. Higher scores indicate a worse outcome. Ma 2003 reported data from this scale.

ii) Social Disability Schedule - SDSS (WHO 1988)

The SDSS is a Chinese simplified version of the World Health Organization's Disability Assessment Schedule and assesses 10 different aspects of social functioning (WHO 1988). Higher scores indicate a worse outcome. Lu 2004 and Saren 2004 reported data from this scale.

iii) Social avoidance and disability scale - SAD (Watson 1969)

The Social Avoidance and Distress Scale (SAD) is a 28-item, self-rated scale used to measure various aspects of social anxiety including distress, discomfort, fear, anxiety, and the avoidance of social situations. Higher scores indicate a worse outcome. Saren 2004 reported data from this scale.

iv) Scale of Social Skills for Psychiatric Inpatients - SSPI (Guo 1995)

This scale is a Chinese rating scale, commonly used for assessing response to antipsychotic treatment. Higher scores indicate a worse outcome. Huang 2005 reported data from this scale.

v) Social Situations questionnaire - SSQ (Bryant 1974)

Measures self-perception of social difficulty; participants rate their anxiety and avoidance of 30 different social situations from zero "no difficulty" to four "avoidance if possible". Higher scores indicate a worse outcome. It is not clear whether this is a validated scale. Hayes 1995 reported data from this scale.

vi) Social Behaviour Schedule - SBS (Wykes 1986)

The scale covers 21 behaviour areas such as destructive behaviours, personal appearance and hygiene, measured on a five-point Likert scale from zero (no problem or acceptable behaviour) to four (serious problem). Higher scores indicate a worse outcome. Hayes 1995 reported data from this scale.

vii) Social functioning scale - SFS (Birchwood 1990)

This scale is an 81-item self-administered questionnaire covering several behaviour areas: employment, social withdrawal, pro-social activities, recreation, interpersonal functioning, perceived independence, competence and perceived independence performance. Higher scores indicate a better outcome. Ng 2006 reported data from this scale.

viii) Conversation with a stranger task - SCON (Wallace 1985)

This assesses the participants' skill in initiating a conversation in an unstructured five-minute interaction with a stranger. It is scored on a rating scale from one "skill not evident" to five "very high level of skill". Coding of the SCON used the system described by Bellack 1990. It is unclear whether the SCON is a validated scale. Hayes 1995 reported data from this scale.

7.2 Mental state

i) Scale for the Assessment of Negative Symptoms - SANS (Andreasen 1983)

This scale allows a global rating of the following negative symptoms: alogia (impoverished thinking), affective blunting, avolition-apathy, anhedonia-asociality, and attention impairment. Assessments are made on a six-point scale from zero (not at all) to five (severe). Higher scores indicate more symptoms. Hayes 1995 and Ng 2006 reported data from this scale.

ii) Scale for the Assessment of Positive Symptoms – SAPS (Andreasen 1983).

This is a six-point scale providing a global rating of positive symptoms such as delusions, hallucinations and disordered thinking. Higher scores indicate more symptoms. Ma 2003 reported data from this scale.

iii) Brief Psychiatric Rating Scale - BPRS (Overall 1962)

This is used to assess the severity of abnormal mental state. The original scale has 16 items, but a revised 18-item scale is commonly used. Each item is defined on a seven-point scale varying from 'not present' to 'extremely severe', scoring from zero to six or one to seven. Scores can range from zero to 126, with high scores indicating more severe symptoms. Cui 2004, Hayes 1995 and Ng 2006 reported data from this scale.

7.3 General Functioning

i) Morningside Rehabilitation Status Scale - MRSS (Affleck 1984)

In this scale four individual areas are rated on an 8-point scale: dependency, occupation and leisure activity, social isolation, and current symptoms. Higher scores indicate a worse outcome. [Lu 2004](#) reported data from this scale.

7.4 Global state

i) Global Assessment Scale - GAS ([Endicott 1976](#))

This is an observer-rated scale for evaluating the overall functioning of a patient during a specified time period on a continuum from psychological or psychiatric sickness to health. Score ranges from zero to 100, where higher score indicates a better outcome. [Hayes 1995](#) reported data from this scale.

ii) Clinical Global Impression Scale - CGI ([Guy 1976](#))

This is used to assess both severity of illness and clinical improvement, by comparing the conditions of the person standardised against other people with the same diagnosis. A seven-point scoring system is usually used with low scores showing decreased severity and/or overall improvement. [Huang 2005](#) reported data from this scale.

7.5 Quality of Life

i) Quality of Life Scale - QLS ([Heinrich 1984](#))

This six-point quality of life scale has been designed as an outcome instrument for schizophrenic deficit syndrome as well as to measure impaired functioning in studies of chronic schizophrenia, to assess the deficit syndrome's impact on the patient's life. There are seven severity steps (zero to six, six being adequately functioning and zero being deficient). The time frame is one month. Four item categories have been identified by factor analysis 1) interpersonal relationships (seven items), 2) instrumental role (four items), 3) intrapsychic function (seven items) and 4) commonplace objects and activities. [Hayes 1995](#) reported data from this scale.

ii) General Well-Being Scale - GWB ([Dupuy 1977](#))

This is a self-administered questionnaire consisting of 18 items covering six dimensions of anxiety, depression, general health, positive well-being, self-control and vitality. There is a total score running from zero to 110, higher scores indicate less distress. [Lu 2004](#) reported data from this scale.

iii) Rosenberg Self-esteem scale - SES ([Rosenberg 1965](#))

The Rosenberg Self-Esteem Scale is a 10-item self-report measure of global self-esteem. It consists of 10 statements related to overall feelings of self-worth or self-acceptance. The items are answered on a four-point scale ranging from strongly agree to strongly disagree. The SES has also been administered as an interview. Scores range from 10 to 40, with higher scores indicating higher self-esteem. [Lu 2004](#) reported data from this scale.

Excluded studies

We excluded 104 studies. Of these, seven studies were not randomised. The other 97 studies were randomised but either the experimental groups were allocated to a programme that had some elements of social skills but also incorporated other training interventions, for example life skills and cognitive behavioural therapies, or the control group was not only standard care, but for example, holistic therapy. We did, however, include studies that used a discussion group as an attention control.

Awaiting assessment

Eight studies are awaiting assessment.

Ongoing studies

We found eight ongoing studies, three have social skills training programmes as the intervention ([NCT00338975 2006](#), [NCT00791882 2008](#), [NCT00183625 2005](#)), two include health management training with the social skills training ([NCT00069433 2003](#), [Pratt 2008](#)), one has cognitive behavioural social skills training as the intervention ([NCT00237796 2005](#)), another social cognition and interaction training ([NCT00601224 2008](#)) and one attention shaping procedures ([NCT00391677 2006](#)).

Risk of bias in included studies

We prepared a 'Risk of bias' assessment for each trial. Our judgments regarding the overall risk of bias in individual studies is illustrated in [Figure 2](#) and [Figure 3](#). Overall, we felt the risk of bias in the included studies to be high.

Figure 2. Risk of bias Summary for included studies

Figure 3. Risk of bias Summary for included studies

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding (performance bias and detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

Allocation

All studies were stated to be randomly assigned. However, only three of the studies described how allocation to intervention was undertaken: Cui 2004, Ng 2006 and Saren 2004 each used a random numbers table. Only Ng 2006 described the allocation concealment; it was unclear in the remaining studies.

Blinding

Only Tsang 2001 was stated to be double blind, although it was unclear if participants in the control group were blinded. In five of the studies the assessors were blinded (Dobson 1995, Hayes 1995, Huang 2005, Ng 2006 and Potelunas 1982), although in Potelunas 1982 it was unclear whether all the raters were blinded.

Incomplete outcome data

Two studies did not have any incomplete data (Lu 2004 and Ma 2003), seven studies did not address incomplete outcome data adequately and it was unclear in four of the studies (Mayang 1990, Potelunas 1982, Ng 2006 and Tsang 2001).

Selective reporting

Four of the studies were free from selective reporting (Huang 2005; Ma 2003; Ng 2006 and Saren 2004), the remaining nine studies were rated as high risk of bias for selective reporting.

Other potential sources of bias

It was unclear in all of the trials except Dobson 1995 whether they were free from other biases. In Dobson 1995 there was bias from allowing the control group to begin social skills training before the end of the follow-up period and we downgraded this trial to high risk for other potential sources of bias.

Effects of interventions

See: [Summary of findings for the main comparison SOCIAL SKILLS versus STANDARD CARE for schizophrenia](#); [Summary of findings 2 SOCIAL SKILLS versus DISCUSSION CONTROL for schizophrenia](#)

For dichotomous data we calculated risk ratios (RR) and their 95% confidence intervals (CIs). For continuous data, we calculated mean differences (MD) and 95% CIs.

1. COMPARISON 1: SOCIAL SKILLS versus STANDARD CARE

1.1 Social functioning

1.1.1 Social functioning: Average endpoint score

We found significant differences between social skills and standard care on all scales that measured social functioning (Analysis 1.1). Lu 2004 reported data on the Social Disability Schedule (SDSS) at eight weeks (1 RCT, n = 112, MD -1.50 CI -2.39 to -0.61) and Saren 2004 at 12 months (1 RCT, n = 143, MD -10.00 CI -11.35 to -8.65). Saren 2004 also reported data on the Social Avoidance and Distress Scale (SAD) at 12 months follow-up (1 RCT, n = 143, MD -16.00 CI -17.04 to -14.96) and Huang 2005 reported data on the Scale of Social-skills for Psychiatric Inpatients (SSPI) at six months follow-up (1 RCT, n = 67, MD -6.06 CI -7.17 to -4.95). In addition, Ma 2003 reported data for general functioning on the Disability Assessment Scale (DAS) at 26 weeks follow-up and also found a significant difference in favour

of the social skills training group (1 RCT, n = 120, MD -6.8 CI -10.52 to -3.08).

1.2 Relapse

Two studies reported on the number of participants relapsing, with follow-up between six months and 12 months. A significant difference was found in favour of the social skills group (2 RCTs, n = 263, RR 0.52 CI 0.34 to 0.79; Analysis 1.2). The results showed moderate heterogeneity ($I^2 = 40\%$).

1.3 Global state: not clinically improved

Huang 2005 reported data for this outcome at six months follow-up and found that significantly more participants showed a clinical improvement in global state in the social skills training group compared to the standard care group (1 RCT, n = 67, RR 0.29 CI 0.12 to 0.68; Analysis 1.3).

1.4 Service outcome: re-hospitalisation

Saren 2004 reported data on re-hospitalisation at 12 months follow-up and showed a significant difference in favour of the social skills group (1 RCT, n = 143, RR 0.53 CI 0.30 to 0.93; Analysis 1.4).

1.5 Mental state

1.5.1 Average endpoint score in negative and positive symptoms

Hayes 1995 and Ma 2003 measured negative symptoms on the SANS scale with eight and 18 weeks follow-up, respectively, and found a significant difference in favour of the social skills training group (2 RCTs, n = 187, MD -8.92 CI -10.46 to -7.38). Ma 2003 also measured positive symptoms on the SAPS scale, and also found a significant difference favouring social skills training (1 RCT, n = 120, MD -1.90 CI -3.37 to -0.43; Analysis 1.5).

1.5.2 Average change in general and negative symptoms

Cui 2004 reported the average change in mental state at 12 weeks follow-up (Analysis 1.6). General symptoms were measured using the BPRS (1 RCT, n = 91, MD -4.01 CI -7.52 to -0.50) and negative symptoms were measured using the SANS (1 RCT, n = 91, MD -7.70, CI -12.33 to -3.17), both of which showed a significant improvement in symptoms in the social skills group compared with standard care.

1.6 General functioning: average endpoint score

Lu 2004 reported data on the Morningside Rehabilitation Status Scale (MRSS) at eight weeks follow-up and found a significant difference in favour of the social skills training for the participants rehabilitation status (1 RCT, n = 112, MD -10.60 CI -17.47 to -3.73; Analysis 1.8).

1.7 General functioning: employment

(Kopelowicz 1998) reported whether participants were employed at the end of the study and found no difference between treatment groups (n = 46, RR 5.43 CI 0.28 to 107.33) Analysis 1.9.

1.8 Leaving the study early

We found no significant differences between social skills training and standard care for the number of participants leaving the study early with follow-up between eight weeks and 12 months (9 RCTs, n = 719, RR 2.04 CI 1.00 to 4.16; Analysis 1.10). In Kopelowicz 1998, two people in the social skills group dropped out because

they had found employment, but despite this there was very low heterogeneity for these results ($I^2 = 10\%$).

1.9 Quality of Life: average endpoint score

Lu 2004 measured quality of life at 8 weeks follow-up on two scales, the General Well-Being scale ($n = 112$, MD -7.60 CI -12.18 to -3.02) and the Self-Esteem scale ($n = 112$, MD -8.30 CI -10.07 to 6.53), both of which showed a significant difference in favour of the social skills training (Analysis 1.11).

2. COMPARISON 2: SOCIAL SKILLS versus DISCUSSION CONTROL

2.1 Social functioning: average endpoint score

Two studies reported data for this outcome at six months follow-up, each on two different scales, none of which showed a significant difference between social skills training and a discussion control (Analysis 2.1). Hayes 1995 measured social functioning on the Social situations questionnaire (SSQ) ($n = 63$, MD -1.10 CI -11.14 to 8.94) and the conversation with a stranger task (SCON) ($n = 63$, MD -2.50 CI -5.52 to 0.52). Ng 2006 used the Social Functioning Scale (SFS) ($n = 36$, MD 4.60 CI -7.54 to 16.74) and the Social behaviour schedule (SBS) ($n = 36$, MD 0.50 CI -2.56 to 3.56).

2.2 Relapse

This outcome was reported by Ng 2006 at six months follow-up and no significant difference was found between the treatment groups (1 RCT, $n = 33$, RR 2.12 CI 0.44 to 10.10; Analysis 2.2).

2.3 Global state: average endpoint score

Hayes 1995 reported data for global state on the Global Assessment Scale at six months follow-up and found no significant difference between the social skills training and the discussion control (1 RCT, $n = 63$, MD 4.50 CI -1.20 to 10.20) (Analysis 2.3).

2.4 Mental state: average endpoint score

Two trials reported the average endpoint score for general symptoms at six months follow-up on the BPRS scale and found no significant difference between the treatment groups (2 RCTs, $n = 99$, MD 0.22 CI -4.05 to 4.49; Analysis 2.4). The results showed high heterogeneity ($I^2 = 54\%$). In addition, the two trials also found no significant difference in negative symptoms on the SANS scale (2 RCTs, $n = 99$, MD 2.89 CI -4.43 to 10.22; Analysis 2.4). These results were moderately heterogeneous ($I^2 = 19\%$).

2.5 Leaving the study early

Two trials reported data for this outcome at three months and six months follow-up and showed no significant difference between the social skills training and discussion control (2 RCTs, $n = 69$, RR 1.58 CI 0.37 to 6.68; Analysis 2.5). The results showed no heterogeneity ($I^2 = 0\%$).

2.6 Quality of life

Hayes 1995 reported data on quality of life at six months follow-up and found no significant difference between the treatment groups (Analysis 2.6). (1 RCT, $n = 63$, MD 3.70 CI -6.47 to 13.87).

3. Missing outcomes

None of the studies evaluated general behaviour, engagement with services, satisfaction with treatment and economic outcomes.

DISCUSSION

Summary of main results

The summary below reflects the outcomes chosen for the 'Summary of findings' tables chosen to be of clinical importance before seeing the data. These are considered to be the main findings of this review. For all outcomes, we judged the quality of evidence to be *very low* - randomisation was not well described, observation bias was impossible to exclude and few attempts were made to minimise it, and outcomes were poorly reported.

1. COMPARISON 1: SOCIAL SKILLS versus STANDARD CARE

1.1 Social functioning

We found it surprising that - for this comparison - social functioning was just so poorly reported. The use of various scales made any potential analysis prone to problems from the very many assumptions that would have had to be made. Four studies reported on 585 people but different scales were used in each with little help for the reader in the interpretation of what outcomes would mean in everyday life.

1.2 Relapse/rehospitalisation

Two trials suggest ($n = 263$) that the risk of relapse is halved in between six and 12 months follow-up. The low-quality data are also moderately heterogeneous - but this is an encouraging finding - mirroring that of the risk of rehospitalisation. If only rehospitalisation had some suggestion of decrease and not relapse then it may have been argued that the putative increase in social skills would have helped avoid admission. However, this is not the case and there is a suggestion that the social skills programmes help offset the relapse as well. This finding, as others, need replicated in larger studies.

1.3 Mental state: general symptoms

Mental state outcomes were few and is it not clear that the social skills programmes have any effect.

1.4 Global state: not clinically improved.

The global state outcome, as measured by the CGI, was also favouring social skills programmes. This is in keeping with the relapse and rehospitalisation outcomes but is only based on one very small study ($n = 67$).

1.5 General functioning

One small study ($n = 112$) reported on general functioning. We have not been able to find explanation of what a 10-point decline would mean in everyday life, but the decline did favour the social skills programme group.

1.6 Quality of life

Finally, the quality of life measure also favoured the social skills programme group in one study ($n = 112$).

1.7 Overall

The overall impression that we are left with is that social skills programmes, in the hands of expert and committed practitioners - who these trialists were - may have some valuable effects (please see [Implications for research](#)).

2. COMPARISON 2: SOCIAL SKILLS versus DISCUSSION CONTROL

As stated above, we thought that it would not be right to summate a social skills programme versus standard care comparison with that comparing the social skills programme to a more active discussion group control. However, data were more thin and inconclusive.

2.1 Social functioning

Two studies (total $n = 63$ people) reported on two different scales. There did not seem to be any difference between the social skills programme and the discussion group control.

2.2 Relapse

One tiny study ($n = 35$) reported on relapse with no differences between groups. Such outcomes should be reported as a matter of routine - but it would seem likely that much larger studies are needed to highlight differences with any degree of meaningful confidence.

2.3 Global state, mental state, quality of life

In the one study of 63 people global state was unchanged. This applies to mental state (2 RCTs, $n = 99$) and quality of life 1 RCT, 63 people).

2.4 Overall

When social skills training was compared to this discussion control, no evidence was found to suggest that social skills training was superior to the control group for improving social functioning, employment, relapse rates, mental state, global state, quality of life and leaving the study early.

Overall completeness and applicability of evidence

1. Completeness

Even for outcomes for which we identified usable data, because all studies were of a small sample size (range 18 to 148) we feel that no outcomes could be labelled as complete. We did not find studies with any data for the following outcomes: general behaviour, engagement with services, satisfaction with treatment and economic outcomes.

2. Applicability

The definition of social skills training varied between studies, and we have tried to be as consistent as possible when screening potential studies. All programmes had an element of social problem solving and used techniques of modelling, role-play and social reinforcement. Some trials focused on interpersonal communication such as conversation and assertiveness skills, whereas others were more diverse and included symptom and medication management. The focus of the studies also differed, with the aim of some to reduce stress and the risk of relapse and others focusing on employment.

Five of the studies were conducted in China and reported in Chinese (Cui 2004; Huang 2005; Lu 2004, Ma 2003; Saren 2004), a further two were conducted in Hong Kong and reported in English (Ng 2006 and Tsang 2001) and one was in Taiwan and also reported in English (Chien 2003). Of the remaining five studies, three were conducted in the USA, one in Canada and one in Australia. Most of the data for the results are from the Chinese studies and those conducted in Hong Kong.

Should we have been able to synthesise more data across the inevitable varied definitions of 'social skills programme' and different care cultures we might have been able to see if, despite these differences, findings were consistent - and in being so, supported the idea of wide applicability. More data are needed.

Quality of the evidence

1. Methods

Most studies did not address incomplete data adequately as they did not use an intention-to-treat analysis. Only three of the 13 included studies described an adequate sequence generation, and only one described the methods used to conceal allocation. Twelve of the studies were not blinded and in one (Tsang 2001), it was unclear. Four studies were free from selectively reporting the outcomes. Dobson 1995 was not free from other biases and it was unclear in the remaining studies. All the studies were small.

2. Reporting

Reporting was very poor. Many of the trials presented data that we were not able to use, mostly because authors had not reported either means or SDs, or data were not from a validated scale. For two included trials we were not able to use any data (Mayang 1990 and Potelunas 1982) and for a further four, we could only use data for one of the outcomes.

2. Consistency of measure

For the outcomes for which data were available, with the exception of leaving the study early, only one or two small trials provided data. The studies used different assessment scales and we were unable to pool the divergent outcome data, which further hinders the detection of potential treatment effects.

Potential biases in the review process

We have worked only with published reports. By doing this we may be perpetuating a reporting and publishing bias. In addition, it was not possible to tell if there was publication bias, as most of the 13 included trials did not provide useful data, and a funnel plot could not be performed. Five of the reports were written in Chinese. These studies were assessed and data extracted by one person who is fluent in Mandarin (JX).

We do not think that we embarked on this review with prior biases as to the effects of the programme of care - and have tried to keep to the protocol guidance we stipulated before seeing any data.

We realise the search date is out of date and new studies may have been published which could alter the results of this review. We are currently assessing results of a new search and aim to update this review within the next six months.

Agreements and disagreements with other studies or reviews

We do not know of any other relevant quantitative review in this topic.

AUTHORS' CONCLUSIONS

Implications for practice

1. For people with schizophrenia

Studies are still so limited that this package of care has to be thought of as experimental. There is no indication that these social skills programmes do harm and some that they do good. If asked to join a social skills programme, the person could be encouraged that randomisation occurs to add to the body of useful knowledge.

2. For clinicians

Whether social skills programme do any more good than other interventions is unproven. Less sophisticated approaches may be just as effective. Until more evidence is available, social skills programmes should be thought of as experimental and not fully tested.

3. For policy makers

Compared with standard care, social skills training may improve the social skills of schizophrenic patients and reduce relapse rates, but at present, the evidence is very limited. In addition, there is no evidence to suggest that social skills training is superior to the act of discussing problems in a group. Currently, because of lack of good, consistent, applicable data social skills programme have to be seen to be vulnerable to replacement by other approaches with more robust evidence.

Implications for research

1. General

Only four of the included studies predate CONSORT (Begg 1996; Moher 2001) but many had not followed guidance in their reporting. Clear and strict adherence to the [CONSORT statement](#) may well have resulted in this review having more data. Full availability of all data from each study could greatly help future reviewers ([AllTrials](#)).

2. Specific

2.1 Reviews

Many excluded trials could find a place in new or existing systematic reviews. It is difficult to categorise all these studies for presentation in a table but we have assigned them broad categories and suggest Cochrane reviews that may cover these areas ([Table 1](#)).

2.2 Trials

If social skills training programmes are to be incorporated into the treatment of people living with schizophrenia, more reliable evidence is needed. Future trials should involve all consumers of care, including the patients, families and carers, organisations that provide care for those with schizophrenia and not only focus on research outcomes. There is certainly a need for a large multi-centre randomised controlled trial to show if social skills training is affected by cultural differences. Interpretation of social skills programmes research would be enhanced if future trials made use of validated measures - perhaps even only those used in routine care and preferably agreed upon by a [COMET-type](#) approach.

We are aware that enormous effort and care goes into the design of a trial and that we can only suggest some thoughts about design from our understanding of what has gone on before ([Table 2](#)). We have, however, looked at these trials very carefully and do think that there are some lessons to be learnt about gaining valuable information from simplicity of design. After all, with the complexity of design that has gone before, we are left in the dark about the most basic effects of this approach.

ACKNOWLEDGEMENTS

Many thanks must go to Dr. Adib Essali who first introduced us to The Cochrane Collaboration. Thanks also go to Damascus School of Medicine/Syria for its encouragement. The Cochrane Schizophrenia Group Editorial Base in Nottingham produces and maintains standard text for use in the Methods section of their reviews. We have used this text as the basis of what appears here and adapted it as required.

Our thanks also go to Jun Xia (JX) for her translation of all Chinese studies and to Karla Soares Weiser (KSW) for her assistance with the selection of studies and data extraction.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]

Chien 2003

Methods	Allocation: randomised. Blinding: no. Duration: 4 weeks (follow-up 1 month). Setting: inpatients. Design: parallel. Country: Taiwan.
Participants	Diagnosis: schizophrenia (DSM-IV). N = 84.* Sex: M 43, F 35. Age: mean ~ 42 years. History: illness (1-35 years; mean ~ 17 years), history of social skills training (19 patients).
Interventions	1. Social skills training: Group treatment phase - 60-minute social skills training course twice a week for 4 weeks to improve patients conversation and assertiveness skills (N = 35). 2. Routine nursing care treatment (N = 43).
Outcomes	Leaving the study early.* Unable to use - Mental state: PANSS (only pre-treatment results reported). Social functioning: Social anxiousness scale (IAS) (only pre-treatment results reported). Social functioning: Interpersonal communication satisfaction scale (data not reported for control group). Social functioning: The Assertive skills scale (data not reported for control group).
Notes	*The number randomised is stated as 84. Eight losses to follow-up are reported, but the final number in the analysis is 78.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"A table of random numbers was used to select 28 subjects from the first subgroup and randomly assigned 14 of them to the experimental group or control group. This same procedure was repeated with the second and the third subgroups of subjects".
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias)	High risk	Not stated.

Social skills programmes for schizophrenia (Review)

Chien 2003 (Continued)

All outcomes

Incomplete outcome data (attrition bias) All outcomes	High risk	"Two subjects in the experimental group withdrew from the study before treatment one because of medical disease that required an inter-hospital transfer and the other who stabilized discharge from the hospital. Two subjects in the experimental group withdrew because they refused to participate. One subject in each of the groups withdrew during the training because of being transferred to another ward. Two subjects in the experimental group were excluded from the study because they were able to participate in less than half of the training sessions (four times)".
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Cui 2004

Methods	Allocation: randomised. Blinding: no. Duration: 12 weeks. Setting: inpatients. Design: parallel. Country: China.
Participants	Participants: schizophrenia (CCMD-2-R). N = 100. Sex: M 100. Age: average ~44 ±7 years History: average length of illness ~ 20 ± 6 years.
Interventions	1. Social skills training + routine drug therapy. Training is delivered in groups of 12 or 13, employing UCLA Social and independent Living Skills programme. Training contents include: 1) general social interpersonal skills training, using video demonstration, role play and discussion; 2) educate patients of the purpose and function of antipsychotic medication; 3) medication management; 4) how to recognise drug adverse effect; 5) opportunity to discuss issues relating to drug therapy. Frequency of intervention is 90-120 minutes per session, 3 sessions per week for 12 weeks (N = 50). 2. Control group: routine drug therapy (N = 50).
Outcomes	Leaving the study early. Mental state: BRPS and SANS ("decreased rate" reported = (before treatment score - after treatment score)/before treatment score X 100%). Unable to use - Social functioning: Social disability screening schedule (SDSS) (no mean and SD).
Notes	Study in Chinese.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation was done with random number tables.

Cui 2004 (Continued)

Allocation concealment (selection bias)	Unclear risk	Not stated.
Blinding (performance bias and detection bias) All outcomes	High risk	Not stated.
Incomplete outcome data (attrition bias) All outcomes	High risk	There were five dropouts from the social skills training group and four from the control group. People who left the study early were not included in the final analysis.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Dobson 1995

Methods	Allocation: randomised. Blinding: no (raters blinded). Duration: 11 weeks (3 months follow-up). Setting: inpatients. Design: parallel. Country: Canada.
Participants	Diagnosis: schizophrenia (structured clinical interview for DSM-III-R). N = 33. Sex: M 21, F 12. Age: 18- 55 years. History: schizophrenic, 18 to 55 years, low-average intelligence or higher.
Interventions	1. Social skills training: first three weeks - basic communication skills; second three weeks - assertiveness training; third three weeks - individual communication and assertive goal setting. Four one-hour sessions per week over nine week period (N = 18). 2. Social milieu: structured activities including supportive discussion groups, exercise groups and activity groups. Occurred at same time of day and same length of time as social skills training group (N = 15). Neuroleptic medication for all patients.
Outcomes	Leaving the study early. Unable to use - Mental state: PANSS (no SDs). Relapse and re-hospitalisation (confounding effect of social milieu participants beginning social skills training*)
Notes	* One week of assessments before the treatment, nine weeks of treatment, and one week of assessments after the treatment. Three month follow-ups were completed for all patients, at that point social milieu participants were able to participate in social skills training. The social skills group received additional assessment at 6 months follow-up. Rehospitalisation data and relapse data were collected on all patients at 6 months and 1 years after treatment.

Risk of bias

Dobson 1995 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"randomly assigned" no further information given.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Single blind: "None of the assessments were completed by the group therapists for subjects in the study, and none of the treatment groups were led by the investigators".
Incomplete outcome data (attrition bias) All outcomes	High risk	There were 5 dropouts: 2 from the social milieu group and 3 from the social skills group. "The reasons they gave for dropping out were unrelated to the treatment".
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	High risk	Protocol not available. The follow-up period for social milieu group was limited mid-study so they could also receive social skills training, which they had expressed interest in to the investigators.

Hayes 1995

Methods	Allocation: randomised. Blinding: no (raters blinded). Duration: 18 weeks (plus 6 months booster period*). Setting: outpatients. Design: parallel. Country: Australia.
Participants	Diagnosis: schizophrenia. N = 63. Sex: M 47, F16. Age: mean ~ 36 years (18-65 years). History: psychotic symptoms, significant residual impairment, deficit on social and skills and conversation tasks.
Interventions	1. Social skills training: emphasised interpersonal skills, social problem solving, positive time use skills, generalisation enhancement techniques, and used instructions, modelling, behaviour rehearsal, feedback, and structured homework (N = 32).** 2. Discussion group condition: focused on interpersonal relations and purposeful use of time using open ended questions, paraphrasing, reflecting, and summarising the participants' comments to promote self-disclosure (N = 31).** Both interventions consisted of 36 sessions each of 75 minutes duration, over 18 weeks in small groups between 5 and 7 participants. Neuroleptic medication maintenance doses for all patients.
Outcomes	Social functioning: Simulated Social Interaction Test (SSIT), conversation with a stranger task (SCON) and Social Situations Questionnaire (SSQ). Mental state: BPRS, negative symptoms (SANS). Global state (GAS). Quality of Life (QLS). Unable to use -

Social skills programmes for schizophrenia (Review)

Hayes 1995 (Continued)

Leaving the study early (not reported which groups dropouts had been assigned to).
 Relapse (number relapsing from each group not reported).
 Social functioning: Time Diary (not reported for 6-month follow-up).
 Quality of life: Adapted Pleasant Events Schedule (APES) (total scores not reported).
 Satisfaction with treatment: Evaluation of therapist (data not reported).

Notes

* During this period patients received decreasing frequency of training.
 ** Number randomised to each group not reported. We have assumed that N = 32 for the social skills training group and N = 31 the discussion group.

22 participants (35%) attended less than half the scheduled sessions and classed as non completers. 45 participants (71%) were reassessed at post-treatment; 37 of these were treatment completers. At follow-up, 34 participants were assessed; 32 were treatment completers.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"subjects were assigned randomly" no further information.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Not stated. "All research assistants conducting interviews and rating measures were uninformed to the treatment condition of participants".
Incomplete outcome data (attrition bias) All outcomes	High risk	18 dropouts at post treatment assessment, another 11 had dropped out at follow-up assessment. Dropouts were reported as either in hospital, unable to be reached or declined to participate, it was not reported to which groups they had been assigned.
Selective reporting (reporting bias)	High risk	Reported insufficient funds to code time diary data for follow-up assessment.
Other bias	Unclear risk	Protocol not available. Sample size not calculated. Source of funding: National Health and Medical Research Council of Australia and University Queensland.

Huang 2005

Methods	Allocation: randomised. Blinding: single blind (assessor blind). Duration: 6 months. Setting: outpatients. Design: parallel. Country: China.
Participants	Diagnosis: schizophrenia (CCMD-3). N = 73. Sex: M 48 F19*. Age: mean ~41years, SD ~7 years. History: current length of hospitalisation is at least 2 years, overall length of illness at least 10 years.
Interventions	1. Social skills training + routine drug medication, recreational activities and work in the wards: training is delivered in groups of 8-9 people, 2 hours per weeks for 24 weeks. (N = 37)

Huang 2005 (Continued)

2. Standard care: Routine drug therapy, recreational activities and work in the wards (N = 36).

Outcomes	Leaving the study early. Mental state: SANS. Social functioning: Scale of Social Skills for Psychiatric Inpatients (SSPI). Global state: No clinically important change (CGI).
Notes	In Chinese. * number who completed the study.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised, no further details given.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Raters were blinded.
Incomplete outcome data (attrition bias) All outcomes	High risk	Four participants dropped out of the social skills training group and two from the control group. Dropouts were excluded from the final analysis.
Selective reporting (reporting bias)	Low risk	All stated outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Kopelowicz 1998

Methods	Allocation: randomised. Blinding: no. Duration: 3 months. Setting: inpatients. Design: parallel. Country: USA.
Participants	Diagnosis: schizophrenia and schizoaffective disorders (DSM-IV). N = 46. Sex: M 30, F 16. Age: mean ~ 33.9 years. History: in hospital (mean ~ 2 years) prior to the study.
Interventions	1. Social skills training: Spanish language version of the UCLA Social and Independent Living Series. Three months of skills training four days a week. (N = 22). 2. Customary care: monthly visits to a psychiatrist who prescribed antipsychotic medication (N = 24).
Outcomes	Leaving the study early.** Unable to use - Social functioning: Skill acquisition and generalisation* (no mean and SD).

Social skills programmes for schizophrenia (Review)

Kopelowicz 1998 (Continued)

Mental state: UCLA Expanded BPRS (no mean and SD).

Notes

* Generalisation of skills to home environment.

** Two participants dropped out due to finding employment.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"Randomised", no further details provided.
Allocation concealment (selection bias)	Unclear risk	No information given.
Blinding (performance bias and detection bias) All outcomes	High risk	Not stated.
Incomplete outcome data (attrition bias) All outcomes	High risk	"Two patients dropped out of skills training because they obtained full time employment and were thus unable to participate." No further details given.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Lu 2004

Methods	Allocation: randomised. Blinding: no. Duration: 8 weeks. Setting: inpatients. Design: parallel. Country: China
Participants	Diagnosis: schizophrenia (CCMD-2-R). N = 112. Sex: male and female. Age: 18-60 years. History: mean duration of illness ~9.9 years, SD ~7.1 years.
Interventions	1. Social skills training + routine antipsychotic medication: training included targeted problem solving training - breaking down complicated daily problems into small and simple parts, teaching patients through repeated explanation and demonstration to eventually solve the complex problems. Training to improve patients' cognitive skills (attention, planning) with the aim of gradually improving patient's social function. Training was 60 minutes per session and 2 sessions per week for 8 weeks (N = 56) 2. Routine antipsychotic medication only (N = 56)
Outcomes	Leaving the study early. General functioning: Morningside rehabilitation status scale (MRSS). Social functioning: Social Disability screening schedule (SDSS). Quality of Life: General well-being schedule (GWB).

Lu 2004 (Continued)

Self-esteem scale (SES).

Notes In Chinese.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation method is not described.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Not stated.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete outcome data.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Ma 2003

Methods	Allocation: randomised. Blind: no. Duration: 8 weeks intervention + 26 weeks follow-up. Setting: outpatients. Design: parallel. Country: China.
Participants	Diagnosis: schizophrenia (CCMD-3). N = 120. Sex: not reported. Age: not reported. History: not reported.
Interventions	1. Social skills training group: UCLA Social and independent Living Skills programme guidelines, including three major elements: 1) independent social living skills training, e.g. draft plans on reintegrate to society and cope with stressful life events; 2) medication management, e.g. getting to know the effect and side effects of antipsychotic drugs, learn to recognise and deal with medication side effect; 3) symptom self-monitoring. Means of delivering the training including the use of video, role play, problem solving discussions. Frequency of the session is 90 to 120minutes per session, one session a week for 8 weeks (N = 60). 2. Control group: conventional community care (N = 60).
Outcomes	Leaving the study early. Mental state: positive symptoms (SAPS) and negative symptoms (SANS). General functioning: Disability Assessment Scale (DAS). Relapse.

Social skills programmes for schizophrenia (Review)

Ma 2003 (Continued)

Notes In Chinese.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised with random number tables.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Not blinded.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete outcome data.
Selective reporting (reporting bias)	Low risk	All stated outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Mayang 1990

Methods	Allocation: randomised. Blinding: no. Duration: 4 sessions of training, follow-up 4 weeks. Setting: inpatients. Design: parallel. Country: USA.
Participants	Diagnosis: schizophrenia. N = 18. Sex: F 18. Age: early 20s to mid-50s. History: able to express themselves verbally, a recent history of physical and/or verbal aggression, deficient in adaptive problem solving skills.
Interventions	1. Treatment group: problem solving skills training (receiving skills, processing skills and sending skills) involving instructions, modelling, feedback, role playing, social reinforcement. Four sessions of 45 minutes of training (N = 6). 2. Interaction group: non-treatment interaction with trainers (N = 6). 3. Control group: did not receive any training or interaction with trainers (N = 6).
Outcomes	Unable to use - Social functioning: problem solving skills and number of seclusion hours (no SDs).
Notes	

Risk of bias

Bias	Authors' judgement	Support for judgement

Social skills programmes for schizophrenia (Review)

Mayang 1990 (Continued)

Random sequence generation (selection bias)	Unclear risk	"Randomly assigned", no further details given.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Not blinded.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No information provided.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample sizes not calculated

Ng 2006

Methods	Allocation: randomised. Blinding: No (raters were blinded). Duration: 8 weeks + 6 months follow-up. Setting: Inpatients. Design: Parallel. Country: Hong Kong.
Participants	Diagnosis: Schizophrenia, DSM-IV criteria. N = 36. Sex: M 18, F 18. Age: 18- 65 years. History: All participants were already admitted at a rehabilitation ward for chronic psychiatric patients, diagnosed with schizophrenia, no organic central nervous system disorder or history of substance misuse in the previous 12 months.
Interventions	1. Social skills training (SST): training in receiving skills, processing skills and sending skills using behavioural techniques including instruction, taped modelling, role-play practise, verbal feedback, social reinforcement, coaching, prompting, and homework assignment. 30 to 32 hours of treatment within eight weeks (N = 18).* 2. Supportive group discussion: topics included practical tips on money management and information on application for social security allowances. Special attention was paid to avoid discussions on interpersonal skills issues and use of behavioural techniques (N = 18).
Outcomes	Leaving the study early. Social functioning: Social behaviour Schedule, Social Functioning Scale. Psychopathology: BPRS and SANS. Relaspe. Unable to use- Role Play Test (total scores not reported).
Notes	* Both groups received 2 sessions per week for 8 weeks, and standard care.

Risk of bias
Social skills programmes for schizophrenia (Review)

Ng 2006 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Patients were randomised using a random number table, and stratified for gender, medication type and hospitalisation duration.
Allocation concealment (selection bias)	Low risk	"Randomisation was done by an administrator...The administrator was only aware of the code number, name, date of birth, and stratification criteria for each patient."
Blinding (performance bias and detection bias) All outcomes	High risk	Raters were blinded.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	"Three participants allocated to SST and 2 allocated to supportive group discussion dropped out before completion of the trial." "All patients who relapsed and were withdrawn from the trial during the treatment phase were included as treatment failures. All missing data were given mean values of that particular variable at that particular assessment point."
Selective reporting (reporting bias)	Low risk	All pre-specified outcomes were reported.
Other bias	Unclear risk	Protocol not published a priori. Funding: not reported.

Potelunas 1982

Methods	Allocation: randomised - table of random numbers. Blindness: no (unclear if all raters were blinded). Duration: 6 weeks. Setting: outpatients*. Design: parallel. Country: USA.
Participants	Diagnosis: schizophrenia. N = 45. Sex: F 45. Age: mean ~ 33 years (21-25 years). History: volunteers, females, previous hospitalisation under the diagnosis of schizophrenia, participation in the program beyond five weeks.
Interventions	1. Social skills training: four one-hour sessions over four weeks of videotaped presentation of eight problem situations, videotaped modelling, behaviour rehearsal, coaching and feedback (N = 15). 2. Discussion control: four one-hour sessions over four weeks of videotaped presentation of eight problem situations, with discussion (N = 15). 3. No treatment control (N = 15).
Outcomes	Leaving the study early. Unable to use - Overall rating form (invalidated due to problems in the administration of the form).** Supervisee Self Efficacy Test (not validated scale). Supervisee Social Competency Test (not validated scale). Nonverbal assertiveness scale (no overall score given).
Notes	* Psychiatrically disabled who are well enough to have been discharged from the hospital, but still needs some time in a supportive environment.

Social skills programmes for schizophrenia (Review)

Potelunas 1982 (Continued)

** Many of the supervisors were changed for the patients between pre and post tests, thus most of the forms were not filled out by the same supervisor for each patient.

Social skills training was given as part of a work adjustment programme.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	A table of random numbers was used.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	The primary experimenter was not seen by participants on a regular basis, but it is not stated whether they were blind to group allocation. Three research assistants blind to treatment condition independently rated the videotapes.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	No information provided.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Sample size calculation done. Source of funding not reported. Protocol not available.

Saren 2004

Methods	Allocation: randomised using random number table. Blinding: no. Duration: 10 weeks intervention + 12 months follow-up. Setting: outpatients. Design: parallel. Country: China.
Participants	Diagnosis: schizophrenia (CCMD-2-R, ICD-10). N = 148. Sex: male and female. Age: mean ~48 years, SD~16 years. History: mean length of illness ~18 years, SD~13 years.
Interventions	1. Social skills training + routine drug treatment: 1) training in making eye contact - when and where is appropriate and how to make eye contact ; 2) facial expression - promote positive facial expression, e.g. smile and nod head from time to time when converse with others; 3) tone of voice - avoid flat tone of voice and try to appear enthusiastic; 4) language fluency, using logical expressions and avoid short sentences without adjectives; 5) posture and gesture, how to coordinate body language; 6) overall enthusiasm. Training is provided in groups of between 10-12 people, 60to 90minutes per session, 3 sessions per week for 10 weeks. (N = 74) 2. Routine drug treatment (N = 74).
Outcomes	Leaving study early. Relapse. Rehospitalisation.

Social skills programmes for schizophrenia (Review)

Saren 2004 (Continued)

Social avoidance and disability scale (SAD).
 Social disability screening schedule (SDSS).

Notes In Chinese.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomised using random number table
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	High risk	Not blinded.
Incomplete outcome data (attrition bias) All outcomes	High risk	Two participants dropped out of the social skills training group due to a change of address; In the control group 3 participants left dropped out, also due to a change of address. These were not included in the final analysis.
Selective reporting (reporting bias)	Low risk	All stated outcomes reported
Other bias	Unclear risk	Protocol not available. Sample size not calculated.

Tsang 2001

Methods	Allocation: randomised. Blinding: unclear. Duration: 10 weeks (3 months follow-up). Setting: inpatients. Design: parallel. Country: Hong Kong.
Participants	Diagnosis: schizophrenia. N = 97. Sex: M 60, F 37. Age: 18- 50 years. History: unemployed patients, have at least fifth grade education.
Interventions	<ol style="list-style-type: none"> 1. Social skills training with follow-up support: basic social skills (facial expression, gestures etc.), basic social survival skills (personal appearance, tidiness) and core work-related skills. Follow-up support consisted of contact with group members and the trainer. Ten weekly group sessions lasting 1.5 to 2 hours, with approximately 6 to 8 people in each group (N = 30). 2. Social skills training without follow-up support: same programme as described above but no follow-up support (N = 6). 3. Standard psychiatric care (N = 41).
Outcomes	Employment.

Tsang 2001 (Continued)

Unable to use - Social functioning measures - self-administered check-list score, role-play test score, nonverbal skills (no means and SDs).

Notes The purpose of the training was to help mentally ill persons to find and keep a job.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomly assigned by residential facility, not individually.
Allocation concealment (selection bias)	Unclear risk	Not addressed.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	"During the entire process of data collection, all participants and those responsible for rating participants' performance were blind to the group status of the participants, and participants did not know that there were groups with and without follow up." It is unclear if the control group was blinded.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	There were no dropouts reported from the two intervention groups, but no information whether there were dropouts in the control group.
Selective reporting (reporting bias)	High risk	Not all expected outcomes reported.
Other bias	Unclear risk	Protocol not available. Sample sizes not calculated.

Scales

BPRS = Brief Psychiatric Rating Scale

CGI = Clinical Global Impression

GAS = Global Assessment Scale

PANSS = Positive and Negative Syndrome Scale

QLS = Quality of Life Scale

SANS = Scale for the Assessment of Negative Symptoms

SAPS = Scale for the Assessment of Positive Symptoms

Other

CCMD = Chinese Classification of Mental Disorders

DSM = Diagnostic and Statistical Manual of Mental Disorders

SD = standard deviation

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
ACTRN12609000317291	Ongoing study. Allocation: randomised. Participants: people with psychosis and personality disorders. Intervention: Collaborative therapy which provides education and coping strategies to enhance self management of mental illness versus treatment as usual.
Alter 1993	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders. Intervention: Coping skills training versus no training.

Social skills programmes for schizophrenia (Review)

Study	Reason for exclusion
Armstrong 1991	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders. Interventions: life skills program (SST, life management, nutrition, problem solving, self-control skills) versus supportive psychotherapeutic milieu (social milieu, assistance with life skills, supportive environment).
Barrowclough 2001	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders (ICD-10, DSM-IV), and substance abuse or dependence (DSM-IV). Interventions: integrated intervention programme (motivational intervention, CBT, family intervention) and routine care versus routine care alone.
Beal 1977	Allocation: randomised. Diagnosis: schizophrenia (diagnostic criteria not reported). Intervention: remotivation therapy and activities versus remotivation therapy and social living groups versus remotivation therapy.
Brown 1983	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III). Interventions: life skills program (interpersonal, nutrition, health, finance, time management, and community networks) versus rehabilitation condition (recreation, art, occupational therapy).
Browne 1996	Allocation: unclear. Participants: people with schizophrenia (DSM-III-R). Interventions: psychosocial and educative program versus conventional rehabilitation.
Bruns 1992	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III-R). Interventions: psychotherapeutic treatment versus leisure time activities.
Buchbauer 1986	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III). Interventions: positive assertion training versus negative assertion training versus discussion control versus complete assertion (positive and negative).
Cannon 1985	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorder. Interventions: psychosocial rehabilitation model (everyday skills, work skills, communication skills, medication) versus control group (occupational therapy, work therapy, family services).
Cerniglia 1978	Allocation: randomised. Participants: schizophrenic patients. Intervention: treatment programme of patient decision making and self-management versus routine care.
Chabannes 2008	Allocation: randomised - no further details given. Participants: participants meeting criteria for a schizophrenia spectrum disorder according to the DSM-IV criteria. Interventions: "Soleduc" psychoeducational program (8 module, 7 session presentations, presented three times) versus non-specific psychosocial group training (sessions of oral information about schizophrenia and its treatment according to the standard of each participating centre).
Chan 2009	Allocation: randomly assigned - no further description. Participants: Individuals diagnosed with schizophrenia according to the criteria of the DSM-IV. Interventions: Psychoeducation program (teaches clients and their families about disorders, treatments, coping techniques, and available resources) 10 sessions conducted over 3 months on a weekly basis versus control group. Both groups received the same access to routine care.

Study	Reason for exclusion
Chandler 2000	Allocation: randomised. Participants: 40% had a diagnosis of schizophrenia, 23% had diagnoses of schizoaffective disorder and 14% of bipolar disorder. Interventions: Social skills training modules as an adjunct to an assertive community treatment program versus assertive community treatment only.
Choi 2006	Allocation: random allocation - no further details. Participants: Persons with a DSM-IV-based diagnosis of schizophrenia or schizoaffective disorder and on stable antipsychotic medications. Interventions: Social cognition enhancement training and standard psychiatric rehabilitation training vs. standard psychiatric rehabilitation training only.
Cormier 1995	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: psychoeducational program versus leisure activities versus usual follow-up.
Daniels 1998	Allocation: randomised. Participants: people with schizophrenia or schizoaffective disorder (DSM-IV). Intervention: Interactive behavioral therapy (IBT): an approach to social skills training with a combined focus on cognitive-behavioural techniques and group process strategies versus waiting list control group (N = 20).
DeCarlo 1985	Allocation: randomised - no further description. Participants: people with schizophrenia or depression. Interventions: verbal therapy versus activities group versus normal milieu therapy. Outcome: results were not broken down for each group (schizophrenia or depression).
Deng 2007	Intervention: Social skills training +routine care versus routine care alone. Training including: 1) interpersonal communication training; 2) confidence training; 3) recreational activities with token economy for good behaviour.
Denicola 1980	Allocation: randomised. Diagnosis: schizophrenia. Intervention: job training using three modelling conditions versus videotaped didactic presentation of instruction and control group.
Dincin 1982	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-II). Interventions: comprehensive rehabilitation program (individual casework, vocational rehabilitation, social rehabilitation, residential facilities, prevention of rehospitalisation) versus supportive treatment program.
Eisler 1978	Allocation: randomised. Diagnosis: schizophrenia. Intervention: Social skills training using the Behavioural Assertiveness Test-Revised (BAT-R) versus social skills training with modeling using the BAT-R versus rehearsal of scenes from the BAT-R.
Falloon 1977	Allocation: randomised - no further description. Participants: people with social skills deficits (social phobia, personality disorders, inadequate, depressive neurosis, schizophrenia, drug/alcohol abuse, obsessive compulsive neurosis, sexual deviation). Interventions: cohesive group discussion versus modelling and role-rehearsal versus modelling, role-rehearsal and daily social homework.
Finch 1977	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: interpersonal skills training versus normal hospital routine.

Study	Reason for exclusion
	Outcome: unusable data.
Fiorillo 2004	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: training program (psychoeducation, communication and problem solving training) versus augmented program (coping skills, meetings, exercises on the application of psychoeducation sessions).
Foxx 1985	Allocation: randomised (matched on the basis of their pre-assessment). Participants: people with schizophrenia (most of the participants). Interventions: game based social skills versus game based social skills.
Fuentes 2007	Allocation: randomised. Participants: people with schizophrenia (ICD-10). Intervention: Social perception module of IPT (integrated therapy program for schizophrenic patients) versus standard care control group.
Galderisi 2009	Allocation: randomised. Participants: clinical diagnosis of chronic schizophrenia or schizoaffective disorder according to the DSM-IV criteria, stable pharmacological treatment. Interventions: Integrated rehabilitation program, including individualised cognitive and social skills training versus standard structured leisure activities.
Gao 2006	Allocation: quasi-randomised according to odd and even number (possibly hospital admission number, but does not specify). Intervention including 1) independent living skills training, 2) social skills training; 3) team work training; 4) social activities training.
Glynn 1999	Allocation: randomised. Participants: individuals with DSM-IV diagnosis of schizophrenia or schizoaffective disorder on the basis of interviews with the Structured Clinical Interview for DSM-IV. Interventions: clinic-based skills training supplemented with manual-based generalisation sessions in the community, or clinic-based skills training alone.
Granholm 2002	Allocation: randomised - no further description. Participants: old people with schizophrenia, schizoaffective disorder (DSM-IV). Interventions: cognitive behavioural social skills training versus treatment as usual.
Gudeman 1981	Allocation: randomised - no further description. Participants: people with schizophrenia with minimum life daily skills. Interventions: Quarterway rehabilitation program (general integrative rehabilitation system) versus inpatients care.
Hayes 1991	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III-R). Interventions: activity therapy and social skills training versus activity therapy and social skills training (initiation time is different).
Hogarty 1973	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-II). Interventions: (factorial design 2 X 2) major role therapy versus control, chlorpromazine versus placebo.
Hogarty 2001	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorder with cognitive disability. Interventions: cognitive enhancement therapy versus enriched supportive therapy (social skills, psychoeducation, stress avoidance skills).
Horan 2009	Allocation: randomly assigned - no further description.

Study	Reason for exclusion
	Participants: patients meeting DSM-IV criteria for schizophrenia or schizoaffective disorder. Interventions: social cognitive intervention: affect perception, social perception, attributional style, Theory of Mind versus Control intervention: illness self-management and relapse prevention skills training, a module of the UCLA Social and Independent Living Skills Program.
Jaffe 1976	Allocation: randomisation unclear. Participants: psychosis (mainly schizophrenia), retardation. Interventions: modelling treatment versus instructions versus attention treatment.
Jenner 2004	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders, psychotic disorder (not otherwise specified). Interventions: hallucination focused integrative treatment (coping skills, CBT, psychoeducation, rehabilitation, and medication) versus routine care.
Jeppesen 2001	Allocation: randomised - no further description. Participants: people with schizophrenia spectrum disorder (ICD-10) and recent onset. Interventions: integrated treatment (AST, Psychoeducational multi family groups, SST) versus standard care.
Jerrell 1996	Allocation: randomised, URN randomisation method. Participants: people with psychotic disorder or major affective disorders (DSM-III-R), substance abuse. Interventions: behavioural skills training (CBT, reinforcement, social skills and independent living skills) versus intensive case management versus 12-step recovery model.
Kern 2005	Allocation: randomised. Participants: people with schizophrenia or schizoaffective disorder (DSM-IV criteria). Interventions: Social skills training: errorless learning versus symptom management module of UCLA Social and Independent Living Skills.
Kim 1997	Allocation: unclear. Participants: people with schizophrenia (DSM-IV). Interventions: family psychoeducation, patient psychoeducation, SST and routine care versus routine care alone.
Lecomte 1999	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders (DSM-III and SCID). Interventions: empowerment and self-esteem treatment (increase in self-esteem, self-worth, competence, as well as the ability to set goals and use active coping strategies) versus control.
Lee 1994	Allocation: quasi-randomised.
Lehman 2002	Allocation: randomised - no further description. Participants: people with severe mental illnesses. Interventions: Individual Placement and Support program (work therapy) versus psychosocial rehabilitation program.
Li 2008	Intervention: rehabilitation training + routine care versus routine care alone. Rehabilitation training including 1) independent living skills training; 2) social skills training; 3) cognitive behavioural training.
Li 2008a	Intervention: social skills training versus routine antipsychotic treatment. Main components of the training including 1) independent living skill training; 2) behavioural correction, e.g. return a borrowed book to library and basis social manners; 3) simple exercises and leisure activities; 4) outings - day trips.

Study	Reason for exclusion
Liang 2006	Intervention: social skills training + routine care versus routine care. Training including 1) independent living skills training; 2) introducing new activities and broaden patients hobbies; 3) social skills training; 4) psychoeducation.
Lieberman 1981	Allocation: randomised. Participants: schizophrenia (DSM-III, PES, CATEGO criteria). Intervention: social skills training versus holistic therapy.
Lieberman 1998	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: psychosocial occupational therapy versus social and independent living-skills program.
Lieberman 2002	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: (factorial design 2 X 2) haloperidol versus risperidone , social living skills versus social living skills and IVAST (in vivo amplified skills training).
Lindsay 1980	Allocation: randomised. Diagnosis: schizophrenia. Study took place on a token economy ward.
Linszen 1994	Allocation: randomised - no further description. Participants: people with schizophrenia or related disorder (DSM-III-R): 55% schizophrenia, 13% schizophreniform, 21% schizoaffective disorder, 11% other schizophrenia-related disorders. Interventions: individual oriented psychosocial intervention versus individual and family oriented psychosocial intervention.
Lu 2003	Allocation: randomised - no further description. Participants: inpatient with chronic inpatient schizophrenia (CCMD). Interventions: hospitalised occupational rehabilitation and routine care versus ordinary treatment (psychotherapy, work and amusement, music, drugs, and behavioural correction).
Lundin 1990	Allocation: randomised. Participants: people with schizophrenia. Interventions: Social skills as part of a psychosocial rehabilitation programme versus control group with maintenance drug treatment and one afternoon of social training per week.
Malm 2003	Allocation: randomised - no further description. Participants: people with schizophrenia spectrum disorder (DSM-IV). Interventions: integrated care (CBT, 24-hour crisis response, stress management, clinical decision making) versus rational rehabilitation.
Mausbach 2008	Allocation: randomised. Participants: persistent psychotic disorders. Intervention: Functional Adaptation and Skills training (FAST) versus PEDAL (culturally tailored version of FAST) versus control support group.
May 1985	Allocation: randomisation unclear. Participants: people with mental diseases. Interventions: life skills training (problem solving, interpersonal communication and fitness training) versus group counseling and occupational therapy.
McLatchie 1981	Allocation: randomised - no further description. Participants: people with schizophrenia (most of the participants). intervention : interpersonal problem solving therapy versus relaxation therapy.

Study	Reason for exclusion
Medalia 2000	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorder (DSM-IV). Interventions: problem-solving remediation group (using micro-computerised exercises) versus memory remediation group versus control group. All patients were treated with medications before and during the study.
Mariana 2006	Allocation: not randomised. Participants: people with schizophrenia according to DSM-IV criteria. Interventions: adapted version of UCLA Social and independent living skills program versus control group, receiving conventional outpatient treatment for schizophrenia.
Mueller 2005	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: cognitive social skills training for vocational functioning versus conventional unspecific social skills training.
Mueser 2001	Allocation: randomised - no further description. Participants: people with severe mental illness. Interventions: Individual Placement and Support (work therapy) versus psychiatric rehabilitation program versus standard services.
Munjiza 1999	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: psychopharmacotherapy in a milieu therapy versus group therapy and pharmacotherapy.
Munroe 1995	Allocation: randomised - no further description. Participants: people with schizophrenia and their relatives. Interventions: social skills training program (time limited) versus psychoeducation for relatives versus both treatments in parallel. outcomes: unusable data.
NCT00071591 2003	Ongoing trial. Intervention: Functional Adaptation Skills Training (FAST) versus psychosocial support group.
Ni 2008	Intervention: social skills training versus care as usual. Three main components: 1) 10 weeks were spent solely social skills training; 2) then 10 months on occupational training, e.g. cooking, gardening, cleaning, being shop assistant, craft work; 3) finally 10 months on return to community skills training, including training on medication management, symptom self-monitoring, managing finances, how to utilise community services.
Nordentoft 1999	Allocation: randomised - no further description. Participants: people with schizophrenia, schizophrenia-like psychosis (criteria of international classification of disease). Interventions: integrative treatment (psychoeducation, social skills training and family involvement) versus standard treatment.
Norman 2002	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III-R, SCID). Interventions: stress management versus social activities.
Nuechterlein 2005	Allocation: randomised - no further description. Participants: people with schizophrenia (recent onset). Interventions: individual placement and supportive and work fundamental modules versus traditional vocational rehabilitation.
Nuttbrock 1997	Allocation: randomised - no further description. Participants: people with mental illness (DSM-III-R), substance abuse.

Study	Reason for exclusion
	Interventions: community residence versus therapeutic community.
O'Keefe 2003	Allocation: unclear. Participants: people with schizophrenia, schizoaffective disorder. Interventions: workplace fundamental modules versus supported employment.
Odhner 1970	Allocation: randomised - no further description. Participants: people with schizophrenia nonparanoid. Interventions: performance tasks versus verbal tasks.
Oei 1981	Allocation: randomised - no further description. Participants: people with chronic schizophrenia - females only. Interventions: no visit to patient versus 1 visit/week versus 2 visits/week versus 3 visits/week.
Patterson 2005	Allocation: randomised. Participants: Schizophrenia or schizoaffective disorder. Intervention: "PEDAL" Program for Training and Development of Skills in Latinos, which is culturally tailored and in Spanish to enhance the functioning of Latino patients with schizophrenia who live in the community versus "FAST" Equivalent skills training program with no cultural tailoring versus time equivalent support group
Patterson 2006a	Allocation: randomised. Diagnosis: DSM-IV-based chart diagnosis of schizophrenia or schizoaffective disorder. Intervention: Functional Adaptation and Skills training (FAST) versus a time-equivalent attention-control program.
Paul 1977	Allocation: not randomised, matched groups design. Participants: people with schizophrenia. Interventions: social learning programme and token economy versus milieu environmental therapy versus traditional hospital therapy.
Petersen 2005	Allocation: randomised - no further description. Participants: people with schizophrenia spectrum (ICD-10) (first episode). Interventions: integrated treatment (psychoeducation, SST, psychoeducational family treatment) versus standard care.
Prentice 2003	Allocation: randomised - no further description. Participants: people with schizophrenia. Interventions: social skills training versus decision-making training.
Razali 2000	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM IV). Interventions: behavioural family therapy versus cultured modified family therapy.
Rosenbaum 2005	Allocation: randomised - no further description. Participants: people with schizophrenic spectrum disorder (ICD-10). Interventions: supportive psychodynamic psychotherapy versus integrated treatment (assertive, psychosocial and educational treatment program) versus TAU.
Rossotto 2003	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders. Interventions: psychoeducational treatment (the community re-entry program) versus standard educational classes.
Smith 1999	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders (DSM-III-R).

Study	Reason for exclusion
	Interventions: skills training (community re-entry program) and medication versus supportive psychotherapy and medication.
Tang 2007	Allocation: randomised. Participants: schizophrenic patients. Intervention: experimental intervention is social skills training, including independent living skills training; 2) medication self-management training; 3) symptom self-monitoring training.
Tarrier 2000	Allocation: randomised. Participants: people with schizophrenia. Interventions: cognitive behavioural therapy versus supportive counselling and routine care.
Test 1989	Allocation: randomised - no further description. Participants: people with schizophrenia and schizotypal personality disorder (research diagnostic criteria), schizotypal personality disorders DSMIII. Interventions: training community living (TCL) (system management, optimally supportive environment) versus Dane models system (bio/psycho/social services similar to TCL but organised in different way) invoked depending on individuals needs.
Torres 2002	Allocation: randomly assigned - no further description. Participants: People meeting DSM-IV criteria for schizophrenia, all receiving antipsychotic medication. Interventions: 1) Playing “El Tren” (team problem solving board game emphasizing positive reinforcement, repetition and procedural learning, designed to overcome negative symptoms), social skills training, psychomotor skills training and occupational therapy. 2) Social skills training, psychomotor skills training and occupational therapy. 3) Occupational therapy only.
Tsang 2009	Allocation: randomly assigned using SPSS. Participants: People suffering from SMI (operationally defined as schizophrenia, schizo-affective disorder, bipolar disorder, recurrent major depression, or borderline personality disorder) following DSM-IV criteria. Interventions: Integrated supported employment (ISE) program, which augments Individual Placement & Support (IPS) with social skills training (SST), IPS only, and traditional vocational rehabilitation (TVR).
Urioste 2005	Allocation: randomised - no further description. Participants: people with schizophrenia, schizoaffective disorders. Interventions: psychosocial tool (GAIN Acceptance Approach) versus approach as usual in supporting acceptance of long-acting risperidone.
Vauth 2005	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-IV). Interventions: computer-assisted cognitive strategy training versus self-management skills for negative symptoms (time scheduling, mastery, pleasure techniques).
Ventegodt 2001	Allocation: randomised - no further description. Participants: people with schizophrenia, delusional disorder, paranoid state. Interventions: integrative treatment (assertive community treatment, psychoeducation and social skills training) versus standard treatment.
Walker 1969	Allocation: randomisation not efficiently described. Participants: people with mental diseases. Interventions: community hospital industrial rehabilitation placement (CHIRP) versus employment without community hospital industrial rehabilitation.
Weinman 1974	Allocation: not randomised, control group is matched on the basis of age and length of hospitalisation.

Study	Reason for exclusion
	Participants: people with chronic psychotic disorders. Interventions: community treatment versus socioenvironmental therapy versus traditional hospital treatment.
Weng 2005	Allocation: randomised - no further description. Participants: people with schizophrenia (DSM-III-R). Interventions: rehabilitation program (SST, daily living skills, relaxation therapy, occupational therapy, educational program, and medication) versus control group.
Whetstone 1986	Allocation: quasi-randomised. Participants: people with schizophrenia (American Psychiatric Association). Interventions: social dramatic scenarios versus control.
Wiersma 2004	Allocation: randomised - no further description. Participants: people with chronic schizophrenia with hallucination. Interventions: integrated treatment condition (rehabilitation, coping skills, family treatment, cognitive behavioural intervention) versus standard care.
Wirshing 1991	Allocation: randomised. Participants: schizophrenic patients. Intervention: Medication management and symptom management versus standard supportive psychotherapy.
Xiang 2002	Allocation: randomised. Participants: schizophrenic patients Intervention: skills training vs routine care. Training package includes elements of independent living skills training, medication management training, symptom self-monitoring training.
Xiang 2007	Allocation: randomised. Participants: schizophrenic (DSM IV). Interventions: community re-entry module of the UCLA Social and independent living skills programme versus group psycho-education,.
Xu 2008	Intervention: social skills training versus routine care. Training including 1) medication management training; 2) social skills training; 3) occupational skills training
Yang 2003	Allocation: not randomised.
Yue 1998	Intervention: target behaviour therapy versus care as usual.
Zhang 2002	Allocation: randomised. Participants: 67 schizophrenia patients and 59 affective disorder patients; Intervention: psychoeducation versus care as usual
Zheng 2006	Allocation: randomised. Participants: schizophrenic patients. Intervention: life skills training including 1) independent living skills training; 2) social skills training; 3) art appreciation and other recreational activities versus routine care.

CBT = cognitive behavioural therapy
CCMD = Chinese Classification of Mental Disorders
DSM-IV = Diagnostic and Statistical Manual of Mental Disorders, 4th edition
ICD-10 - International Classification of Diseases, tenth revision.

Characteristics of ongoing studies *[ordered by study ID]*

NCT00069433 2003

Trial name or title	Skills training for schizophrenia: enhancing outcomes
Methods	Randomised controlled trial.
Participants	People with schizophrenia.
Interventions	1. Intensive symptom management and social skills training. 2. Group therapy.
Outcomes	Not reported.
Starting date	Not reported.
Contact information	Not reported.
Notes	ClinicalTrials.gov Identifier: NCT00069433 2003 . Trial suspended.

NCT00183625 2005

Trial name or title	The effectiveness of supplementing supported employment with behavioral skills training in schizophrenia patients taking risperidone or olanzapine
Methods	Randomised controlled trial.
Participants	People with schizophrenia.
Interventions	1. Social skills training 2. Individual placement and support Drug intervention1. Olanzapine Drug intervention 2. Risperidone
Outcomes	Functional outcome. Quality of life.
Starting date	June 2000.
Contact information	
Notes	ClinicalTrials.gov Identifier: NCT00183625 2005 .

NCT00237796 2005

Trial name or title	Functional rehabilitation of older patients with schizophrenia.
Methods	Randomised controlled trial.
Participants	Older patients with schizophrenia.
Interventions	1. Cognitive behavioural social skills training. 2. Supportive contact.

NCT00237796 2005 (Continued)

Outcomes	Social functioning (at baseline); End of treatment (9-month follow-up); 9-month post-treatment (18-month follow-up); additionally, at midtreatment (4.5 months). Secondary outcomes: Neuropsychological functioning, cognitive insight, psychotic symptoms, and health services utilisation, will be conducted at baseline, end of treatment (9-month follow-up), and 9-month post-treatment (18-month follow-up).
Starting date	February 2005.
Contact information	Jody Delapena, BA 858-552-8585 Ext. 2743 jodelapena@popmail.ucsd.edu Sherry Edwards, BA 858-552-8585 Ext. 2275 sedwards@ucsd.edu
Notes	ClinicalTrials.gov identifier NCT00237796 2005 .

NCT00338975 2006

Trial name or title	Cognitive behavioral social skills training for improving social functioning in people with schizophrenia
Methods	Randomised controlled trial.
Participants	People with schizophrenia.
Interventions	1. Cognitive behavioural therapy. 2. Social skills training. 3. Goal setting. 4. Active supportive contact.
Outcomes	Primary outcomes: Measured at months 9, 15, and 21: Social functioning. Secondary outcomes: Measured at months 9, 15, and 21: Neuropsychological functioning; Cognitive insight; Psychotic symptoms; Health services utilisation.
Starting date	June 2005.
Contact information	Sherry Edwards 858-552-8585 Ext. 2275 sedwards@ucsd.edu.
Notes	ClinicalTrials.gov identifier NCT00338975 2006 .

NCT00391677 2006

Trial name or title	Attention shaping procedures for improving psychosocial skills among adults with schizophrenia
Methods	Randomised controlled trial.
Participants	People with schizophrenia.
Interventions	1. Attention shaping procedures plus basic conversation skills training (BCS). 2. BCS alone.
Outcomes	Primary outcomes: Measured 6 months post-intervention: Observational ratings of in-group attentiveness; observational ratings of in-group attentiveness in non-study groups; changes in knowledge of information about social skills taught in the study; changes in ability to demonstrate behavioural skills taught in the study; level of social functioning.

NCT00391677 2006 (Continued)

Secondary outcomes: Measured 6 months post-intervention: Self-efficacy; working alliance; satisfaction with treatment.

Starting date	December 2006.
Contact information	Steven M. Silverstein, PhD 732-235-5149 silvers1@umdnj.edu. Igor Malinovski 732-235-5148 malinovsky01@icqmail.com.
Notes	ClinicalTrials.gov identifier NCT00391677 2006 .

NCT00601224 2008

Trial name or title	Social cognition and interaction training for improving social functioning in people with schizophrenia
Methods	Randomised controlled trial.
Participants	People with schizophrenia.
Interventions	1. Social cognition and interaction training (SCIT) 2. Treatment as usual (TAU)
Outcomes	Face emotion identification task (FEIT). Face emotion discrimination task (FEDT). The hinting task. The awareness of social inference test (TASIT). Ambiguous intentions hostility questionnaire (AIHQ).
Starting date	June 2007.
Contact information	Piper S. Meyer, PhD 919-843-5262 psmeyer@email.unc.edu.
Notes	ClinicalTrials.gov identifier: NCT00601224 2008

NCT00791882 2008

Trial name or title	Evaluation of social skills training in reducing negative symptoms in patients with refractory schizophrenia
Methods	Randomised controlled trial.
Participants	People with refractory schizophrenia.
Interventions	1. Social skills training. 2. Control group.
Outcomes	Response: at least 20% decrease in PANSS - negative subscale after 20 weeks, in comparison with baseline, maintained at 26 weeks follow-up.
Starting date	February 2009.
Contact information	Helio Elkis, MD PhD + 55 11 30697531 helkis@usp.br Silvia Scemes, BSc + 55 11 30697808 silviascemes@gmail.com

Social skills programmes for schizophrenia (Review)

NCT00791882 2008 (Continued)

Notes

[NCT00791882 2008.](#)
Pratt 2008

Trial name or title	Helping older people experience success: an integrated model of psychosocial rehabilitation and health care management for older adults with serious mental illness.
Methods	Randomised controlled trial.
Participants	Older people with serious mental illness.
Interventions	1. Social skills training and health management. 2. Standard care.
Outcomes	Not reported.
Starting date	Not reported.
Contact information	Sarah Pratt, Ph.D., Assistant Professor of Psychiatry, Dartmouth Psychiatric Research Center, 105 Pleasant Street, Main Building, Concord, NH 03301, USA. E-mail: sarah.i.pratt@dartmouth.edu.
Notes	

PANSS = Positive and Negative Syndrome Scale

DATA AND ANALYSES
Comparison 1. SOCIAL SKILLS versus STANDARD CARE

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Social functioning: average endpoint score (various scales)	4		Mean Difference (IV, Fixed, 95% CI)	Totals not selected
1.1 SDSS (higher = worse)	2		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.2 SAD (higher = worse)	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.3 SSPI (higher = worse)	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
1.4 DAS (higher = worse)	1		Mean Difference (IV, Fixed, 95% CI)	0.0 [0.0, 0.0]
2 Relapse	2	263	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.34, 0.79]
3 Global state: not clinically improved.	1	67	Risk Ratio (M-H, Fixed, 95% CI)	0.29 [0.12, 0.68]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
4 Service outcome: rehospitalisation	1	143	Risk Ratio (M-H, Fixed, 95% CI)	0.53 [0.30, 0.93]
5 Mental state: average endpoint score	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
5.1 Negative symptoms (SANS, higher = worse)	2	187	Mean Difference (IV, Fixed, 95% CI)	-8.92 [-10.46, -7.38]
5.2 Positive symptoms (SAPS, higher = worse)	1	120	Mean Difference (IV, Fixed, 95% CI)	-1.90 [-3.37, -0.43]
6 Mental state: average change in score	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
6.1 General symptoms (BPRS, higher = worse)	1	91	Mean Difference (IV, Fixed, 95% CI)	-4.01 [-7.52, -0.50]
6.2 Negative symptoms (SANS, higher = worse)	1	91	Mean Difference (IV, Fixed, 95% CI)	-7.7 [-12.23, -3.17]
7 Behaviours: Rated as worse	1	48	Risk Difference (M-H, Fixed, 95% CI)	0.0 [-0.16, 0.16]
7.1 aggressive behaviour	1	12	Risk Difference (M-H, Fixed, 95% CI)	0.0 [-0.27, 0.27]
7.2 interaction with staff	1	12	Risk Difference (M-H, Fixed, 95% CI)	0.0 [-0.27, 0.27]
7.3 interaction with patients	1	12	Risk Difference (M-H, Fixed, 95% CI)	0.0 [-0.27, 0.27]
7.4 problem solving ability	1	12	Risk Difference (M-H, Fixed, 95% CI)	0.0 [-0.27, 0.27]
8 General functioning: average endpoint score (MRSS, higher = worse)	1	112	Mean Difference (IV, Fixed, 95% CI)	-10.60 [-17.47, -3.73]
9 General functioning: Not employed	1	46	Risk Ratio (M-H, Fixed, 95% CI)	5.43 [0.28, 107.33]
10 Leaving the study early	9		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
10.1 Any reason	9	719	Risk Ratio (M-H, Fixed, 95% CI)	2.04 [1.00, 4.16]
11 Quality of life: average endpoint score (various scales)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
11.1 GWB (higher = better)	1	112	Mean Difference (IV, Fixed, 95% CI)	-7.60 [-12.18, -3.02]
11.2 SES (higher = better)	1	112	Mean Difference (IV, Fixed, 95% CI)	-8.3 [-10.07, -6.53]

Analysis 1.1. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 1 Social functioning: average endpoint score (various scales).

Study or subgroup	Social skills		Standard care		Mean Difference		Mean Difference Fixed, 95% CI
	N	Mean(SD)	N	Mean(SD)	Fixed, 95% CI		
1.1.1 SDSS (higher = worse)							
Lu 2004	56	4.3 (2.2)	56	5.8 (2.6)	+		-1.5[-2.39,-0.61]
Saren 2004	72	6 (3)	71	16 (5)	++		-10[-11.35,-8.65]
1.1.2 SAD (higher = worse)							
Saren 2004	72	9 (2)	71	25 (4)	+		-16[-17.04,-14.96]
1.1.3 SSPI (higher = worse)							
Huang 2005	33	5.9 (2.2)	34	12 (2.5)	+		-6.06[-7.17,-4.95]
1.1.4 DAS (higher = worse)							
Ma 2003	60	9.4 (7.6)	60	16.2 (12.6)	+		-6.8[-10.52,-3.08]

Favours social skills -20 -10 0 10 20 Favours standard care

Analysis 1.2. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 2 Relapse.

Study or subgroup	Social skills	Standard care	Risk Ratio M-H, Fixed, 95% CI	Weight	Risk Ratio M-H, Fixed, 95% CI
	n/N	n/N			
Ma 2003	6/60	18/60		38.96%	0.33[0.14,0.78]
Saren 2004	18/72	28/71		61.04%	0.63[0.39,1.04]
Total (95% CI)	132	131		100%	0.52[0.34,0.79]

Total events: 24 (Social skills), 46 (Standard care)
Heterogeneity: Tau²=0; Chi²=1.68, df=1(P=0.2); I²=40.38%
Test for overall effect: Z=3.03(P=0)

Favours social skills 0.1 0.2 0.5 1 2 5 10 Favours standard care

Analysis 1.3. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 3 Global state: not clinically improved..

Study or subgroup	Social skills	Standard care	Risk Ratio M-H, Fixed, 95% CI	Weight	Risk Ratio M-H, Fixed, 95% CI
	n/N	n/N			
Huang 2005	5/33	18/34		100%	0.29[0.12,0.68]
Total (95% CI)	33	34		100%	0.29[0.12,0.68]

Total events: 5 (Social skills), 18 (Standard care)
Heterogeneity: Not applicable
Test for overall effect: Z=2.83(P=0)

Favours social skills 0.01 0.1 1 10 100 Favours standard care

Analysis 1.4. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 4 Service outcome: rehospitalisation.

Analysis 1.5. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 5 Mental state: average endpoint score.

Analysis 1.6. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 6 Mental state: average change in score.

Analysis 1.7. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 7 Behaviours: Rated as worse.

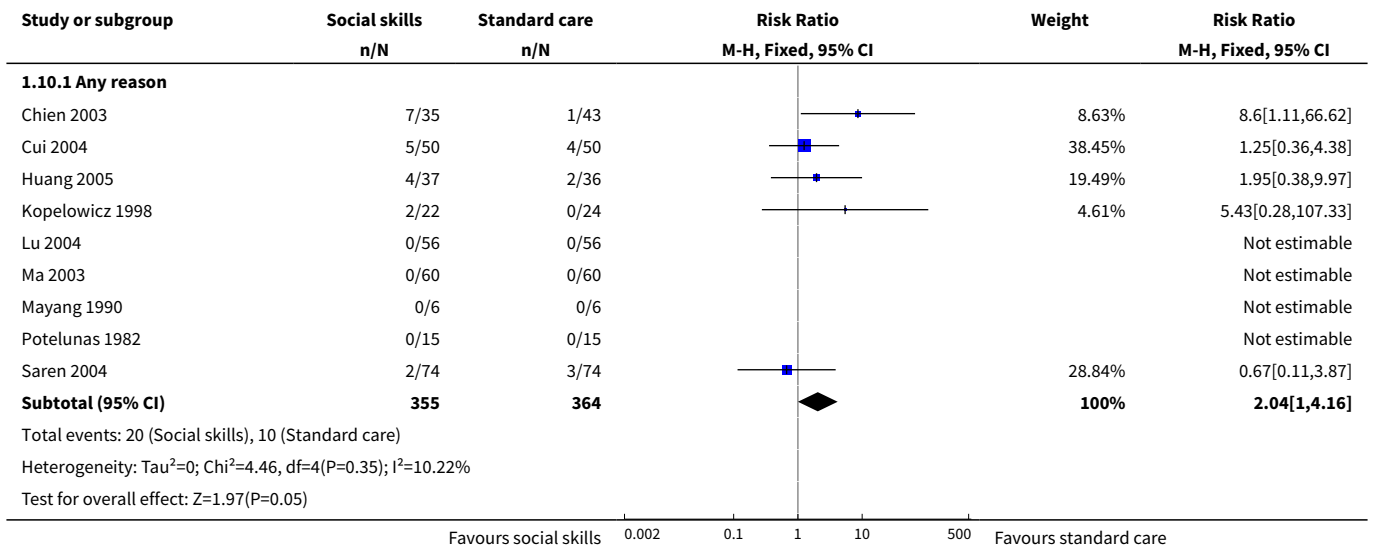

Analysis 1.8. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 8 General functioning: average endpoint score (MRSS, higher = worse).

Analysis 1.9. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 9 General functioning: Not employed.

Analysis 1.10. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 10 Leaving the study early.

Analysis 1.11. Comparison 1 SOCIAL SKILLS versus STANDARD CARE, Outcome 11 Quality of life: average endpoint score (various scales).

Comparison 2. SOCIAL SKILLS versus DISCUSSION CONTROL

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Social functioning: average endpoint score (various scales)	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
1.1 SSQ (higher = worse)	1	63	Mean Difference (IV, Fixed, 95% CI)	-1.10 [-11.14, 8.94]
1.2 SCON (higher = better)	1	63	Mean Difference (IV, Fixed, 95% CI)	-2.5 [-5.52, 0.52]
1.3 SFS (higher = better)	1	36	Mean Difference (IV, Fixed, 95% CI)	4.60 [-7.54, 16.74]
1.4 SBS (higher = worse)	1	36	Mean Difference (IV, Fixed, 95% CI)	0.5 [-2.56, 3.56]
2 Relapse	1	35	Risk Ratio (M-H, Fixed, 95% CI)	2.12 [0.44, 10.10]
3 Global state: average endpoint score (GAS, higher = better)	1	63	Mean Difference (IV, Fixed, 95% CI)	4.50 [-1.20, 10.20]
4 Mental state: average endpoint score	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
4.1 General symptoms (BPRS, higher = worse)	2	99	Mean Difference (IV, Fixed, 95% CI)	0.22 [-4.05, 4.49]
4.2 Negative symptoms (SANS, higher = worse)	2	99	Mean Difference (IV, Fixed, 95% CI)	2.89 [-4.43, 10.22]
5 Leaving the study early	2	69	Risk Ratio (M-H, Fixed, 95% CI)	1.58 [0.37, 6.68]
6 Quality of life: average endpoint score (QLS, higher = better)	1	63	Mean Difference (IV, Fixed, 95% CI)	3.70 [-6.47, 13.87]

Analysis 2.1. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 1 Social functioning: average endpoint score (various scales).

Analysis 2.2. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 2 Relapse.

Analysis 2.3. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 3 Global state: average endpoint score (GAS, higher = better).

Analysis 2.4. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 4 Mental state: average endpoint score.

Analysis 2.5. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 5 Leaving the study early.

Analysis 2.6. Comparison 2 SOCIAL SKILLS versus DISCUSSION CONTROL, Outcome 6 Quality of life: average endpoint score (QLS, higher = better).

ADDITIONAL TABLES

Table 1. Broad areas for review suggested by excluded studies

Broad category	Sub-category	Excluded study	Cochrane review
Culture-specific modification of therapies		Mausbach 2008; Patterson 2005; Razali 2000	
Education		Browne 1996; Chabannes 2008; Chan 2009; Cormier 1995; Linszen 1994; Munroe 1995; Rossotto 2003; Xiang 2007; Zhang 2002	
Integrated programme - often involving some aspect of social skills training		Barrowclough 2001; Fiorillo 2004; Fuentes 2007; Galderisi 2009; Gao 2006; Jenner 2004; Jeppesen 2001; Malm 2003; Nordentoft 1999; Petersen 2005; Rosenbaum 2005; Torres 2002; Ventegodt 2001; Weng 2005; Wiersma 2004; Jerrell 1996; Kim 1997; Test 1989; Xiang 2002	
Leisure activities		Bruns 1992; Cormier 1995; Galderisi 2009; Norman 2002	
Medication		Hogarty 1973; Liberman 2002;	
Other packages or approaches to care		Weinman 1974; Falloon 1977; Hayes 1991; Jaffe 1976; Lindsay 1980; Liberman 1981; Munjiza 1999; Nuttbrock 1997; Oei 1981; Urioste 2005	
Rehabilitation programme		Cannon 1985; Choi 2006; Dincin 1982; Gudeman 1981; Lehman 2002; Li 2008; Lu 2003; Lundin 1990; Malm 2003; Mueser 2001	
Skills training	Life skills	Zheng 2006; May 1985; Armstrong 1991; Brown 1983; Cannon 1985; Moriana 2006	
	Other	Falloon 1977; Falloon 1977; Finch 1977; Glynn 1999; Horan 2009; Jerrell 1996; Kern 2005; Liberman 1998; Liberman 2002; Mausbach 2008; NCT00071591 2003; Odhner 1970; Patterson 2006a; Smith 1999; Test 1989; Wirshing 1991	
	Social	Chandler 2000; Deng 2007; Eisler 1978; Eisler 1978; Foxx 1985; Foxx 1985; Granholm 2002; Horan 2009; Kern 2005; Li 2008a; Liang 2006; Liberman 1981; Mueller 2005; Mueller 2005; Munroe 1995; Munroe 1995; Ni 2008; Prentice 2003; Tang 2007; Xiang 2007; Xu 2008	
Therapy	Focused around employment/vocational	Denicola 1980; Lehman 2002; Mueser 2001; Nuechterlein 2005; O'Keefe 2003; Tsang 2009; Walker 1969	

Table 1. Broad areas for review suggested by excluded studies (Continued)

Non-specific	Bruns 1992; Buchbauer 1986; NCT00071591 2003
Occupational	May 1985; Torres 2002; Liberman 1998
Specific named approach	Buchbauer 1986; Jaffe 1976; Patterson 2006a; Yue 1998; Tarrier 2000; Hogarty 2001; ACTRN12609000317291; Vauth 2005; Alter 1993; Prentice 2003; Whetstone 1986; Lecomte 1999; Cerniglia 1978; Razali 2000; Daniels 1998; Hogarty 1973; Medalia 2000; Paul 1977; DeCarlo 1985; Munjiza 1999; Jaffe 1976; Torres 2002; McLatchie 1981; Medalia 2000; McLatchie 1981; Beal 1977; Vauth 2005; Choi 2006; Paul 1977; Weinman 1974; Norman 2002; Rosenbaum 2005; Smith 1999; Dincin 1982; Hogarty 2001; Tarrier 2000; Wirshing 1991; DeCarlo 1985

Table 2. Suggested design of study

Methods	Allocation: randomised, clearly described and concealed. Duration: 1 year or more.
Participants	Diagnosis: schizophrenia. N = 300. Age: adults. Sex: men or women. History: perhaps once an episode of moderate severity has subsided and after a period of stability.
Interventions	1. Social skills programme: delivered in a way that is possible in routine care with minimal additional resource. 2. Standard care.
Outcomes	Healthy days. Mental state: improved to important degree. Global state: improved to important degree, relapse. Service use: admission, time in hospital. Social functioning: employment status, relationships. Quality of life: improved to important degree. Economic outcomes: cost. Adverse effect: Any important adverse event

WHAT'S NEW

Date	Event	Description
28 April 2015	Amended	Author added to byline.

CONTRIBUTIONS OF AUTHORS

Muhammad Qutayba Almerie - helped write protocol, selection of studies and data extraction (based on 2006 search)

Muhammad Okba Al Marhi - helped write protocol, selection of studies and data extraction (based on 2006 search) .

Mohamad Jawoosh - helped write protocol, screened the search results, appraised the papers, extracted data, managed them and then entered them into RevMan (based on 2006 search).

Mohamad Alsabbagh - helped write protocol, selection of studies and data extraction (based on 2006 search)

Hosam Matar - helped write protocol, selection of studies and data extraction (based on 2006 search)

Nicola Maayan - selection of studies, data extraction (based on 2010 search) completion of the 'Summary of findings' tables, risk of bias tables, completion of report.

Hanna Bergman - selection of studies, data extraction (based on 2010 search).

DECLARATIONS OF INTEREST

All review authors have no conflict of interest.

Hanna Bergman and Nicola Maayan - work for Enhance Review Ltd, a company that carries out systematic reviews mostly for the public sector. We currently do not provide services for the pharmaceutical industry.
