ABSTRACT

Background

Babies with breech presentation (bottom first) are at increased risk of complications during birth, and are often delivered by caesarean section. The chance of breech presentation persisting at the time of delivery, and the risk of caesarean section, can be reduced by external cephalic version (ECV - turning the baby by manual manipulation through the mother's abdomen). It is also possible that maternal posture may influence fetal position. Many postural techniques have been used to promote cephalic version.

Objectives

The objective of this review was to assess the effects of postural management of breech presentation on measures of pregnancy outcome. We evaluated procedures in which the mother rests with her pelvis elevated. These include the knee-chest position, and a supine position with the pelvis elevated with a wedge-shaped cushion.

Search methods

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register (22 August 2012).

Selection criteria

Randomised and quasi-randomised trials comparing postural management with pelvic elevation for breech presentation, with a control group.

Data collection and analysis

One or both review authors assessed eligibility and trial quality.

Main results

We have included six studies involving a total of 417 women. The rates for non-cephalic births, Caesarean section and Apgar scores below 7 at one minute, regardless of whether ECV was attempted or not, were similar between the intervention and control groups (risk ratio (RR) 0.98; 95% confidence interval (CI) 0.84 to 1.15; RR 1.10; 95% CI 0.89 to 1.37; RR 0.88; 95% CI 0.50 to 1.55).

Authors' conclusions

There is insufficient evidence from well-controlled trials to support the use of postural management for breech presentation. The numbers of women studied to date remain relatively small. Further research is needed.

PLAIN LANGUAGE SUMMARY

Cephalic version by postural management for breech presentation

There is currently not enough evidence for encouraging the mother to adopt different postures during pregnancy in order to change a breech baby's position in the womb.

Babies born in the breech position (bottom first) are more likely to have problems during birth than babies born head first (cephalic). There are different ways of trying to encourage the baby to turn so that he/she can be born head first. Some of these involve the mother adopting different postures. This review of six trials, involving 417 women, found too little evidence to support the use of certain postures to change the baby's position in pregnancy to head down. Further research is required.

BACKGROUND

Babies with breech presentation (bottom first) are at increased risk of complications during birth. This risk can be reduced by planned caesarean section (Hofmeyr 2003). The chance of breech presentation persisting at the time of delivery, and the risk of caesarean section, can be reduced by external cephalic version (ECV - turning the baby by manual manipulation through the mother's abdomen) (Hofmeyr 1996). Other methods used to attempt to correct the position of the baby include acupuncture, homoeopathy and postural methods. Over the years many postural techniques have been used by midwives, doctors and traditional birth attendants to promote cephalic version (Hofmeyr 1989). Little, however, has appeared in the medical literature on this subject. Elkins 1982 reported an uncontrolled trial of the knee-chest position, assumed for 15 minutes every two hours of waking for five days. Use of this procedure in 71 women with ultrasound-confirmed breech presentation after 37 weeks' gestation was followed by a normal cephalic birth in 65 cases. This method has been modified by researchers (e.g. knee-chest position assumed with full urinary bladder three times a day for seven days) (Chenia 1987). Another postural method is 'Indian version', assuming the supine, head-down position with the pelvis supported by a wedge-shaped cushion for 10 to 15 minutes once or twice a day (Bung 1987).

OBJECTIVES

To assess the effects on presentation at and method of delivery, and perinatal morbidity and mortality, of postural management for breech presentation.

METHODS

Criteria for considering studies for this review

Types of studies

Clinical trials comparing the effects of postural management with pelvic elevation for breech presentation on clinically meaningful outcomes, with a control group (no treatment); random or quasi-random allocation to a treatment and control group; violations of allocated management and exclusions after allocation not sufficient to materially affect outcomes.

Types of participants

Women with singleton breech presentation.

Types of interventions

Postural management entailing relaxation with the pelvis in an elevated position.

Types of outcome measures

We have included outcome data if reasonable measures were taken to minimise observer bias; missing data were insufficient to materially influence conclusions; data were available for analysis according to original allocation, irrespective of protocol violations; and data were available in a format suitable for analysis.

Primary outcomes

- Non-cephalic birth
- Caesarean section

Secondary outcomes

- Apgar score less than seven at one minute
- Apgar score less than seven at five minutes
- Poor perinatal outcome as defined by trial authors

Search methods for identification of studies

Electronic searches

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register by contacting the Trials Search Co-ordinator (22 August 2012).

The Cochrane Pregnancy and Childbirth Group's Trials Register is maintained by the Trials Search Co-ordinator and contains trials identified from:

1. monthly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
2. weekly searches of MEDLINE;
3. weekly searches of EMBASE;
4. handsearches of 30 journals and the proceedings of major conferences;
5. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Details of the search strategies for CENTRAL, MEDLINE and EMBASE, the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service can be found in the 'Specialized Register' section within the editorial information about the [Cochrane Pregnancy and Childbirth Group](#).

Trials identified through the searching activities described above are each assigned to a review topic (or topics). The Trials Search Co-ordinator searches the register for each review using the topic list rather than keywords.

We did not apply any language restrictions.

Data collection and analysis

For the 2010 update, we used the following methods when assessing the trial identified by the updated search (Founds 2006). For the methods used when assessing the trials identified in earlier versions of this review, see [Appendix 1](#).

Selection of studies

GJ Hofmeyr (GJH) (first review author) and T Lawrie (TL) (see [Acknowledgements](#)) independently assessed for inclusion the study identified as a result of the search strategy. We resolved any disagreement through discussion.

Data extraction and management

We designed a form to extract data. For the eligible study, GJH and TL extracted the data using the agreed form. We resolved discrepancies through discussion and, if required, would have consulted R Kulier (RK). We entered data into Review Manager software ([RevMan 2008](#)) and checked them for accuracy.

Assessment of risk of bias in included studies

GJH and TL independently assessed the risk of bias for each study using the criteria outlined in the *Cochrane Handbook for*

Systematic Reviews of Interventions (Higgins 2009). We resolved any disagreement by discussion and, if required, would have consulted RK.

(1) Sequence generation (checking for possible selection bias)

We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

- low risk (any truly random process, e.g. random number table; computer random number generator),
- high risk (any non-random process, e.g. odd or even date of birth; hospital or clinic record number) or,
- unclear risk of bias.

(2) Allocation concealment (checking for possible selection bias)

We described for each included study the method used to conceal the allocation sequence and determined whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- low risk (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear risk of bias.

(3) Blinding (checking for possible performance bias)

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judge that the lack of blinding could not have affected the results. We assessed blinding separately for different outcomes or classes of outcomes.

We assessed the methods as:

- low risk, high risk or unclear risk of bias for participants;
- low risk, high risk or unclear risk of bias for personnel;
- low risk, high risk or unclear risk of bias for outcome assessors.

(4) Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations)

We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. We assessed methods as:

- low risk;
- high risk;
- unclear risk of bias.

(5) Selective reporting bias

We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found.

We assessed the methods as:

- low risk (where it was clear that all of the study's pre-specified outcomes and all expected outcomes of interest to the review had been reported);
- high risk (where not all the study's pre-specified outcomes had been reported; one or more reported primary outcomes were not pre-specified; outcomes of interest were reported incompletely and so could not be used; study failed to include results of a key outcome that would have been expected to have been reported);
- unclear risk of bias.

(6) Other sources of bias

We described for each included study any important concerns we had about other possible sources of bias.

We assessed whether each study was free of other problems that could put it at risk of bias:

- high risk;
- low risk;
- unclear risk of bias.

(7) Overall risk of bias

We made explicit judgements about whether studies were at high risk of bias, according to the criteria given in the *Handbook* (Higgins 2009). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it likely to impact on the findings. We explored the impact of the level of bias through undertaking sensitivity analyses - see [Sensitivity analysis](#).

Measures of treatment effect

Dichotomous data

For dichotomous data, we present results as a summary risk ratio (RR) with 95% confidence intervals (CI).

Continuous data

We analysed no continuous data for this review. In future updates of this review, if more data become available, we will analyse continuous data using the mean difference if outcomes are measured in the same way between trials. We will use the standardised mean difference to combine trials that measure the same outcome but use different methods.

Unit of analysis issues

Cluster-randomised trials

We did not identify any cluster-randomised trials for inclusion in this update. In future updates, if we identify any cluster-randomised trials, they will be included in the analyses along with the individually randomised trials, following the guidelines described in the *Handbook* (Section 16.3.4 and 16.3.6). We will also acknowledge heterogeneity in the randomisation unit and perform

a sensitivity and subgroup analysis to investigate the effects of the randomisation unit.

Crossover trials

We have not included crossover trials.

Dealing with missing data

For included studies, we noted levels of attrition. We explored the impact of including studies with high levels of missing data in the overall assessment of treatment effect by using sensitivity analysis. For all outcomes, we carried out analyses, as far as possible, on an intention-to-treat basis, i.e. we attempted to include all participants randomised to each group in the analyses, and all participants were analysed in the group to which they were allocated, regardless of whether or not they received the allocated intervention. The denominator for each outcome in each trial was the number randomised minus any participants whose outcomes were known to be missing.

Assessment of heterogeneity

We assessed statistical heterogeneity in each meta-analysis using the T^2 , I^2 and Chi^2 statistics. We regarded heterogeneity as substantial if T^2 was greater than zero and either I^2 was greater than 30% or there was a low P value (less than 0.10) in the Chi^2 test for heterogeneity.

Assessment of reporting biases

In future updates of this review, if there are 10 or more studies in the meta-analysis, we will investigate reporting biases (such as publication bias) using funnel plots. We will assess funnel plot asymmetry visually, and use formal tests for funnel plot asymmetry. For continuous outcomes we will use the test proposed by Egger 1997, and for dichotomous outcomes we will use the test proposed by Harbord 2006. If we detect asymmetry in any of these tests, or by a visual assessment, we will perform exploratory analyses to investigate it.

Data synthesis

We carried out statistical analysis using the Review Manager software (RevMan 2008). We used fixed-effect meta-analysis for combining data where it was reasonable to assume that studies were estimating the same underlying treatment effect: i.e. where trials were examining the same intervention, and we judged the trials' populations and methods to be sufficiently similar. If there had been clinical heterogeneity sufficient to expect that the underlying treatment effects differed between trials, or if we had detected substantial statistical heterogeneity, we would have used random-effects meta-analysis to produce an overall summary if an average treatment effect across trials had been considered clinically meaningful. We would have treated the random-effects summary as the average range of possible treatment effects and we would have discussed the clinical implications of treatment effects differing between trials. If the average treatment effect had not been clinically meaningful we would not have combined trials. If we had used random-effects analyses, the results would have been presented as the average treatment effect with its 95% confidence interval, and the estimates of T^2 and I^2 .

Subgroup analysis and investigation of heterogeneity

If, in future updates of this review, we identify substantial heterogeneity, we will investigate it using subgroup analyses and sensitivity analyses. We will also consider whether an overall summary is meaningful, and if it is, use random-effects analysis to produce it.

We carried out the following subgroup analyses:

1. no external cephalic version attempted;
2. external cephalic version attempted.

We used only primary outcomes in subgroup analyses.

For fixed-effect inverse variance meta-analyses we assessed differences between subgroups by interaction tests. For random-effects and fixed-effects meta-analyses using methods other than inverse variance, we assessed differences between subgroups by inspection of the subgroups' confidence intervals; non-overlapping confidence intervals indicated a statistically significant difference in treatment effect between the subgroups.

Sensitivity analysis

We would have performed sensitivity analyses for aspects of the review that could have the results; for example, where there had been a risk of bias associated with the quality of some of the included trials. These will be carried out in future updates of this review, as required.

RESULTS

Description of studies

See table of [Characteristics of included studies](#) and [Characteristics of excluded studies](#).

Risk of bias in included studies

See table of [Characteristics of included studies](#), particularly the 'Methods' and 'Notes' sections.

[Chenia 1987](#) modified Elkins's procedure to be used three times a day for seven days with a full urinary bladder. Seventy-six black women with breech presentation beyond 37 weeks' gestation were allocated by randomised sealed envelope to a study and a control group.

[Bung 1987](#) reported a controlled trial of 'Indian' version. The women were encouraged to lie down once or twice a day for 10 to 15 minutes in the supine, head-down position, the pelvis being supported by a wedge-shaped cushion. Sixty-one women with breech presentation between the 30th and 35th weeks of pregnancy were allocated according to odd and even days of the month to a study and a control group.

[Hartadottir 1992](#) 'randomised' women with breech presentation after 34 weeks' gestation to a group taught to assume the knee-chest position for 15 minutes twice a day, or to a control group. There were three exclusions after randomisation, and compliance was poor in some women.

[Obwegeser 1999](#) randomly allocated 109 women to an 'Indian version' or control group, but six left the clinic (lost to follow-up) and three were withdrawn for poor compliance.

Smith 1999 evaluated the knee-chest position, and differed from the others in that external cephalic version was offered to the women if the breech presentation persisted after a week (47/51 in the postural group, 44/49 in the control group). This may have obscured the effect of the procedure to some extent. For this reason, we have performed sub-group analysis for trials with and without external cephalic version (ECV) attempt. ECV was successful in one of the postural group and four of the control group (Smith 1999).

Founds 2006 randomised women with singleton breech presentation between 34 and 38 weeks to a group taught to assume the maternal knee-chest position for 15 minutes three times daily, or to a control group. There were two protocol deviations in the study group and one woman was lost to follow-up. We applied an intention-to-treat analysis.

In other respects, the studies were methodologically sound. Double blinding was not possible, but the measures of outcome other than Apgar score were not subject to observer bias. The results may, however, have been affected by a chance preponderance of primigravid women in the experimental group in four studies: 11/39 versus 4/37 (Chenia 1987), 15/30 versus 11/31 (Bung 1987), 19/30 versus 13/25 (Hartadottir 1992) and 9/14 versus 4/11 (Founds 2006).

Because the basic principle of the two techniques investigated is similar, namely relaxation in a position in which the pelvis is elevated above the level of the shoulders, the findings of the studies have been combined. It should, however, be noted that the gestation at enrolment differed between the studies.

Effects of interventions

We included six studies involving a total of only 417 women. There was no effect on the rate of non-cephalic births (risk ratio (RR) 0.98; 95% confidence interval (CI) 0.84 to 1.15; six trials, 417 women; Analysis 1.1), overall caesarean section rate (RR 1.10; 95% CI 0.89 to 1.37; five trials, 317 women; Analysis 1.2) and rate of low Apgar score at one minute (RR 0.88; 95% CI 0.50 to 1.55; three trials, 237 women; Analysis 1.3). The findings are consistent, at the 95% CI, with anything between a moderate positive and a negative effect. These findings held for the subgroup in which external cephalic version was not attempted, and the group overall, but may have been affected by a chance preponderance of primigravid women in the intervention groups (see Description of studies). The two

trials which showed a tendency to reduced non-cephalic births were those in which the procedure was started as early as 30 weeks' gestation (Bung 1987; Obwegeser 1999).

DISCUSSION

The studies must be regarded as too small to establish conclusively whether or not postural management is effective.

The results of the trials are consistent with each other.

AUTHORS' CONCLUSIONS

Implications for practice

To date, there is insufficient evidence from well-controlled trials to support the routine use of postural management in clinical practice.

Implications for research

The controlled trials reported to date are too small to support or refute the evidence from uncontrolled trials of the value of postural management for breech presentation.

Because of the simplicity of postural management and its potential wide application in different settings, it is reasonable that the procedure be evaluated further by means of larger randomised clinical trials. These should include evaluation of the effect of the gestational age on the effectiveness of these procedures, and exploration of women's views. Additional procedures which might be investigated to facilitate version include maternal hydration to increase amniotic fluid volume, and performing the procedure with a full bladder to aid disengagement of the presenting breech from the mother's pelvis.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Bung 1987

Methods	Allocated according to odd and even days of the month.
Participants	Singleton breech presentation at 30 to 35 weeks.
Interventions	'Indian version' (10 to 15 minutes once or twice a day in the supine, head-down position with the pelvis supported by a wedge-shaped cushion) (n = 30), compared with control group (n = 31).
Outcomes	Non-cephalic births; caesarean sections; Apgar score < 7 at 1 minute.
Notes	More primigravidas in study group (15/30 vs 11/31).

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Allocated according to odd or even days of the month.
Allocation concealment (selection bias)	High risk	Inadequate.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Incomplete outcome data (attrition bias) All outcomes	Low risk	
Other bias	High risk	More primigravidas in study group (15/30 vs 11/31).

Chenia 1987

Methods	Randomised sealed envelopes used.
Participants	Singleton breech presentation beyond 37 weeks. All participants were black women.
Interventions	Knee-chest position assumed with full urinary bladder 3 times a day for 7 days (n = 39), compared with control group (n = 37).
Outcomes	Non-cephalic births; caesarean sections; Apgar score < 7 at 1 minute.
Notes	More primigravidas in the study group (11/39 vs 4/37).

Risk of bias

Cephalic version by postural management for breech presentation (Review)

Copyright © 2012 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chenia 1987 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomised.
Allocation concealment (selection bias)	Low risk	Sealed envelopes.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No missing data.
Selective reporting (reporting bias)	Low risk	
Other bias	High risk	Moderate risk. More primigravidas in the study group (11/39 vs 4/37).

Founds 2006

Methods	Randomised controlled trial, randomisation by coin tossing.
Participants	25 women with singleton breech presentations between 34 and 38 weeks. Excluded if there was a history of heart disease, hypertension, preterm labour, third trimester bleeding or uterine/placenta abnormalities.
Interventions	Study group (14) were asked to do maternal knee-chest posture for 15 minutes 3 times per day for 7 days, and were given a log to record time spent in the posture.
Outcomes	Presentation at labour, mode of delivery, birthweight, Apgar scores.
Notes	2 protocol deviations and one woman was lost to follow-up in study group. Intention-to-treat analysis applied. 9/14 in study group were primigravidas vs 4/11 in control group.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation by coin tossing.
Allocation concealment (selection bias)	Unclear risk	Not described.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No missing data.

Cephalic version by postural management for breech presentation (Review)

Founds 2006 (Continued)

Other bias	High risk	Moderate risk. More primigravidas (9/14) in study group than in control group (4/11).
------------	-----------	---

Hartadottir 1992

Methods	'Randomized', method not specified. 3 withdrawals after randomisation (2 found to be cephalic on sonar, 1 lost to follow-up). The women in the control group were not informed that they were participating in a trial.
Participants	Singleton breech presentation beyond 34 weeks.
Interventions	Women asked to assume knee-chest position for 15 minutes twice a day (n = 30), compared with control group (n = 31). Compliance was poor in some women.
Outcomes	Non-cephalic births; caesarean section.
Notes	More primigravidas in study group (19/30 versus 13/25).

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	'Randomized', method not specified.
Allocation concealment (selection bias)	Unclear risk	Not described.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Selective reporting (reporting bias)	Unclear risk	3 subjects excluded after randomisation.
Other bias	High risk	Moderate risk. 3 subjects excluded after randomisation. More primigravidas in study group (19/30 versus 13/25).

Obwegeser 1999

Methods	Separate computerised randomisation for primiparas and multiparas.
Participants	Inclusion criteria: ultrasound-confirmed, uncomplicated singleton breech pregnancy, 30-32 weeks' gestation. Exclusion criteria: uterine or pelvic abnormalities, maternal or fetal disease.
Interventions	Asked to assume a supine position with the pelvis elevated by a 30-35cm cushion, for periods of 10 minutes, twice daily (n = 50); compared with control group (n = 50).
Outcomes	Spontaneous version.
Notes	Universitätsfrauenklinik, Vienna. 3 women withdrawn from the study group because of poor compliance. Pilot study to calculate sample size. Study ended after the first year because of the large sample size needed to show a small difference.

Obwegeser 1999 (Continued)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Separate computerised randomisation for primiparas and multiparas.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Other bias	High risk	9 post-randomisation withdrawals: 6 women left the clinic (lost to follow-up) and 3 women withdrawn because of poor compliance.

Smith 1999

Methods	Randomised sealed envelopes using variable blocks and stratified by parity. No blinding of allocation.
Participants	Inclusion criteria: singleton breech presentation, gestational age 36 weeks or more. Exclusion criteria: placenta praevia, antepartum haemorrhage, fetal growth restriction, hypertensive disease, previous uterine surgery, uterine anomaly, ruptured membranes, fetal anomaly, contraindication to vaginal delivery, fetal death.
Interventions	Asked to assume the knee-chest position for 15 minutes, 3 times a day, for a week (n = 51). Compared with no postural management (n = 49). Both groups offered external cephalic version if still a breech presentation after a week.
Outcomes	Breech presentation at birth; caesarean section; fetal and maternal complications.
Notes	1990 to 1997. Adelaide, Australia. Estimated sample size 288. Stopped after 100 due to slow enrolment.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomised sealed envelopes using variable blocks and stratified by parity.
Allocation concealment (selection bias)	Low risk	Sequentially numbered opaque envelopes.
Blinding (performance bias and detection bias) All outcomes	High risk	Not feasible.
Incomplete outcome data (attrition bias) All outcomes	Low risk	
Selective reporting (reporting bias)	Low risk	

Smith 1999 (Continued)

Other bias	Low risk	Baseline characteristics similar.
------------	----------	-----------------------------------

vs: versus

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Bullough 1987	Excluded because the planned trial was not conducted.
Cardini 1998	Excluded because posture was not used. May be included in a separate review. 130 primigravidas in the 33rd week of gestation were randomised to receive stimulation of acupoint BL 67 by moxa rolls for 7 to 14 days. The 130 in the control group received routine care. The intervention group experienced a mean of 48.45 fetal movements per day versus 35.35 in the control group (95% confidence interval (CI) for difference, 10.56 to 15.60). During the 35th week of gestation, 98 in the intervention group were cephalic versus 62 in the control group (risk ratio (RR) 1.58; 95% CI, 1.29 to 1.94). Despite the fact that 24 subjects in the control group and 1 subject in the intervention group underwent external cephalic version, 98 in the intervention group were cephalic at birth versus 81 in the control group (RR 1.21; 95% CI 1.02 to 1.43).
Van Drooge 1984	Excluded because the technique of hyperextension is fundamentally different from the techniques used in the other studies. Allocation of women at 32 to 38 weeks was by envelope. Unfortunately, there were more nulliparous women in the study than the control group (11/20 versus 7/20). Version was less common, but not significantly so, in the study than in the control group (7/20 versus 9/20).

DATA AND ANALYSES
Comparison 1. Cephalic version by postural management

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Non-cephalic births	6	417	Risk Ratio (M-H, Fixed, 95% CI)	0.98 [0.84, 1.15]
1.1 No external cephalic version attempted	5	317	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.75, 1.14]
1.2 External cephalic version attempted	1	100	Risk Ratio (M-H, Fixed, 95% CI)	1.10 [0.87, 1.38]
2 Caesarean section	5	317	Risk Ratio (M-H, Fixed, 95% CI)	1.10 [0.89, 1.37]
2.1 No external cephalic version attempted	4	217	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.84, 1.57]
2.2 External cephalic version attempted	1	100	Risk Ratio (M-H, Fixed, 95% CI)	1.05 [0.80, 1.38]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
3 Apgar score < 7 at 1 minute	3	237	Risk Ratio (M-H, Fixed, 95% CI)	0.88 [0.50, 1.55]
3.1 No external cephalic version attempted	2	137	Risk Ratio (M-H, Fixed, 95% CI)	0.90 [0.42, 1.91]
3.2 External cephalic version attempted	1	100	Risk Ratio (M-H, Fixed, 95% CI)	0.85 [0.36, 2.03]
4 Apgar score < 7 at 5 minutes	2	125	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.07, 3.82]
4.1 No external cephalic version attempted	1	25	Risk Ratio (M-H, Fixed, 95% CI)	0.79 [0.06, 11.20]
4.2 External cephalic version attempted	1	100	Risk Ratio (M-H, Fixed, 95% CI)	0.32 [0.01, 7.68]

Analysis 1.1. Comparison 1 Cephalic version by postural management, Outcome 1 Non-cephalic births.

Analysis 1.2. Comparison 1 Cephalic version by postural management, Outcome 2 Caesarean section.

Analysis 1.3. Comparison 1 Cephalic version by postural management, Outcome 3 Apgar score < 7 at 1 minute.

Analysis 1.4. Comparison 1 Cephalic version by postural management, Outcome 4 Apgar score < 7 at 5 minutes.

APPENDICES

Appendix 1. Methods used to assess trials included in previous versions of this review

The following methods were used to assess [Bung 1987](#); [Chenia 1987](#); [Hartadottir 1992](#); [Obwegeser 1999](#); [Smith 1999](#). Trials under consideration were evaluated for methodological quality and appropriateness for inclusion according to the prespecified selection criteria, without consideration of their results. Individual outcome data were included in the analysis if they met the prespecified criteria in 'Types of outcome measures'. Included trial data were processed as described in [Clarke 2000](#).

Data were extracted from the sources and entered onto the Review Manager computer software ([RevMan 2000](#)), checked for accuracy, and analysed as above using the RevMan software. For dichotomous data, risk ratios and 95% confidence intervals were calculated, and in the absence of heterogeneity, results were pooled using a fixed-effect model.

WHAT'S NEW

Date	Event	Description
22 August 2012	New citation required but conclusions have not changed	Review updated with new search date.
22 August 2012	New search has been performed	Search updated, No new trials identified

HISTORY

Protocol first published: Issue 2, 1996
Review first published: Issue 2, 1996

Date	Event	Description
10 September 2010	New search has been performed	Search updated. One new trial included (Founds 2006), conclusions unchanged.
1 October 2009	New search has been performed	Search updated. One report added to Studies awaiting classification (Founds 2006).
1 September 2008	Amended	Converted to new review format.
30 September 2001	New search has been performed	Search updated.

CONTRIBUTIONS OF AUTHORS

GJ Hofmeyr prepared the original version and maintains the review. R Kulier revised and quality-checked the original review and contributed to the writing of this update.

DECLARATIONS OF INTEREST

None known.

SOURCES OF SUPPORT

Internal sources

- University of Witwatersrand, South Africa.
- Department of Obstetrics and Gynaecology, Geneva University Hospital, Switzerland.

External sources

- South African Medical Research Council, South Africa.
