Background and Aim: Although air pollution is a serious problem in Ahvaz, the association between air pollution and respiratory diseases has not been studied enough in this area. The aim of this study was to determine the relation between short-term exposure to air pollutants and the risk of hospital admissions due to asthma, COPD, and bronchiectasis in Ahvaz.

Methods: Hospital admissions data and air pollutants including O₃, NO, NO₂, SO₂, CO, PM₁₀, and PM_{2.5} were obtained from 2008 to 2018. Adjusted Quasi-Poisson regression with a distributed lag model, controlled for trend, seasonality, weather, weekdays, and holidays was used for data analysis.

Results: The results showed a significant increase in hospital admissions for asthma (RR=1.004, 95% CI: 1.002–1.007) and COPD (RR=1.003, 95% CI: 1.001–1.005) associated with PM_{2.5}. PM₁₀ was associated with increased hospital admissions due to bronchiectasis in both genders (Men: RR=1.003, 95% CI: 1.001–1.006) (Female: RR=1.003, 95% CI: 1.000–1.006). NO₂ was also associated with an increased risk of hospital admissions for asthma (RR=1.040, 95% CI: 1.008–1.074) and COPD (RR=1.049, 95% CI: 1.010–1.090). SO₂ was associated with the risk of hospital admissions of asthma (RR=1.069, 95% CI: 1.017–1.124) and bronchiectasis (RR=1.030, 95% CI: 1.005–1.056). Finally, CO was associated with COPD (RR=1.643, 95% CI: 1.233–2.191) and bronchiectasis (RR=1.542, 95% CI: 1.035–2.298) hospital admissions.

Conclusion: Short-term exposure to air pollutants significantly increases the risk of hospital admissions for asthma, COPD, and bronchiectasis in the adult and elderly population.

Keywords: air pollution, particulate matter, asthma, COPD, bronchiectasis

Introduction

Air pollution is one of the biggest environmental health hazards that affects most world countries.¹ Air pollution causes more than 3% of years of life loss, globally which is significantly more than the previous forecast in 2000.² Studies have estimated that the years of life lost (DALYs) worldwide due to air pollution have been 141,456,000 years, in 2013. According to a WHO report, at least 7 million people have died due to air pollution in 2012.³ Also in 2012, low-income and middle-income countries in Southeast Asia and the western Pacific region had the highest levels of air pollution.⁴

Air pollution is widely associated with respiratory diseases.^{5–7} The effects of air pollution on the respiratory system include increased respiratory symptoms, decreased lung function, and increased incidence of chronic cough and bronchitis.^{8,9} Epidemiological and clinical studies show that in children and adults, increased hospital

admissions, lung diseases, lung cancer,¹⁰ bronchiectasis,^{11–14} respiratory infection, pulmonary embolism, asthma,^{2,6,15–18} and chronic obstructive pulmonary diseases (COPD)^{9,19–23} are affected by air pollution.

Globally, 334 million people suffer from asthma and it is the most common chronic childhood disease. Asthma affects 14% of children worldwide and it is on the rise.²⁴ Over the past 30 years, evidence has shown that air pollution negatively affects the respiratory health of children with and without asthma.²⁵ In the study done by Khreis et al, the relation between exposure to traffic-related air pollution and childhood asthma in Bradford, England, was evaluated. This study estimated that 15% to 33% of annual childhood asthma cases were related to urban air pollution.²⁶

Also, a study by Bouazza et al, on children, in Paris, showed that there was a significant relation between exposure to air pollution especially particulate matter (PM) and exacerbations of asthma symptoms in children visiting the emergency department.²⁷

Another study by Salimi et al, about long-term exposure to air pollution and hospitalization for respiratory diseases in Australia, showed that there was a weak but direct relation between exposure to air pollution and hospitalization for asthma.²⁸

According to the American College of Lung Physicians (CHEST) report in 2018, 65 million people suffer from chronic obstructive pulmonary disease (COPD) and 3 million die each year, making it the third leading cause of death worldwide.²⁴ COPD is expected to become the leading cause of death worldwide in the next 15 years (26). According to a WHO report in 2014, 33% of deaths due to COPD are related to exposure to air pollution.⁴

A study by Brakema et al, in Kyrgyzstan, during 2015–2014 found that the prevalence of COPD was directly associated with moderate to high PM_{2.5} concentrations.²⁹ Also, Phosri et al, found that there was a significant relation between exposure to NO₂, CO, PM₁₀ and increased hospital admissions because of pneumonia, COPD, and asthma in Bangkok, Thailand; while O₃ and SO₂ were associated with hospital admission for COPD and asthma as well.³⁰ A study by Gao et al performed in Beijing, China, showed that short-term exposure to PM_{2.5}, PM₁₀, NO₂, SO₂, and CO caused hospitalization due to COPD.³¹

Air enters the lungs through bronchioles that contain very small glands that produce mucus secretions. These secretions keep the ducts moist and absorb dust and airborne germs. The inner walls of the bronchioles are covered with ciliates that

circulate the external particles along with the mucosal secretions and drive them out from the pharynx. If the bronchioles get injured, they can no longer keep themselves clean and as a result, the mucus secretions accumulate in the bronchioles and overflow into adjacent tubes. In this way, the bronchioles are susceptible to infection by bacteria, resulting in inflammation, and lesions called bronchiectasis. Bronchiectasis can cause chronic cough, bloody sputum, lung abscess, lung infection, and septicemia.^{32,33}

A study done by Garcia-Olivé et al, in Barcelona, Spain, between 2007 and 2015, found that SO₂, NO, NO₂, O₃ and CO were significantly associated with increased risk of hospital admissions due to exacerbation of bronchiectasis.¹⁴ A study by Zhao et al, in Dongguan, China, indicated that short-term exposure to CO increases the risk of asthma, bronchiectasis, pneumonia, and respiratory disease.¹¹

Ahvaz is a major metropolis in Iran that has suffered from environmental problems such as air, water,³⁴ and soil pollution for many years³⁵ and recently sand storms have further devastated the people.^{36,37} Nowadays Ahvaz has twice the national average prevalence of asthma.³⁸ The aim of this study was to determine the relation between short-term exposure to air pollution and hospital admissions for asthma, COPD, and bronchiectasis in Ahvaz during 2008 to 2018.

Methods

This ecological time series study was conducted from March 2008 to March 2018 in Ahvaz, Iran. Outcome data for these 10 years, based on the tenth version of the International Classification of Diseases (ICD-10), including J45.9 for asthma, J44.1, and J44.9 for COPD and J47 for bronchiectasis.

There are 7 public and 12 private hospitals in Ahvaz. Outcome data were obtained from 2 large hospitals which were referral hospitals for respiratory diseases.

Daily data on air pollutants including carbon monoxide (Average 24 hrs CO, ppm), particles less than 2.5 μm (Average 24 hrs PM_{2.5}, μg/m³), particles less than 10 μm in diameter (Average 24 hrs PM₁₀, μg/m³), nitrogen dioxide (Average 24 hrs NO₂, ppm), nitrogen monoxide (Average 24 hrs NO, ppm), and sulfur dioxide (Average 24 hrs SO₂, ppm), and ozone (Average 24 hrs O₃, ppm), were inquired from March 2008 to March 2018, from the Khuzestan Province, Department of Environment. Air pollutants were measured in four stations located in different parts of Ahvaz.

The average of daily mean levels of air pollutants, from all four stations were used as the pollution level for the whole city, in the statistical models. Meteorological data including daily temperature and relative humidity were inquired from the Khuzestan Meteorological Organization for the same period.

A time series regression model was used to investigate the relation between hospital admissions for asthma, COPD, and bronchiectasis; and air pollutants.³⁹

When the dependent variable is a count, Poisson models from the generalized linear models (GLM) family are used. In this study, since the variance of the outcome variable was larger than the mean, a quasi-Poisson model was used.^{40,41} So one the Quasi-Poisson model and distributed lag models were used to estimate the relation between the outcomes and exposure to air pollutants. In this study, the long-term trend, seasonality, relative humidity, temperature, and holidays (DOW) were adjusted in the final model. The effect of seasonality and long-term trend was adjusted through a flexible spline function of time with a degree of freedom of 7 per year.³⁹ The effect of humidity and temperature was also controlled by a natural cubic spline function with 3 and 6 degrees of freedom, respectively.^{39,40,42}

The distributed lag models were run from 0 to 7 days lag and risk ratios with 95% confidence intervals were calculated for hospital admissions of asthma, COPD, and bronchiectasis for every 10 units increase in air pollutants. In order to avoid the co-linearity effect between air pollutants, models were run for each pollutant separately, using the adjusted unconstrained DLM models.^{40,43} Also, the relation between outcomes and exposure to air pollutants were calculated in age and gender groups. Analysis was performed using R.3.5.3 software and the level of significance was set at less than 0.05. Other details on the analysis methods can be found in similar previously published articles.^{41,44}

Results

During the 10-year study period, the total number and average hospital admissions for asthma were 3090, and 0.8 ± 1.8 ; for COPD, it was 4534, and 1.2 ± 1.7 and for bronchiectasis, it was 1994, and 0.6 ± 1.0 . The highest number of hospital admissions for asthma have been in people less than 60 years old (2508). But the highest number of hospital admissions for COPD (2909) and bronchiectasis (1007) were in >60 year olds.

Mean daily concentrations of PM_{10} and $PM_{2.5}$ were 245.5 and $85.9 \mu\text{g}/\text{m}^3$, respectively, which have been higher

than the United States Environmental Protection Agency's 24 hrs standard in 1997 which is 150 and $65 \mu\text{g}/\text{m}^3$, respectively (Table 1). The time trend of ambient air pollutants during 2008–2018 has been shown in Figure 1.

Table 2 shows the Spearman correlations between air pollutants and meteorological parameters in Ahwaz. Some variables show significant statistical correlation.

Tables 3–5 show significant relation between exposure to $PM_{2.5}$, PM_{10} , NO, NO_2 , SO_2 , CO, and hospital admissions because for asthma, COPD, and bronchiectasis for up to 7 days after exposure.

Association Between $PM_{2.5}$ and Asthma, COPD, and Bronchiectasis

There was a significant and direct relation between exposure to $PM_{2.5}$ and hospital admissions for asthma in the general population, men, women, and people less and above 60 years old. And as per $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$, the risk of asthma hospital admissions in the total population increased significantly by 0.4% (lag 2), in men by 0.4% (lag 6), in women by 0.6% (lag 2), and in ≤ 60 years old (lag 2) and >60 years old by 0.5% (zero lag) (Table 3).

The results also showed that per $10 \mu\text{g}/\text{m}^3$ increase in $PM_{2.5}$, the risk of COPD hospital admissions in the total population, both genders and ≤ 60 years old, increased 0.3%, 0.3%, and 0.4% at lag 2, respectively (Table 4). On the other hand, per $10 \mu\text{g}/\text{m}^3$ increase in PM_{10} , the risk of hospital admissions for bronchiectasis in men and women, increased 0.3% at lag 2 and 6, respectively (Table 5).

Association Between NO_2 and Asthma and COPD

NO_2 was associated with the risk of hospital admissions for asthma in the total population, men, ≤ 60 years old and >60 years old; and hospital admissions for COPD in women; and per $10 \mu\text{g}/\text{m}^3$ increase in NO_2 , the risk of hospital admissions for asthma in the total population increased by 4% and 3.3% (in lag 1 and 3), in the male population by 5.2% (in lag 1), and in the ≤ 60 years old by 4.2% (in lag 1) and >60 years old by 6.9% (lag 4). Hospital admissions due to COPD increased 4.9% after 4-day lags in the female population (Tables 3 and 4).

Association Between NO and Asthma and COPD

Exposure to NO was associated with the risk of hospital admissions for asthma in the total population, women and >60 years old, and the risk of hospital admissions for

COPD in the total population, men, women, and >60 years old and per 10 µg/m³ increase in NO, the risk of hospital admissions for asthma increased in the total population, by 2.5% in lag 1, in the female population by 4.1% in lag 1 and in >60 years old by 6.5% and 5.7% in lag 1 and 3, respectively. Also, in relation to NO and COPD hospital admissions, a 2.1% and 1.7% increase in lag 1 and 3 in the total population, 2% in lag 1 in the male population, 2.8% in lag 3 in the female population, as well as an 2.2% and 2% increase in lag 1 and 3 in population of >60 years old was observed (Tables 3 and 4).

Association Between SO₂ and Asthma and Bronchiectasis

SO₂ was associated with the risk of hospital admissions for asthma and bronchiectasis and per 10 µg/m³ increase in SO₂, the risk of hospital admissions for asthma in people >60 years old, increased 6.9% in lag 2. Also, per 10 µg/m³ increase in SO₂, the risk of hospital admissions of bronchiectasis in the total population increased 3% and 2.7% in lag 1 and 4, in the male population increased 5.4% in lag

1, in the female population 4.6% in lag 4 and in >60 years old 4.3% in lag 1 (Tables 3 and 5).

Association Between CO and COPD and Bronchiectasis

CO was associated with COPD and bronchiectasis hospital admissions and per 10 µg/m³ increase in CO, the risk of hospital admissions for COPD in the female population increased 64.3% in lag zero. Also, per 10 µg/m³ increase in CO the risk of hospital admissions for bronchiectasis, increased in the total population by 54.2% in lag 4, in the women population by 44.9% in lag zero and 82.2% in lag 4 and in the population >60 years old 100% in lag 4 (Tables 4 and 5).

There was no significant relation between exposure to O₃ and hospital admissions for asthma, COPD, or bronchiectasis.

Discussion

In this study, a significant direct relation was observed between short-term exposure to PM_{2.5}, NO, NO₂, SO₂,

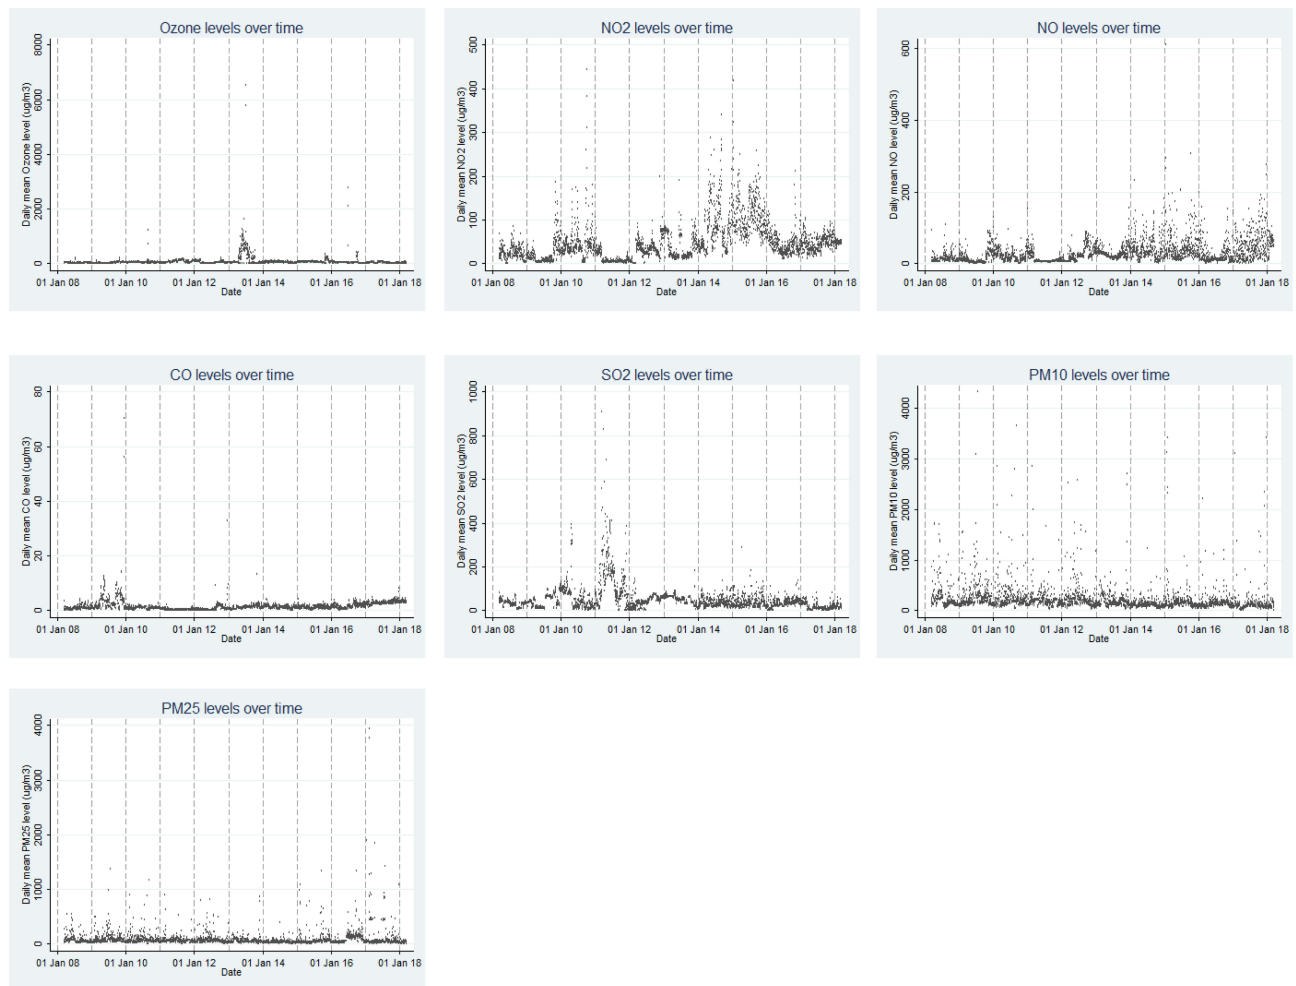

Figure 1 The average daily concentration of O₃, NO₂, NO, CO, SO₂, PM₁₀ and PM_{2.5} during the study period.

and hospital admissions due to asthma. This relation has been seen in many other studies as well. In China, exposure to air pollutants including PM_{2.5}, PM₁₀, NO₂, and SO₂ significantly increased the risk of hospital admissions for COPD and asthma, especially among women, children,

and the elderly;⁴⁵ and in Barcelona, Spain, high levels of NO₂ were related with the number of asthma patients admitted to emergency departments and hospitals.⁷ Other Chinese studies showed that PM_{2.5} and CO were the major air pollutants that increased hospital admissions due to

Notes: *Statistically significant. ^aAdjusted for trend, seasonality, temperature, relative humidity, weekdays, and holidays.

asthma; NO₂, CO, PM₁₀, PM_{2.5}, and SO₂ exacerbated asthma symptoms¹⁶ and NO₂, O₃, PM₁₀, and PM_{2.5} increased hospital admissions and asthma.⁶ Increase in hospital admissions for asthma has been significantly related to increase in NO₂ concentrations in several other studies as well.^{2,15}

Although in this study children were not evaluated separately, studies conducted in North America, show that exposure to air pollution has negative effects on children with asthma,²⁵ and in China, asthma symptoms exacerbated among children, by increased concentrations of NO₂, CO, PM₁₀, PM_{2.5}, and SO₂.¹⁵ Liu et al found that in Liaoning Province, China, every 10 µg/m³ increase in NO₂ was associated with an increased risk of asthma in 6–13-year-old children.¹⁷

Researchers think NO₂ stimulates the lungs and causes bronchitis and pneumonia; and SO₂ in people with asthma, bronchitis and emphysema can cause severe respiratory problems and lung damage.^{2,16} Asthma is caused by inflammation of the airways and in response to stimuli including air pollutants. The most important mechanism that NO₂ can create and exacerbate asthma is the peroxidation of cell membrane lipids and producing various-free radicals that generally reduce the structure and function of airways.⁴⁶ In addition, exposure to NO₂ can increase the release of inflammatory mediators such as interleukin-8.⁴⁷ SO₂, also causes airway inflammation and bronchial spasm and airway obstruction fibrosis by increasing the β tumor growth factor level and eosinophils.⁴⁸

In this study, the effect of air pollution was adjusted for temperature. However, a study from Taiwan showed that

exposure to PM_{2.5} increased hospital admissions for asthma more on warm days (more than 23°C) than cold days (below 23°C).⁴⁹ The interactions between temperature and air pollution should be more thoroughly investigated in future studies.

Several studies confirm the results of our study that the effect of air pollution also depends on age group. A study from South Korea found that the effects of exposure to PM₁₀, CO, and NO₂ were significantly different in different age groups.⁵⁰

In this study, a significant and direct relation was observed between short-term exposure to PM_{2.5}, NO₂, NO, CO, and hospital admissions due to COPD in the total population, women, men, adults, and the elderly. Other studies have shown the significant effect of increased ambient NO₂ with hospital admissions due to COPD or asthma in Shiraz, Iran;⁵¹ the Netherlands,²⁰ and Italy.⁵² In Taiwan, increase in PM_{2.5} and PM₁₀, increased hospital admissions for COPD, asthma, and pneumonia;^{19,53} and in Italy increase in PM₁₀, increased the risk of hospitalization due to COPD in the whole year, and this effect was stronger in the warm season.⁵² A review estimated that each 10 µg/m³ increase in PM_{2.5}, NO₂ and SO₂ was associated with a 2.5%, 4.2%, and 1.2% increase in hospital admissions and COPD emergencies, respectively.⁵⁴ And other reviews stated that exposure to PM_{2.5}, NO₂ and SO₂ was significantly related to hospital admissions and COPD mortality;⁵⁵ and short-term exposure to air pollutants including NO₂, CO, SO₂, and particles including PM_{2.5} and PM₁₀ were related to the exacerbation of COPD.⁵⁶ Authors also found that CO had a greater impact on COPD in hot seasons.⁵⁶

Table 4 The Relative Risk (95% CIs) of COPD Admissions with an Increase of 10 µg/M³ in PM_{2.5}, NO, NO₂, and CO According to Single Lag, Adjusted Unconstrained and Constrained DLM Models^a

Notes: *Statistically significant. ^aAdjusted for trend, seasonality, temperature, relative humidity, weekdays, and holidays.

In this study, there was a significant and direct relation between short-term exposure to PM₁₀, SO₂, CO and hospital admissions due to bronchiectasis. Studies from Barcelona, Spain,¹⁴ and Dongguan, China¹¹ confirm these findings. The risk of exacerbation of bronchiectasis significantly increased in Dundee, with increase in PM₁₀ and NO₂, on the same day; and the effect of NO₂ was stronger in spring.¹³ In Beijing, China, exposure to PM_{2.5}, PM₁₀, NO₂, SO₂, and CO was significantly related to increased admissions for upper respiratory tract infections, acute bronchitis, pneumonia, and acute bronchiectasis; and PM₁₀, SO₂, CO, and O₃ was also associated with outpatient admissions due to acute exacerbation of COPD and asthma.¹²

Researchers think air pollutants have complex effects on the airways of respiratory patients, and cause inflammation, mucosal edema, and toxicity. PM can cause oxidative stress in the dendritic cells of the immune system

and this exacerbates asthma. In addition, phagocytosis of damaged airway macrophage cells, which results in increased prostaglandin E2 levels, are other adverse effects of inhalation of carbon particles. The direct relation between CO and asthma is not clear. It seems that CO can exacerbate asthma through airway stimulation.¹⁸

One of the main mechanisms that explain the relation between exposure to air pollutants and COPD is oxidative stress. Oxidative stress can damage the airway epithelium and weaken the immune system. Air pollutants can also cause inflammation in the lungs and further decrease pulmonary function in COPD patients. The determinants of COPD exacerbation are still largely unknown.⁵⁶

Although the mechanism of the effect of air pollutants on respiratory diseases is not fully understood, possible mechanisms include airway epithelial cell destruction, interference with cellular signaling pathways, destruction of lung parenchyma, various inflammatory responses,

Table 5 The Relative Risk (95% CIs) of Bronchiectasis Admissions with an Increase of 10 $\mu\text{g}/\text{M}^3$ in PM_{10} , SO_2 , and CO According to Single Lag, Adjusted Unconstrained and Constrained DLM Models^a

destruction in cellular immunity and epithelial changes. Pulmonary inflammation is produced through two pathways: the first is the generation of oxidative stress by free radicals that can be produced by exposure to air pollutants. The other is the reduction of immunological function through suppression of macrophages. In vitro and in vivo studies have also shown that air pollution can cause inflammation in the respiratory system, toxic responses in alveolar cells, and increased release of anti-inflammatory cytokines.¹²

The vast amount of literature leaves little doubt about the destructive effects of air pollution on the human respiratory system. Air pollution control needs proper political management and the cooperation of multiple sectors in societies, which is weakly achieved in developing countries.

This study was the first to analyze respiratory outcomes based on age and sex in Ahvaz. One of the limitations of this study was the use of aggregated data, and the fact that

its results cannot be directly generalized to the individual level. Also in this study, we were unable to control for individual confounders including occupation, eating habits, smoking, socioeconomic status, and migration that may have affected hospital admissions.

Conclusion

The results showed that air pollutants including PM_{2.5}, PM₁₀, NO₂, NO, CO, and SO₂ were associated with the risk of hospital admissions due to asthma, COPD, and bronchiectasis; in men, women, adults, and the elderly. This study emphasizes the need to reduce air pollution in Ahvaz.

Details of Ethics Approval

All patients signed a consent form while admitted and allowed their information to be used for research purposes. Researchers received de-identifiable data. The ethics clearance of the present study was acquired from the Ethics

Committee of Ahvaz Jundishapur University of Medical Sciences (Ethics Code: IR.AJUMS.REC.1397.641).

Acknowledgment

This study was funded and supported by Ahvaz Jundishapur University of Medical Sciences with Grant No: APRD-9705.

International Journal of Chronic Obstructive Pulmonary Disease

Dovepress

Publish your work in this journal

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management

protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-chronic-obstructive-pulmonary-disease-journal>
