## ABSTRACT

### Background

Heavy menstrual bleeding significantly impairs the quality of life of many otherwise healthy women. Perception of heavy menstrual bleeding is subjective and management usually depends upon what symptoms are acceptable to the individual. Surgical options include conservative surgery (uterine resection or ablation) and hysterectomy. Medical treatment options include oral medication and a hormone-releasing intrauterine device (LNG-IUS).

### Objectives

To compare the effectiveness, safety and acceptability of surgery versus medical therapy for heavy menstrual bleeding.

### Search methods

We searched the following databases from inception to January 2016: Cochrane Gynaecology and Fertility Group Trials Register, the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, EMBASE, PsycINFO and clinical trials registers (clinical trials.gov and ICTRP). We also searched the reference lists of retrieved articles.

### Selection criteria

Randomised controlled trials (RCTs) comparing conservative surgery or hysterectomy versus medical therapy (oral or intrauterine) for heavy menstrual bleeding.

### Data collection and analysis

Two review authors independently selected the studies, assessed their risk of bias and extracted the data. Our primary outcomes were menstrual bleeding, satisfaction rate and adverse events. Where appropriate we pooled the data to calculate pooled risk ratios (RRs) or mean differences, with 95% confidence intervals (CIs), using a fixed-effect model. We assessed heterogeneity with the  $I^2$  statistic and evaluated the quality of the evidence using GRADE methods.

### Main results

We included 15 parallel-group RCTs (1289 women). Surgical interventions included hysterectomy and endometrial resection or ablation. Medical interventions included oral medication and the levonorgestrel-releasing intrauterine device (LNG-IUS). The overall quality of the evidence for different comparisons ranged from very low to moderate. The main limitations were lack of blinding, attrition and imprecision. Moreover, it was difficult to interpret long-term study findings as many women randomised to medical interventions subsequently underwent surgery.

*Surgery versus oral medication*

Surgery (endometrial resection) was more effective in controlling bleeding at four months (RR 2.66, 95% CI 1.94 to 3.64, one RCT, 186 women, moderate quality evidence) and also at two years (RR 1.29, 95% CI 1.06 to 1.57, one RCT, 173 women, low quality evidence). There was no evidence of a difference between the groups at five years (RR 1.14, 95% CI 0.97 to 1.34, one RCT, 140 women, very low quality evidence).

Satisfaction with treatment was higher in the surgical group at two years (RR 1.40, 95% CI 1.13 to 1.74, one RCT, 173 women, moderate quality evidence), but there was no evidence of a difference between the groups at five years (RR 1.13, 95% CI 0.94 to 1.37, one RCT, 114 women, very low quality evidence). There were fewer adverse events in the surgical group at four months (RR 0.26, 95 CI 0.15 to 0.46, one RCT, 186 women). These findings require cautious interpretation, as 59% of women randomised to the oral medication group had had surgery within two years and 77% within five years.

#### *Surgery versus LNG-IUS*

When hysterectomy was compared with LNG-IUS, the hysterectomy group were more likely to have objective control of bleeding at one year (RR 1.11, 95% CI 1.05 to 1.19, one RCT, 223 women, moderate quality evidence). There was no evidence of a difference in quality of life between the groups at five or 10 years, but by 10 years 46% of women originally assigned to LNG-IUS had undergone hysterectomy. Adverse effects associated with hysterectomy included surgical complications such as bladder or bowel perforation and vesicovaginal fistula. Adverse effects associated with LNG-IUS were ongoing bleeding and hormonal symptoms.

When conservative surgery was compared with LNG-IUS, at one year the surgical group were more likely to have subjective control of bleeding (RR 1.19, 95% CI 1.07 to 1.32, five RCTs, 281 women, low quality evidence,  $I^2 = 15\%$ ). Satisfaction rates were higher in the surgical group at one year (RR 1.16, 95% CI 1.04, to 1.28, six RCTs, 442 women,  $I^2 = 27\%$ ), but this finding was sensitive to the choice of statistical model and use of a random-effects model showed no conclusive evidence of a difference between the groups. There was no evidence of a difference between the groups in satisfaction rates at two years (RR 0.93, 95% CI 0.81 to 1.08, two RCTs, 117 women,  $I^2 = 1\%$ ).

At one year there were fewer adverse events (such as bleeding and spotting) in the surgical group (RR 0.36, 95% CI 0.15 to 0.82, three RCTs, moderate quality evidence). It was unclear what proportion of women assigned to LNG-IUS underwent surgery over long-term follow-up, as there were few data beyond one year.

#### **Authors' conclusions**

Surgery, especially hysterectomy, reduces menstrual bleeding more than medical treatment at one year. There is no conclusive evidence of a difference in satisfaction rates between surgery and LNG-IUS, though adverse effects such as bleeding and spotting are more likely to occur with LNG-IUS. Oral medication suits a minority of women in the long term, and the LNG-IUS device provides a better alternative to surgery in most cases. Although hysterectomy is a definitive treatment for heavy menstrual bleeding, it can cause serious complications for a minority of women. Most women may be well advised to try a less radical treatment as first-line therapy. Both LNG-IUS and conservative surgery appear to be safe, acceptable and effective.

## **PLAIN LANGUAGE SUMMARY**

### **Surgery versus medical therapy for heavy menstrual bleeding**

#### **Review question**

Cochrane review authors compared the effectiveness, safety and acceptability of surgery versus medical therapy for heavy menstrual bleeding.

#### **Background**

Heavy menstrual bleeding is a common problem, which can impair a woman's quality of life. Surgical treatment includes hysterectomy and various methods of endometrial ablation or resection (cutting out or destroying the lining of the uterus). Medical treatment includes various oral medications and a hormone-releasing device that is implanted in the uterus (levonorgestrel-releasing intrauterine device, LNG-IUS).

#### **Study characteristics**

We included 15 randomised controlled trials that compared surgery versus oral medication or LNG-IUS. Participants were 1289 women with self reported heavy menstrual bleeding. The evidence is current to January 2016.

#### **Key results**

Hysterectomy, endometrial surgery and the LNG-IUS were all effective in reducing heavy menstrual bleeding, though surgery was most effective, at least over the short term. These treatments suited most women better than oral medication. Although hysterectomy will stop heavy menstrual bleeding, it is associated with serious complications and most women should probably try a less radical treatment as first-line therapy. Both conservative surgery and LNG-IUS appear to be safe, acceptable and effective.

**Quality of the evidence**

The quality of the evidence ranged from very low to moderate. The main limitations were lack of blinding, attrition and imprecision. It was difficult to interpret study findings over long-term follow-up because a large number of women randomised to medical treatment subsequently underwent surgery.

## SUMMARY OF FINDINGS

### Summary of findings for the main comparison. Surgery versus oral medication for women with heavy menstrual bleeding

#### Surgery versus oral medication for women with heavy menstrual bleeding

**Population:** women with heavy menstrual bleeding

**Intervention:** surgery

**Comparison:** oral medication

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Quality of the evidence (GRADE)	Comments
	Risk with oral medication	Risk with Surgery				
Control of bleeding (cure or improvement to acceptable level) At 4 months	312 per 1000	829 per 1000 (605 to 1000)	RR 2.66 (1.94 to 3.64)	186 (1 RCT)	⊕⊕⊕⊙ MODERATE <sup>1</sup>	—
Control of bleeding (cure or improvement to acceptable level) At 2 years	616 per 1000	795 per 1000 (653 to 968)	RR 1.29 (1.06 to 1.57)	173 (1 RCT)	⊕⊕⊕⊙ LOW <sup>12</sup>	—
Control of bleeding (cure or improvement to acceptable level) At 5 years	754 per 1000	859 per 1000 (731 to 1000)	RR 1.14 (0.97 to 1.34)	140 (1 RCT)	⊕⊕⊕⊙ VERY LOW <sup>1234</sup>	—
Overall satisfaction with treatment At 2 years	558 per 1000	781 per 1000 (631 to 971)	RR 1.40 (1.13 to 1.74)	173 (1 RCT)	⊕⊕⊕⊙ MODERATE <sup>1</sup>	—
Overall satisfaction with treatment At 5 years	710 per 1000	802 per 1000 (667 to 973)	RR 1.13 (0.94 to 1.37)	141 (1 RCT)	⊕⊕⊕⊙ VERY LOW <sup>14</sup>	—
Adverse events at 4 months	495 per 1000	129 per 1000 (74 to 228)	RR 0.26 (0.15 to 0.46)	186 (1 RCT)	⊕⊕⊕⊙ MODERATE <sup>5</sup>	—

\***The risk in the intervention group** (and its 95% confidence interval) is based on the median risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**CI:** confidence interval; **RCT:** randomised controlled trial; **RR:** risk ratio; **OR:** odds ratio

### GRADE Working Group grades of evidence

**High quality:** We are very confident that the true effect lies close to that of the estimate of the effect

**Moderate quality:** We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

**Low quality:** Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

**Very low quality:** We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

- <sup>1</sup>No blinding. High rate of cross-over: 59% of women in the medical group had undergone surgery by two years and 77% by five years.
- <sup>2</sup>Confidence intervals compatible with advantage in the surgical group or no clinically meaningful difference between the groups.
- <sup>3</sup>High attrition by five years - 23% attrition rate.
- <sup>4</sup>Confidence intervals compatible with advantage in either group or no clinically meaningful difference between the groups.
- <sup>5</sup>No blinding.

### Summary of findings 2. Surgery versus LNG-IUS for women with heavy menstrual bleeding

#### Surgery versus LNG-IUS for women with heavy menstrual bleeding

**Population:** women with heavy menstrual bleeding

**Intervention:** surgery

**Comparison:** LNG-IUS

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Quality of the evidence (GRADE)	Comments
	Risk with LNG-IUS	Risk with Surgery				
Objective control of bleeding: menstrual loss under 80 ml per cycle LNG-IUS versus hysterectomy At 1 year	897 per 1000	995 per 1000 (941 to 1000)	RR 1.11 (1.05 to 1.19)	223 (1 RCT)	⊕⊕⊕○ MODERATE <sup>1</sup>	—
Subjective control of bleeding: PBAC no more than 75 per cycle Endometrial resection or ablation versus LNG-IUS At 1 year	767 per 1000	912 per 1000 (820 to 1000)	RR 1.19 (1.07 to 1.32)	281 (5 RCTs)	⊕⊕○○ LOW <sup>12</sup>	—
Satisfaction rate: surgery versus LNG-IUS Endometrial ablation versus LNG-IUS At 1 year	630 per 1000	693 per 1000 (617 to 781)	RR 1.10 (0.98 to 1.24)	332 (5 RCTs)	⊕⊕○○ LOW <sup>12</sup>	—

Satisfaction rate: surgery versus LNG-IUS	894 per 1000	832 per 1000 (724 to 966)	RR 0.93 (0.81 to 1.08)	117 (2 RCTs)	⊕⊕○○ LOW <sup>1 2</sup>	—
Endometrial ablation versus LNG-IUS At 2 years						
Proportion of women with adverse events	559 per 1000	285 per 1000 (201 to 414)	RR 0.51 (0.36 to 0.74)	201 (3 RCTs)	⊕⊕⊕○ MODERATE <sup>2</sup>	—
Endometrial ablation versus LNG-IUS. At one year						

\***The risk in the intervention group** (and its 95% confidence interval) is based on the median risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**CI:** confidence interval; **LNG-IUS:** levonorgestrel-releasing intrauterine device; **PBAC:** pictorial blood loss assessment chart; **RCT:** randomised controlled trial; **RR:** risk ratio; **OR:** odds ratio

#### GRADE Working Group grades of evidence

**High quality:** We are very confident that the true effect lies close to that of the estimate of the effect

**Moderate quality:** We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

**Low quality:** Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

**Very low quality:** We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

<sup>1</sup>Confidence intervals compatible with benefit in the surgical arm or no clinically meaningful difference between the groups.

<sup>2</sup>Studies unblinded.

## BACKGROUND

### Description of the condition

Heavy menstrual bleeding, also known as menorrhagia, is a common gynaecological problem that creates a major burden in terms of quality of life and financial costs for many women (Frick 2009). Heavy menstrual bleeding also uses substantial healthcare resources (Liu 2007). A general practice (GP) survey of menstruating women conducted in the UK found that the 12-month incidence of self reported menorrhagia was 25%, without significant variation by age (Shapley 2004). A comparable prevalence rate is likely in other western countries. In New Zealand, a GP database indicated that about 2.3% of GP consultations for women aged under 50 years were for heavy menstrual bleeding (RNZCGP 2002). Rates in non-western countries are unknown.

Heavy menstrual bleeding has been defined as a blood loss of 80 ml or more per menstrual cycle (Hallberg 1966), which is unrelated to pregnancy or known pelvic or systemic disease. However, perception of heavy bleeding is highly subjective and the actual blood loss of women seeking medical care is often less than 80 ml. When menstrual blood loss is measured, only about half of the women attending gynaecology clinics with a complaint of menorrhagia have a loss of 80 ml per cycle or more (Chimbira 1980; Higham 1999).

An objective measure of blood loss has been devised, which involves soaking used sanitary pads and tampons and calculating the optical density of the resulting solution (Hallberg 1964). This method is accurate but is also complicated and time consuming. A simpler measure is the pictorial blood loss assessment chart (PBAC), whereby a woman assesses the blood loss on her used sanitary pads or tampons and assigns a numerical score accordingly (Higham 1990). Though popular, the PBAC system has not proved to be reliable and appears to have little advantage over a woman's subjective report of her blood loss, which in practice is usually the primary consideration (Reid 2000).

More recently it has been suggested that total menstrual fluid loss may be used as an assessment of menorrhagia (Reid 2005). Measurement is determined by the difference in weight of tampons or pads before and after use. Total menstrual fluid loss has been found to correlate well with changes in objective menstrual blood loss and may be of more relevance to women concerned mainly about flooding (rather than the composition of the loss).

### Description of the intervention

A minority of women reporting heavy menstrual bleeding may simply require reassurance that their blood loss is within the normal range.

### Medical interventions

Where active management is preferred, first-line treatment is generally medical. Several alternatives are available, including:

- the levonorgestrel-intrauterine device (LNG-IUS);
- anti-fibrinolytic drugs;
- non-steroidal anti-inflammatory drugs (NSAIDs);
- progestogens (short or long course);
- the combined oral contraceptive pill;

- danazol;
- a combination of drugs (e.g. tranexamic acid plus a NSAID).

All the medical therapies mentioned above have been shown to be at least partially effective in reducing menstrual blood loss. A decision analysis comparing the efficacy, side effects and consumer acceptability of these treatments ranked them in the order shown above, with the LNG-IUS coming top (NZ Guidelines 1998).

### Surgical interventions

Surgery may be indicated for women who have completed childbearing and for whom medical treatment is ineffective or intolerable, or it may be chosen as first-line therapy. Again a wide variety of options is available.

Hysterectomy has traditionally been regarded as the definitive surgical treatment for heavy menstrual bleeding and has been one of the most commonly performed operations, with menstrual disorders being a leading indication (Farquhar 2002). The surgery can be performed abdominally, vaginally or laparoscopically but there is good evidence that the vaginal route is associated with shorter recovery time and fewer complications than the abdominal route (Nieboer 2009). However, hysterectomy by any route has a relatively high incidence of short-term complications such as haemorrhage (serious blood loss), infection and wound healing problems and it also requires a lengthy postoperative recovery period. Moreover, a relationship has been found between hysterectomy and early ovarian failure (Farquhar 2005), while long-term effects on cardiovascular (heart) function are unclear. Nevertheless, hysterectomy is 100% successful in treating heavy menstrual bleeding and for most women any problems are relatively short-term. Satisfaction rates after hysterectomy are very high, at over 95% up to three years after surgery (Fergusson 2013).

Given that hysterectomy is a major surgical procedure with significant adverse effects and heavy menstrual bleeding is a benign condition, many women prefer one of the less invasive surgical options that are now available and which conserve the uterus. These procedures are known as endometrial resection or ablation and involve the destruction of the endometrium (the inner lining of the uterus) and the underlying basal glands by various means. Surgery may be preceded by a course of hormonal medication to thin the walls of the endometrium in order to facilitate its removal. Hormones used include goserelin (a gonadotrophin-releasing hormone analogue, or GnRHa) and danazol (Tan 2013).

'First-generation' techniques for endometrial destruction utilise a surgical telescope (hysteroscope) to aid viewing of the uterus along with a variety of electrosurgical or laser tools. These techniques require a general or regional anaesthetic, specialised surgical skill and often a short hospital admission. They are significantly safer than hysterectomy but still involve a small risk of uterine perforation, haemorrhage, fluid overload and infection; the short-term complication rate is around 4% (Overton 1997). There is no guarantee that bleeding will be reduced to acceptable levels in the long term. In one study at around four-year follow-up, 38% of those who had had endometrial ablation went on to receive further surgical treatment of some kind for continued excessive bleeding (Aberdeen 1999).

'Second-generation' techniques utilise the controlled application to the surface of the endometrium of heat, cold, microwave or other forms of energy with sufficient power to produce necrosis (cell death) of the full thickness of the tissue. Most of these techniques are 'non-hysteroscopic', meaning that they can be performed without direct visualisation through a hysteroscope (Lethaby 2013a). They include microwave ablation, a fluid-filled thermal balloon system, free fluid thermal ablation and bipolar electrocautery (NICE 2007). Such methods require sophisticated equipment but less specialised surgical skill than hysteroscopic methods and thus can usually be done as day or outpatient surgery with a local anaesthetic (Jack 2005). Economic modelling suggests that second-generation techniques may be more cost-effective than first-generation methods (Garside 2004). A Cochrane systematic review found that success rates and complication profiles of newer techniques of ablation appear to compare favourably with hysteroscopic techniques (Lethaby 2013a).

Compared to hysterectomy, endometrial destruction techniques have a shorter operation time and hospital stay, quicker recovery, fewer postoperative complications and comparable satisfaction rates. Ongoing contraception is essential for sexually active women after conservative surgery even though fertility is usually not retained (NICE 2007; Opperman 1998). Moreover, women are likely to continue to experience some degree of menstrual bleeding and may need further surgery if menorrhagia persists. This potential need for re-treatment over the long term has narrowed the cost gap between hysterectomy and conservative surgery (Fergusson 2013).

### How the intervention might work

Medical interventions vary in their mode of action, as follows:

- The levonorgestrel-intrauterine device (LNG-IUS) is a device that is implanted in the uterus for up to five years. It releases a low dose of a progestogenic hormone, which acts locally to suppress endometrial activity. The device also provides contraception, with fertility returning when the device is removed. It has been reported to reduce menstrual blood loss by 94% after three months and to be well accepted by most women (Irvine 1998). However, a LNG-IUS frequently causes irregular vaginal bleeding or spotting, especially during the first few months of use (Irvine 1998; Luukkainen 2001). Moreover, some women experience hormonal side effects such as weight gain, breast tenderness and bloating and occasionally the device is expelled spontaneously (Lethaby 2015). Other less common but more severe side effects include the increased risk of pelvic inflammatory disease, should a sexually transmitted infection occur, the increased risk of ectopic pregnancy should pregnancy occur, and the risk of uterine perforation, which is a rare but serious event (NICE 2005). An increased incidence of ovarian cysts has been reported in women using intrauterine progestogenic implants; these are a transient phenomenon, which resolves spontaneously (Brache 2002).
- Anti-fibrinolytic drugs such as tranexamic acid work by inhibiting the breakdown of blood clots (fibrinolysis). These drugs reduce bleeding by about 40% to 50% (Lethaby 2009b), but do not generally alleviate menstrual cramping (Preston 1995). They are taken only during menstruation and are usually well tolerated but can cause mild nausea and diarrhoea (Dunn 1999).

- Non-steroidal anti-inflammatory drugs (NSAIDs) such as mefenamic acid and naproxen reduce blood loss by 33% to 55% and also relieve menstrual cramps. They act by inhibiting the production of prostaglandin (a fatty acid that is typically over-produced in women with heavy menstrual bleeding). They can cause headaches and gastrointestinal disturbances though significant side effects are unlikely as NSAIDs need to be taken only during menstruation (Lethaby 2013).
- Progestogens such as norethisterone and medroxyprogesterone acetate are hormones which suppress endometrial growth and activity. Given as a 21-day course, from day 5 to day 26 of the menstrual cycle, they reduce blood flow substantially (Lethaby 2008). However, they are considered unacceptable for long-term use by many women due to the prevalence of side effects such as breast tenderness, bloating and headaches; they may also precipitate breakthrough bleeding (Irvine 1998). Progestogens have been shown to be less effective if taken as a short course, i.e. only during the luteal phase of the menstrual cycle (between ovulation and menstruation) (Lethaby 2008).
- There is some indication that the combined oral contraceptive pill significantly reduces menstrual blood loss and relieves cramping; in addition it provides contraception (Fraser 1991). However, randomised evidence is very scanty (Farquhar 2009). This treatment may work by inhibiting the growth and development of the endometrium. Side effects include irregular bleeding, especially on treatment initiation. Some women report other hormonal effects such as headaches, nausea, dizziness and breast tenderness, though these are less prevalent with currently available low-dose combined oral contraceptives than with older preparations. Weight gain is often perceived as a side effect of combined oral contraceptive use, but no causal association has been found. The risk of arterial thrombotic events is increased threefold by combined oral contraceptive use, and the risk of venous thromboembolism is doubled; however these serious events remain very rare among healthy women of reproductive age (Dragoman 2014).
- Danazol is a synthetic hormone that causes the endometrium to shrink and is usually highly effective in reducing blood loss. It is generally only used for short-term treatment due to the prevalence and severity of side effects such as weight gain, headache, nausea, tiredness and acne (Beaumont 2007). Barrier contraception is recommended to prevent possible fetal damage (New Ethicals 2000). When treatment is discontinued, the effects of danazol persist for two to three cycles before blood loss returns to pre-treatment levels (Chimbira 1979).

Surgical interventions work by removing or destroying the endometrium, as described in the section above.

### Why it is important to do this review

There are several Cochrane systematic reviews on the effectiveness and acceptability of individual surgical and medical treatments for heavy menstrual bleeding (Beaumont 2007; Farquhar 2009; Fergusson 2013; Lethaby 2008; Lethaby 2013a; Lethaby 2015; Lethaby 2009b). The aim of the present review is to assess the efficacy, safety and acceptability of all forms of medical treatment against all forms of surgery for heavy menstrual bleeding.

## OBJECTIVES

To compare the effectiveness, safety and acceptability of surgery versus medical therapy for heavy menstrual bleeding.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

Randomised controlled trials (RCTs) comparing surgery (conservative surgery or hysterectomy) versus medical therapy (oral, intramuscular or intrauterine) for the treatment of heavy menstrual bleeding.

#### Types of participants

##### Inclusion criteria

- Women of reproductive age with regular heavy menstrual periods measured either objectively (e.g. via the alkaline haematin test) or subjectively (e.g. via the pictorial blood loss assessment chart (PBAC), a menstrual blood loss diary or according to a woman's personal judgement).

##### Exclusion criteria

- Postmenopausal bleeding (over one year since the last menstrual period).
- Irregular menses or intermenstrual bleeding.
- Pathological causes of heavy menstrual bleeding (e.g. uterine cancer).
- Iatrogenic (treatment-related) causes of heavy menstrual bleeding (e.g. non-progestogen-releasing intrauterine contraceptive device).

#### Types of interventions

- Hysterectomy (including abdominal, laparoscopic, vaginal and laparoscopically assisted vaginal), endometrial resection or ablation (including both first and second-generation techniques such as transcervical resection of the endometrium, transcervical rollerball, laser, cryosurgery and balloon therapies).
- Medical treatments for heavy menstrual bleeding, including a levonorgestrel-intrauterine device (LNG-IUS), non-steroidal anti-inflammatory agents, tranexamic acid, the oral contraceptive pill, progestogen in short or long courses, and danazol.

#### Types of outcome measures

##### Primary outcomes

1. Menstrual bleeding, measured at one year\*, two years, five years and 10 years.

\*If studies did not report this outcome at one year we included measures at less than one year and have highlighted where this is the case.

a) Objective assessment of menstrual blood loss, e.g. measured by the modified alkaline haematin method (Hallberg 1964).

b) Subjective assessment of menstrual blood loss, e.g. measured by pictorial blood assessment chart (PBAC) (Higham 1990), or a

woman's perception of improvement recorded in a reproducible and validated format.

2. Satisfaction rate.

3. Adverse effects.

##### Secondary outcomes

4. Quality of life: self reported change in quality of life, recorded in a reproducible and validated format.

5. Requirement for additional surgical or medical treatment for heavy menstrual bleeding.

6. Cost and resource use.

### Search methods for identification of studies

We searched for all published and unpublished RCTs comparing surgery versus medical therapy for heavy menstrual bleeding, without language restriction and in consultation with the Cochrane Gynaecology and Fertility (CGF) Group Trials Search Co-ordinator. We searched all databases from inception to January 14th 2016.

#### Electronic searches

We searched the Specialised Register of the Cochrane Menstrual Disorders and Subfertility Group (Appendix 1), which is based on regular searches of MEDLINE, EMBASE, CINAHL and PsycINFO (from inception), handsearching of 20 relevant journals and conference proceedings, and searches of several key grey literature sources. A full description is given in the Group's module on *The Cochrane Library*.

In addition, we searched the Cochrane Central Register of Controlled Trials (CENTRAL) (Appendix 2), MEDLINE (Appendix 3), EMBASE (Appendix 4), PsycINFO (Appendix 5), CINAHL (Appendix 6) and clinical trials registers (clinical trials.gov and ICTRP).

#### Searching other resources

We also searched citation lists of relevant publications.

### Data collection and analysis

#### Selection of studies

One author (JM) scanned the titles and abstracts of articles retrieved by the search and removed those that were very clearly irrelevant. We retrieved the full texts of all potentially eligible studies. Two review authors (AL, JM) independently examined the full-text articles for compliance with the inclusion criteria and selected the studies that were eligible for inclusion in the review. The review authors attempted to contact study investigators, as required, to clarify study eligibility (for example, with respect to randomisation and blinding). We resolved disagreements as to study eligibility by consensus.

#### Data extraction and management

Two authors (JM and either AL or CM) independently extracted data using a standardised form. For each study, we extracted data on study design, participants, interventions used and outcomes measured. These are presented in the [Characteristics of included studies](#) table. We also extracted data on study findings. These are presented in the [Results](#) and the [Data and analyses](#) sections

of the review. We sought additional data from the principal or corresponding author of studies, if necessary. Where studies had multiple publications, we used the most recent report. We resolved discrepancies by discussion.

### Assessment of risk of bias in included studies

Two review authors (JM and AL) independently assessed the included studies for risk of bias using the Cochrane 'Risk of bias' assessment tool to assess risk of selection bias (random sequence generation and allocation concealment); performance and detection bias (blinding of participants and personnel and outcome assessors); attrition bias (incomplete outcome data); reporting bias (selective reporting); and other bias (Higgins 2011). We resolved disagreements by discussion or by referral to the third review author. We presented the conclusions in the 'Risk of bias' tables, which are incorporated into the interpretation of review findings by means of sensitivity analyses (see below).

### Measures of treatment effect

For dichotomous data (for example, the proportion of women reporting control of bleeding) we used the numbers of events in the control and intervention groups of each study to calculate risk ratios (RRs). For continuous data (for example PBAC scores) we calculated mean differences between treatment groups. We treated ordinal data (for example, quality of life scores) as continuous data. For all outcomes we calculated 95% confidence intervals (CIs).

We used data in meta-analysis only if the underlying distribution of the measurements appeared normal. The ratio of the mean to its standard deviation gives a crude method of assessing skew; if this ratio was less than 2.0 for any group in a trial, or if results were reported in the publication as median and range, we reported the data in text in 'Additional tables'. Where trial results were incomplete (for example, measures of variance were not extractable) or presented only as graphs, we reported the results descriptively in the text.

### Unit of analysis issues

We identified no unit of analysis issues.

### Dealing with missing data

We analysed data on an intention-to-treat basis, as far as possible. Where data were missing, we made attempts to obtain them from the original investigators. Where they were unobtainable, we analysed the available data using the numerator and denominator reported in study results or calculated from reported percentages.

### Assessment of heterogeneity

The authors considered whether the clinical and methodological characteristics of the included studies were sufficiently similar for meta-analysis to provide a meaningful summary. Where pooling was conducted, we examined heterogeneity (variation) between the results of different studies by inspecting the scatter in the data points and the overlap in their CIs and more formally by checking the results of the  $I^2$  statistic (Higgins 2003). This quantity describes the percentage of total variation across studies that is due to heterogeneity rather than chance. We planned to tentatively assign low, moderate and high heterogeneity to  $I^2$  statistics of up to 25%, 26% to 74% and over 75%, respectively. We planned to look at the possible contribution of differences in trial design to any

meta-analyses with an  $I^2 > 50\%$ . Wherever possible, we statistically pooled outcomes.

### Assessment of reporting biases

In view of the difficulty in detecting and correcting for publication bias and other reporting biases, we aimed to minimise their potential impact by ensuring a comprehensive search for eligible studies and by being alert for duplication of data. We planned to use a funnel plot to assess the possibility of small study effects (a tendency for estimates of the intervention effect to be more beneficial in smaller studies) if there were a sufficient number of studies for the same outcome (10 or more).

### Data synthesis

We combined the data from primary studies if they were sufficiently homogeneous. We pooled dichotomous data to calculate pooled RRs with 95% CIs using a fixed-effect model. We displayed graphically an increase in the risk of a particular outcome, which may be beneficial (for example, pain relief) or detrimental (for example, adverse effects), in the forest plots to the right of the centre line; a decrease in the risk of an outcome is shown to the left of the centre line. We combined data for continuous outcomes to calculate means differences (MDs) and 95% CIs.

### Subgroup analysis and investigation of heterogeneity

Where a visual scan of the forest plots indicated heterogeneity, we planned to consider methodological and clinical differences that might account for the outliers. We planned to consider subgroup analyses to investigate significant heterogeneity found during the review process, but to interpret the results of any such analyses with caution as they were not prespecified.

### Sensitivity analysis

We planned to conduct sensitivity analyses for the primary outcomes to determine whether the conclusions are robust to arbitrary decisions made regarding the eligibility and analysis. These analyses would include consideration of whether the review conclusions would have differed if:

- eligibility were restricted to studies without high risk of bias (those with a high risk of bias in any of the domains assessed);
- a random effects-model had been adopted;
- the summary effect measure had been odds ratio rather than a risk ratio.

### Overall quality of the body of evidence: 'Summary of findings' table

We prepared a 'Summary of findings' table using Guideline Development Tool software. This table evaluated the overall quality of the body of evidence for the main review outcomes (menstrual bleeding, satisfaction, adverse events), using GRADE criteria (study limitations (i.e. risk of bias), consistency of effect, imprecision, indirectness and publication bias). We justified, documented and incorporated into the reporting of results our judgements about evidence quality (high, moderate or low) for each outcome.

## RESULTS

### Description of studies

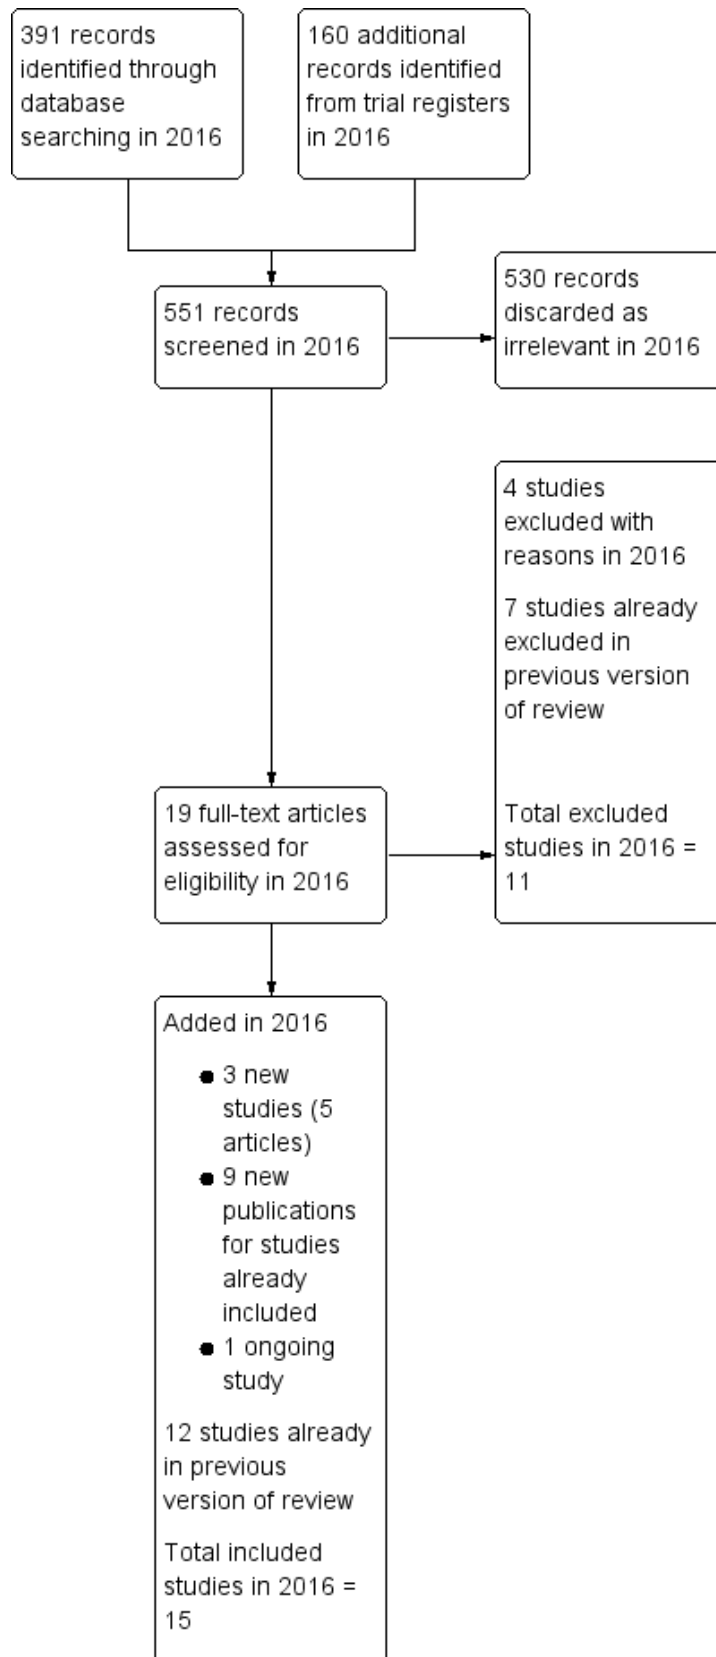

#### Results of the search

Our search in January 2016 retrieved 551 records, of which we checked 19 in full text. We found three new studies (six articles) eligible for inclusion ([Ergun 2012](#) (three articles); [Ghazizadeh 2014](#) (two articles); [Sesti 2012](#)), one new ongoing study ([Herman 2013](#)), and nine articles pertaining to three studies already included in the

review ([de Souza 2010](#) (two articles); [Hurskainen 2001](#) (six articles); [Tam 2006](#)). We excluded four studies ([Ergun 2012a](#); [Ghazizadeh 2011](#); [Shabaan 2011](#); [Shokeir 2013](#)).

The review update includes 15 studies (three new in 2016 plus 12 already in the previous version of the review). The final search date in the previous version was May 2010). Altogether we have excluded 11 studies from the review (four newly excluded in 2016 plus seven already excluded from the previous version of the review). See study flowchart: [Figure 1](#).

**Figure 1. Study flow diagram.**

## Included studies

### Design

Fifteen parallel-group RCTs met the inclusion criteria. They included a total of 1289 women. The trials were conducted at gynaecology outpatient departments of hospitals in Brazil, Egypt, England, Finland, Hong Kong, Iran, Italy, New Zealand, Norway, Scotland, Turkey and the USA. For seven studies the primary outcome was menstrual bleeding, measured as a bleeding score (Barrington 2003; Crosignani 1997; Ergun 2012; Istre 1998; Sesti 2012; Shaw 2007; Soysal 2002; Talis 2006), or by treatment success, a composite measure based on menstrual bleeding rate, removal of the device or need for repeat surgery (Malak 2006). The primary outcome was unclear in one study (Ghazizadeh 2014). Primary outcomes in other studies were health-related quality of life (Hurskainen 2001; Kupperman 2004), and satisfaction with treatment (Cooper 1997). Two studies reported a range of measures of menstrual health and quality of life and did not specify a primary outcome (de Souza 2010; Tam 2006). Duration of follow-up ranged from six months to 10 years.

### Participants

Study participants were women aged 30 to 50 years seeking treatment for heavy menstrual bleeding. None of the studies required objective evidence of menorrhagia, though some excluded women with a PBAC score below a minimum level (which varied from 75 ml to 150 ml).

The expectations of participants varied. Three studies required that women were equally willing to accept medical or surgical management (Cooper 1997; Hurskainen 2001; Kupperman 2004), whereas in four studies the participants were initially prepared to have a hysterectomy (Crosignani 1997; Ghazizadeh 2014; Istre 1998; Malak 2006). Inclusion criteria in seven studies required that women had unsuccessfully tried oral medical treatment (Barrington 2003; de Souza 2010; Ergun 2012; Kupperman 2004; Sesti 2012; Shaw 2007; Tam 2006), which in one had to include cyclical medroxyprogesterone (Kupperman 2004). Many of the participants in other studies had also tried oral medical therapy unsuccessfully.

Ten of the studies specifically stated that women should be premenopausal (Crosignani 1997; Istre 1998; Kupperman 2004; Malak 2006; Tam 2006), should not be postmenopausal (Sesti 2012), should have regular menstrual cycles (de Souza 2010; Ergun 2012; Talis 2006), or should "be menstruating" (Hurskainen 2001). Other studies required women to have heavy menstrual bleeding, but did not have menopausal status as a specific inclusion or exclusion criterion (Barrington 2003; Cooper 1997; Ghazizadeh 2014; Shaw 2007; Soysal 2002). All studies excluded women with abnormal endometrial pathology or other uterine abnormalities such as polyps or fibroids. Other inclusion and exclusion criteria are detailed in the [Included studies](#) table.

### Interventions

Comparisons in the included studies were as follows:

- Endometrial resection versus oral medication (Cooper 1997).
- Hysterectomy versus oral medication (Kupperman 2004).
- Endometrial resection versus LNG-IUS (Crosignani 1997; Ergun 2012; Ghazizadeh 2014; Istre 1998; Malak 2006).

- Thermal balloon ablation versus LNG-IUS (Barrington 2003; de Souza 2010; Shaw 2007; Soysal 2002; Talis 2006; Tam 2006).
- Ablation using bipolar electrocauterisation (NovaSure) versus LNG-IUS (Ghazizadeh 2014).
- Hysterectomy versus LNG-IUS (Hurskainen 2001; Sesti 2012).

In six studies, women in the surgical arm received transcervical endometrial resection with a loop or rollerball (where stated), a 'first-generation' technique (Cooper 1997; Crosignani 1997; Ergun 2012; Ghazizadeh 2014; Istre 1998; Malak 2006); while in seven studies they received a 'second-generation' technique, either thermal balloon ablation (Barrington 2003; de Souza 2010; Shaw 2007; Soysal 2002; Talis 2006; Tam 2006), or bipolar electrocauterisation (Ghazizadeh 2014). In two studies women in the surgical group underwent hysterectomy (Hurskainen 2001; Kupperman 2004).

Medical management in Cooper 1997 consisted of a minimum of three cycles of oral medication. This included progestogens, the combined oral contraceptive pill, tranexamic acid, danazol, hormone replacement therapy and non-steroidal anti-inflammatory drugs. In Kupperman 2004, all women had already tried cyclical medroxyprogesterone acetate and found it unsatisfactory. Ninety per cent of them were prescribed various forms of hormonal therapy, generally combined with a non-steroidal anti-inflammatory drug (in most cases naproxen sodium). Women dissatisfied with one medical therapy were encouraged to try other medical options. Medical management in the other nine studies consisted of LNG-IUS, an intrauterine device releasing 20 µg per day of levonorgestrel (progesterone).

### Outcomes

#### Primary review outcomes

##### Menstrual bleeding

Eleven studies reported menstrual blood loss. One measured blood loss objectively using the alkaline haematin method (Hurskainen 2001), and 10 used self rated bleeding scores, either the Pictorial Blood Loss Assessment Chart (PBAC) (Barrington 2003; Crosignani 1997; Ergun 2012; Istre 1998; Malak 2006; Sesti 2012; Shaw 2007; Soysal 2002; Talis 2006), or a zero to five scale (Cooper 1997).

##### Satisfaction rates

Satisfaction rates were the primary outcome in Cooper 1997 and were also reported by other studies (Crosignani 1997; Ghazizadeh 2014; Shaw 2007; Soysal 2002; Talis 2006).

##### Adverse events

Most studies reported adverse effects, including operative complications, complications with insertion of the LNG-IUS (where applicable) and longer-term adverse effects (for example, pelvic or abdominal pain, irregular bleeding, vaginal discharge, breast tenderness). Kupperman 2004 only reported events requiring hospitalisation. Two studies reported postoperative complications and adverse effects associated with 'treatment failure' (that is removal of the LNG-IUS) (Shaw 2007; Talis 2006); one focused on adverse events in the LNG-IUS group only (Tam 2006). Sesti 2012 reported only short-term adverse events (occurring for up to 30 days postoperatively). Two studies failed to report clear data on adverse events (Ergun 2012; Ghazizadeh 2014), and a third did not report this outcome at all (de Souza 2010).

### Secondary review outcomes

Nine studies reported detailed quality of life data (Cooper 1997; Crosignani 1997; de Souza 2010; Hurskainen 2001; Kupperman 2004; Malak 2006; Soysal 2002; Talis 2006; Tam 2006). For two studies this was the primary outcome (Hurskainen 2001; Kupperman 2004). Tools used to measure quality of life are listed in the table [Characteristics of included studies](#).

All studies reported on requirement for additional surgery or medical treatment, and three analysed cost-effectiveness in detail (Hurskainen 2001; Kupperman 2004; Talis 2006).

### Excluded studies

We excluded 11 studies from the review. Four were non-randomised (Barrington 1997; Ghazizadeh 2011; Romer 2000; Soysal 2005), one was partially randomised but separate data for the randomised group were not obtainable (Assaf 2000), four did not report the comparison of interest (Ergun 2012a; Reid 2005; Shabaan 2011; Shokeir 2013), one did not report the outcomes of interest (Lahteenmaki 1998), and one was discontinued due to poor enrolment (SMART 2000) (see [Excluded studies](#)).

### Risk of bias in included studies

See [Figure 2](#) for a summary of the risk of bias in individual studies and [Figure 3](#) for a summary of each risk of bias item across all included studies.

**Figure 2. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding (performance bias and detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias
Barrington 2003	?	?	-	+	?	-

Tam 2006	+	+	-	-	?	?

**Figure 3. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.**

**Allocation**

**Sequence generation**

Twelve studies described satisfactory methods of sequence generation and we rated them as at low risk of bias in this domain. Three did not clearly describe the method used and we rated them as at unclear risk of bias (Barrington 2003; Ergun 2012; Ghazizadeh 2014)

**Allocation concealment**

Eleven studies described satisfactory methods of allocation concealment and we rated them as at low risk of bias in this domain. Four did not clearly describe the method used and we rated them as at unclear risk of bias (Barrington 2003; Ergun 2012; Ghazizadeh 2014; Malak 2006).

**Blinding**

No studies reported use of blinding, which would clearly be very difficult for most of these comparisons. In view of the subjective nature of our primary outcome measures, we rated all studies as at high risk of bias in this domain.

**Incomplete outcome data**

Nine studies analysed a high proportion of the women randomised (90% to 100%) and provided valid reasons for all or nearly all missing data. No study attempted to impute missing data. We rated six studies as at high risk of attrition bias: in Cooper 1997 18% of the women were missing from the analysis at five years without details of the reasons; in three studies over 25% of women in one or both arms were not included in the analysis (Ergun 2012; Shaw 2007; Tam 2006), and in Talis 2006 only 70% of the women randomised were analysed for PBAC scores at two years.

**Selective reporting**

We rated nine studies as at low risk of this bias as they reported on all expected outcomes, including those that were prespecified, and reported them systematically for both comparison groups based on prospectively collected data. We rated four studies as at unclear

risk of this bias because they did not clearly report adverse events across both intervention groups (Barrington 2003; Ergun 2012; Ghazizadeh 2014; Shaw 2007). Two studies did not clearly specify a primary outcome or clearly report adverse events across both intervention groups and we rated them as at high risk of selective reporting (de Souza 2010; Tam 2006).

**Other potential sources of bias**

We rated five studies as at unclear risk of other bias (Crosignani 1997; Istre 1998; Malak 2006; Soysal 2002; Tam 2006); see Characteristics of included studies for details. We rated two as at high risk of bias due to differences between the groups at baseline (Barrington 2003; Ghazizadeh 2014), and we rated the remainder of the studies as at low risk of other potential bias.

**Source of funding**

Six studies were funded by government or tertiary institutional research grants or received no external funding (Cooper 1997; Crosignani 1997; Hurskainen 2001; Kupperman 2004; Shaw 2007; Tam 2006), though medicated intrauterine devices (where used) or surgical equipment were often supplied by the manufacturer. Two studies were commercially funded (de Souza 2010; Istre 1998). It was not stated how any of the other studies were funded.

**Contact with study authors**

We sought additional information from most of the principal investigators regarding the study design and results. We received replies from the principal investigators of eight studies (de Souza 2010; Ghazizadeh 2014; Hurskainen 2001; Istre 1998; Kupperman 2004; Shaw 2007; Talis 2006; Tam 2006). See Characteristics of included studies for more details on the methodology of all the included studies.

**Effects of interventions**

See: [Summary of findings for the main comparison Surgery versus oral medication for women with heavy menstrual bleeding](#);

**Summary of findings 2** Surgery versus LNG-IUS for women with heavy menstrual bleeding

**1. Surgery versus oral medication**

Two studies made this comparison. They compared endometrial ablation (Cooper 1997) and hysterectomy (Kupperman 2004) versus oral medication.

**PRIMARY OUTCOMES**

**1.1 Menstrual bleeding**

**1.1a Objective measures**

Neither of the studies reported objective assessment of bleeding (such as use of the modified alkaline haematin method).

**1.1b Subjective measures**

One study of 187 women compared transcervical endometrial resection with oral medication and assessed menstrual bleeding at four months, two years and five years (Cooper 1997).

At four months, control of bleeding (cure or improvement to an acceptable level) was reported by more women in the surgical group than in the medical group (risk ratio (RR) 2.66, 95% confidence interval (CI) 1.94 to 3.64, 186 women). Mean self rated bleeding scores were reduced from baseline in both groups but scores were lower in the surgical group (mean difference (MD) -12.70, 95% CI -10.36 to -15.04, 186 women) (Figure 4; Analysis 1.1; Analysis 1.2).

**Figure 4. Forest plot of comparison: 1 Surgery versus oral medication, outcome: 1.1 Control of bleeding (cure or improvement to acceptable level).**

Risk of bias legend

- (A) Random sequence generation (selection bias)
- (B) Allocation concealment (selection bias)
- (C) Blinding (performance bias and detection bias)
- (D) Incomplete outcome data (attrition bias)
- (E) Selective reporting (reporting bias)
- (F) Other bias

At two years surgery was still rated significantly more effective than oral medication in control of bleeding (RR 1.29, 95% CI 1.06 to 1.57, 173 women), but there was no longer evidence of a difference between the groups in bleeding scores (MD -1.40, 95% CI -4.10 to 1.30, 173 women) (Figure 4; Analysis 1.1; Analysis 1.2).

At five years there was no longer evidence of a difference between the groups in control of bleeding (RR 1.14, 95% CI 0.97 to 1.34, 140 women) (Analysis 1.1).

In interpreting the two-year and five-year results for this study, it is relevant to bear in mind that analysis was by intention-to-treat and that by two years of follow-up the majority of women in the

medical group had received surgery (see below: 'Requirement for further surgery').

**1.2 Satisfaction rate**

The study comparing endometrial ablation with oral medication, Cooper 1997, reported on satisfaction levels at four months, two years and five years. Women in the surgical group reported a higher satisfaction rate at four months than women in the medical group (RR 2.80, 95% CI 1.96 to 3.99, 186 women) (Analysis 1.3). At six-month follow-up, in Kupperman 2004 women in the hysterectomy group reported higher levels of satisfaction with symptom resolution (P value ≤ 0.001) and overall health (P value = 0.006) than women in the medical group.

In [Cooper 1997](#), at two years there were still more women in the surgical arm than in the medical arm who were satisfied with their treatment ([Analysis 1.3](#)), but in [Kupperman 2004](#) by this stage there was no evidence of a difference in satisfaction levels in the two groups (P value = 0.68). By five years there was no evidence of a difference between the groups in [Cooper 1997](#) either ([Analysis 1.3](#)).

As noted above, in interpreting the two-year and five-year results for these studies, it is relevant to bear in mind that analysis was by intention-to-treat and that by two years of follow-up the majority of women in the medical groups had received surgery.

### 1.3 Adverse effects

Both studies described adverse effects, though the level of detail varied.

#### Perioperative/short-term adverse events

In [Cooper 1997](#), six women undergoing endometrial resection (6%) had persistent uterine bleeding during surgery that required the temporary insertion of a uterine Foley catheter ([Table 1](#)).

In the hysterectomy group of [Kupperman 2004](#), two women suffered perioperative complications (a superficial injury to the small bowel and a fever) and three had late complications necessitating readmission: one was hypovolaemic and required a laparotomy and salpingo-oophorectomy (removal of the ovaries), one developed a new seizure disorder seven days postoperatively and a third required removal of the cervix due to persistent bleeding ([Table 1](#)).

#### Adverse events over follow-up

[Cooper 1997](#) reported fewer adverse effects in the surgical group than in the medical group at four months (RR 0.26, 95% CI 0.15 to 0.46, 186 women, [Analysis 1.4](#)). Symptoms included nausea, headaches and weight gain in the medical group and new pain in both groups. One woman in the medical arm who had been prescribed danazol suffered a cerebrovascular accident and one who had been prescribed the combined oral contraceptive pill developed hypertension.

[Kupperman 2004](#) reported that two women in the medical group required hospital admission for bleeding problems. One required dilatation and curettage for abnormal uterine bleeding at seven months post-randomisation and the other required a blood transfusion and injection of gonadotrophin-releasing hormone for haemorrhagic vaginal bleeding.

## SECONDARY OUTCOMES

### 1.4 Quality of life and symptom control

Both studies comparing surgery with oral medication reported SF-36 scores ([Cooper 1997](#); [Kupperman 2004](#)). The SF-36 change scores in both these studies had high standard deviations, indicating skewed distribution. Results are therefore recorded in additional tables rather than forest plots (see [Table 2](#)).

In [Cooper 1997](#), at four months SF-36 scores were improved in all or most categories for women in both groups, but all improvements were greater for women in the surgical arm ([Table 2](#)).

At two years SF-36 scores continued to improve from baseline for women in the medical group but generally fell for women in

the surgical group, with the result that there was no evidence of a difference between the groups in the change in scores from baseline. However, by this time 59% of women in the medical group had received surgery. At five years the surgical group had greater improvement from baseline levels in three out of eight SF-36 categories, namely emotional role, mental health and general health ([Table 2](#)).

Similarly, women in the hysterectomy group in [Kupperman 2004](#) reported greater improvements at six months in SF-36 mental health scores (P value  $\leq 0.05$ ) than the medical group. At two years these improvements were maintained in the hysterectomy group but the scores for the medical group had also improved for most categories so that there were few differences between the groups. By then 53% of women in the medical group had had a hysterectomy.

### 1.5 Requirement for additional treatment for heavy menstrual bleeding

#### Requirement for additional surgical treatment

Fewer women in the surgical arms than in the medical arms of these studies required additional surgery (endometrial ablation or hysterectomy or both) within two years of their initial treatment (14% versus 58%): RR 0.25, 95% CI 0.15 to 0.39, two studies, 236 women,  $I^2 = 39%$  ([Analysis 1.5](#)). In the study with five-year follow-up these figures were 26% and 77% respectively (RR 0.35, 95% CI 0.25 to 0.50, 187 women) with about 18% of women in each arm having had a hysterectomy ([Cooper 1997](#)) ([Analysis 1.5](#)). Most of these operative procedures were performed within the first 18 months ([Kupperman 2004](#)) or two years ([Cooper 1997](#)).

#### Requirement for additional medical treatment

The study of endometrial ablation versus oral medication reported this outcome: 7/87 (8%) of women in the surgical group were using medical therapy at two years ([Cooper 1997](#)).

### 1.6 Cost

[Kupperman 2004](#) compared the cost of hysterectomy and oral medication by measuring relative resource use over a 24-month follow-up with assessments conducted three-monthly. In the first 12 months of follow-up, using intention-to-treat analysis, women in the hysterectomy group used significantly more resources (USD 6777 versus USD 4479, P value = 0.03) attributable mainly to use of inpatient care. During the second year of follow-up resource use was roughly equivalent in the surgical and medical groups (USD 1360 versus USD 1338 respectively). Within two years there was a 53% rate of cross-over to hysterectomy in the medical group, which accounted for the similarity in resource use. In 'as-treated' analyses, mean total resource use for women in the medical group who did not subsequently receive hysterectomy was USD 2595 compared to USD 7024 for women in the hysterectomy group.

## 2. Surgery versus levonorgestrel-intrauterine device (LNG-IUS)

### PRIMARY OUTCOMES

Thirteen studies compared surgery with LNG-IUS. In two studies women in the surgical arm underwent hysterectomy ([Hurskainen 2001](#); [Sesti 2012](#)). In the other 11 studies women in the surgical arm underwent conservative surgery: transcervical endometrial resection ([Crosignani 1997](#); [Ergun 2012](#); [Ghazizadeh 2014](#); [Istre 1998](#); [Malak 2006](#)), or ablation with either thermal balloon ([Barrington](#)

2003; de Souza 2010; Shaw 2007; Soysal 2002; Talis 2006; Tam 2006), or electrocautery (Ghazizdeh 2014). One study included two types of ablation (Ghazizdeh 2014).

Since hysterectomy is expected to have a 100% success rate in stopping menstrual bleeding and since adverse effects are commonly related to bleeding patterns, for these outcomes we considered it inappropriate to pool Hurskainen 2001 or Sesti 2012 with studies that used conservative surgery.

## 2.1 Menstrual bleeding

### 2.1a Objective measures

#### Hysterectomy versus LNG-IUS

Hurskainen 2001 reported objective assessment of bleeding at one year, using the modified alkaline haematin method. When analysed by intention-to-treat, including in the LNG-IUS group the 20% of women randomised to the LNG-IUS group who subsequently had a hysterectomy, bleeding was controlled in all women in the hysterectomy group (107/107) and 90% (104/116) in the LNG-IUS group (RR 1.11, 95% CI 1.05 to 1.19, one RCT, 223 women) (Analysis 2.1). When outcomes were analysed at one year by treatment received, no women in the hysterectomy group had any further menstrual bleeding while in the LNG-IUS group 69% of women (80/116) had control of bleeding.

At one year, blood loss was measured objectively in all women in the LNG-IUS group of this study who still had a LNG-IUS in situ, apart from those whose bleeding was nil or negligible. This amounted to 25 women, only one of whom had a loss in excess of 80 ml. The mean loss for the 25 women was 13 ml (range 1 ml to 92 ml).

#### Conservative surgery versus LNG-IUS

No studies of conservative surgery versus LNG-IUS reported objective measures of blood loss.

### 2.1b Subjective measures

#### Hysterectomy versus LNG-IUS

One study of hysterectomy versus LNG-IUS reported this outcome, measured by pictorial blood loss assessment chart (PBAC) scores at one year (Sesti 2012). There was no evidence of a difference between the groups (MD 0.20, 95% CI -5.12 to 5.52, one study, 72 women) (Analysis 2.3). At two years, PBAC scores were lower in the surgical group (MD -52.70, 95% CI -76.50 to -28.90, one RCT, 72 women) (Analysis 2.4).

#### Conservative surgery versus LNG-IUS

Ten studies of conservative surgery versus LNG-IUS reported this outcome. Measures used were self report of "well controlled bleeding" and PBAC scores. Duration of follow-up ranged from six months to five years. Eight studies reported PBAC data that were unsuitable for meta-analysis (see Table 3).

- *Bleeding at up to one year (10 studies)*

Five studies of conservative surgery versus LNG-IUS measured the proportion of women who reported that their bleeding was well controlled by their primary treatment at one year (PBAC score < 75 per cycle or bleeding 'normal' or lighter) (Crosignani 1997; Istre 1998; Malak 2006; Soysal 2002; Tam 2006). Pooled findings favoured the surgical group (RR 1.19, 95% CI 1.07 to 1.32, five studies, 281 women,  $I^2 = 15%$ ) (Figure 5; Analysis 2.2).

**Figure 5. Forest plot of comparison: 2 Surgery versus LNG-IUS, outcome: 2.2 Subjective control of bleeding at up to one year: PBAC  $\leq$  / < 75 per cycle with primary treatment.**

Nine studies of conservative surgery versus LNG-IUS reported PBAC scores at six months (Barrington 2003), or one year (Crosignani 1997; de Souza 2010; Ergun 2012; Istre 1998; Malak 2006; Shaw 2007; Soysal 2002; Talis 2006). All studies reported that both groups had significant reductions from baseline in PBAC scores. In the only one of these studies that reported data suitable for analysis, Soysal 2002, the mean PBAC score at one year was lower in the surgical group (MD -33.20, 95% CI -39.20 to -27.20, one RCT, 67 women) (Analysis 2.3). The other eight studies reported median values or skewed data and their data are reported in an additional table (Table 3). Their findings were inconsistent: five of the eight found no evidence of a difference between the groups in PBAC scores (Barrington 2003; de Souza 2010; Ergun 2012; Istre 1998; Malak 2006), one reported lower PBAC scores in the surgical group (Crosignani 1997), and two reported lower scores in the LNG-IUS group (Shaw 2007; Talis 2006).

- Bleeding at two years (one study)

One study compared conservative surgery versus LNG-IUS and reported median PBAC scores at two years (Istre 1998). PBAC scores decreased in both groups, with no evidence of a difference between the groups (Table 3).

### 2.2 Satisfaction

Five studies reported satisfaction rates, all of which compared conservative surgery versus LNG-IUS (Crosignani 1997; Ergun 2012; Ghazizadeh 2014; Shaw 2007; Soysal 2002; Talis 2006). Satisfaction rates were higher in the surgical group at one year (RR 1.16, 95%

CI 1.04, to 1.28, six RCTs, 442 women, I<sup>2</sup> = 27%) (Analysis 2.5), but there was no evidence of a difference between the groups at two years (RR 0.93, 95% CI 0.81 to 1.08, two RCTs, 117 women, I<sup>2</sup> = 1%) (Analysis 2.6). Findings at one year were sensitive to the choice of statistical model and use of a random-effects model showed no conclusive evidence of a difference between the groups (RR 1.13, 95% CI 1.00 to 1.27, six RCTs, 442 women, I<sup>2</sup> = 4%).

### 2.3 Adverse effects

All of the studies, apart from Barrington 2003 and de Souza 2010, described adverse effects, though the level of detail varied.

#### Hysterectomy versus LNG-IUS

##### Perioperative/short-term adverse effects

(For details see Table 1).

Hurskainen 2001 detailed 35 operative and postoperative complications that occurred among the 107 women in the surgical group who had a hysterectomy. These included perforations of the bladder and bowel, vesicovaginal fistula (creation of an abnormal passage between the vagina and the bladder), urinary retention, intestinal obstruction, postoperative bleeding, severe postoperative pain, peritonitis, fever, wound infection, wound rupture and infected pelvic haematoma (collection of blood) (Table 1). In the LNG-IUS group, insertion of the device was easy for 73% of women but required local anaesthetic for 10% and was impossible for two women (1.7%). One woman had the device removed two hours after insertion due to severe pain.

Sesti 2012 reported that there were no postoperative complications in either group that necessitated readmission, blood transfusion or repeat surgery.

#### Adverse effects over follow-up

(For details see [Table 4](#)).

Sesti 2012 reported that 22% of women in the LNG-IUS group had spotting every month over the first six months. Bleeding patterns improved over the first year but then deteriorated, and at two years bleeding problems were worse than at three-month follow-up.

Hurskainen 2001 reported that within five years, 60 women in the LNG-IUS group (50%) had had the device removed for intermenstrual bleeding, heavy bleeding and/or hormonal symptoms. Fifty of these women subsequently underwent hysterectomy, of whom 15 (30%) experienced surgical complications (most commonly infection and severe abdominal pain). Measures of bone mineral density in this study suggested that hysterectomy may accelerate age-related loss since women in the hysterectomy group, but not in the LNG-IUS group, had a significant decrease in lumbar spine bone mineral density at five-year follow-up ([Analysis 2.8](#)).

Hurskainen 2001 followed up 221 women (94% of randomised women) at 10 years. By this stage, 46% (55/119) of the women in the LNG-IUS group had had a hysterectomy. The effects of the interventions were reported by treatment received. Women treated by hysterectomy were more likely to report feelings of incomplete emptying than LNG-IUS users, and stress urinary incontinence and urinary tract infections were also more common in the hysterectomy group. The hysterectomy group were also

more likely to use medication for urinary incontinence. This study also investigated the effect of the interventions on markers of cardiovascular risk, and reported that women who had hysterectomy had higher levels of serum inflammatory markers and increased use of diabetes medication, compared to LNG-IUS users.

#### Conservative surgery versus LNG-IUS

##### Perioperative/short-term adverse events

(For details see [Table 1](#)).

Four studies comparing conservative surgery with LNG-IUS reported on adverse effects associated with the initial procedure ([Crosignani 1997](#); [Ghazizadeh 2014](#); [Istre 1998](#); [Soysal 2002](#)). All surgical operations were straightforward and no complications occurred during insertion of the LNG-IUS, though cervical dilatation was required by 4% of women to facilitate insertion of the intrauterine device and by 5% of women during balloon ablation.

##### Adverse effects over follow-up

(For details see [Table 4](#)).

At one year, adverse effects were less common in the surgical group (RR 0.51, 95% CI 0.36 to 0.74, three studies, 201 women,  $I^2 = 28%$ ) ([Figure 6](#); [Analysis 2.7](#)). The most commonly reported adverse effect was irregular bleeding and spotting. Adverse effects necessitated removal of the LNG-IUS in two women (7%) in [Ergun 2012](#), four women (13%) in [Malak 2006](#) and five women (23%) in [Tam 2006](#) in the LNG-IUS group during the first year of follow-up. At one year, spontaneous complete or partial expulsion of the LNG-IUS had occurred in two women in [Crosignani 1997](#), two in [Tam 2006](#) and one in [Istre 1998](#).

**Figure 6. Forest plot of comparison: 2 Surgery versus LNG-IUS, outcome: 2.7 Proportion of women with adverse events at one year.**

By two years, [Talis 2006](#) reported that five women in the surgical arm (13%) had experienced possible endometritis requiring antibiotics, five women in the LNG-IUS group (13%) had required removal of the device due to pain, unscheduled bleeding or infection and four devices (10%) had been spontaneously expelled.

**SECONDARY OUTCOMES**

**2.4 Quality of life and symptom control**

**Quality of life**

Seven studies reported quality of life. All compared hysterectomy or conservative surgery versus LNG-IUS. They used a variety of measures, including the EuroQol visual analogue scale ([Hurskainen 2001](#)), the Psychological General Wellbeing Index ([de Souza 2010](#)), and the SF-36 ([Crosignani 1997](#); [Hurskainen 2001](#); [Sesti 2012](#); [Soysal 2002](#); [Talis 2006](#); [Tam 2006](#)). They reported findings at up to one year ([Crosignani 1997](#); [de Souza 2010](#); [Hurskainen 2001](#); [Sesti 2012](#); [Soysal 2002](#); [Talis 2006](#); [Tam 2006](#)), two years ([Talis 2006](#)), five years ([de Souza 2010](#); [Hurskainen 2001](#)), and 10 years ([Hurskainen 2001](#)).

We did not pool data on quality of life due to clinical and statistical heterogeneity and (in some cases) evidence of probable skew. Where the ratio of the mean to the standard deviation was less than two in any domain, we assumed skew and reported the study results in an additional table.

**Hysterectomy versus LNG-IUS**

At one year of follow-up, the smaller study of hysterectomy versus LNG-IUS reported mixed findings, with better quality of life scores in the LNG-IUS group for five of the eight SF-36 domains (mental health, vitality, physical role, emotional role and social function),

better quality of life in the surgical group for one domain (pain), and no evidence of a difference between the groups in other domains ([Sesti 2012](#)) ([Analysis 2.11](#)).

In the larger study of hysterectomy versus LNG-IUS ([Hurskainen 2001](#)), there was an improvement in quality of life in nearly all SF-36 domains in both groups. At one year, women in the hysterectomy group had less pain than women in the LNG-IUS group. Apart from this, there was no evidence of a difference between women in the two groups at one year, five years or 10 years in any of the SF-36 domains ([Table 5](#)). [Hurskainen 2001](#) also measured change in quality of life using the four-item EuroQol visual analogue scale. There was an improvement in scores in both groups, with no evidence of a difference between them at one year (MD 0.00, 95% CI -0.05 to 0.05, 228 women), five years (MD 0.02, 95% CI -0.05 to 0.09, 232 women) or 10 years (MD -0.01, 95% CI -0.06 to 0.06, 221 women) ([Analysis 2.9](#)). Overall, quality of life scores improved during the first five years in both groups but between five and 10 years they diminished, and the scores returned close to the baseline level.

**Conservative surgery versus LNG-IUS**

Four studies of conservative surgery versus LNG-IUS reported SF-36 scores at one year ([Crosignani 1997](#); [Soysal 2002](#); [Talis 2006](#); [Tam 2006](#)). In most respects they found no evidence of a difference between the groups. [Crosignani 1997](#) found no evidence of a difference between the groups in any of the eight SF-36 domains ([Table 6](#)). [Soysal 2002](#) reported higher scores in the surgical group for one SF-36 domain (physical role limitation), but otherwise found no difference between the groups. [Tam 2006](#) reported higher quality of life scores in the surgical group for three domains (general health, mental health, emotional role), but otherwise found no

difference between the groups, and [Talis 2006](#) assessed the SF-36 "General health" domain and found no difference between the groups ([Analysis 2.11](#)).

At two years [Talis 2006](#) again found no difference between the groups ([Analysis 2.12](#)).

Over five-year follow-up [de Souza 2010](#) found no evidence of a change from baseline in either group nor any evidence of a difference between the groups in quality of life, measured with the Psychological General Wellbeing Index ([Analysis 2.10](#)).

## 2.5 Requirement for additional surgical or medical treatment for heavy menstrual bleeding

### Requirement for additional surgical treatment

At one year women having any type of surgical treatment were less likely than women who had a LNG-IUS to require surgery for heavy menstrual bleeding in addition to their allocated treatment (RR 0.23, 95% CI 0.12 to 0.44, six studies, 540 women,  $I^2 = 52%$ ) ([Analysis 2.13](#)). None of the hysterectomy group required additional surgery while about 2% of women who had balloon ablation and 4% of women who had endometrial resection required extra surgery during the first year. Of women who had a LNG-IUS, about 12% required surgery during the first year.

At two years, data were available from two studies comparing conservative surgery versus LNG-IUS. There was no evidence of a difference between the groups, though numbers were small ([Shaw 2007](#); [Talis 2006](#)) ([Analysis 2.14](#)).

At five years, [Hurskainen 2001](#) reported that 50 of the 60 women who no longer had a LNG-IUS in situ had had a hysterectomy (representing 42% of those randomised to LNG-IUS) and one had had thermo-ablation. By 10 years, 55 women in the LNG-IUS group (46% of those randomised to LNG-IUS) had had a hysterectomy.

[Ghazizadeh 2014](#) noted that three women in the hysteroscopic endometrial resection group eventually underwent hysterectomy for heavy bleeding. There was apparently no requirement for additional surgery in the other two groups in this study.

### Requirement for additional medical treatment

Very few women were reported as undergoing additional medical treatment. At one year in one study one woman in the surgical group (< 3%) who had persistent menorrhagia was receiving medical treatment ([Crosignani 1997](#)). At two years five women in the surgical group in [Talis 2006](#) had had a LNG-IUS inserted.

Two studies mentioned re-insertion of the LNG-IUS; this was required by five women in [Hurskainen 2001](#) within the first year and one woman in [Istre 1998](#) within three years. Of 57 women in [Hurskainen 2001](#) who had the LNG-IUS in situ at five years, eight had had a replacement.

## 2.6 Cost and resource use

[Hurskainen 2001](#) compared the cost of hysterectomy and LNG-IUS. Although 42% of the LNG-IUS group subsequently underwent hysterectomy, the overall direct and indirect costs after five years were about 40% lower in the LNG-IUS group. Sensitivity analyses using different cost estimates had little impact on these findings. At 10-year follow-up, the overall costs were lower in the LNG-IUS group

(USD 3423 per participant versus USD 4937), even though 46% of the LNG-IUS group subsequently had surgery.

[Talis 2006](#) reported the cost-effectiveness of thermal balloon ablation versus LNG-IUS. The expected direct and indirect costs of treatment were USD 1693 for ablation and USD 869 for the LNG-IUS. The findings were robust to changes in key drivers of costs. Since the treatments appeared to result in similar quality of life outcomes (measured by the SF-36) the authors concluded that the LNG-IUS was more cost-effective than thermal balloon ablation.

## Heterogeneity

Heterogeneity was low or absent for most analyses, though there was moderate heterogeneity for comparisons between LNG-IUS and conservative surgery for some SF-36 measures and for two-year satisfaction rates.

## Sensitivity analyses and assessment of publication bias

Use of an alternative statistical model negated the statistical significance of one analysis ([Analysis 2.5](#)). Otherwise, sensitivity analyses for the primary outcomes did not substantially influence any of our findings. We could not construct a funnel plot to test for publication bias because there were insufficient studies for any one comparison.

# DISCUSSION

## Summary of main results

A comparison of surgical versus medical treatments is complicated by the variety of treatments available within each modality, particularly with respect to medical approaches. The medical treatment in two of the studies comprised a wide range of oral hormonal and non-hormonal medications. The medical treatment in the other studies was very different, consisting of an intrauterine device. As a result, the focus of this systematic review effectively split into two main comparisons: surgery versus oral medication and surgery versus levonorgestrel-intrauterine device (LNG-IUS).

Women in the surgical arms of these studies underwent a variety of operations that included the relatively simple procedure of endometrial ablation, the more specialised technique of endometrial resection and the radical option of hysterectomy. Despite this, the studies comparing different types of surgery versus LNG-IUS reported fairly consistent findings, save for the inevitable disparity in outcomes measuring blood loss when hysterectomy comprised one of the comparisons.

## Menstrual bleeding

Neither medical treatment nor conservative surgery can rival hysterectomy in achieving 100% cessation of bleeding. No other intervention considered in this review was effective for all women, but some were more effective than others. Endometrial resection was much more successful than oral medication in controlling bleeding at four months' follow-up in [Cooper 1997](#). As most of the women in this study (78%) had tried medical therapy unsuccessfully in the past, it is questionable whether the poor results achieved with oral medication are generalisable to women with heavy menstrual bleeding who newly present for treatment. Conservative surgery was more effective than LNG-IUS in controlling bleeding at one year, but both approaches had high rates of success in all the relevant studies.

## Satisfaction

Definition of treatment success is necessarily subjective and perhaps best based on a woman's satisfaction level and willingness to continue a particular therapy. Women who had transcervical endometrial resection or hysterectomy rated their satisfaction with treatment and their overall quality of life higher than women who had oral medication. However, when conservative surgery (endometrial ablation or resection) was compared with LNG-IUS, rates of satisfaction were high in both groups and did not differ substantially. Similarly, studies that used multidimensional scales to measure quality of life found few differences between surgery and LNG-IUS.

A very high proportion of women randomised to receive medical treatment subsequently required surgery. In [Kupperman 2004](#), 53% of women in the medical group had had a hysterectomy by two years and in [Cooper 1997](#) 77% of women initially assigned oral medication had had surgery within five years. Seventeen per cent (47/275) of women in the LNG-IUS arms of the six relevant studies had had surgery by one year.

## Adverse effects

Adverse effects such as nausea, headaches and weight gain were reported by about half of the women who took oral medication and "bad side effects" were cited by 45% of the 60 women who found the treatment unacceptable at four months ([Cooper 1997](#)). Women with a LNG-IUS also commonly reported adverse effects, often hormonal symptoms such as breast tenderness, bloating and intermenstrual bleeding. The LNG-IUS group was also more likely to develop transient asymptomatic ovarian cysts.

Women who had endometrial resection or balloon ablation were overall less likely to experience adverse effects than women having medical treatment.

The adverse effects of hysterectomy were potentially life-threatening. They included bladder and bowel perforations, infected pelvic haematomas and peritonitis. By treatment received, there were 39 complications among 131 women who had a hysterectomy. A substudy of [Hurskainen 2001](#) evaluated the effect of hysterectomy or LNG-IUS on ovarian function and concluded that hysterectomy but not LNG-IUS appeared to alter intra-ovarian blood flow and possibly impair ovarian function ([Halmesmaki 2007](#)). Moreover at 10-year follow-up, in an "as treated" analysis, stress urinary incontinence and urinary tract infections were more common in women who received a hysterectomy than in ongoing LNG-IUS users and women who had hysterectomy had higher levels of markers for cardiovascular risk. The finding with respect to increased risk of urinary tract infections in the hysterectomy group persisted when the analysis was controlled for the occurrence of lower urinary tract symptoms at baseline ([Heliovaara-Peippo 2010](#)).

## Treatment choice

All the interventions considered in this review significantly reduced menstrual bleeding and improved health-related quality of life from baseline and could be considered for treating menorrhagia. Oral medication may be effective and acceptable for some women, and worth trying before resorting to more invasive procedures, but probably will not suit the majority of women for long-term use. The LNG-IUS presents a suitable alternative to surgery for many women and although it reduces bleeding significantly less than

surgical methods during the first year of use it has the advantage of being easily reversible. Conservative surgery and the LNG-IUS both provide satisfactory treatment for the majority of women who perceive their menstrual blood loss as heavy, and neither precludes further intervention if needed. Our findings suggest that an individual woman's preferences and circumstances are the most important factor in treatment choice. Hysterectomy is the only treatment guaranteed to stop all menstrual bleeding but in view of its potential complications most women may be well advised to try a less radical treatment as first-line therapy.

[Hurskainen 2001](#) explored their data using a multiple regression model in order to identify predictors of outcome at one year. Women without objective menorrhagia (that is at least 80 ml blood loss per menstrual period) had a significantly better outcome with the LNG-IUS than with hysterectomy in scores for health-related quality of life and in partner sexual satisfaction. Neither age nor the presence of fibroids were predictive of outcome. This suggests that pretreatment assessment of menstrual blood loss may be useful for determining which women will require hysterectomy. This approach is complicated by the difficulty in achieving an objective assessment of menstrual blood loss.

## Overall completeness and applicability of evidence

In the included studies the diagnosis of heavy menstrual bleeding was based on self report, with or without a bleeding score chart, and it is possible that many of the participants did not have objective menorrhagia (blood loss > 80 ml/cycle). There was notable disparity in the criteria used for menorrhagia even between studies that used the same measure; the three studies using pictorial blood loss assessment chart (PBAC) scores to determine eligibility for inclusion had thresholds ranging from 75 ml to 150 ml.

The benefits of oral medication as a first-line treatment were not accurately reflected in these studies as the vast majority of women had already tried at least one oral medication without success.

More evidence comparing second-generation surgical methods with intrauterine devices is required, and a multicentre randomised controlled trial (RCT) is currently underway in the Netherlands, comparing the cost-effectiveness of endometrial ablation versus LNG-IUS in women with menorrhagia ([Herman 2013](#)).

## Quality of the evidence

None of the studies were blinded, and blinding would scarcely be feasible for these interventions. We judged that this created a high risk of bias for subjective review outcomes. Another common limitation in the studies was high risk of attrition bias, as six of the studies were missing data for 18% to 30% of randomised participants at follow-up points ranging from one to five years.

The overall quality of the evidence for different comparisons ranged from very low to moderate. The main limitations were lack of blinding, attrition and imprecision. Moreover it was difficult to interpret study findings over follow-up due to confounding associated with women who had been randomised to medical treatment subsequently undergoing surgery.

## Potential biases in the review process

We were unaware of any potential biases in the review process.

## Agreements and disagreements with other studies or reviews

Our findings were largely consistent with a health technology assessment of hysterectomy, endometrial ablation and LNG-IUS for heavy menstrual bleeding (Bhattacharya 2011), which included comparisons of surgery versus LNG-IUS, using individual participant data for a total of 730 women. They concluded that LNG-IUS is potentially cheaper and more effective than first-generation endometrial ablation techniques and that LNG-IUS is associated with similar satisfaction rates to second-generation endometrial ablation. They suggested that there is weak evidence to suggest that hysterectomy is preferable to LNG-IUS in terms of satisfaction rates, and that hysterectomy is considered the most cost-effective strategy. They concluded that owing to its invasive nature and risk of complications hysterectomy is considered a final option by gynaecological experts and consumers.

NICE guidelines review medical and surgical options for treatment of heavy menstrual bleeding and are broadly in agreement with our findings (NICE 2007). The guidelines support the use of LNG-IUS as first-line medical treatment, provided long-term (at least 12 months) use is anticipated and that hormonal treatment is acceptable. With regard to surgery, they support the use of endometrial ablation as first or second-line therapy where bleeding is having a severe impact on a woman's quality of life, and she does not want to conceive in the future. They recommend consideration the following second-generation techniques: impedance-controlled bipolar radiofrequency ablation (described in this review as bipolar electrocauterisation), fluid-filled thermal balloon endometrial ablation, microwave endometrial ablation and free fluid thermal endometrial ablation. They suggest that first-generation ablation techniques are appropriate provided hysteroscopic myomectomy is to be included in the procedure. NICE recommend against using hysterectomy as a routine first-line treatment solely for heavy menstrual bleeding.

## AUTHORS' CONCLUSIONS

### Implications for practice

Surgery, especially hysterectomy, reduces menstrual bleeding more than medical treatment at one year. There is no conclusive evidence of a difference in satisfaction rates between surgery and a levonorgestrel-intrauterine device (LNG-IUS), though adverse effects such as bleeding and spotting are more likely to occur with LNG-IUS. Oral medication suits a minority of women in the long term, and a LNG-IUS device provides a better alternative to surgery in most cases. A high proportion of women initially treated with oral medication, conservative surgery or LNG-IUS require further intervention. Although hysterectomy is a definitive treatment for heavy menstrual bleeding, it can cause serious complications and most women may be well advised to try a less radical treatment as first-line therapy. Both LNG-IUS and conservative surgery appear to be safe, acceptable and effective.

### Implications for research

It is claimed that second-generation techniques for endometrial ablation are safer and easier to perform than hysteroscopic methods (Lethaby 2013a), and further evidence comparing second-generation surgical methods with intrauterine devices is required. A multicentre randomised controlled trial (RCT) is currently underway in the Netherlands, comparing the cost-effectiveness of endometrial ablation versus LNG-IUS in women with menorrhagia. We await the results with interest.

\* Indicates the major publication for the study

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies [ordered by study ID]

#### Barrington 2003

Methods	Number randomised: 50 Losses to follow-up: 4 (2 in each group) No power calculation described Source of funding: not reported Years: not reported
Participants	Inclusion criteria: women with menorrhagia refractory to medical therapy  Exclusion criteria: uterine cavity over 12 cm long, malignant or premalignant pathology (pre-treatment endometrial biopsy taken)
Interventions	Surgery: thermal balloon ablation  Medical treatment: LNG-IUS
Outcomes	PBAC score Amenorrhoea
Notes	No measures of variance or tests of significance were reported for the change from baseline in each group nor for the difference in change between the groups: we have made attempts to contact the author for more data

#### Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not described
Allocation concealment (selection bias)	Unclear risk	Not described
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	All women received their allocated treatment. 44/50 analysed for primary outcome at 6 months. Reasons for withdrawal/dropout given.
Selective reporting (reporting bias)	Unclear risk	Adverse effects/tolerability not reported. Follow-up only 6 months.
Other bias	High risk	PBAC scores significantly higher in the surgical group at baseline

#### Cooper 1997

Methods	Randomised controlled trial 86 eligible women (of 273) refused randomisation, in most cases due to preference for a particular treatment. They were followed up separately. Number randomised: 187
---------	--

**Cooper 1997** (Continued)

Number analysed: 186 at 4 months, 173 at 2 years, 143 at 5 years  
 Failures to receive allocated treatment: 10 women in the medical group stopped treatment before 4-month follow-up  
 Losses to follow-up: 1 woman from the medical group was lost to follow-up by 4 months; 14 were lost to follow-up at 2 years (7 from each group); 43 were lost to follow-up at 5 years (20 from the surgical group, 23 from the medical group). At 5 years, operative details were available for 176/187 women randomised.  
 Analysis by intention-to-treat for women who completed follow-up at each stage, with secondary analysis according to the number of medical treatments used prior to gynaecological referral.  
 Power calculation: sample of 180 gives 80% power to detect a 20% difference in satisfaction rate at a 5% level of significance. This was achieved at 4 months but not at 2 or 5 years.  
 After 4-month follow-up all recruits could request further and/or different treatment  
 Source of funding: Scottish Office Department of Health  
 Years: 1994-95

Participants	<p>Included: 187 women referred to gynaecologists at Aberdeen Royal Infirmary, Scotland for treatment of clinically diagnosed dysfunctional uterine bleeding (i.e. uterus &lt; 10 weeks' pregnancy size and normal endometrial pathology)          Mean age 42 years          Family complete          Excluded: women referred specifically for surgery</p>
Interventions	<p>Surgical arm: injection of gonadotrophin-releasing hormone analogue followed 5 weeks later by transcervical resection of endometrium using rollerball coagulation to fundus and cornua plus loop resection of cavity walls.          Medical arm: 3 cycles of medical treatment not previously used by patient, as selected by senior gynaecologist          Actual treatment received:          33% (31 women) received progestogens (prescribed only to women with heavy and irregular periods; days 12 to 25, or 5 to 25 if there was also dysmenorrhoea)          26% (24 women) received combined pill (second-generation with 30 µg of estradiol)          23% (22 women) received tranexamic acid (1 g 4 times daily for first 5 days of period in women with regular periods, plus mefenamic acid 500 mg 3 times a day if there was associated dysmenorrhoea)          16% (15 women) received danazol (200 mg daily for 90 days)          2% (2 women) received hormone replacement therapy with a non-steroidal anti-inflammatory drug          All women could request further and/or different treatment at 4-month follow-up</p>
Outcomes	<p>Primary outcome: treatment satisfaction (direct question)          Other outcomes: subjective relief of menstrual symptoms, bleeding score (1 to 5), pain score (1 to 5), anxiety and depression score (HADS)          Health-related quality of life: SF-36, premenstrual symptoms          Treatment acceptability (direct question and semantic differential technique)          Preferred subsequent treatment          Additional treatment received          Haemoglobin level</p>
Notes	<p>14 did not complete 2-year questionnaire but data on their surgical status obtained from hospital database           43 did not complete 5-year questionnaire, but data on the surgical status of 32 of these obtained from hospital database</p>
<b>Risk of bias</b>	
<b>Bias</b>	<b>Authors' judgement</b> <b>Support for judgement</b>
Random sequence generation (selection bias)	Low risk                      Computer randomisation

**Cooper 1997** (Continued)

Allocation concealment (selection bias)	Low risk	Allocation by serially numbered, opaque envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	High risk	143/187 analysed at 5 years. Reasons for withdrawal/dropout given in 11 cases.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Low risk	No other potential bias identified

**Crosignani 1997**

Methods	<p>Randomised controlled trial 27 (of 97) women refused randomisation: 14 requested endometrial ablation, 9 requested hysterectomy, 4 lost to further contact. Number randomised: 70 Failures to receive allocated treatment: nil Losses to follow-up: 1 woman in the medical group was lost to follow-up after 6/12 check and excluded from further analysis Analysis by intention-to-treat for women who completed follow-up Power calculation assumed that at 1 year there would be a 30 ml difference in mean blood loss between the 2 arms: this did not occur so power calculation invalidated Source of funding: Italian National Research Council; LNG-IUSs supplied by Leiras Oy Pharmaceuticals</p>
Participants	<p>70 premenopausal women referred to a gynaecology clinic in Milan for hysterectomy for menorrhagia (diagnosed by history, haemoglobin and iron levels and PBAC score <math>\geq 100</math> month for 2 months as per menstrual diary) Mean age: 44 Normal uterus on hysteroscopy Normal endometrial pathology on biopsy Uterus <math>\leq</math> volume of 8-week pregnancy, calculated by ultrasound Family complete, not breastfeeding Excluded: women <math>&lt;</math> 38 years Use of oestrogens or progestogens in previous 3/12 Use of GnRH antagonists in previous 6/12 Recent use of other hormonal agents or drugs that could affect menstrual blood loss Serious concomitant illness Myoma <math>&gt;</math> 3 cm diameter</p>
Interventions	<p>Surgical arm: endometrial resection during early proliferative phase of cycle, using rollerball electrode for cornua and fundus, and loop for rest of cavity. All surgery performed by the same surgeon, who specialised in operative hysteroscopy. Medical arm: intrauterine device releasing 20 <math>\mu</math>g of levonorgestrel daily inserted within 7 days of start of menstruation.</p>
Outcomes	<p>Primary outcome: reduction in menstrual bleeding at 1 year, measured by PBAC subjective bleeding score Other outcomes: amenorrhoea/oligomenorrhoea rates Health-related quality of life: SF-36 Treatment satisfaction Additional treatment received</p>

**Crosignani 1997** (Continued)

 Adverse effects  
 Haemoglobin level

Notes —

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer randomisation
Allocation concealment (selection bias)	Low risk	Allocation by sequentially numbered, opaque, sealed envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	69/70 analysed. Reason for withdrawal/dropout given.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Unclear risk	SF-36 not completed at baseline - unclear whether groups were equivalent

**de Souza 2010**

Methods	Randomised controlled trial Single centre  84 women screened: 24 excluded, 2 withdrew consent Number randomised: 58 Number analysed: 58 at 1 month, 55 for most outcomes at 6 and 12 months Failures to receive allocated treatment: nil Losses to follow-up: 3 by 12 months Analysis by intention-to-treat for all women who completed follow-up Power calculation: 58 patients would detect a difference of over 40% between proportions and a difference of more than 1 standard deviation between the means of the 2 groups, with 90% power and 95% CI Trial conducted: 2005-2007 Source of funding: Bayer Schering Pharma Laboratory
Participants	Women aged at least 35 years referred to a university clinic for treatment of menorrhagia refractory to medication, 3-month washout period, regular menstrual cycles, menstrual blood loss over 80 ml according to PBAC, negative pregnancy test, uterine volume under 200 ml (length × width × height × 0.45), completed family  Exclusion criteria: intracavitary abnormalities, pelvic inflammatory disease, suspected endometrial pathology, abnormal endometrial histology, abnormal cervical cytology, previous endometrial resection and ablation, any other pathology for which hysterectomy would be more appropriate
Interventions	Surgical arm: thermal balloon ablation under general anaesthetic in operating room, during days 1 to 15 of menstrual cycle

**de Souza 2010** (Continued)

Medical arm: levonorgestrel-releasing intrauterine device, inserted during days 1 to 15 of menstrual cycle

Outcomes

Menstrual blood loss measured by PBAC and Hb

Bleeding pattern (amenorrhoea, intermenstrual bleeding)

Quality of life measured by Psychological General Wellbeing Index (PGWBI)

Outcomes measured at 1, 6 and 12 months

Treatment failure (increase in blood loss, no increase in Hb)

Notes —

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Computer-generated randomisation list"
Allocation concealment (selection bias)	Low risk	"Sequentially numbered, opaque, sealed envelopes"
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	55/58 women included in 6-month and 12-month analyses; exclusions explained
Selective reporting (reporting bias)	Unclear risk	Primary outcome not clearly defined, adverse effects not reported
Other bias	Low risk	No other potential bias identified

**Ergun 2012**

Methods

Randomised controlled trial

Number randomised: 58

Failures to receive allocated treatment

Losses to follow-up: 16

Analysis by ITT: no

Power calculation: not reported

Source of funding: not stated

Participants

Included: women with abnormal uterine bleeding not responding to medical treatment (progesterone, oral contraceptive, NSAIDs etc.) aged over 35, regular menstrual cycle, score of 100 on PBAC

Mean age: Not reported

**Ergun 2012** (Continued)

	Excluded: pregnancy, pelvic infection, uterine abnormality, suspicious endometrial pathology on TVUS
Interventions	Surgical arm: rollerball endometrial ablation (n = 31) Medical arm: LNG-IUS (n = 27) Actual treatment received: all
Outcomes	Blood loss: PBAC (end scores), satisfaction on a 5-point scale, need for additional treatment
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"Patients were randomised ..."
Allocation concealment (selection bias)	Unclear risk	Method not reported
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	High risk	58 patients randomised (31 in rollerball group and 27 in LNG-IUS group). 7/31 (22.6%) withdrew from the rollerball group and 9/27 (33%) withdrew from the LNG-IUS group, so only 72% (42/58) were included in the analysis. These latter numbers were used in the analysis with no method described for analysing missing data.
Selective reporting (reporting bias)	Unclear risk	The authors noted that they investigated adverse effects but these were not adequately reported
Other bias	Unclear risk	Not possible to determine how similar the groups were at baseline; no measure of statistical variation (e.g. SD) reported

**Ghazizadeh 2014**

Methods	Randomised controlled trial Number randomised: 110 patients Failures to receive allocated treatment unclear – numbers who were analysed were not reported Losses to follow-up unclear (for satisfaction, it looks as though 3 were lost to follow-up in the HER group) Analysis by ITT: no Power calculation: not reported Source of funding: not reported
Participants	Included: consecutive women with menorrhagia. Patients were candidates for hysterectomy. They had all been treated with hormonal therapy for at least 6 months and had shown no response to this therapy.

**Ghazizdeh 2014** (Continued)

Mean age: 40 (35 to 45)

Excluded:

Patients who were pregnant or who were null-gravid or primiparous, and those who had had an abnormal Pap smear, genital infection, hormonal disorder, hormonal treatment, anomalous uterus, any intra-cavity disorder, coagulative disorder, or an abnormal endometrial biopsy were excluded. With regard to myomas, they only excluded those submucosal myomas that were > 2 cm and intramural myomas that moved the endometrial layer. A uterine cavity > 11 cm was also classified as an exclusion criterion.

Interventions	<p>Surgical arm 1: hysteroscopic endometrial resection. Endometrial resection was done by monopolar loop resection with a depth of 3 mm to 5 mm, and rollerball resection with superficial cauterisation was applied to the cornual region (n = 32)</p> <p>Surgical arm 2: bipolar electrocauterisation (NovaSure) endometrial ablation (n = 30)</p> <p>Medical arm: Mirena (n = 48)</p> <p>Actual treatment received: appears to be as above</p>
Outcomes	<p>Treatment success (according to decreased blood loss and less interaction between bleeding and normal activity) - measure unclear, data not used in analysis</p> <p>Complications (data not used as totals unclear)</p> <p>Resurgery</p> <p>Satisfaction</p>
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	"divided randomly into 3 groups ..." Big difference in group sizes.
Allocation concealment (selection bias)	Unclear risk	Method not reported
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	Satisfaction rates reported for 107/110 women (97%)
Selective reporting (reporting bias)	Unclear risk	The authors noted that they investigated adverse effects but these were not adequately reported
Other bias	High risk	<p>Study reports contradictory statements about menorrhagia:</p> <p>1. "The rate of menorrhagia was very high in 89.6% of patients in the Mirena group, 53.3% in the NovaSure group and 67.7% in the HER group (p = 0.005)." [This appears to refer to baseline].</p>

**Ghazizadeh 2014** (Continued)

2. "Before treatment, the rate of menorrhagia was high in 100% of patients in the Mirena group, 96.7% in the NovaSure group, and 93.5% in the hysteroscopic endometrial resection group ( $p = 0.225$ )."

Also there are very large discrepancies between the groups for other baseline characteristics

**Hurskainen 2001**

Methods	<p>Randomised controlled trial 5 centres 598 women screened, 362 not randomised (184 not eligible, 178 not willing) Number randomised: 236 Number analysed: 232 Failures to receive allocated treatment: 12 women: 2 in the LNG-IUS group (IUS could not be inserted); 8 in the hysterectomy group (including 2 who had LNG-IUS and 5 who cancelled surgery due to reduced blood loss or due to job or family situation). In 2 cases, women had hysterectomy 12 months after randomisation. Losses to follow-up: 4 at 5 years (2 in the LNG-IUS group, 2 in the hysterectomy group (1 died, 1 withdrew)) Analysis by intention-to-treat for all women who completed follow-up Power calculation: 80% power to detect a 7.5% difference between groups at a 5% level of significance Trial conducted 1994-2002 Source of funding: Academy of Finland, National Research and Development Center for Welfare and Health (STAKES), University research grants. LNG-IUSs provided by Leiras Oy Pharmaceuticals</p>
Participants	<p>Women referred to 1 of 5 university hospitals in Finland for treatment of menorrhagia Age 35 to 49, menstruating, premenopausal, family complete, suitable for either treatment</p> <p>Exclusion criteria: Submucous fibroids, endometrial polyps, ovarian tumours or cysts &gt; 5 cm diameter, cervical disease, urinary and bowel symptoms or pain caused by large fibroids, lack of indication for hysterectomy, metrorrhagia bleeding between periods) as main complaint Previous unsuccessful treatment with LNG-IUS History of cancer Severe depression Acne (Assessed by history and by cervical smear, endometrial biopsy, transvaginal ultrasound and hysteroscopy if necessary to exclude any of the above)</p> <p>Mean age 43 49% had fibroids 59% had <math>\geq 80</math> ml blood loss</p>
Interventions	<p>Surgical arm: hysterectomy: abdominal (20%), vaginal (28%) or laparoscopic (52%), done (or supervised) by an experienced gynaecologist, with a mean waiting time of 6.7 months (range 12 days to 21 months) Medical arm: levonorgestrel-releasing intrauterine device inserted at randomisation</p>
Outcomes	<p>Primary outcome: Health-related quality of life by EuroQol EQ-5D questionnaire</p> <p>Other outcomes: Quality of life by RAND 36-item health survey</p> <p>Objective bleeding (alkaline haematin method), amenorrhoea/oligomenorrhoea rates Health-related quality of life (RAND 36-item health survey and EuroQol EQ-5D questionnaire) Menopausal symptoms (Kupperman test of menopausal distress) General health on VAS (0 to 100)</p>

Notes

—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation done separately for each centre (drawn from a hat), using randomly varying clusters
Allocation concealment (selection bias)	Low risk	Allocated by numbered, opaque, sealed envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	232/236 analysed at 5 years (98%). Reasons for withdrawal/dropout given in 2 cases.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Low risk	No other potential bias identified

**Istre 1998**

Methods

Randomised controlled trial  
 Number randomised: 60  
 Number analysed: 52 at 1 year, 44 at 2 years, 40 at 3 years  
 Failures to receive allocated treatment: 1 in surgical arm (refused treatment due to new relationship)  
 Deviations from study protocol: 2 women in the LNG-IUS group (1 had a PBAC score of 60 at baseline, 1 became postmenopausal between 12 and 36 months); 2 in the surgical group (2 became menopausal at 12 months, 1 of whom requested to withdraw from study)  
 Losses to follow-up:  
 At 1 year: 9 women lost to follow-up or excluded from all or some of the analyses: 3 in the surgical arm (1 who refused treatment, as above; 2 excluded ? due to ineligibility); 6 patients in the LNG-IUS arm who discontinued treatment (3 for persistent irregular bleeding, 2 for pain, 1 for acne)  
 At 2 years: 16 women lost to follow-up  
 At 3 years: 20 (?19 - see notes) women lost to follow-up or excluded from all or some analyses: 9 (?8 - see notes) in the surgical arm (3 as above plus 6 who required further surgery), 11 from the LNG-IUS arm (9 who discontinued due to side effects, 2 who withdrew from study)  
 Analysis by intention-to-treat for primary outcome (i.e. whether primary treatment controlled bleeding). For other outcomes (e.g. bleeding rates) results were only reported for women who continued original allocated treatment and had no further intervention  
 Power analysis: 15 participants per group calculated to give 80% power to detect a 15 ml difference between treatments at 5% significance  
 Source of funding: Schering, Berlin. 2 trial investigators were employees of Schering.  
 Years: enrolment 1993-1995

**Istre 1998** (Continued)

Participants	<p>60 premenopausal women aged 30 to 49 years who had sought medical attention for heavy menstrual bleeding, referred by general practitioner for surgery to gynaecological outpatient clinic in Oslo specialising in operative hysteroscopy. Required to have a PBAC score &gt; 75 for 2 months before randomisation.</p> <p>Family complete Regular uterine cavity ≤ 10 cm in length</p> <p>Exclusions: Breast feeding Current pregnancy Sub serous myoma &gt; 40 mm diameter Use of hormonal medication within past 3 months History of thrombo-embolic disease or liver disease Any abnormal intrauterine pathology Pelvic inflammatory disease within past 6 months or current infection</p> <p>Participants were initially prepared to undergo hysterectomy. 40% had unsuccessfully tried medical therapy. The rest had either refused conservative surgery or had had no previous treatment.</p> <p>Median age: 41</p>
Interventions	<p>Surgical arm: endometrial resection with diathermy loop (regardless of day of menstrual cycle) under spinal block or general anaesthesia Medical arm: levonorgestrel-releasing intrauterine device inserted within 7 days of start of menstruation</p>
Outcomes	<p>Primary outcome: treatment success (defined as a PBAC subjective bleeding score ≤ 75 at 12 months, no re-surgery in TCRE group, no removal of device in LNG-IUS group) amenorrhoea/oligomenorrhoea rates (bleeding diary) Genital health: defined by the trialist as an "overall feeling of lower abdominal health")</p> <p>Quality of life on a VAS: hot flushes, sweating, sleeping problems, dyspareunia (pain on intercourse), vaginal dryness, urinary frequency, nervousness, depression, oedema, libido Additional treatment received Adverse effects</p>
Notes	<p>There are minor discrepancies in data concerning the number of losses to follow-up at each time point Large number of withdrawals: 33% of participants did not complete 3-year follow-up NB LNG-IUS not assessed: at the onset of the study, it was not commonly used in the USA</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomisation
Allocation concealment (selection bias)	Low risk	Allocation by sealed, opaque, sequentially numbered envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	High risk	Large number of withdrawals in the LNG-IUS group: 33% of participants did not complete 3-year follow-up, therefore not included in the analysis for the primary outcome (PBAC score)

**Istre 1998** (Continued)

Selective reporting (re-reporting bias)	Low risk	All expected outcomes reported
Other bias	Unclear risk	There are minor discrepancies in the data concerning the number of losses to follow-up at each time point

**Kupperman 2004**

Methods	<p>Randomised controlled trial</p> <p>Multicentre</p> <p>Number of women screened for inclusion: 1557 (of whom 544 excluded as they did not meet the inclusion criteria)</p> <p>Number of women with abnormal uterine bleeding: 1013</p> <p>Number of women eligible for randomisation: 184 (of whom 92 were in the original study group and had unsuccessfully been treated with cyclic MPA for 3 to 5 months and 92 became eligible in the second year of the trial, having been unsuccessfully treated with cyclic MPA for at least 3 months outside of the trial - see notes)</p> <p>Number of women randomised: 63 (38 of 92 women in the original study group, plus 25* of 92 women who became eligible in the second year)</p> <p>Losses to follow-up: 4 (2 in each group) for efficacy outcomes</p> <p>Number analysed: 59 for efficacy outcomes; 58 for resource use</p> <p>Failures to receive allocated treatment: 3/31 in the hysterectomy group did not undergo surgery. In the medical group all received medical treatment; 17 also received hysterectomy</p> <p>Analysis by intention-to-treat and 'as treated'</p> <p>Power calculation: 60 participants give 90% power to detect a 6.8% change in the SF-36 mental health score, P value = 0.05 (the authors state that a 3 to 5-point difference shows meaningful improvement). The original power calculation was scaled down to allow for a smaller sample size, due to recruitment difficulties</p> <p>Trial conducted August 1997 to December 2000</p> <p>Source of funding: grant from the Agency for Health Care Research and Quality</p> <p>Years: August 1997 to December 2000</p>
Participants	<p>Inclusion criteria:</p> <p>Premenopausal women aged 31 to 49 with abnormal uterine bleeding (&gt; 7 days of flow each month or heavy flow with haematocrit &lt; 32%), recruited in clinical centres at Alabama or Tennessee Universities, USA, who were dissatisfied with medical treatment including a course of cyclic MPA for at least 3 months</p> <p>Exclusion criteria:</p> <p>Other causes of anaemia, FSH &gt; 30, pregnancy, desire to maintain fertility, endocrinopathy, coagulation problems, treatment for abnormal bleeding with depo-MPA or GnRH antagonist within the past 6 months, oral contraceptive or intrauterine device use within the past 3 months, contraindications to study medications, potential problems with subject compliance, participation in another trial, evidence of pelvic pathology for which hysterectomy or other specific directed therapy was indicated (e.g. neoplasia, cancer, hyperplasia, intrauterine polyps, submucous myomas)</p> <p>Recruitment strategy: mass mailing, medical records review, advertisements in local mass media, physician referrals</p> <p>Mean age: 41</p> <p>Participant characteristics: 45% African American, 45% obese (BMI &gt; 30)</p>
Interventions	<p>Surgery:</p> <p>Abdominal or vaginal hysterectomy as decided by gynaecologist. Prophylactic oophorectomy discouraged.</p> <p>Medical treatment:</p> <p>As decided by participating gynaecologist, who was told that "preferred" treatment was a combination of low-dose oral contraceptives with 21 active days and 7 placebo days monthly and/or a cyclic prostaglandin synthetase inhibitor (PSI) for 5 days over the menstrual period. If therapy unsuccessful,</p>

**Kupperman 2004** (Continued)

another could be substituted. Women dissatisfied with one medical therapy were encouraged to try other medical options.

Actual treatment received:

Hysterectomy group: 10/28 abdominal hysterectomy, 18/28 vaginal hysterectomy

Medical group: 29/32 hormonal treatment ± PSI (5/32 cyclic progestogen, 2/32 continuous progestogen, 3/32 prostaglandin 8/32 combined oestrogen and progestogen, 2/32 oestrogen only) inhibitor only. 17/32 women received PSI, most commonly naproxen (15/17)

**Outcomes**

Health-related quality of life, measured by a range of instruments, the primary one being the mental component summary of SF-36 but also including (among others) 12 items from the MOS mental health inventory, 2 from a health distress scale and complete sleep problems, 4-item body attitudes questionnaire, 5 sexual functioning scales  
SF-36 physical component summary  
Overall health, measured by EuroQol VAS and single-item global health question  
Single-item ratings of symptom resolution and symptom satisfaction  
Symptom resolution  
Satisfaction

Resource use over 2-year follow-up (inpatient and outpatient services, including all diagnostic and therapeutic procedures), using Diagnosis-Related Groups, relative value units associated with Current Procedural Terminology codes: these assign relative weights and values to services, based on estimated average resource use

**Notes**

\*25 women (of 92 screened) who had been treated unsuccessfully with MPA outside of the trial joined the trial in the second year because of difficulty recruiting participants from the original MPA study group

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation using randomly permuted blocks of sizes 4, 6 and 8
Allocation concealment (selection bias)	Low risk	Allocated by sequenced randomisation envelopes opened in front of a witness
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	59/63 analysed. Reasons for withdrawal/dropout given.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Low risk	No other potential bias identified

**Malak 2006**

**Methods**

Randomised controlled trial  
Number randomised: 60 (30 in each group)  
Losses to follow-up: nil for treatment success  
Number analysed: 60/60 for treatment success

**Malak 2006** (Continued)

All women received their allocated treatment  
Analysis by ITT  
Power calculation reported  
Source of funding: not reported  
Years: not reported

**Participants**

**Inclusion criteria:**  
Premenopausal women aged 40 to 50 years with regular uterine cavity, no wish for pregnancy, spontaneous cycles, scheduled for hysterectomy for excessive uterine bleeding (PBAC score > 100 monthly) with or without dysmenorrhoea

**Exclusion criteria:**  
Fibroid > 3 cm diameter, > 3 fibroids on ultrasound, possible malignancy or active liver disease, adnexal tumours/cysts, pelvic inflammatory disease with past 12 months.

Participant characteristics: 80% had previous failed attempt at conservative medical treatment

Mean age: 46 to 47 years

Setting: Kasr El-Aini Hospital, Cairo University

**Interventions**

LNG-IUS, with only barrier contraceptive methods  
Endometrial resection

**Outcomes**

Efficacy: treatment choice at 6 months or at discontinuation

Treatment success with primary intervention (PBAC score < 75 at 12 months), no removal of LNG-IUS or repeat surgery

Quality of life (by EuroQol - visual analogue scale: EQ-VAS)

Adverse events

**Notes**

—

**Risk of bias**

<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>
Random sequence generation (selection bias)	Low risk	"Using a randomisation table"
Allocation concealment (selection bias)	Unclear risk	States sealed envelopes. Unclear whether sequentially numbered and opaque.
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	No losses to follow-up for primary outcome
Selective reporting (reporting bias)	Low risk	Reports all expected outcomes
Other bias	Unclear risk	Text inconsistent re nature of primary outcome - states "the primary measure of efficacy was the woman's decision at six months or at discontinuation...":

**Malak 2006** (Continued)

treatment decision is an outcome that applies to only one group. However, text goes on to propose a more detailed definition that applies to both groups.

**Sesti 2012**

Methods	Randomised controlled trial  Number randomised: 72  Failures to receive allocated treatment: nil  Losses to follow-up: nil  Analysis by ITT: yes  Power calculation: yes  Source of funding: not reported
Participants	Included: women with HMB unresponsive to medical treatment; age 35 to 50 years, completed family; failed appropriate first-line oral medical therapy; normal PAP smear; no pelvic pathology on US; normal endometrial biopsy; PBAC > or = 100 (average of 2 cycles)  Mean age: 47.1 and 47.5 years  Excluded: previous endometrial resection/ablation; previous insertion of LNG-IUS; any uterine pathology on scan or hysteroscopy; any pathology where hysterectomy indicated; not fully investigated abnormal uterine bleeding; postmenopausal bleeding
Interventions	Surgical arm: hysterectomy (laparoscopic supracervical)  Medical arm: LNG-IUS  Actual treatment received: as randomised
Outcomes	Primary outcome; effects on PBAC at 12 months (end scores)  Other outcomes: changes in haemoglobin levels, presence of anaemia; bleeding frequency/length; quality of life; intensity of postoperative pain; early postoperative complications
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"computer generated list using serially numbered opaque sealed envelopes"
Allocation concealment (selection bias)	Low risk	"computer generated list using serially numbered opaque sealed envelopes" – "blindly allocated"
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	72 randomised and 72 included in the analysis

**Sesti 2012** (Continued)

Selective reporting (reporting bias)	Low risk	All prespecified outcomes reported
Other bias	Low risk	No other potential bias identified

**Shaw 2007**

Methods	<p>Randomised controlled trial</p> <p>Number randomised: 66 (33 in each group)</p> <p>Number analysed: 46/66 for PBAC at 12 months</p> <p>All women in LNG-IUS group and 30/33 in surgical group received their allocated treatment</p> <p>Power calculation reported</p> <p>Source of funding: no specific external funding; 30 balloon treatment systems donated and research nurse part-funded by educational grant (advised by email from author)</p> <p>Years: 2001-2003</p>
Participants	<p>Inclusion criteria:</p> <p>Women with idiopathic menorrhagia aged 25 to 49 years in whom prior appropriate oral medical treatment had failed. Family complete, normal histology, normal ultrasound (fibroids up to 2.5 cm OK), normal cervical smear, PBAC score &gt; 120 (mean over 2 cycles)</p> <p>Exclusion criteria:</p> <p>Previous LNG-IUS or endometrial resection/ablation, abnormal uterine bleeding, other pathology, sub-mucous fibroid, uterine cavity &lt; 7 cm or over 11 cm</p> <p>Mean age: 43</p>
Interventions	<p>LNG-IUS</p> <p>Thermal balloon ablation</p>
Outcomes	<p>Change in PBAC score at 12 months (median and range)</p> <p>Changes in Hb and ferritin at 6 months</p> <p>Patient satisfaction</p> <p>Hysterectomy rate at 2 years</p> <p>Treatment discontinuation (e.g. for adverse events, menorrhagia, LNG-IUS expulsion)</p>
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Computer generated"
Allocation concealment (selection bias)	Low risk	"Sequentially sealed opaque envelope ...numbered 1 to 100"
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.

**Shaw 2007** (Continued)

Incomplete outcome data (attrition bias) Primary outcomes	High risk	46/66 analysed for PBAC score at 12 months; withdrawals/dropouts described
Selective reporting (reporting bias)	Unclear risk	Adverse effects not systematically reported
Other bias	Low risk	No other potential bias identified

**Soysal 2002**

Methods	Randomised controlled trial Number randomised: 72 Number analysed: 72 Failures to receive allocated treatment: none Losses to follow-up: none Analysis by intention-to-treat for some outcomes only - 6 women who had hysterectomy due to treatment failure (1 in the surgical group, 5 in the LNG-IUS group) were not included in outcome measures for bleeding, satisfaction or haemoglobin Power calculation: 60 women required in each group to give 80% power to detect a 15 ml difference in blood loss at a 5% level of significance. (Objective loss to be estimated, based on PBAC score). Source of funding: not stated Years: 1999-2001
Participants	Women aged over 40 complaining of menorrhagia who refused or did not respond to medical treatment, seen at university medical centre in Turkey Documented PBAC scores of > 150 for 2 consecutive months before randomisation Median age: 44 years Family complete Normal blood tests, transvaginal ultrasonography, hysteroscopy, endometrial suction biopsy or cervical smear examination No discrete intramural or subserous myomas > 2 cm diameter Regular uterine cavity ≤ 8-week pregnancy and < 190 ml on ultrasonography Exclusions: Any medical disorder other than iron deficiency anaemia Abnormal intrauterine pathology
Interventions	Surgical arm: thermal balloon ablation under local anaesthetic. Endometrium thinned preoperatively by monthly injections of GnRH analogue for 2 months before surgery Medical arm: levonorgestrel-releasing intrauterine device inserted within 7 days of start of menstruation
Outcomes	Primary outcome: menstrual blood flow reduction, measured by PBAC subjective bleeding score and haemoglobin Other outcomes: health-related quality of life: SF-36, HAD depression scale Treatment satisfaction Additional treatment received Adverse effects
Notes	Standard deviations reported for PBAC scores are very low - could these be standard errors? Unable to contact author for clarification. No repeat treatments given - women for whom initial treatment failed (persistent or new symptoms, loss of intrauterine device, treatment unacceptable) had hysterectomy.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

**Soysal 2002** (Continued)

Random sequence generation (selection bias)	Low risk	Computer randomisation
Allocation concealment (selection bias)	Low risk	Allocation by serially numbered, opaque, sealed envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	Low risk	All randomised women analysed
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Unclear risk	Standard deviations reported for PBAC scores are very low - could these be standard errors? Unable to contact author for clarification.

**Talis 2006**

Methods	<p>Randomised controlled trial</p> <p>Number screened: 177 of whom 71 were ineligible; 23/106 eligible women declined randomisation</p> <p>Number randomised: 83, of whom 4 were excluded as submucous fibroids were found at hysteroscopy</p> <p>Losses to follow-up: 11 by 2 years (3 in the LNG-IUS group, 8 in the ablation group)</p> <p>Number analysed: 79 for treatment success, 54 for PBAC at 2 years (excluded 11 failures and 2 exclusions from the LNG-IUS group; 10 failures and 2 exclusions from the surgical group)</p> <p>Failures to receive allocated treatment: 4 excluded as above. All others received allocated treatment.</p> <p>Analysis was not by ITT</p> <p>Power calculation: for 80% power to detect a 50-point difference in PBAC score, 30 women were needed for each arm</p> <p>Source of funding: Academic research grant</p> <p>Years: 1999-2001</p>
Participants	<p>Included: women with self described HMB who had completed their family, aged 25 to 50 years, and had a regular cycle with discrete episodes of menstruation occurring every 3 to 6 weeks</p> <p>Excluded: women with ultrasound abnormalities (submucosal fibroids, intramural fibroids &gt; 3 cm diameter, large subserosal fibroids, endometrial polyps); laboratory abnormalities (follicle-stimulating hormone level (FSH) &gt; 30 IU/l, adverse endometrial histology); or hysteroscopic abnormalities (submucosal fibroids, endometrial polyps), incidental adnexal abnormality on ultrasound, severe inter-menstrual bleeding, severe dysmenorrhoea, severe pre-menstrual pain, chronic pelvic pain, medical contraindications to either study treatment, previous endometrial ablation or resection, uninvestigated post-coital bleeding or untreated abnormal cervical cytology</p>
Interventions	<p>Diagnostic hysteroscopy followed by:</p> <p>Surgical arm: balloon ablation (Thermachoice)</p> <p>or</p> <p>Medical arm: LNG-IUS (Mirena)</p> <p>Both interventions under local anaesthetic if tolerated, or else under general anaesthetic</p>
Outcomes	<p>Primary: menstrual loss, measured by PBAC</p> <p>Satisfaction, quality of life and menstrual symptoms, measured by questionnaire</p> <p>Secondary: haemoglobin level</p> <p>Treatment side effects</p>

**Talis 2006** (Continued)

Treatment failure (for the LNG-IUS this was confirmed expulsion, completed removal or the initiation of alternative therapy. For thermal balloon ablation this was the initiation of medication or the completion of alternative surgery, such as hysterectomy).  
Cost-effectiveness: including direct and indirect costs of treatment, subsequent medical treatment, lost income and medical treatment for failed procedures: see publication for details of economic modelling

Notes

**Talis 2006** excluded women with treatment failure from the analysis: only 75% of women randomised were included in the analysis at 1 year, while only 58% were included at 2 years

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomisation in blocks of 20
Allocation concealment (selection bias)	Low risk	Allocation by serially numbered, opaque envelopes
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	High risk	58/83 (70%) analysed for PBAC at 2 years: treatment failures excluded
Selective reporting (reporting bias)	Low risk	All expected outcomes reported
Other bias	Low risk	No other potential bias identified

**Tam 2006**

Methods	<p>Randomised controlled trial Number randomised: 44 (22 in each group) Losses to follow-up: 1 Number analysed: 33/44 for PBAC at 12 months 18/22 women in the LNG-IUS group and 15/22 in the surgical group received their allocated treatment Power calculation not reported Source of funding: no external funding (advised by email from author) Years: not stated</p>
Participants	<p>Inclusion criteria: Women aged over 40 years with a documented history of excessive menstrual bleeding for at least 3 months, family complete, prior oral medical treatment unsuccessful, not on any hormonal treatment</p> <p>Exclusion criteria: Uterus &gt; 10 weeks' gravid size, submucosal fibroids, endometrial polyps, contraindications to interventions, possible malignancy</p> <p>Participant characteristics: Mean age: 44 years Recruited via outpatient gynaecology clinic</p>

**Tam 2006** (Continued)

Setting: university-affiliated tertiary referral centre, Hong Kong

Interventions	LNG-IUS Thermal balloon endometrial ablation (with endometrial priming)
Outcomes	Menstrual pattern at 1 year (self reported) Adverse effects Haemoglobin and iron status Health status: SF-36 (using norms for Hong Kong Chinese)
Notes	Study authors report a statistically significant difference between the intervention groups in haemoglobin level at 1 year - MDs not significantly different in RevMan analysis in this review

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Computer generated random number series"
Allocation concealment (selection bias)	Low risk	Sequentially numbered, opaque, sealed envelopes (personal correspondence with author)
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding not feasible. Our primary review outcomes are subjective and therefore susceptible to bias related to lack of blinding.
Incomplete outcome data (attrition bias) Primary outcomes	High risk	33/44 analysed at 1 year (reasons for withdrawals and dropouts given)
Selective reporting (reporting bias)	Unclear risk	Does not clearly specify a primary outcome. Adverse events not reported clearly across both groups.
Other bias	Unclear risk	Low rate of acceptance among eligible participants (44/73)

BMI: body mass index  
 FSH: follicle-stimulating hormone  
 GnRH: gonadotrophin-releasing hormone  
 HER: hysteroscopic endometrial resection  
 HMB: heavy menstrual bleeding  
 ITT: intention-to-treat  
 LNG-IUS: levonorgestrel-releasing intrauterine device  
 MD: mean difference  
 MOS: Medical Outcomes Study  
 MPA: medroxyprogesterone acetate  
 NSAID: non-steroidal anti-inflammatory drug  
 PBAC: pictorial blood loss assessment chart  
 PSI: prostaglandin synthetase inhibitor  
 SD: standard deviation  
 TVUS: transvaginal ultrasound  
 US: ultrasound  
 VAS: visual analogue scale

**Characteristics of excluded studies** [ordered by study ID]

Study	Reason for exclusion
<a href="#">Assaf 2000</a>	Only partially randomised; unable to obtain separate data for randomised group
<a href="#">Barrington 1997</a>	A prospective study of levonorgestrel intrauterine device only - no control group
<a href="#">Ergun 2012a</a>	Assesses tranexamic acid as an adjunct to surgery
<a href="#">Ghazizadeh 2011</a>	Described as randomised but states that women could choose their treatment
<a href="#">Lahteenmaki 1998</a>	Compares levonorgestrel intrauterine device to medical treatment with respect to proportion of women on each treatment cancelling their decision to have hysterectomy
<a href="#">Reid 2005</a>	Compares 2 medical treatments (LNG-IUS and mefenamic acid)
<a href="#">Romer 2000</a>	Not randomised
<a href="#">Shabaan 2011</a>	Compares 2 medical interventions
<a href="#">Shokeir 2013</a>	Assesses gestagens as an adjunct to surgery
<a href="#">SMART 2000</a>	Closed due to poor enrolment
<a href="#">Soysal 2005</a>	Compares levonorgestrel intrauterine device with thermal balloon ablation in women with myoma-related menorrhagia. Not randomised - uses historical controls.

LNG-IUS: levonorgestrel- releasing intrauterine device

**Characteristics of ongoing studies** [ordered by study ID]

**Herman 2013**

Trial name or title	Herman 2013
Methods	RCT
Participants	Women $\geq$ 34 years with heavy menstrual bleeding, PBAC score > 150 points. Planned sample size = 266
Interventions	A strategy starting with a levonorgestrel-releasing intrauterine device or a strategy starting with endometrial ablation
Outcomes	PBAC score at 24 months, patient satisfaction, complications, number of re-interventions, menstrual bleeding pattern, quality of life, sexual function, sick leave and costs
Starting date	—
Contact information	m.herman@mmc.nl
Notes	—

PBAC: pictorial blood loss assessment chart

RCT: randomised controlled trial

TCRE: transcervical resection of the endometrium

## DATA AND ANALYSES

### Comparison 1. Surgery versus oral medication

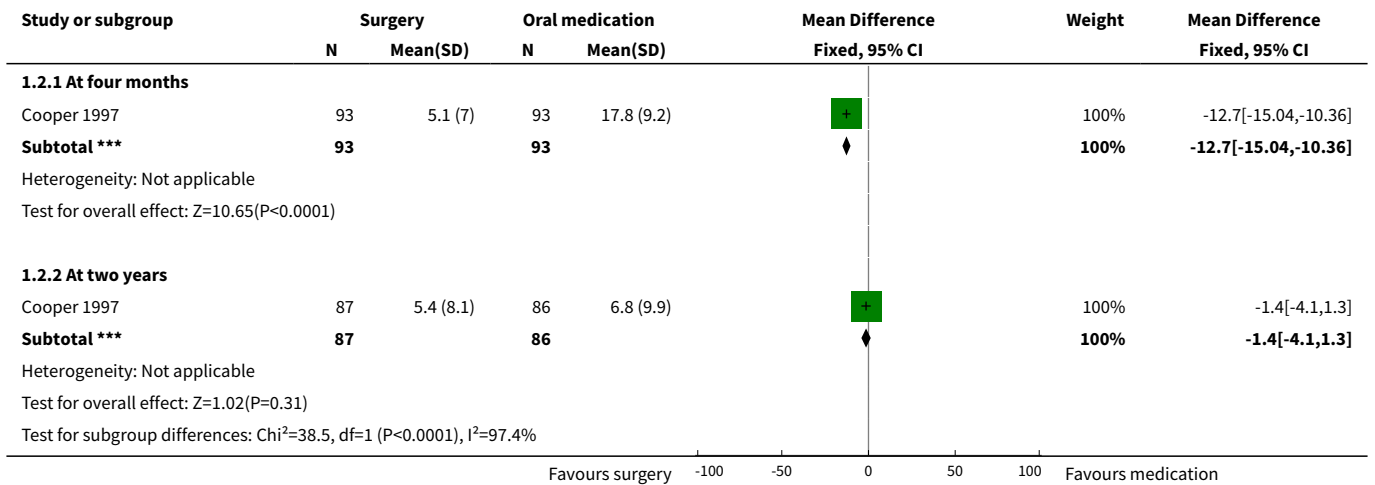

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
<b>1 Control of bleeding (cure or improvement to acceptable level)</b>	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.1 At four months	1	186	Risk Ratio (M-H, Fixed, 95% CI)	2.66 [1.94, 3.64]
1.2 At two years	1	173	Risk Ratio (M-H, Fixed, 95% CI)	1.29 [1.06, 1.57]
1.3 At five years	1	140	Risk Ratio (M-H, Fixed, 95% CI)	1.14 [0.97, 1.34]
<b>2 Bleeding score</b>	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
2.1 At four months	1	186	Mean Difference (IV, Fixed, 95% CI)	-12.70 [-15.04, -10.36]
2.2 At two years	1	173	Mean Difference (IV, Fixed, 95% CI)	-1.40 [-4.10, 1.30]
<b>3 Overall satisfaction with treatment</b>	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
3.1 At four months	1	186	Risk Ratio (M-H, Fixed, 95% CI)	2.8 [1.96, 3.99]
3.2 At two years	1	173	Risk Ratio (M-H, Fixed, 95% CI)	1.40 [1.13, 1.74]
3.3 At five years	1	141	Risk Ratio (M-H, Fixed, 95% CI)	1.13 [0.94, 1.37]
<b>4 Proportion reporting adverse effects at four months</b>	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
<b>5 Additional surgery for HMB received</b>	2		Odds Ratio (M-H, Fixed, 95% CI)	Subtotals only
5.1 By two years	2	236	Odds Ratio (M-H, Fixed, 95% CI)	0.12 [0.06, 0.22]
5.2 By five years	1	187	Odds Ratio (M-H, Fixed, 95% CI)	0.11 [0.06, 0.22]

#### Analysis 1.1. Comparison 1 Surgery versus oral medication, Outcome 1 Control of bleeding (cure or improvement to acceptable level).

**Analysis 1.2. Comparison 1 Surgery versus oral medication, Outcome 2 Bleeding score.**

**Analysis 1.3. Comparison 1 Surgery versus oral medication, Outcome 3 Overall satisfaction with treatment.**

**Comparison 2. Surgery versus LNG-IUS**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
<a href="#">1 Objective control of bleeding at one year: menstrual loss &lt; 80 ml per cycle</a>	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

**ADDITIONAL TABLES**

**Table 1. Operative and postoperative complications in the surgical arm**

Study ID	Operation	No. of operations	Operative problems	Postoperative/late problems
Cooper 1997	Transcervical endometrial resection	93	Persistent uterine bleeding necessitating uterine catheterisation for 6 hours (6)	Nil
Crosignani 1997	Transcervical endometrial resection	35	Nil	Nil
de Souza 2010	Thermal balloon ablation	28	Nil reported	Nil reported
Ergun 2012	Rollerball ablation	31	Nil reported	Nil reported
Ghazizadeh 2014	Endometrial resection or ablation	62	Nil reported	Nil reported
Hurskainen 2001	Hysterectomy: vaginal (30), abdominal (22), laparoscopic (57)	109	Bladder perforation (3), bowel perforation (1)	Occurred in a total of 33 women: wound infection (12), wound rupture (2), infected pelvic haematoma (6), postoperative fever (2), peritonitis (1), ileus (2), urinary retention (4), severe abdominal pain (3), vesicovaginal fistula (1), postoperative bleeding (2), ureter lesion (1)
Istre 1998	Transcervical endometrial resection	29	Nil	None stated
Kupperman 2004	Hysterectomy	28	1 woman had superficial thermal injury to small bowel during lysis of adhesions	Occurred in a total of 4 women: 1 had postoperative fever 1 had hypovolaemia 6 days postoperatively, requiring salpo-oophorectomy plus readmission 21 days postoperatively for haematemesis and oesophagitis 1 had a new seizure disorder 9 days postoperatively 1 had trachelectomy 15 months after supracervical hysterectomy, for persistent cyclic bleeding
Malak 2006	Endometrial resection	30	All surgery uneventful	1 woman had repeat surgery due to haematometra
Sesti 2012	Laparoscopic supracervical hysterectomy	36	None reported	None reported
Shaw 2007	Thermal balloon ablation	33	1 technical failure with equipment - surgery did not proceed	15 women stayed overnight due to cramping lower abdominal pain. Use of a paracervical block was introduced following which only 1 woman needed an overnight stay.
Soysal 2002	Thermal balloon ablation	36	2 required cervical dilatation	Nil

**Table 1. Operative and postoperative complications in the surgical arm** (Continued)

Talis 2006	Thermal balloon ablation	39	1 required general anaesthetic	5 women received post-operative antibiotics for possible endometritis
Tam 2006	Thermal balloon ablation	15	3 women required additional surgery for endometrial polyps (2) or submucosal fibroid (1)	—

**Table 2. SF-36: Surgery versus oral medication**

Study	SF-36 category	Time	Surgical mean change	Medical mean change	Change difference	P value change difference

**Table 4. Adverse effects (other than operative): surgery versus LNG-IUS**

Study	Surgical arm	Surgical adverse effects	IUS arm	IUS adverse effects
Crosignani 1997	n = 35	Weight gain (3), headache (3), decreased libido (2), pelvic pain (1), anxiety/depression (1)	n = 34	Occasional heavy bleeding (3), irregular spotting (12), bloating (10), weight gain (8), breast pain (6), headache (4), pelvic pain (2), decreased libido (2), hair loss (2), acne (2), anxiety/depression (2), hypertension (1), leg pain (1)
de Souza 2010	n = 28	No adverse effects reported	n = 30	No adverse effects reported
Ergun 2012	n = 31	1 woman had endometrial collection due to synechia, which required drainage	n = 27	2 women requested removal of LNG-IUS at 3 months due to bleeding; most common side effect was spotting, especially in the first 3 months
Ghazizadeh 2014	n = 62	In hysteroscopic resection group (n = 32): post-treatment pain (1), spotting (1)  No adverse effects in the ablation group	n = 48	No adverse effects reported
Hurskainen 2001	n = 117	No adverse effects reported during follow-up (see Table 8 for operative and postoperative adverse effects)	n = 119	Symptoms requiring discontinuation of treatment: intermenstrual bleeding (42), hormonal symptoms (18), lower abdominal pain (6 - 2 of whom were diagnosed with diverticulitis), depression (2), recurrent thromboembolic disease (1), benign ovarian cyst (1)
Istre 1998	n = 29	New symptoms within first year: pelvic pain/inflammation (4), bleeding (3), vaginitis (1), genital ulceration (1), abdominal pain (1)  Significant adverse events within 3 years (not necessarily treatment related): endometriosis (1), significant menstrual bleeding and pain (1), stroke 1.5 months post-surgery (in hypertensive participant), pelvic inflammatory disease (3), adenomyosis (1), myometritis (1), abnormal Pap test (3)	n = 30	New symptoms within first year: bleeding disorders (6), abdominal pain (4), breast tenderness (3), headache (2), acne (2), mood changes (1), pelvic pain or vaginal discharge (7)  Significant adverse events within 3 years (not necessarily treatment-related): severe oedema (1), uterine inflammation (3), pelvic inflammatory disease (2) partial expulsion (1)
Malak 2006	n = 30	7 women reported 1 or more local adverse events: irregular bleeding/spotting (4), pelvic pain (3), vaginal discharge (4); 10 reported generalised symptoms: abdominal pain (5), breast tenderness (3),	n = 30	9 women reported 1 or more local adverse events: pelvic pain and local tenderness (4), bleeding (5), vaginitis (2), genital ulceration (1). 2 reported generalised events: abdominal pain (1), haematometra requiring repeat ER (1)

**Table 4. Adverse effects (other than operative): surgery versus LNG-IUS** (Continued)

		headache (2), acne (2), mood changes (1)		
Sesti 2012	n = 36	None reported	n = 36	At 2 years bleeding problems were worse than at 3-month follow-up: 1 woman still had menorrhagia, while 5 reported ongoing intermenstrual spotting
Shaw 2007	n = 33	Adverse events requiring discontinuation of treatment (n = 7): dysmenorrhoea and bleeding (2), continuing menorrhagia (5)	n = 33	Adverse events requiring discontinuation of treatment (n = 13): coil expulsion (2), prolonged bleeding/spotting (6), continuing menorrhagia (5)
Soysal 2002	n = 36	Mastalgia (1), weight gain (4), mood swings (1), bloating (2), dysmenorrhoea (2), lower abdominal pain - haematometra (1)	n = 36	Spotting (6), mastalgia (5), weight gain (10), mood swings (2), bloating (8), acne/greasy skin (7), nausea (4), headache (1), leg pain (1), spontaneous expulsion of LNG-IUS (1)
Talis 2006	n = 39	Suspected endometritis requiring antibiotics (5), dysmenorrhoea (1)	n = 40	Spontaneous expulsion (4), pain requiring removal of device (2), "unscheduled bleeding" (2), actinomycoses (1)
Tam 2006	n = 15	Adverse effects not mentioned in this group	n = 18	Irregular spotting and/or persistent menorrhagia (5); no reports of breast discomfort or bloating

## WHAT'S NEW

Date	Event	Description
28 January 2016	New search has been performed	Updated with three new RCTs ( <a href="#">Ergun 2012</a> ; <a href="#">Ghazizdeh 2014</a> ; <a href="#">Sesti 2012</a> ). One ongoing RCT identified ( <a href="#">Herman 2013</a> ). 'Summary of findings' table added. Number of outcomes reduced.
28 January 2016	New citation required but conclusions have not changed	The conclusions of this review have not changed with the addition of 3 new studies.

## HISTORY

Protocol first published: Issue 4, 2002

Review first published: Issue 2, 2003

Date	Event	Description
25 April 2010	New search has been performed	Added four new RCTs ( <a href="#">de Souza 2010</a> ; <a href="#">Malak 2006</a> ; <a href="#">Shaw 2007</a> ; <a href="#">Tam 2006</a> ); added new data for other RCTs ( <a href="#">Hurskainen 2001</a> ; <a href="#">Talis 2006</a> ); changed from ORs to RRs to make results easier to interpret; added NNTs; updated background and discussion sections.
6 November 2008	Amended	Converted to new review format.
9 December 2005	New citation required and conclusions have changed	Substantive amendment.

## CONTRIBUTIONS OF AUTHORS

Jane Marjoribanks: developed the background section, edited the objectives and selection criteria, searched for and selected the studies, extracted the data and wrote the text and update.

Anne Lethaby: contributed to the background section, drafted the objectives and selection criteria, formulated the methods, searched for and selected the studies, extracted the data, checked study quality, provided statistical advice and commented on the drafts on several occasions.

Cindy Farquhar: initiated and conceptualised the protocol and commented on the drafts.

## DECLARATIONS OF INTEREST

None known.

Cindy Farquhar and Anne Lethaby are authors of one of the included trials ([Talis 2006](#)). However they have no present or past affiliations or other involvement in any organization or entity with an interest in the review's findings that might lead to a real or perceived conflict of interest.

Jane Marjoribanks has no present or past affiliations or other involvement in any organization or entity with an interest in the review's findings that might lead to a real or perceived conflict of interest.

## SOURCES OF SUPPORT

### Internal sources

- University of Auckland, New Zealand.

### External sources

- No sources of support supplied

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In early versions of the review we reported menstrual loss as "change in menstrual loss". From 2016 onwards we combined change and end scores where studies reported continuous outcomes on the same scale (as recommended in the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2011](#))), and we renamed the outcomes as simply "menstrual loss".

In the 2016 update, we endeavoured to reduce the number of primary outcomes and the number of outcomes overall, in line with current Cochrane policy that outcomes should be as few as possible and that primary outcomes should normally reflect at least one potential benefit and at least one potential area of harm. We achieved this by the following changes:

- In earlier versions of the review quality of life and need for additional surgery were primary outcomes. From 2016 onwards these became secondary outcomes.

- For the outcome "quality of life", we limited the measure to "self-reported change in quality of life, recorded in a reproducible and validated format". Previously this outcome also included the measure "self reported change in premenstrual symptoms and dysmenorrhoea (painful periods) recorded in a reproducible and validated format".
- We deleted the outcome "haemoglobin level" in line with the Cochrane policy of giving preference to patient-reported outcomes rather than biochemical measures.
- We reduced the number of time points for follow-up to one year (or less), two years, five years and 10 years.

In 2016 we decided not to report numbers needed to treat to benefit (NNTBs) with our effect estimates, as these are misleading given the very high cross-over rates between treatment arms.

## INDEX TERMS

### Medical Subject Headings (MeSH)

Antifibrinolytic Agents [therapeutic use]; Contraceptives, Oral, Hormonal [therapeutic use]; Endometrium [surgery]; Hysterectomy; Intrauterine Devices, Medicated; Menorrhagia [surgery] [\*therapy]; Quality of Life; Randomized Controlled Trials as Topic

### MeSH check words

Adult; Female; Humans; Middle Aged
