ABSTRACT

Background

Nutritional rickets is a disease which affects children, especially in low- and middle-income countries. It causes problems such as skeletal deformities and impaired growth. The most common cause of nutritional rickets is vitamin D deficiency. Vitamin D administered with or without calcium is commonly regarded as the mainstay of treatment. In some sunny countries, however, where children are believed to have adequate vitamin D production from exposure to ultraviolet light, but who are deficient in calcium due to low dietary intake, calcium alone has also been used in the treatment of nutritional rickets. Therefore, it is important to compare the effects of vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children living in different settings.

Objectives

To assess the effects of vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children.

Search methods

We searched CENTRAL, MEDLINE, LILACS, WHO ICTRP Search Portal and ClinicalTrials.gov. The date of the last search of all databases was 25 July 2019. We applied no language restrictions.

Selection criteria

We included randomised controlled trials (RCT) involving children aged 0 to 18 years with nutritional rickets which compared treatment with vitamin D, calcium or a combination of vitamin D and calcium.

Data collection and analysis

Two review authors independently screened the title and abstracts of all studies, extracted data and assessed the risk of bias of included studies. We resolved any disagreements by consensus or recourse to a third review author. We conducted meta-analyses for the outcomes reported by study authors. For dichotomous outcomes, we calculated the risk ratio (RR) and 95% confidence interval (CI) and, for continuous outcomes, we calculated mean differences (MD) with 95% CIs. We assessed the certainty of the evidence of the included studies using GRADE.

Main results

We identified 4562 studies; of these, we included four RCTs with 286 participants. The studies compared two or more of the following: vitamin D, calcium or vitamin D plus calcium. The number of participants randomised to receive vitamin D was 64, calcium was 102 and vitamin D plus calcium was 120. Two studies were conducted in India and two were conducted in Nigeria. None of the included studies had a low risk of bias in all domains. Three studies had a high risk of bias in at least one domain. The age of the participants ranged between six months and 14 years. The duration of follow-up ranged between 12 weeks and 24 weeks.

Two studies compared vitamin D to calcium. There is low-certainty evidence that, at 24 weeks' follow-up, calcium alone improved the healing of rickets compared to vitamin D alone (RR 3.26, 95% CI 1.59 to 6.69; $P = 0.001$; 1 study, 71 participants). Comparing vitamin D to calcium showed no firm evidence of an advantage or disadvantage in reducing morbidity (fractures) (RR 0.27, 95% CI 0.03 to 2.32; $P = 0.23$; 1 study, 71 participants; very low-certainty evidence). Adverse events were not reported.

Two studies compared vitamin D plus calcium to vitamin D at 12 or 24 weeks. Vitamin D plus calcium improved healing of rickets compared to vitamin D alone at 24 weeks' follow-up (RR 3.06, 95% CI 1.49 to 6.29; $P = 0.002$; 1 study, 75 participants; low-certainty evidence). There is no conclusive evidence in favour of either intervention for reducing morbidity (fractures) (RR 0.24, 95% CI 0.03 to 2.08; $P = 0.20$; 1 study, 71 participants; very low-certainty evidence) or adverse events (RR 4.76, 95% CI 0.24 to 93.19; $P = 0.30$; 1 study, 39 participants; very low-certainty evidence).

All four included studies compared vitamin D plus calcium to calcium at different follow-up times. There is no conclusive evidence on whether vitamin D plus calcium in comparison to calcium alone improved healing of rickets at 24 weeks' follow-up (RR 1.17, 95% CI 0.72 to 1.90; $P = 0.53$; 2 studies, 140 participants; very low-certainty evidence). Evidence is also inconclusive for morbidity (fractures) (RR 0.89, 95% CI 0.06 to 13.76; $P = 0.94$; 1 study, 72 participants; very low-certainty evidence) and adverse events (RR 4.29, 0.22 to 83.57; $P = 0.34$; 1 study, 37 participants; very low-certainty evidence).

Most of the evidence in the review is low or very low certainty due to risk of bias, imprecision or both.

None of the included studies assessed all-cause mortality, health-related quality of life or socioeconomic effects. One study assessed growth pattern but this was not measured at the time-point stipulated in the protocol of our review (one or more years after commencement of therapy).

Authors' conclusions

This review provides low-certainty evidence that vitamin D plus calcium or calcium alone improve healing in children with nutritional rickets compared to vitamin D alone. We are unable to make conclusions on the effects of the interventions on adverse events or morbidity (fractures).

PLAIN LANGUAGE SUMMARY

Vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children

Review question

To assess the effects of vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children.

Background

Nutritional rickets is a disease of the bones that affects mostly children in low- and middle-income countries. Children with nutritional rickets typically have deformed bones, may not grow well and experience other health problems. A lack of vitamin D is the most common cause of nutritional rickets. As such, nutritional rickets is usually treated by giving the child vitamin D with or without calcium. In some sunny countries, however, calcium alone has been used to treat nutritional rickets in children who are believed to have adequate vitamin D from their exposure to sunlight but who lack adequate calcium in their diet. This review was conducted to find out whether vitamin D, calcium or a combination of vitamin D and calcium is best for the treatment of nutritional rickets in children.

Study characteristics

We found four randomised controlled trials (clinical trials where people are randomly put into one of two or more treatment groups) that compared vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children. The 286 children in the studies were aged six months to 14 years. Following treatment, the children were monitored for between 12 and 24 weeks.

This evidence is up to date as of 25 July 2019.

Key results

We found evidence that using calcium alone or vitamin D plus calcium to treat nutritional rickets may improve healing when compared to using vitamin D alone. We are uncertain about the effects on fractures of calcium alone compared to vitamin D alone. We are uncertain

about the effects on fractures or other side effects of vitamin D plus calcium compared to vitamin D alone. We are uncertain about the effects of vitamin D plus calcium compared to calcium alone on healing of rickets, fractures and side effects.

None of the studies reported on growth pattern (differences in height, weight, height for age, weight for age), death from any cause, socioeconomic effects (cost of treatment, resources lost due to illness or due to absence of the caregiver from work, cost of visits to hospital or health facility) and health-related quality of life.

Reliability of the evidence

The reliability of the evidence for all the outcomes in our review is low or very low. The reason for the uncertainty is mostly due to the low number of participants in the studies and the low number of studies included in the review. Imprecise results and the potential to arrive at wrong conclusions because of the way the trials were conducted in some of the studies also contributed to the level of uncertainty.

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Vitamin D or calcium for the treatment of nutritional rickets in children

Vitamin D or calcium for the treatment of nutritional rickets in children

Patients: children with nutritional rickets

Settings: outpatients

Intervention: calcium

Comparison: vitamin D

Outcomes	Vitamin D	Calcium	Relative effect (95% CI)	No of participants (studies)	Certainty of the evidence (GRADE)	Comments
Healing of rickets (number) Definition: normal alkaline phosphatase and bone radiograph Follow-up: 24 weeks	189 per 1000	617 per 1000 (301 to 1266)	RR 3.26 (1.59 to 6.69)	71 (1)	⊕⊕○○ Low^a	—
Morbidity (number) Definition: fractures Follow-up: 24 weeks	108 per 1000	29 per 1000 (3 to 251)	RR 0.27 (0.03 to 2.32)	71 (1)	⊕○○○ Very low^b	—
Adverse events (number)	Not reported					—
All-cause mortality	Not reported					—
Health-related quality of life	Not reported					—
Growth pattern	Not reported at time point stipulated in protocol (≥ 1 years after commencement of therapy)					—
Socioeconomic effects	Not reported					—

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **RR:** risk ratio.

GRADE Working Group grades of evidence

High quality: further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: we are very uncertain about the estimate.

*Assumed risk was derived from the event rates in the comparator groups.

^aDowngraded two levels because of serious imprecision (small number of participants, one study only), see [Appendix 14](#).

^bDowngraded three levels because of very serious imprecision (small number of participants, one study only, and CI consistent with benefit and harm), see [Appendix 14](#).

Summary of findings 2. Vitamin D plus calcium versus vitamin D for the treatment of nutritional rickets in children

Vitamin D plus calcium versus vitamin D for the treatment of nutritional rickets in children

Patients: children with nutritional rickets

Settings: outpatients

Intervention: vitamin D + calcium

Comparison: vitamin D

Outcomes	Vitamin D	Vitamin D + calcium	Relative effect (95% CI)	No of participants (studies)	Certainty of the evidence (GRADE)	Comments

^cDowngraded by three levels because of risk of bias (performance bias and potential reporting bias) and very serious imprecision (small number of participants, one study only, and CI consistent with benefit and harm), see [Appendix 16](#).

BACKGROUND

Description of the condition

Rickets is a disease of children caused by failure of the growing bone to calcify, leading to skeletal deformities, impaired growth, and other clinical features which vary depending on the age of the child and the stage of the disease. Most children are affected within the first 18 months of life (Pettifor 2004). Rickets is more prevalent among young children in low- and middle-income countries and is a notable cause of deformities in children in Africa, the Indian subcontinent, Asia, the Middle East and parts of southern Europe (Prentice 2008). About 555,000 children in Bangladesh between the ages of one year and 15 years have deformities caused by rickets (UNICEF 2015). Rickets occurs in both dark- and light-skinned children but dark-skinned children are more commonly affected. Lerch 2007 distinguished three categories of children who are affected: infants with fair skin; infants with intermediate or dark skin living in their indigenous area and infants with intermediate or dark skin living in an area with lower ultraviolet B (UVB) irradiation than in their indigenous area.

Skeletal deformities associated with rickets are the result of delayed or failed mineralisation of the matrix at the growth plates in children before fusion of the epiphyses (Greenbaum 2011). Bowing of legs (*genu varum*), knock knees (*genu valgum*), and soft, asymmetrical, deformable skull (*craniotabes*) are the most common skeletal deformities associated with rickets. Other features include frontal bossing, rachitic rosary of the ribcage (swelling of the costochondral junction of the ribs), enlargement of the wrists and ankles, deformation of the limbs, hypocalcaemic convulsions, chest deformity (*pigeon chest*) and delayed motor movement (Agarwal 2009; Greenbaum 2011; Ozkan 2010; Weisberg 2004). Bone pain or tenderness in the arms, pelvis, legs or spine; delayed formation of teeth; loss of muscle strength (decreased muscle tone); impaired growth; increased bone fractures; skeletal deformities and abnormal spine curves (*kyphosis* or *scoliosis*) are also associated with rickets (Greenbaum 2011). Some skeletal deformities caused by rickets may require corrective surgery, positioning or bracing (Greenbaum 2011).

Vitamin D deficiency is the most common cause of rickets. There are two major types of rickets: calcipenic (hypocalcaemic) rickets and phosphopenic (hypophosphataemic) rickets. Calcipenic rickets is subdivided into nutritional rickets, vitamin D dependent rickets (type I or 1-alpha-hydroxylase deficiency; type II or hereditary resistance to vitamin D), and defects in vitamin D absorption or metabolism of calcium or vitamin D. Nutritional rickets may be caused by dietary deficiency of vitamin D, calcium or phosphorus; cases due to deficiency of calcium or phosphorus are less common (Pettifor 2012). Exclusively breastfed infants who do not receive vitamin D supplementation, dark-skinned infants and infants born to mothers who were vitamin D deficient during pregnancy are most affected (Misra 2008; Pettifor 2004).

Rickets may be diagnosed clinically by physical examination and taking a medical history, and confirmed biochemically or radiographically (Nield 2006). Biochemical findings in rickets include normal or decreased blood levels of calcium; elevated blood levels of alkaline phosphatase (ALP) or parathyroid hormone; normal, decreased or increased blood levels of phosphate; and decreased blood levels of 25-hydroxy vitamin D (25-OHD) in vitamin D deficiency rickets (Pettifor 2005; Shaw 2004; Thacher

2003). Findings from radiographic investigations include cupping, flaring and fraying of the metaphysis, rachitic rosary, and angular deformities of the bones of the arms and legs (Greenbaum 2011; Hochberg 2003).

Although rickets was prevalent in Europe and the USA between the late nineteenth century and the early twentieth century, the discovery of the antirachitic properties of vitamin D and subsequent fortification of foods with vitamin D led to its eradication in the 1930s (Jessop 1950; Welch 2000). In more recent times, however, there has been a re-emergence of rickets in these and other industrialised countries (Welch 2000; Wendling 2007). Callaghan 2006 reported an overall incidence of 7.5 cases per 100,000 per year in one survey in 2001 of children under five years of age in the UK (West Midlands). Most of the children were of black African or African-Caribbean origin. The overall annual incidence rate in Canada in 2004 was 2.9 cases per 100,000.

Studies carried out to assess the prevalence of rickets in Asia and Africa show wide variation of prevalence rates from 42% in Ethiopian to 9% in Nigerian children aged six months to three years (Pfitzner 1988; Prentice 2008). The treatment of rickets depends on the type and cause, and usually includes supplementation with vitamin D, its metabolites, calcium or a combination. Goals of treatment are to relieve symptoms and correct the cause of the condition in order to prevent the disease from returning (Greenbaum 2011).

Description of the intervention

Rickets is treated by administration of vitamin D, calcium or both, or phosphorus depending on the underlying cause. With particular reference to nutritional rickets, vitamin D administered with or without calcium is commonly regarded as the mainstay of treatment (Greenbaum 2011; Reddy 2008). Vitamin D is administered orally or intramuscularly as ergocalciferol (vitamin D₂) or cholecalciferol (vitamin D₃). Various vitamin D preparations, dosages (high versus low), dosing schedules (single versus multiple) and administration routes (oral or intramuscular) are available. Where a child's compliance with a treatment regimen may be difficult, vitamin D may be given as a single administration of 100,000 IU to 600,000 IU over one to five days (high-dose therapy or 'Stosstherapie', Balasubramanian 2013; Misra 2008; Pettifor 2014a). Adverse events such as hypercalcaemia and hypercalciuria have been reported with such therapy (Cesur 2003). Vitamin D may also be administered in smaller doses over several weeks. Exposure to ultraviolet (UV) radiation/sunlight and improved nutrition are also recommended. Rich dietary sources of vitamin D include liver, fish, milk, infant formula and other foods fortified with vitamin D such as margarine.

Calcium alone has also been used in the treatment of nutritional rickets especially in children who reside in sunny countries and who are believed to have adequate vitamin D production from exposure to UV light but are deficient in calcium due to low dietary intake. In supplements, the two main forms of calcium are calcium carbonate and calcium citrate. Calcium carbonate is inexpensive, convenient and readily available. It is highly dependent on stomach acid for absorption, and works more efficiently when taken with food. Calcium citrate is well absorbed and can be taken with or without food. Other forms of calcium in supplements or fortified foods are calcium phosphate, calcium lactate and calcium gluconate. These supplements contain varying amounts of elemental calcium.

Calcium citrate contains 21% calcium, and calcium carbonate 40% calcium by weight. When these supplements are taken, the percentage of calcium absorbed by the body depends on the total amount of elemental calcium taken at one time. As the amount of elemental calcium taken increases, the percentage absorbed decreases. Absorption is highest with doses of elemental calcium 500 mg or less (Ross 2011).

Adverse effects of vitamin D or calcium

Adverse effects from vitamin D or calcium are uncommon if given in the correct dose. However, if doses of vitamin D or calcium are too high, hypercalcaemia (high levels of calcium in the blood), which can cause soft tissue calcification and kidney stones, and hypercalciuria (high levels of calcium in the urine) with varying degrees of renal insufficiency, can occur. High calcium intake can cause constipation, and may also interfere with the absorption of iron and zinc.

Vitamin D toxicity, also called hypervitaminosis D, is a rare but potentially serious condition that occurs when there are excessive amounts of vitamin D in the body due to very high doses of vitamin D supplements. Hypercalcaemia is responsible for most of the symptoms of vitamin D toxicity. Early symptoms of vitamin D toxicity include gastrointestinal disorders such as anorexia, diarrhoea, constipation, nausea and vomiting. Other symptoms include bone pain, drowsiness, irregular heartbeat, loss of appetite, muscle and joint pain, frequent urination, excessive thirst, weakness, nervousness, itching and kidney stones (Schwalfenberg 2007).

How the intervention might work

Vitamin D deficiency results in the failure of mineralisation of growing bones manifesting clinical and radiological features of rickets. Vitamin D replacement therapy in the presence of adequate dietary calcium results in the resolution of the features of rickets. Calcium deficiency (from inadequate dietary intake or malabsorption) increases the catabolism of vitamin D and ultimately results in vitamin D deficiency and rickets. In such settings where poor dietary calcium intake is the dominant cause of rickets, calcium replacement therapy (with or without vitamin D) will be needed to achieve resolution of the symptoms of rickets (Pettifor 2004).

Interventions for the treatment of nutritional rickets include supplementation of vitamin D, calcium supplementation or a combination of both. Educational interventions include nutritional counselling and advice on exposure to sunlight.

Why it is important to do this review

Rickets constitutes a significant public health problem, particularly in low- and middle-income countries. In recent years there has been a re-emergence of rickets in high-income countries such as the UK and the USA where it was thought to have been eradicated (Allgrove 2004; Nield 2006; Pal 2001). Most occurrences of rickets are in children with dark skin or of non-white origin such as African Americans and South East Asians.

Although vitamin D deficiency has been thought to be the predominant cause of nutritional rickets there is evidence that calcium deficiency is the major cause of rickets in Africa and some parts of Asia. It has been observed that where calcium deficiency

is primarily responsible for the occurrence of rickets and where levels of 25-OHD are normal, treatment with vitamin D alone may not result in resolving the disease (Thacher 1999). A combination of vitamin D and calcium or calcium alone has been recommended in these instances. There is evidence that low dietary calcium intakes play a significant role in the pathogenesis of rickets which has implications for the choice of appropriate treatment and preventive interventions (Pettifor 2014b).

A number of studies have been carried out to compare vitamin D and calcium in the treatment of nutritional rickets (both calcium deficiency and vitamin D deficiency rickets). Studies have also compared various regimens of vitamin D for the treatment of rickets. Thacher 2006 conducted a narrative review of non-randomised studies that assessed the prevalence and causes of nutritional rickets. The objective and findings presented by Thacher 2006 did not include evaluation of the effectiveness of interventions for treating nutritional rickets. A search of major electronic health research databases found no systematic review or meta-analysis of studies that assessed the effects of these interventions. Therefore, there is a need to carry out a systematic review to assess the effects of interventions for treating nutritional rickets.

OBJECTIVES

To assess the effects of vitamin D, calcium or a combination of vitamin D and calcium for the treatment of nutritional rickets in children.

METHODS

Criteria for considering studies for this review

Types of studies

We included randomised controlled trials (RCTs).

Types of participants

Children up to 18 years of age with nutritional rickets.

Diagnostic criteria for (nutritional) rickets

Nutritional rickets refers to rickets confirmed by a combination of clinical, radiological and biochemical features, and shown to be due to any of the following aetiological categories (Pettifor 2004): vitamin D deficiency, calcium deficiency or a combination of vitamin D and calcium deficiency.

Clinical diagnosis is established by carrying out a complete physical and dental examination of the child and taking the medical, social and nutritional history to identify following features: enlargement of wrists, craniotabes (softening of the skull bones), rachitic rosary, bowing of legs, pigeon chest and frontal bossing. Other important clinical findings, apart from bone deformities, that will be used to establish clinical diagnosis, are hypocalcaemic convulsions, hypotonia (muscle weakness) and growth retardation. The diagnosis of rickets is supported by radiological and biochemical features characteristic of the disease.

Radiological investigations for diagnosis of rickets include radiographs of the wrists or knees. Key radiological findings are metaphyseal cupping or fraying and widening of epiphysis. Other

radiological findings may include fractures, osteopenia or widened wrists and ankles.

Biochemical investigations include assessment of calcium, phosphorus and ALP blood levels. Rickets is characterised by low blood calcium levels (less than 8.5 mg/dL), low phosphorus levels (less than 4.5 mg/dL) and high ALP levels (greater than 461 U/L). There may be other abnormal biochemical findings such as elevated parathyroid hormone levels (greater than 55 pg/mL) and low vitamin D as evidenced by low 25-OHD levels (less than 15 ng/dL).

Types of interventions

We investigated the following comparisons of intervention versus control/comparator.

Interventions and comparators

- Calcium compared with vitamin D.
- Vitamin D plus calcium compared with calcium or vitamin D.

Concomitant interventions had to be identical in both the intervention and comparator groups to establish fair comparisons. If a study included multiple groups, we included any group that met the inclusion criteria for this review. We investigated any type, dose and route of administration of vitamin D or calcium, as well as different forms of vitamin D or calcium. Furthermore, we distinguished between supplementation and fortification interventions.

Minimum duration of intervention

For calcium given alone or in combination with vitamin D, the minimum duration was at least eight weeks. This did not apply to studies that used one day high-dose therapy.

Minimum duration of follow-up

We included studies with a minimum duration of interventions of eight weeks.

We defined any follow-up period going beyond the original time frame for the primary outcome measure as specified in the power calculation of the studies' protocols as an extended follow-up period (also called open-label extension study) (Buch 2011; Megan 2012).

Summary of specific exclusion criteria

- Preterm children.
- Children above 18 years of age.
- Children with comorbidities such as HIV, sickle cell anaemia.
- Quasi-randomised trials and other non-RCT study designs.

Types of outcome measures

We did not exclude studies because one or several of our primary or secondary outcome measures were not reported in the publication. When a study reported none of our primary or secondary outcomes, we did not include this study but planned to provide some basic information in an additional table.

We extracted the following outcomes, using the methods and time points specified below.

Primary outcomes

- Healing of rickets.
- Morbidity.
- Adverse events.

Secondary outcomes

- All-cause mortality.
- Health-related quality of life.
- Growth pattern.
- Socioeconomic effects.

Method of outcome measurement

- Healing of rickets: defined as resolution of clinical and radiological features of rickets.
- Morbidity: defined as infections (such as acute lower respiratory tract infections, e.g. pneumonia), hypocalcaemic seizures, fractures.
- Adverse events: such as hypercalcaemia, hypercalciuria, hypervitaminosis D.
- All-cause mortality: defined as death from any cause.
- Health-related quality of life: evaluated by a validated instrument such as Short Form 36 questionnaire (SF-36).
- Growth pattern: defined as differences in height, weight, height for age, weight for age and weight for height scores.
- Socioeconomic effects: defined as cost of treatment, resources lost due to illness or due to absence of the caregiver from work, cost of visits to hospital or health facility.

Timing of outcome measurement

- Healing of rickets and socioeconomic effects: measured at 12 or more weeks after commencement of therapy.
- Morbidity: at any time from when the intervention was administered.
- Adverse events: from commencement of the intervention to at least four weeks after stopping treatment.
- All-cause mortality: measured at any time during the study.
- Health-related quality of life: measured at any time during follow-up.
- Growth pattern: at one or more years after commencement of therapy.

Search methods for identification of studies

Electronic searches

We searched the following sources on 25 July 2019 from inception of each database to the specified date and placed no restrictions on the language of publication.

- Cochrane Central Register of Controlled Trials (CENTRAL) via the Cochrane Register of Studies Online (CRSO), 25 July 2019.
- MEDLINE Ovid (Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Ovid MEDLINE Daily and Ovid MEDLINE; from 1946 to 23 July 2019).
- LILACS (Latin American and Caribbean Health Science Information database; from 1982 to "Last update: 15/07/2019").
- ClinicalTrials.gov (www.clinicaltrials.gov), 25 July 2019.

- World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) (www.who.int/trialsearch/), 25 July 2019.

We did not include Embase in our search, as RCTs indexed in Embase are now prospectively added to CENTRAL via a highly sensitive screening process ([Cochrane 2018](#)).

We continuously applied a MEDLINE (via OvidSP) email alert service established by the Cochrane Metabolic and Endocrine Disorders (CMED) Group to identify newly published trials using the same search strategy as described for MEDLINE ([Appendix 1](#)).

Searching other resources

We tried to identify other potentially eligible studies or ancillary publications by searching the reference lists of included studies, systematic reviews, meta-analyses and health technology assessment reports. In addition, we contacted authors of included studies to identify additional information on the retrieved studies and establish if further studies that we may have missed exist. We define grey literature as records detected in ClinicalTrials.gov or WHO ICTRP.

Data collection and analysis

Selection of studies

At least two review authors (MC, DG, JO) independently scanned the abstract, title or both, of every record we retrieved in the literature searches, to determine which studies we should assess further. We obtained the full text of all potentially relevant records. We resolved any disagreements through consensus or by recourse to a third review author (MM). If we could not resolve a disagreement, we categorised the study as a 'study awaiting classification' and contacted the study authors for clarification. We presented an adapted PRISMA flow diagram to show the process of study selection ([Liberati 2009](#)).

We did not use abstracts or conference proceedings for data extraction because this information source does not fulfil CONSORT requirements which is "an evidence-based, minimum set of recommendations for reporting randomised trials" ([CONSORT; Scherer 2018](#)).

Data extraction and management

For studies that fulfilled our inclusion criteria, two review authors (MC, JO) independently extracted key information on participants, interventions and comparators. We reported data on efficacy outcomes and adverse events using standardised data extraction sheets from the Cochrane Metabolic and Endocrine Disorders (CMED) Group. We resolved any disagreements by discussion, or if required, by consultation with a third review author (MM or DG) (for details, see [Characteristics of included studies](#) table; [Table 1](#); [Appendix 2](#); [Appendix 3](#); [Appendix 4](#); [Appendix 5](#); [Appendix 6](#); [Appendix 7](#); [Appendix 8](#); [Appendix 9](#); [Appendix 10](#); [Appendix 11](#); [Appendix 12](#); [Appendix 13](#); [Appendix 14](#); [Appendix 15](#); [Appendix 16](#)).

We planned to provide information, including the study identifier for potentially relevant ongoing studies in the Characteristics of

ongoing studies table and in [Appendix 7](#) entitled 'Matrix of study endpoint (publications and trial documents)'. We tried to find the protocol for each included study and reported primary, secondary and other outcomes from these protocols alongside the data from the study publications in [Appendix 7](#).

We emailed all authors of included studies to enquire whether they would be willing to answer questions regarding their studies. We presented the results of this survey in [Appendix 13](#). Thereafter, we sought relevant missing information on the study from the primary study author(s), if required.

Dealing with duplicate and companion publications

In the event of duplicate publications, companion documents or multiple reports of a primary study, we maximised the information yield by collating all available data and used the most complete dataset aggregated across all known publications. We listed duplicate publications, companion documents, multiple reports of a primary study and study documents of included studies (such as trial registry information) as secondary references under the study ID of the included study. Furthermore, we also listed duplicate publications, companion documents, multiple reports of a study and trial documents of excluded studies (such as trial registry information) as secondary references under the study ID of the excluded study.

Data from clinical trials registers

If data from included studies were available as study results in clinical trials registers, such as ClinicalTrials.gov or similar sources, we made full use of this information and extracted data. If there was also a full publication of the study, we collated and critically appraised all available data. If an included study was marked as a completed study in a clinical trial register, but no additional information was available, we added this study to the [Characteristics of studies awaiting classification](#) table.

Assessment of risk of bias in included studies

Two review authors (MC, DG) independently assessed the risk of bias of each included study. We resolved any disagreements by consensus or by consultation with a third review author (MM). In the case of disagreement, we consulted the rest of the review author team and made a judgement based on consensus. If adequate information was not available from study authors, study protocols or both, we contacted the study authors to request missing data on risk of bias items.

We used the Cochrane 'Risk of bias' assessment tool ([Higgins 2019a](#)), assigning assessments of low, high or unclear risk of bias (for details, see [Appendix 2](#); [Appendix 3](#)). We evaluated individual bias items as described in the *Cochrane Handbook for Systematic Reviews of Interventions* according to the criteria and associated categorisations contained therein ([Higgins 2019a](#)).

We presented a 'Risk of bias' graph and a 'Risk of bias' summary figure ([Figure 1](#); [Figure 2](#)). We distinguished between self-reported, investigator-assessed and adjudicated outcome measures.

Figure 1. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included trials (blank cells indicate that the particular outcome was not measured in some trials).

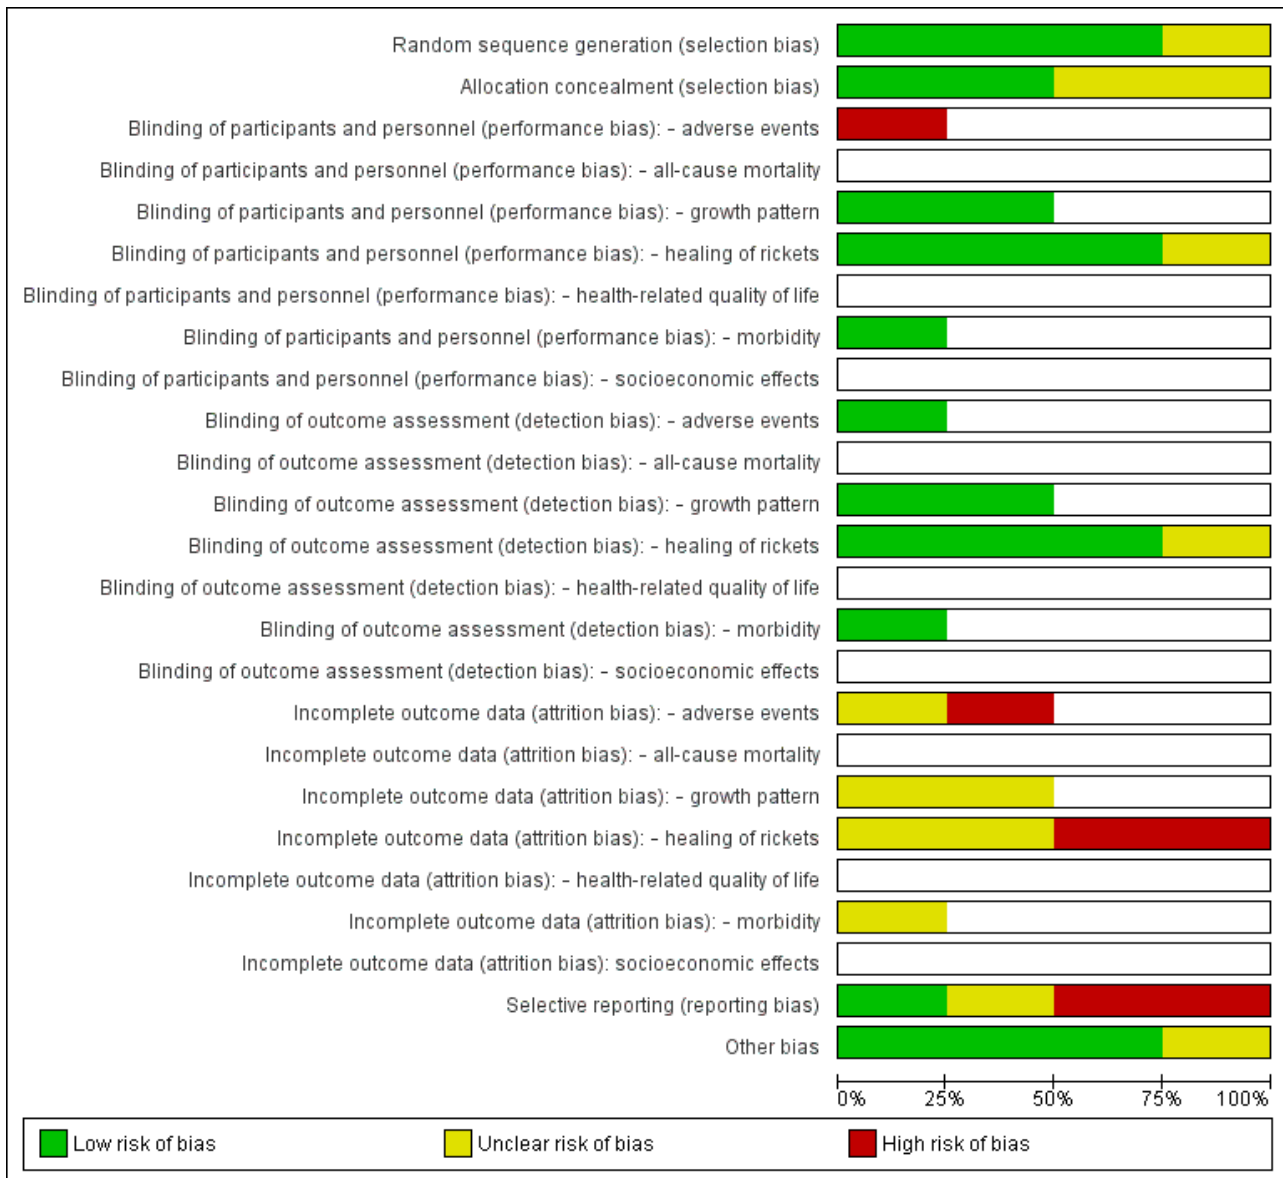

Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included trial (blank cells indicate that the particular outcome was not measured in some trials)

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias) - adverse events	Blinding of participants and personnel (performance bias) - all-cause mortality	Blinding of participants and personnel (performance bias) - growth pattern	Blinding of participants and personnel (performance bias) - healing of rickets	Blinding of participants and personnel (performance bias) - health-related quality of life	Blinding of participants and personnel (performance bias) - morbidity	Blinding of participants and personnel (performance bias) - socioeconomic effects	Blinding of outcome assessment (detection bias) - adverse events	Blinding of outcome assessment (detection bias) - all-cause mortality	Blinding of outcome assessment (detection bias) - growth pattern	Blinding of outcome assessment (detection bias) - healing of rickets	Blinding of outcome assessment (detection bias) - health-related quality of life	Blinding of outcome assessment (detection bias) - morbidity	Blinding of outcome assessment (detection bias) - socioeconomic effects	Incomplete outcome data (attrition bias) - adverse events	Incomplete outcome data (attrition bias) - all-cause mortality	Incomplete outcome data (attrition bias) - growth pattern	Incomplete outcome data (attrition bias) - healing of rickets	Incomplete outcome data (attrition bias) - health-related quality of life	Incomplete outcome data (attrition bias) - morbidity	Incomplete outcome data (attrition bias) - socioeconomic effects	Selective reporting (reporting bias)	Other bias
Aggarwal 2013	+	+	-			+				+			+				-				-			+	+
Balasubramanian 2003	+	?				?							?								-			-	?
Thacher 1999	?	+		+	+		+				+	+		+			?		?	?		?		?	+
Thacher 2014	+	?		+	+						+	+							?	?				-	+

We considered the following self-reported outcomes.

- Morbidity.
- Adverse events.
- Health-related quality of life.
- Socioeconomic effects.

We considered the following outcomes to be investigator-assessed.

- Healing of rickets.
- Morbidity.
- Adverse events.
- All-cause mortality.
- Growth pattern.
- Socioeconomic effects.

Summary assessment of risk of bias

Risk of bias for a study across outcomes

Some risk of bias domains, such as selection bias (sequence generation and allocation sequence concealment), affect the risk of bias across all outcome measures in a study. In case of high risk of selection bias, all endpoints investigated in the associated study were marked as high risk. Otherwise, we did not perform a summary assessment of the risk of bias across all outcomes for a study.

Risk of bias for an outcome within a study and across domains

We assessed the risk of bias for an outcome measure by including all entries relevant to that outcome (i.e. both study level entries and outcome specific entries). We considered low risk of bias to denote a low risk of bias for all key domains, unclear risk to denote an unclear risk of bias for one or more key domains and high risk to denote a high risk of bias for one or more key domains.

Risk of bias for an outcome across studies and across domains

To facilitate our assessment of the certainty of evidence for key outcomes, we assessed risk of bias across studies and domains for the outcomes included in the 'Summary of finding' tables. We defined the evidence as being at low risk of bias when most information came from studies at low risk of bias, unclear risk of bias when most information came from studies at low or unclear risk of bias, and high risk of bias when a sufficient proportion of information came from studies at high risk of bias.

Measures of treatment effect

When at least two included studies are available for a comparison and a given outcome, we tried to express dichotomous data as a risk ratio (RR) or odds ratio (OR) with 95% confidence intervals (CIs). For continuous outcomes measured on the same scale (e.g. weight loss in kilograms), we estimated the intervention effect using the mean difference (MD) with 95% CIs. For continuous outcomes measuring the same underlying concept (e.g. health-related quality

of life) but using different measurement scales, we calculated the standardised mean difference (SMD). We expressed time-to-event data as hazard ratio (HR) with 95% CIs.

Unit of analysis issues

We took into account the level at which randomisation occurred, such as cross-over studies, cluster-randomised trials and multiple observations for the same outcome. If more than one comparison from the same study was eligible for inclusion in the same meta-analysis, we either combined groups to create a single pair-wise comparison or appropriately reduced the sample size so that the same participants did not contribute more than once (splitting the 'shared' group into two or more groups). While the latter approach offers some solution to adjusting the precision of the comparison, it does not account for correlation arising from the same set of participants being in multiple comparisons (Higgins 2019b).

We attempted to re-analyse cluster-RCTs that had not appropriately adjusted for potential clustering of participants within clusters in their analyses. The variance of the intervention effects was inflated by a design effect (DEFF). Calculation of a DEFF involves estimation of an intracluster correlation (ICC). We obtained estimates of ICCs through contact with authors, or imputed them using estimates from other included studies that reported ICCs, or using external estimates from empirical research (e.g. Bell 2013). We planned to examine the impact of clustering using sensitivity analyses.

Dealing with missing data

If possible, we obtained missing data from the authors of the included studies. We carefully evaluated important numerical data such as screened, randomly assigned participants as well as intention-to-treat, and as-treated and per-protocol populations. We investigated attrition rates (e.g. dropouts, losses to follow-up and withdrawals), and we critically appraised issues concerning missing data and imputation methods (e.g. last observation carried forward).

In studies where the standard deviation (SD) of the outcome was not available at follow-up or could not be calculated, we standardised by the mean of the pooled baseline SD from those studies that reported this information.

Where included studies did not report means and SDs for outcomes and we not received the needed information from study authors, we imputed these values by estimating the mean and variance from the median, range, and the size of the sample (Hozo 2005).

We investigated the impact of imputation on meta-analyses by performing sensitivity analyses, and we reported per outcome which studies were included with imputed SDs.

Assessment of heterogeneity

In the event of substantial clinical or methodological heterogeneity, we did not report study results as the pooled effect estimate in a meta-analysis.

We identified heterogeneity (inconsistency) by visually inspecting the forest plots and by using a standard Chi² test with a significance level of $\alpha = 0.1$ (Deeks 2019). In view of the low power of this test, we also considered the I² statistic – which quantifies inconsistency across studies – to assess the impact of heterogeneity on the meta-analysis (Higgins 2002; Higgins 2003). When we identified

heterogeneity, we attempted to determine the possible reasons for it by examining individual characteristics of the study and subgroups.

Assessment of reporting biases

If we included 10 or more studies that investigated a particular outcome, we used funnel plots to assess small study effects. Several explanations may account for funnel plot asymmetry, including true heterogeneity of effect with respect to study size, poor methodological design (and hence bias of small studies) and selective non-reporting (Kirkham 2010). Therefore, we interpreted results carefully (Sterne 2011).

Data synthesis

We planned to undertake (or display) a meta-analysis only if participants, interventions, comparisons and outcomes were sufficiently similar to ensure a result that was clinically meaningful. Unless good evidence shows homogeneous effects across studies, we primarily summarised data that were of low risk of bias using a random-effects model (Wood 2008). We interpreted random-effects meta-analyses with due consideration to the whole distribution of effects, ideally by presenting a prediction interval (Borenstein 2017a; Borenstein 2017b; Higgins 2009). A prediction interval needs at least three studies to be calculated and specifies a predicted range for the true treatment effect in an individual study (Riley 2011). For rare events (such as event rates below 1%), we used Peto's OR method, provided that there was no substantial imbalance between intervention and comparator group sizes and intervention effects are not exceptionally large. In addition, we also performed statistical analyses according to the statistical guidelines presented in the *Cochrane Handbook for Systematic Reviews of Interventions* (Deeks 2019).

Subgroup analysis and investigation of heterogeneity

We expected the following characteristics to introduce clinical heterogeneity, and we planned to carry out subgroup analyses for these, including investigation of interactions (Altman 2003).

- Studies in low- and middle-income countries compared to those in high-income countries.
- Dosing scheme.
- Age.
- Sex.
- Type of supplementation/fortification.

Sensitivity analysis

We planned to perform sensitivity analyses to explore the influence of the following factors (when applicable) on effect sizes by restricting analysis to the following.

- Published studies.
- Taking into account risk of bias, as specified in the [Assessment of risk of bias in included studies](#) section.
- Very long or large studies, to establish the extent to which they dominated the results.

We used the following filters, if applicable: diagnostic criteria, imputation used, language of publication (English versus other languages), source of funding (industry versus other) or country (depending on data).

We also tested the robustness of results by repeating the analyses using different measures of effect size (RR, OR, etc.) and different statistical models (fixed-effect and random-effects models).

Certainty of the evidence

We presented the overall certainty of evidence for each outcome specified below, according to the GRADE approach, which takes into account issues related to internal validity (risk of bias, inconsistency, imprecision, publication bias) and external validity (such as directness of results). Two review authors (MC, DG) independently rated the certainty of evidence for each outcome. We resolved any differences in the assessment by discussion or consulting a third review author (MM).

We included an appendix entitled 'Checklist to aid consistency and reproducibility of GRADE assessments', to help with standardisation of the 'Summary of findings' tables (Meador 2014). Alternatively, we planned to use GRADEpro Guideline Development Tool (GDT) software and planned to present evidence profile tables as an appendix (GRADEpro GDT 2015). We presented results for the outcomes as described in the [Types of outcome measures](#) section. If meta-analysis was not possible, we presented the results in a narrative format in the 'Summary of findings' table. We justified all decisions to downgrade the quality of studies using footnotes, and we made comments to aid the reader's understanding of the Cochrane Review where necessary.

'Summary of findings' table

We presented a summary of the evidence in a 'Summary of findings' table. This provided key information about the best estimate of the magnitude of the effect, in relative terms and as absolute differences, for each relevant comparison of alternative management strategies; the numbers of participants and studies addressing each important outcome; and a rating of overall confidence in effect estimates for each outcome. We created the

'Summary of findings' table based on the methods described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Schünemann 2019), along with Review Manager 5 software (Review Manager 2014). We presented in the 'Summary of findings' table the following interventions: calcium compared with vitamin D, vitamin D plus calcium compared with vitamin D and vitamin D plus calcium compared with calcium.

We reported the following outcomes, listed according to priority.

- Healing of rickets.
- Morbidity.
- Adverse events.
- All-cause mortality.
- Health-related quality of life.
- Growth pattern.
- Socioeconomic effects.

RESULTS

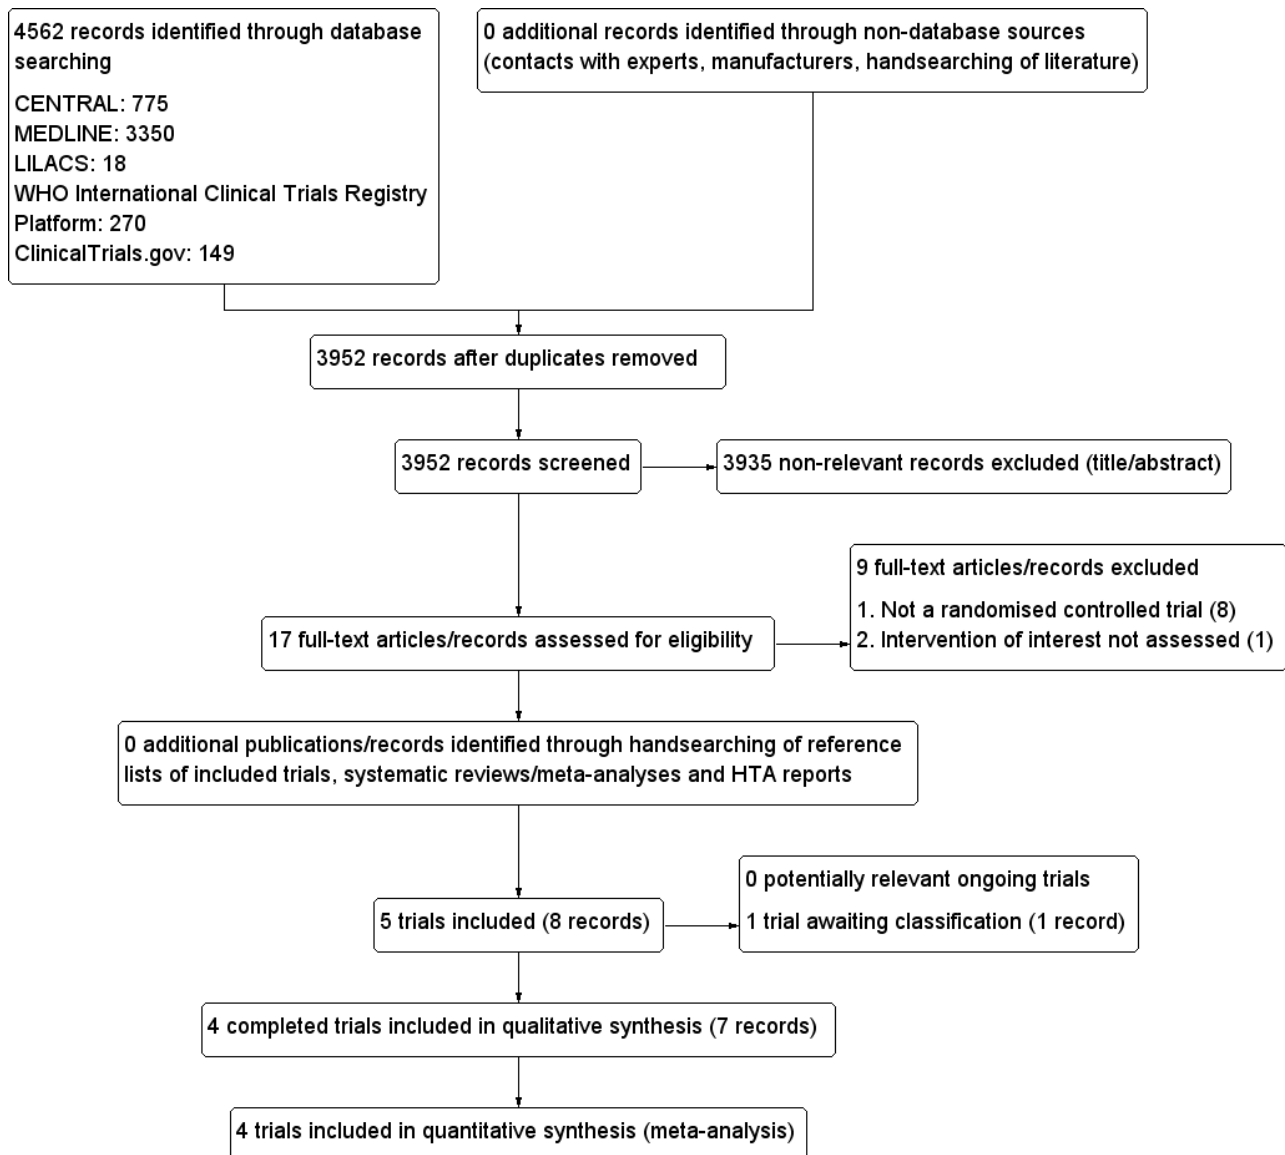

Description of studies

For a detailed description of studies, see [Table 1; Characteristics of included studies; Characteristics of excluded studies; and Characteristics of ongoing studies tables.](#)

Results of the search

Electronic search of databases and the continuous MEDLINE (via OvidSP) search yielded 4562 records. We did not identify any additional records through searching of non-databases sources. After removal of duplicates, we obtained and screened 3952 unique records. Three review authors independently screened titles and abstracts of these records following which 3937 records were excluded. We assessed the full text of 15 studies for eligibility and four studies (five publications) met the inclusion criteria (see [Figure 3](#)).

Figure 3. Trial flow diagram.

Included studies

Four studies met the inclusion criteria and were included in the review. A detailed description of the characteristics of included studies is presented elsewhere (see [Characteristics of included studies](#) table; [Appendix 4](#); [Appendix 5](#); [Appendix 6](#)). The following is a succinct overview.

Source of data

All data included in the review were obtained from reports published in medical journals except for some additional data which was obtained through correspondence with the study authors by email. Specific data obtained from study authors were:

- baseline data on number of children randomised to study groups for [Thacher 1999](#);
- data on adverse events, serum alkaline phosphate values, serum 25-OHD values and radiological scores at 12 and 24 weeks for [Thacher 2014](#);

- data on blinding of participants and personnel, study design and reasons for loss to follow-up for [Aggarwal 2013](#).

For details of correspondence with authors, see [Appendix 13](#).

Comparisons

Two of the included studies had two groups which compared vitamin D plus calcium versus calcium alone or calcium with placebo ([Balasubramanian 2003](#); [Thacher 2014](#)). The two other included studies had three groups which compared vitamin D plus calcium versus calcium (alone or with placebo) versus vitamin D (alone or with placebo) ([Aggarwal 2013](#); [Thacher 1999](#)). Doses and route of administration of vitamin D varied between studies. Four studies/study arms administered calcium orally in the form of calcium lactate or calcium carbonate and the form was unclear in one study ([Appendix 4](#)).

Overview of study populations

- Studies included 286 participants.
- The number of participants randomised to intervention groups was 184 and comparator groups was 102.
- The percentage of participants finishing the studies was 85.3% in the intervention groups and 83.3% in the comparator groups.
- Individual sample size in the studies ranged from 24 to 123.

Study design

- All included studies were parallel RCTs. Two studies had a two-group parallel design (Balasubramanian 2003; Thacher 2014), and two studies had a three-group parallel design (Aggarwal 2013; Thacher 1999).
- Three studies had a superiority design (Balasubramanian 2003; Thacher 1999; Thacher 2014); Aggarwal 2013 had an equivalence design.
- Two studies gave placebo in conjunction with an active treatment (Thacher 1999; Thacher 2014).
- Two studies were performed at a single centre except for Balasubramanian 2003 that was performed at two centres and Thacher 1999 for which the number of centres was unclear.
- One study was not blinded (Aggarwal 2013), and it was unclear whether participants and personnel were blinded in the remaining three studies.
- Three studies blinded outcome assessors (Aggarwal 2013; Thacher 1999; Thacher 2014). It was unclear whether the assessors were blinded in the remaining study (Balasubramanian 2003).
- Balasubramanian 2003 did not state the year in which the study was conducted. The remaining three studies were conducted between 1996 and 2009.
- Mean duration of the intervention in the studies ranged from 12 weeks to 24 weeks while the duration of follow-up also ranged from 12 weeks to 24 weeks.
- There was no run-in period for any of the included studies.
- None of the studies was terminated before time due to benefit or harm.

Settings

Two of the studies were conducted in India (Aggarwal 2013; Balasubramanian 2003), and two in Nigeria (Thacher 1999; Thacher 2014). All were conducted in hospital facilities.

Participants

- All participants were from low- to middle-income countries.
- Sixty-eight per cent of participants were of African ethnicity (Thacher 1999; Thacher 2014), and 32% were Asian (Aggarwal 2013; Balasubramanian 2003).
- Only one study reported the duration of rickets and this ranged from 0.5 months to 108 months (Thacher 2014).
- One hundred and fifty-five participants were girls and 131 were boys. Two studies recruited almost equal proportion of boys and girls (Aggarwal 2013; Balasubramanian 2003), while the other two studies recruited more girls (Thacher 1999; Thacher 2014).
- The mean age of the participants ranged from six months to 14 years.

- None of the studies reported comorbidities, cointerventions or comedication used by participants.
- The major exclusion criteria in the included studies were a history of renal disease, liver diseases or tuberculosis; history of consuming calcium, vitamin D supplements or multivitamins in the preceding three months to six months; history of treatment with anticonvulsant or antiepileptic drugs and cases presenting with hypocalcaemic seizures.

Diagnosis

Diagnosis of rickets was confirmed biochemically or radiologically, or both. Aggarwal 2013 and Thacher 2014 diagnosed rickets radiologically (radiographs of the wrist and knee) using Thacher's 10-point scale (Thacher 2000). Thacher's 10-point scale is a scoring system to assess the radiographic changes in the wrists and knees of people with rickets, where 0 represents no rickets and 10 represents severe rickets. In Aggarwal 2013, a radiological score of greater than 1.5 indicated rickets, while Thacher 2014 diagnosed children with rickets as those with a radiographic score of at least 2.5 on a 10-point scale. In addition, Aggarwal 2013 reported that based on currently accepted paediatric standards, children with serum 25-OHD levels less than 20 ng/mL were considered to have vitamin D deficiency.

Balasubramanian 2003 confirmed the diagnosis of rickets if the children had characteristic radiological changes and elevated serum ALP level (SAP) (greater than 375 IU/L). However, the author did not describe how radiological changes were assessed. Thacher 1999 diagnosed rickets clinically and radiologically. Children with deformities characteristic of rickets (such as genu varum and genu valgum) had radiography of the wrists and knees and active rickets was diagnosed if the epiphyseal plate was wider than normal and there was concave cupping or fraying of the metaphyseal margins on the radiographs.

Interventions

- None of the included studies reported administration of any treatment before the start of the study.
- Two studies had three groups comparing vitamin D plus calcium versus calcium or vitamin D (Aggarwal 2013; Thacher 1999). The remaining two studies compared vitamin D plus calcium versus calcium (Balasubramanian 2003; Thacher 2014).
- Three studies administered calcium orally, as calcium carbonate (Balasubramanian 2003; Thacher 1999; Thacher 2014), while one study did not specify the form of elemental calcium used (Aggarwal 2013). Two studies administered vitamin D orally (Balasubramanian 2003; Thacher 2014), and two administered vitamin D intramuscularly (Aggarwal 2013; Thacher 1999).
- Total daily doses of calcium and vitamin D varied between studies (Appendix 4).
- Two studies used a placebo (Thacher 1999; Thacher 2014). However, the placebo was not given alone but in conjunction with an active treatment (Appendix 4).
- All studies used adequate interventions and comparators.

Outcomes

All four included studies explicitly stated a primary/secondary endpoint in their publications. Healing of rickets was the most commonly defined primary outcome (Appendix 7). All studies reported healing of rickets. Only one study reported

on morbidity and growth pattern (Thacher 1999). None of the studies reported on all-cause mortality, health-related quality of life and socioeconomic effects. One study reported adverse events (Aggarwal 2013). Only two studies had trial registration documents (Aggarwal 2013; Thacher 2014). The endpoints reported in Aggarwal 2013 did not differ from the prespecified endpoints in the trial document. Some of the secondary outcomes specified by Thacher 2014 were not reported in the publication; however, these did not include any of the outcomes of interest. The number of outcomes of interest reported by the studies ranged between one and three. Definition of endpoint for healing of rickets based on radiological and biochemical criteria was provided by all the studies, although these varied. Adverse events, morbidity or growth pattern were not defined as study endpoints. Aggarwal 2013 reported specific adverse events and Thacher 1999 reported fractures (type of morbidity) at different time points in the study.

Excluded studies

We excluded nine studies after evaluation of the full publication. The main reasons for exclusion were that they were not RCTs (for further details, see [Characteristics of excluded studies](#) table).

Studies awaiting classification

One study is awaiting classification as we could not obtain a copy of the publication (El'chaninov 1969).

Ongoing studies

We found no ongoing studies.

Risk of bias in included studies

For details on the risk of bias of the included studies, see [Characteristics of included studies](#) table.

For an overview of review authors' judgements about each risk of bias item for individual studies and across all studies, see [Figure 1](#) and [Figure 2](#).

Allocation

One study was at low risk of selection bias (random sequence generation and allocation concealment) (Aggarwal 2013). In two studies, there was random sequence generation but it was unclear whether there was allocation concealment (Balasubramanian 2003; Thacher 2014). Although we judged allocation concealment to be adequate in Thacher 1999, the method of random sequence generation was unclear.

Blinding

None of the included studies stated explicitly that blinding of the participants and personnel was undertaken. However, we were able to confirm from the study authors that there was no blinding of participants or personnel in Aggarwal 2013. In three studies, there was insufficient information to determine whether participants and personnel were blinded (Balasubramanian 2003; Thacher 1999; Thacher 2014).

We judged blinding of participants and personnel to be adequate for three studies for healing of rickets (Aggarwal 2013; Thacher 1999; Thacher 2014). Only one study reported on adverse events (Aggarwal 2013). As neither the participants or personnel were blinded in this study, we judged blinding of participants and

personnel for adverse events at high risk of performance bias. Similarly, only Thacher 1999 assessed and reported on morbidity (fractures). We judged the risk of performance bias to be low for this outcome. Two studies reported growth pattern (Thacher 1999; Thacher 2014). We considered the risk of performance bias for this outcome to be low.

One study stated explicitly that outcome assessors were blinded (Aggarwal 2013). Two studies blinded outcome assessors for some of the outcomes (Thacher 1999; Thacher 2014). Specifically, in Thacher 1999, study personnel who assessed healing of rickets were blinded. However, it was unclear whether personnel that assessed growth pattern and morbidity were blinded. Similarly in Thacher 2014, it was not clear whether personnel assessing growth pattern or healing of rickets were blinded. However, we judged detection bias for these studies to be low because the outcomes were objective and were unlikely to be affected by absence of blinding. One study did not provide enough information to enable us assess whether outcome assessors in the study were blinded (Balasubramanian 2003).

Overall, we judged detection bias for healing of rickets to be low. Three studies had low risk of detection bias (Aggarwal 2013; Thacher 1999; Thacher 2014), while we were unable to determine whether outcome assessors were blinded in one study (Balasubramanian 2003).

We judged the overall risk of detection bias to be low for adverse events, morbidity and growth pattern. Only one study reported on adverse events (Aggarwal 2013) and one on morbidity (Thacher 1999). Two studies reported on growth pattern (Thacher 1999; Thacher 2014).

Incomplete outcome data

Attrition rates varied widely, being 6% in Thacher 2014, 11% in Thacher 1999, 16% in Aggarwal 2013, and 67% in Balasubramanian 2003. All four included studies reported losses to follow-up. One of the studies reported the reasons for loss to follow-up as failure of participants to return (Thacher 2014). We were, however able to obtain reasons for loss to follow-up for one additional study by contacting study authors (Aggarwal 2013). The reasons given by the study authors were the participants were not contactable, felt they were well or shifted treatment to another hospital.

We judged overall bias due to attrition to be unclear for most of the reported outcomes. However, Balasubramanian 2003 and Aggarwal 2013 had high loss to follow-up and we judged this to have a possible impact on healing of rickets.

None of the studies used intention-to-treat analysis.

Selective reporting

Two studies had a published protocol (Aggarwal 2013; Thacher 2014). We judged the risk of reporting bias to be low for Aggarwal 2013 as all outcomes were reported as prespecified in the protocol. However, we considered the risk of reporting bias to be high for two studies (Balasubramanian 2003; Thacher 2014). Thacher 2014 stated the primary outcome 'combined attainment of a radiographic score of 1.5 or less and a SAP concentration of 350 U/L or less' in the publication but as 'XR [radiological] healing of rickets' in the protocol. Although there was no protocol for Balasubramanian 2003, the author did not report data on

radiological measurements even though these were taken. We could not ascertain the risk of reporting bias for [Thacher 1999](#). For full details of ORBIT (Outcome Reporting Bias In Trials), see [Appendix 8](#).

Other potential sources of bias

We did not detect any other potential sources of bias for three studies ([Aggarwal 2013](#); [Thacher 1999](#); [Thacher 2014](#)). However, we judged the risk of bias for one study to be unclear because data for baseline characteristics of participants for the two groups were not separated and so it was not possible to assess if baseline imbalances existed across groups ([Balasubramanian 2003](#)).

Effects of interventions

See: [Summary of findings for the main comparison Vitamin D or calcium for the treatment of nutritional rickets in children](#); [Summary of findings 2 Vitamin D plus calcium versus vitamin D for the treatment of nutritional rickets in children](#); [Summary of findings 3 Vitamin D plus calcium versus calcium for the treatment of nutritional rickets in children](#)

Baseline characteristics

For details of baseline characteristics, see [Appendix 5](#) and [Appendix 6](#).

Vitamin D versus calcium

Two studies compared vitamin D to calcium ([Aggarwal 2013](#); [Thacher 1999](#)). [Thacher 1999](#) compared vitamin D plus placebo to calcium plus placebo while [Aggarwal 2013](#) compared vitamin D alone to calcium alone.

Primary outcomes

Healing of rickets

Normal alkaline phosphatase and bone radiograph

[Aggarwal 2013](#) reported healing of rickets based on normal ALP and bone radiograph at 12 weeks and [Thacher 1999](#) reported normal ALP and bone radiograph at 24 weeks. At 12 weeks, 2/17 children were healed in the calcium group compared to 3/19 in the vitamin D group. There was no clear difference in the proportion of children healed of rickets between the two groups at 12 weeks (RR 0.75, 95% CI 0.14 to 3.94; P = 0.73; 1 study, 36 participants; very low-certainty evidence; [Analysis 1.1](#)). At 24 weeks, the proportion of participants who were healed of rickets was higher in the calcium group compared to the vitamin D group (RR 3.26, 95% CI 1.59 to 6.69; P = 0.001; 1 study, 71 participants; low-certainty evidence; [Analysis 1.1](#)).

Serum alkaline phosphatase

Two studies assessed SAP ([Aggarwal 2013](#); [Thacher 1999](#)). Both studies assessed SAP at 12 weeks but only one study assessed SAP at 24 weeks ([Thacher 1999](#)). At 12 weeks, there was no clear difference in the SAP of participants in the vitamin D and calcium groups (MD -37 U/L, 95% CI -129 to 56; P = 0.44; 2 studies, 107 participants; very low-certainty evidence; [Analysis 1.2](#)), but at 24 weeks, the MD in SAP was -148 U/L in favour of calcium (95% CI -241 to -55; P = 0.002; 1 study, 71 participants; low-certainty evidence).

Serum 25-hydroxy vitamin D

Two studies measured serum 25-OHD at 12 weeks ([Aggarwal 2013](#); [Thacher 1999](#)) and one study at 24 weeks ([Thacher 1999](#)). At 12 weeks, comparing vitamin D with calcium showed an MD in serum 25-OHD of -8.5 ng/mL in favour of vitamin D (95% CI -13.9 to -3.0; P = 0.002; 2 studies, 107 participants; low-certainty evidence; [Analysis 1.3](#)). At 24 weeks, vitamin D also improved serum 25-OHD levels compared to calcium (MD -14.0 ng/mL, 95% CI -20.3 to -7.7; P < 0.001; 1 study, 71 participants; low-certainty evidence; [Analysis 1.3](#)).

Radiological score

At 12 and 24 weeks, there was no clear difference in the mean radiological score (Thacher's 10-point scale) for participants in the vitamin D group when compared to the calcium group (at 12 weeks: MD 0.4, 95% CI -1.2 to 2.0; P = 0.60; 2 studies, 107 participants; very low-certainty evidence; [Analysis 1.4](#); at 24 weeks: MD -0.5, 95% CI -1.1 to 0.1; P = 0.10; 1 study, 71 participants; very low-certainty evidence; [Analysis 1.4](#)).

Morbidity

[Thacher 1999](#) reported on morbidity with regard to fractures. A comparison of vitamin D versus calcium showed no clear difference between the proportion of participants who had fractures in the two groups (RR 0.27, 95% CI 0.03 to 2.32; P = 0.23; 1 study, 71 participants, very low-certainty evidence; [Analysis 1.5](#)). At 24 weeks, 1/34 children had a fracture in the calcium group compared to 4/37 children in the vitamin D group.

Adverse events

Neither study reported adverse events.

Secondary outcomes

All-cause mortality

Neither study reported all-cause mortality.

Health-related quality of life

Neither studies reported health-related quality of life.

Growth pattern

Neither study reported growth pattern at the time point stipulated in our protocol (one or more years after commencement of therapy).

Socioeconomic effects

Neither study reported socioeconomic effects.

Vitamin D plus calcium versus vitamin D

Two studies compared vitamin D plus calcium versus vitamin D ([Aggarwal 2013](#); [Thacher 1999](#)).

Primary outcomes

Healing of rickets

Normal alkaline phosphatase and bone radiograph

Two studies reported healing of rickets based on normal ALP and bone radiograph at 12 weeks ([Aggarwal 2013](#)), and at 24 weeks ([Thacher 1999](#)). At 12 weeks, there was a greater number of participants with healing of rickets in the vitamin D plus calcium group compared to vitamin D alone (RR 3.17, 95% CI 1.03 to

9.77; $P = 0.05$; 1 study, 39 participants; very low-quality evidence; [Analysis 2.1](#)). At 24 weeks, there was also a greater number of participants with healing of rickets in the vitamin D plus calcium group compared to vitamin D alone (RR 3.06, 95% CI 1.49 to 6.29; $P = 0.002$; 1 study, 75 participants; low-certainty evidence; [Analysis 2.1](#)). At 24 weeks, 22/38 children were healed in the vitamin D plus calcium group compared to 7/37 children in the vitamin D alone group.

Serum alkaline phosphatase

[Aggarwal 2013](#) and [Thacher 1999](#) reported SAP levels at 12 weeks, while only [Thacher 1999](#) reported SAP at 24 weeks. At 12 weeks and 24 weeks, vitamin D plus calcium improved SAP compared with vitamin D (at 12 weeks: MD -157 U/L, 95% CI -245 to -68; $P < 0.001$; 2 studies, 114 participants; low-certainty evidence; [Analysis 2.2](#); at 24 weeks: MD -155 U/L, 95% CI -243 to -67; $P < 0.001$; 1 study, 75 participants; low-certainty evidence; [Analysis 2.2](#)).

Serum 25-hydroxy vitamin D

A comparison of serum 25-OHD levels for vitamin D plus calcium versus vitamin D at showed no clear difference between the two groups at 12 weeks or 24 weeks (at 12 weeks: MD 7.0 ng/mL, 95% CI -3.0 to 17.1; $P = 0.17$, 2 studies, 114 participants; very low-certainty evidence; [Analysis 2.3](#); at 24 weeks: MD 6.0 ng/mL, 95% CI -1.5 to 13.5; $P = 0.12$; 1 study, 75 participants; very low-certainty evidence; [Analysis 2.3](#)).

Radiological score

[Aggarwal 2013](#) and [Thacher 1999](#) reported radiological score (Thacher's 10-point scale) at 12 weeks, but only [Thacher 1999](#) reported the score at 24 weeks. At 12 and 24 weeks, the comparison favoured vitamin D plus calcium (at 12 weeks: MD -0.7, 95% CI -1.1 to -0.4; $P < 0.001$; 2 studies, 114 participants; low-certainty evidence; [Analysis 2.4](#); at 24 weeks: MD -1.0, 95% CI -1.6 to -0.4, $P < 0.001$; 1 study, 75 participants; low-certainty evidence; [Analysis 2.4](#)).

Morbidity

Only [Thacher 1999](#) reported the number of participants with fractures. There was no clear difference between the proportion of participants with fractures in the vitamin D plus calcium group compared to the vitamin D group (RR 0.24, 95% CI 0.03 to 2.08; $P = 0.20$; 1 study, 75 participants; very low-certainty evidence; [Analysis 2.5](#)). At 24 weeks, 1/38 children had a fracture in the vitamin D plus calcium group compared to 4/37 children in the vitamin D alone group.

Adverse events

[Aggarwal 2013](#) reported adverse events, namely asymptomatic hypercalcaemia and hypercalciuria. There was no clear difference in the number of adverse events in the two groups: 2/20 participants in the vitamin D plus calcium group compared to 0/19 participants in the vitamin D group had an adverse event (RR 4.76, 95% CI 0.24 to 93.19; $P = 0.30$; 1 study, 39 participants; very low-certainty evidence; [Analysis 2.6](#)).

Secondary outcomes

All-cause mortality

Neither study reported all-cause mortality.

Health-related quality of life

Neither study reported health-related quality of life.

Growth pattern

Neither study reported growth pattern at the time point stipulated in our protocol (one or more years after commencement of therapy).

Socioeconomic effects

Neither study reported socioeconomic effects.

Vitamin D plus calcium versus calcium

Three studies compared vitamin D plus calcium versus calcium ([Aggarwal 2013](#); [Balasubramanian 2003](#); [Thacher 2014](#)).

Primary outcomes

Healing of rickets

Normal alkaline phosphatase and bone radiograph

Three studies measured the proportion of participants with normal ALP and bone radiograph at 12 weeks ([Aggarwal 2013](#); [Balasubramanian 2003](#); [Thacher 2014](#)). At 12 weeks, comparing the proportion of participants healed of rickets in the vitamin D plus calcium group with the calcium alone group showed a RR of 2.81 (95% CI 0.25 to 31.22; $P = 0.40$; 3 studies, 113 participants; very low-quality evidence; [Analysis 3.1](#)). There was a high level of heterogeneity between the three studies. After elimination of [Balasubramanian 2003](#), where all children in both the intervention and comparator group (4 in each group) experienced healing, the RR was 4.85 (95% CI 1.57 to 15.01) in favour of vitamin D plus calcium.

Two studies measured the proportion of participants with normal ALP and bone radiograph at 24 weeks ([Thacher 1999](#); [Thacher 2014](#)). At 24 weeks, the proportion of children healed of rickets did not differ between the vitamin D plus calcium group and the calcium group (RR 1.17, 95% CI 0.72 to 1.90; $P = 0.53$; 2 studies, 140 participants; very low-certainty evidence, [Analysis 3.1](#)). At 24 weeks, 51/81 children were healed in the vitamin D plus calcium group compared to 32/59 children in the calcium alone group.

Serum alkaline phosphatase

Three studies assessed SAP levels at 12 weeks ([Aggarwal 2013](#); [Thacher 1999](#); [Thacher 2014](#)), and two studies at 24 weeks ([Thacher 1999](#); [Thacher 2014](#)).

At 12 weeks, the participants who received vitamin D plus calcium had better SAP levels than those who received calcium alone (MD -110 U/L, 95% CI -183 to -36; $P = 0.003$; 3 studies, 177 participants; low-certainty evidence; [Analysis 3.2](#)). At 24 weeks, however, there was no clear difference in SAP (MD -8 U/L, 95% CI -73 to 58; $P = 0.82$; 2 studies, 140 participants; very low-certainty evidence; [Analysis 3.2](#)).

Serum 25-hydroxy vitamin D

Three studies measured serum 25-OHD levels. [Aggarwal 2013](#) measured serum 25-OHD at 12 weeks, while [Thacher 1999](#) and [Thacher 2014](#) measured serum 25-OHD levels at 12 weeks and 24 weeks.

At 12 weeks, there was no clear difference in serum 25-OHD for children in the vitamin D plus calcium group compared to children in the calcium group (MD 10.4 ng/mL, 95% CI -0.8 to 21.7; $P = 0.07$; 3 studies, 177 participants; very low-certainty evidence; [Analysis 3.3](#)). At 24 weeks, a comparison of serum 25-OHD for vitamin D plus calcium versus calcium favoured calcium (MD 13.2 ng/mL, 95% CI 0.5 to 25.9; $P = 0.04$; 2 studies, 140 participants; low-certainty evidence; [Analysis 3.3](#)).

Radiological score

A comparison of vitamin D plus calcium with calcium alone at 12 and 24 weeks favoured vitamin D plus calcium (at 12 weeks: MD in radiological score (Thacher's 10-point scale) -1.3, 95% CI -2.2 to -0.4; $P = 0.004$; 3 studies, 177 participants; low-certainty evidence; [Analysis 3.4](#); at 24 weeks: MD -0.6, 95% CI -0.9 to -0.2; $P = 0.002$; 2 studies, 140 participants; low-certainty evidence; [Analysis 3.4](#)).

Morbidity

Only [Thacher 1999](#) reported the number of participants with fractures. There was no clear difference in the number of fractures in the two groups (RR 0.89, 95% CI 0.06 to 13.76; $P = 0.94$; 1 study, 72 participants; very low-quality evidence; [Analysis 3.5](#)). At 24 weeks, 1/38 children had a fracture in the vitamin D plus calcium group compared to 1/34 children in the calcium alone group.

Adverse events

Only [Aggarwal 2013](#) assessed adverse events. There was no clear difference in the risk of adverse events comparing vitamin D plus calcium to calcium alone (RR 4.29, 95% CI 0.22 to 83.57; $P = 0.34$; 1 study, 37 participants; very low-quality evidence; [Analysis 3.6](#)). There was asymptomatic hypercalcaemia and hypercalciuria at 12 weeks in 2/20 children in the calcium plus vitamin D group compared to 0/17 children in the calcium alone group.

Secondary outcomes

All-cause mortality

None of the studies reported all-cause mortality.

Health-related quality of life

None of the studies reported health-related quality of life.

Growth pattern

None of the studies reported growth pattern at the time point stipulated in our protocol (one or more years after commencement of therapy).

Socioeconomic effects

None of the studies reported socioeconomic effects.

Subgroup analyses

We did not perform subgroups analyses because there were not enough studies to estimate effects in various subgroups and for some studies data were not presented in a manner that allowed for subgroup analyses.

Sensitivity analyses

We did not perform sensitivity analyses because of the low number of studies included in the review.

Assessment of reporting bias

We did not draw funnel plots due to limited number of studies.

DISCUSSION

Summary of main results

This systematic review assessed the effects of vitamin D, calcium or a combination of vitamin D and calcium in children aged six months to 14 years with nutritional rickets. We found four studies with 286 randomised participants. The studies reported on healing of rickets, morbidity (fractures) and adverse events (non-symptomatic hypercalcaemia and hypercalciuria). None of the studies reported all-cause mortality or other patient-important outcomes (health-related quality of life and socioeconomic effects). One study reported on growth pattern ([Thacher 1999](#)), but this was not measured at time points specified in our protocol (one or more years after commencement of therapy) ([Chibuzor 2017](#)).

A summary of the main results for the outcomes reported by study authors is as follows.

- In comparison to vitamin D, administering calcium to children with rickets may improve the healing of rickets (normal ALP and bone radiograph) (low-certainty evidence).
- We are uncertain whether calcium reduces the risk of fractures compared to vitamin D (very low-certainty evidence).
- Vitamin D plus calcium may lead to improvement in the healing of rickets compared to vitamin D (normal ALP and bone radiograph) (low-certainty evidence).
- We are uncertain whether vitamin D plus calcium reduces the risk of fractures compared to vitamin D (very low-certainty evidence).
- We are uncertain whether vitamin D plus calcium reduces the risk of adverse events compared to vitamin D (very low-certainty evidence).
- We are uncertain whether vitamin D plus calcium improves healing of rickets compared to calcium (very low-certainty evidence).
- We are uncertain whether vitamin D plus calcium reduces the risk of fractures compared to calcium (very low-certainty evidence).
- We are uncertain whether vitamin D plus calcium reduces the risk of adverse events compared with calcium (very low-certainty evidence).

Overall completeness and applicability of evidence

We carried out an extensive search of biomedical databases to identify all relevant studies. We also searched the reference lists of all included studies but did not identify any additional studies from this source. The search identified four RCTs for inclusion in the review, but these studies had low number of participants. For additional information on baseline data, risk of bias domains, and outcomes, we contacted authors. Three study authors provided additional data. All the studies included participants of interest and compared vitamin D versus calcium, or vitamin D plus calcium versus calcium or vitamin D plus calcium versus calcium. The outcomes assessed by the studies were limited. Only healing of rickets, morbidity (fractures) and adverse events were assessed as indicated in our protocol by the study authors. Although growth pattern was measured and reported by one study ([Thacher 1999](#)), it

was not measured at the time point stipulated in our protocol (one or more years after commencement of therapy).

All the studies were carried out in low- and middle-income countries where rickets is mostly found; as such the findings of the review are applicable to people from regions most affected by rickets.

Quality of the evidence

The body of evidence provided by the four studies included in the review does not allow us to make a robust conclusion on whether vitamin D, calcium or a combination of vitamin D and calcium is most effective for the treatment of nutritional rickets in children aged 0 to 18 years. We rated the certainty of the evidence to be low to very low for all outcomes according to GRADE.

For vitamin D versus calcium, the certainty of the evidence was based on one RCT for two outcomes measured. We downgraded the certainty of the evidence for healing of rickets to low because of serious imprecision (small number of studies and sample size). We also downgraded the certainty of the evidence for morbidity to very low because of very serious imprecision (small number of studies, small sample size and CI consistent with benefit and harm).

For vitamin D plus calcium versus vitamin D, studies measured three outcomes: healing of rickets, morbidity and adverse events. The certainty of the evidence for healing of rickets and morbidity was based on one RCT (Thacher 1999), while the certainty of evidence for adverse events was based on one RCT (Aggarwal 2013). We considered the certainty of the evidence for healing of rickets to be low because of serious imprecision (small number of studies and sample size) and the certainty of the evidence for morbidity to be very low because of very serious imprecision (small number of studies, small sample size and CI consistent with benefit and harm). For adverse events, we rated the certainty of the evidence to be very low because of risk of bias (performance and attrition bias) and very serious imprecision (small number of studies, small sample size and CI consistent with benefit and harm).

The third comparison was vitamin D plus calcium versus calcium. Three studies provided evidence. Two studies provided evidence for healing of rickets (Thacher 1999; Thacher 2014), one study provided evidence for morbidity (Thacher 1999), and one study provided evidence for adverse events (Aggarwal 2013). We downgraded the certainty of the evidence for healing of rickets to very low because of risk of bias (selective reporting) and serious imprecision (small number of studies and CI consistent with benefit and harm). For morbidity, we considered the certainty of the evidence to be very low because of very serious imprecision (small number of studies, small sample size and CI consistent with benefit and harm). For adverse events, we downgraded the evidence to very low because of the risk of bias (performance bias and potential reporting bias) and very serious imprecision (small number of studies, small sample size and CI consistent with benefit and harm).

Potential biases in the review process

We made considerable effort to avoid bias in the review process. As such, we conducted a comprehensive search of relevant databases to identify studies for inclusion in the review and did not apply any language or date restrictions to the search. In addition, we adhered to the protocol (Chibuzor 2017): two review authors screened all abstracts identified by the search and assessed the risk of bias for

the included studies. We rated the certainty of the evidence using GRADE methodology. There was some heterogeneity between the included studies but we could not explore the reasons for the heterogeneity using a funnel plot due to the small number of included studies.

Agreements and disagreements with other studies or reviews

The Global Consensus Recommendations on Prevention and Management of Nutritional Rickets recommends a combination of vitamin D and calcium for the treatment of nutritional rickets in children (Munns 2016). In agreement with this recommendation, our review found low-certainty evidence that vitamin D plus calcium may lead to improvement in the healing of rickets compared to vitamin D alone. However, we are uncertain based on the findings of our review, whether vitamin D plus calcium improves healing or rickets compared to calcium alone. We are also uncertain whether vitamin D plus calcium reduces the risk of adverse events or morbidity when compared to vitamin D alone or calcium alone. We did not find any other published systematic review on vitamin D, calcium or a combination of vitamin D and calcium for treatment of nutritional rickets in children.

AUTHORS' CONCLUSIONS

Implications for practice

Low-certainty evidence showed that vitamin D plus calcium instead of vitamin D alone may lead to improvement in the healing of rickets. In comparison to vitamin D alone, administering calcium alone to children with rickets may improve the healing of rickets (low-certainty evidence). We did not find sufficient evidence to support or discourage the current practice of vitamin D plus calcium for the treatment of nutritional rickets.

Implications for research

We found only four studies with small sample sizes for inclusion in this review. The studies were conducted in lower- or middle-income countries. Most of the studies did not measure any of the secondary outcomes including patient-important outcomes. Although one study measured growth pattern, this outcome was measured at 24 weeks which was too early to determine the impact of the intervention on growth. The risk of bias in some of the included studies and imprecision affected our ability to make firm conclusions on the certainty of the evidence.

More large, well-conducted randomised controlled trials conducted in lower-, middle- and high-income countries and which assess the interventions in the review are needed. Such studies should measure all-cause mortality, growth pattern, health-related quality of life and socioeconomic effects in addition to the primary outcomes to enable us make firm conclusions about the effects of the interventions for treatment of nutritional rickets in children. Studies should have a longer follow-up period to enable the researchers to measure outcomes such as growth pattern at time points which can provide meaningful evidence for clinical decision making.

ACKNOWLEDGEMENTS

The review authors thank the Cochrane Metabolic and Endocrine Disorders (CMED) Group's Information Specialist (Maria-Inti

Metzendorf) for the development of the search strategy. The review authors would like to thank the CMED Group for their support in the development of the review.

The review authors and the CMED editorial base are grateful to the peer reviewer Christian Lerch, Paediatrician, Garbsen, Germany, for his time and comments.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]

Aggarwal 2013

Methods

Study design: parallel randomised controlled trial, randomisation ratio 1:1:1

Aggarwal 2013 (Continued)

Participants	<p>Inclusion criteria: children aged 6 months to 5 years with clinical and radiological features of nutritional rickets</p> <p>Exclusion criteria: participants with features suggestive of non-nutritional aetiology (renal or hepatic disease, malabsorption states, antiepileptic drug intake or any chronic illness), cases presenting with hypocalcaemic seizures or with history of consuming calcium or vitamin D supplements in the preceding 6 months</p> <p>Diagnostic criteria: radiographs of left wrist and knee obtained and evaluated by 2 separate observers using the method developed by Thacher 2000 on a 0- to 10-point scale. A radiological score of > 1.5 indicated rickets.</p> <p>Setting: hospital</p> <p>Age group: children, adolescents</p> <p>Gender distribution: girls and boys</p> <p>Country where study was performed: India</p>
Interventions	<p>Interventions:</p> <p>I1: vitamin D 600,000 IU single intramuscular injection and elemental calcium 75 mg/kg orally in 3 divided doses per day for 12 weeks</p> <p>I2: elemental calcium 75 mg/kg orally in 3 divided doses per day for 12 weeks</p> <p>Comparator: 600,000 IU vitamin D single intramuscular injection</p> <p>Duration of intervention: 12 weeks</p> <p>Duration of follow-up: 12 weeks</p> <p>Number of study centres: 1</p> <p>Run-in period: none</p> <p>Extension period: none</p>
Outcomes	<p>Outcomes reported</p> <ul style="list-style-type: none"> • Healing of rickets • Adverse events
Study details	<p>Study terminated early: no</p> <p>Trial identifier: CTRI/2010/091/000448</p>
Publication details	<p>Language of publication: English</p> <p>Funding: no funding support</p> <p>Publication status: peer-reviewed journal</p>
Stated aim for study	<p>Quote: "We endeavoured to study the effect of supplementation with calcium, vitamin D or a combination of these two on healing of nutritional rickets in Indian children."</p>
Notes	
Risk of bias	
Bias	Authors' judgement Support for judgement

Aggarwal 2013 (Continued)

Random sequence generation (selection bias)	Low risk	Quote (trials register CTRI/2010/091/000448): "Computer generated randomization." Quote: "the subjects were randomized using block randomization to one of the following three treatment arms ..." (p129, 'randomization and treatment allocation', paragraph 1).
Allocation concealment (selection bias)	Low risk	Quote: "allocation concealment was achieved using opaque sealed envelopes" (p129, 'randomization and treatment allocation', paragraph 1). Quote (trials register): "Sequentially numbered, sealed, opaque envelopes."
Blinding of participants and personnel (performance bias) – adverse events	High risk	Comment: participants and personnel were not blinded (information obtained from study author), outcome measure likely influenced by lack of blinding.
Blinding of participants and personnel (performance bias) – healing of rickets	Low risk	Comment: participants and personnel were not blinded (information obtained from study author), outcome measure unlikely influenced by lack of blinding.
Blinding of outcome assessment (detection bias) – adverse events	Low risk	Quote: "Both the radiologist and the biochemist were blinded to treatment protocol" (p129, 'randomization and treatment allocation', paragraph 1).
Blinding of outcome assessment (detection bias) – healing of rickets	Low risk	Quote: "Both the radiologist and the biochemist were blinded to treatment protocol" (p129, 'randomization and treatment allocation', paragraph 1).
Incomplete outcome data (attrition bias) – adverse events	High risk	Comment: attrition rates high and disparate attrition rates between interventions (calcium + vitamin D 9.1%, calcium 22.7%, vitamin D 17.4%) with possible impact on outcome measure.
Incomplete outcome data (attrition bias) – healing of rickets	High risk	Comment: attrition rates high and disparate attrition rates between interventions (calcium + vitamin D 9.1%, calcium 22.7%, vitamin D 17.4%) with possible impact on outcome measure.
Selective reporting (reporting bias)	Low risk	Comment: all outcomes stated in protocol were assessed in the manner pre-specified in the protocol.
Other bias	Low risk	Comment: we did not identify additional sources of bias.

Balasubramanian 2003

Methods	Study design: parallel randomised controlled trial, randomisation ratio 1:1
Participants	Inclusion criteria: children and adolescents clinically suspected to have rickets or osteomalacia, attending the Endocrinology Department, Sanjay Gandhi Postgraduate Institute and the Pediatrics Department and Rehabilitation and Artificial Limb Center, King George's Medical College, all in Lucknow (latitude 26°N) in northern India. Rickets/osteomalacia confirmed if characteristic radiological changes were present and SAP > 375 IU/L in children, this being 3 times the upper limit of the normal for adults. Exclusion criteria: evidence of renal or liver disease, history of treatment with anticonvulsants, treatment with vitamin D or calcium or for tuberculosis in preceding 3 months

Balasubramanian 2003 (Continued)

Diagnostic criteria: rickets/osteomalacia confirmed if characteristic radiological changes were present and SAP > 375 IU/L in children, this being 3 times the upper limit of the normal for adults

Setting: hospital

Age group: children, adolescents

Gender distribution: girls and boys

Country where study was performed: India

Interventions

Intervention: elemental calcium 1 g as calcium carbonate orally in 3 divided doses per day and vitamin D either as 6000 IU orally per day for 3 months or 600,000 IU vitamin D in a single oral dose

Comparator: elemental calcium 1 g as calcium carbonate orally in 3 divided doses per day for 3 months

Duration of intervention: 3 months

Duration of follow-up: 3 months

Number of study centres: 2

Run-in period: none

Extension period: none

Outcomes
Outcome reported

- Healing of rickets

Study details

Study terminated early: no

Trial ID: not stated

Publication details

Language of publication: English

Funding: not stated

Publication status: peer-reviewed journal

Stated aim for study

Quote: "We conducted this study to characterize calcium intake, sun exposure, and serum vitamin D levels in subjects with and without rickets, and to elucidate the etiology of nutritional rickets in young children and adolescents in our region."

Notes
Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>Quote: "For group 1 cases were randomised by numbers generated by a random number table to receive one of two treatment protocols" (p202, 'Treatment and follow-up')</p> <p>Quote: "Similar randomization was planned initially for group 3 ... randomization was abandoned and all were given vitamin D ..."</p> <p>Comment: group 1 (childhood rickets) = preadolescent children; group 2 (childhood controls) = children presenting to the paediatrics outpatient department for acute illnesses, such as upper respiratory tract infection; group 3 (adolescent rickets) = adolescents (boys with testicular volume \geq 4 mL and girls with Tanner breast stage \geq 2 and aged \leq 20 years); group 4 (adolescents</p>

Balasubramanian 2003 (Continued)

controls) = adolescents drawn from children attending the endocrine outpatient clinic for exogenous obesity or euthyroid goitre.

Comment: 2 comparison groups without rickets or osteomalacia were studied (group 2 vs group 4)

Comment: group 1 received calcium (10 participants, group 1A) or calcium + vitamin D (14 participants, group 1B)

Allocation concealment (selection bias)	Unclear risk	Comment: not described
Blinding of participants and personnel (performance bias) – healing of rickets	Unclear risk	Comment: not described
Blinding of outcome assessment (detection bias) – healing of rickets	Unclear risk	Comment: not described
Incomplete outcome data (attrition bias) – healing of rickets	High risk	<p>Quote: "Of the 24 children in group 1, 14 presented for follow-up at 1 month and eight at 3 months of therapy."</p> <p>Comment: attrition rate was high, total attrition was about 33%. In addition, attrition rates varied between the groups (calcium + vitamin D 71.4%, calcium 60%). Reasons for loss of participants in each group were not given (p204, 'follow up').</p>
Selective reporting (reporting bias)	High risk	Comment: data for radiological measurements not reported.
Other bias	Unclear risk	Comment: unclear whether there were any other sources of bias. Data for baseline characteristics of participants in groups 1A and 1B are not separated so it was not possible to assess if baseline imbalances existed across groups.

Thacher 1999

Methods	Study design: parallel randomised controlled trial, randomisation ratio 1:1:1
Participants	<p>Inclusion criteria: children with deformities characteristic of rickets (genu varum, genu valgum and widened wrists) were recruited within and around Jos, Nigeria (population 360,100), through posters, radio announcements and word of mouth. Each child was examined, and a parent or guardian was interviewed. Children aged 1 to 14 years and who had clinical evidence of rickets underwent radiography of the wrists and knees. Rickets was considered active if the epiphyseal plate was wider than normal and there was concave cupping or fraying of the metaphyseal margins on the radiographs.</p> <p>Exclusion criteria: not stated</p> <p>Diagnostic criteria: children were eligible for enrolment if they had a radiographic score of ≥ 2.5 on a validated 10-point scoring method that assessed the severity of rickets in the growth plates of the distal radius and ulna and around the knee.</p> <p>Setting: hospital</p> <p>Age group: children, adolescents</p> <p>Gender distribution: girls and boys</p>

Thacher 1999 (Continued)

Country where study was performed: Nigeria

Interventions	<p>Interventions:</p> <p>I1: vitamin D 600,000 U intramuscular injection at enrolment and after 12 weeks + calcium carbonate 200 mg tablets – 2 tablets in the morning and 3 in the evening ≥ 30 minutes before eating (total dose, 1000 mg of elemental calcium daily)</p> <p>I2: calcium carbonate 200 mg chewable tablets – 2 tablets in the morning and 3 in the evening at least 30 minutes before eating (total dose, 1000 mg of elemental calcium daily) and an injection of placebo (light mineral oil) at enrolment and after 12 weeks</p> <p>Comparator: vitamin D 600,000 U intramuscular injection at enrolment and after 12 weeks and chewable placebo tablets (candy containing no calcium but similar in appearance to calcium tablets) – 2 in the morning and 3 in the evening ≥ 30 minutes before eating</p> <p>Duration of intervention: 24 weeks</p> <p>Duration of follow-up: 24 weeks</p> <p>Number of study centres: unclear</p> <p>Run-in period: none</p> <p>Extension period: none</p>	
Outcomes	<p>Outcomes reported</p> <ul style="list-style-type: none"> • Healing of rickets • Morbidity • Growth pattern 	
Study details	<p>Study terminated early: no</p> <p>Trial ID: not stated</p>	
Publication details	<p>Language of publication: English</p> <p>Funding: non-commercial funding (supported by a grant from the Thrasher Research Fund, Salt Lake City)</p> <p>Publication status: peer-reviewed journal</p>	
Stated aim for study	<p>Quote: "We report the results of a 24-week controlled trial to test the hypothesis that calcium supplementation with or without vitamin D is superior to vitamin D alone for the treatment of rickets in Nigerian children."</p>	
Notes		
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	<p>Quote: "Eligible children were randomly assigned in blocks of nine to receive vitamin D, calcium, or both" (p564, 'Study Protocol').</p> <p>Comment: no details</p>
Allocation concealment (selection bias)	Low risk	<p>Quote: "Medication kits were serially numbered and contained the complete 24-week treatment for each child. The randomization code was kept at the University of Utah and was not broken until all data had been collected. The medications were dispensed in sealed, opaque packets, and vitamin D or</p>

Thacher 1999 (Continued)

placebo was administered intramuscularly on two occasions by a nurse while the investigators were in a different room" (p564, 'study protocol').

Blinding of participants and personnel (performance bias) – growth pattern	Low risk	<p>Quote: "The medications were dispensed in sealed, opaque packets, and vitamin D or placebo was administered intramuscularly on two occasions by a nurse while the investigators were in a different room". (P564, study protocol).</p> <p>Comment: outcome measure unlikely influenced by potential lack of blinding.</p>
Blinding of participants and personnel (performance bias) – healing of rickets	Low risk	<p>Quote: "The medications were dispensed in sealed, opaque packets, and vitamin D or placebo was administered intramuscularly on two occasions by a nurse while the investigators were in a different room. Children assigned to the vitamin D group received an intramuscular injection of 600,000 U of vitamin D at enrollment and after 12 weeks. They were also provided chewable placebo tablets (candy containing no calcium but similar in appearance to calcium tablets) and instructed to take two in the morning and three in the evening at least 30 minutes before eating. Children assigned to the calcium group were supplied chewable 200-mg tablets of calcium carbonate and were instructed to take two tablets in the morning and three in the evening at least 30 minutes before eating (total dose, 1000 mg of elemental calcium daily). They were given an injection of placebo (light mineral oil) at enrollment and after 12 weeks. The combination-therapy group received both vitamin D and calcium in the doses given above." (p564, 'study protocol').</p> <p>Comment: outcome measure unlikely influenced by potential lack of blinding.</p>
Blinding of participants and personnel (performance bias) – morbidity	Low risk	<p>Quote: "The medications were dispensed in sealed, opaque packets, and vitamin D or placebo was administered intramuscularly on two occasions by a nurse while the investigators were in a different room. Children assigned to the vitamin D group received an intramuscular injection of 600,000 U of vitamin D at enrollment and after 12 weeks. They were also provided chewable placebo tablets (candy containing no calcium but similar in appearance to calcium tablets) and instructed to take two in the morning and three in the evening at least 30 minutes before eating. Children assigned to the calcium group were supplied chewable 200-mg tablets of calcium carbonate and were instructed to take two tablets in the morning and three in the evening at least 30 minutes before eating (total dose, 1000 mg of elemental calcium daily). They were given an injection of placebo (light mineral oil) at enrollment and after 12 weeks. The combination-therapy group received both vitamin D and calcium in the doses given above" (p564, 'study protocol').</p> <p>Comment: outcome measure unlikely influenced by potential lack of blinding.</p>
Blinding of outcome assessment (detection bias) – growth pattern	Low risk	<p>Comment: unclear who assessed growth pattern (height and weight); however, this is an objective measurement and is unlikely to be influenced by absence of blinding.</p>
Blinding of outcome assessment (detection bias) – healing of rickets	Low risk	<p>Quote: radiographs: "Each radiograph was independently scored by three physicians who were unaware of the child's treatment assignment, and the mean value of the three scores was used for the analysis" (p564, 'Data and Sample Collection').</p> <p>Biochemical: "Biochemical testing was performed by Associated Regional University Pathologists (Salt Lake City)" (p564, 'Biochemical Measurements').</p>
Blinding of outcome assessment (detection bias) – morbidity	Low risk	<p>Comment: unclear who assessed morbidity; however, in the case of this study, the outcome (fractures) was an objective measurement and unlikely to be influenced by absence of blinding.</p>

Thacher 1999 (Continued)

Incomplete outcome data (attrition bias) – adverse events	Unclear risk	Comment: attrition rates differed between intervention groups (calcium + vitamin D 5%, calcium + placebo 16.7%, vitamin D + placebo 9.8%). Unclear whether the outcome measure was influenced by these attrition rates.
Incomplete outcome data (attrition bias) – growth pattern	Unclear risk	Comment: attrition rates differed between intervention groups (calcium + vitamin D 5%, calcium + placebo 16.7%, vitamin D + placebo 9.8%). Unclear whether the outcome measure was influenced by these attrition rates.
Incomplete outcome data (attrition bias) – healing of rickets	Unclear risk	Comment: attrition rates differed between intervention groups (calcium + vitamin D 5%, calcium + placebo 16.7%, vitamin D + placebo 9.8%). Unclear whether the outcome measure was influenced by these attrition rates.
Incomplete outcome data (attrition bias) – morbidity	Unclear risk	Comment: attrition rates differed between intervention groups. Unclear whether the outcome measure was influenced by these attrition rates.
Selective reporting (reporting bias)	Unclear risk	Comment: protocol for study not available.
Other bias	Low risk	Comment: no other sources of bias were identified.

Thacher 2014

Methods	Study design: parallel randomised controlled trial, randomisation ratio 2:1
Participants	<p>Inclusion criteria: children with radiographic score ≥ 2.5 on a validated 10-point scoring method that assessed the severity of rickets in the growth plates of the distal radius and ulna and around the knee</p> <p>Exclusion criteria: not specifically stated</p> <p>Diagnostic criteria: radiographic score ≥ 2.5 on a validated 10-point scoring method that assessed the severity of rickets in the growth plates of the distal radius and ulna and around the knee</p> <p>Setting: hospital</p> <p>Age group: children, adolescents</p> <p>Gender distribution: girls and boys</p> <p>Country where study was performed: Nigeria</p>
Interventions	<p>Intervention: oral calcium, 3.5 g powdered limestone (containing approximately 938 mg of elemental calcium) twice daily + vitamin D₂ 50,000 IU (ergocalciferol) orally once every 4 weeks for 24 weeks</p> <p>Comparator: oral calcium, 3.5 g powdered limestone (containing approximately 938 mg of elemental calcium) twice daily + placebo, which was a single vitamin B complex tablet, once every 4 weeks for 24 weeks</p> <p>Duration of intervention: 24 weeks</p> <p>Duration of follow-up: 24 weeks</p> <p>Number of study centres: 1</p> <p>Run-in period: none</p> <p>Extension period: none</p>
Outcomes	Outcomes reported

Thacher 2014 (Continued)

- Healing of rickets

Study details	Study terminated early: no	
	Trial ID: NCT00949832	
Publication details	Language of publication: English	
	Funding: non-commercial funding (this study was supported by Grant Number 1 UL1 RR024150 from the National Center for Research Resources (NCRR), a component of the National Institutes of Health (NIH) and the NIH Roadmap for Medical Research.)	
	Publication status: peer-reviewed journal	
Stated aim for study	Quote: "The objective of this randomised controlled trial was to compare the response of rickets to calcium treatment as limestone with and without vitamin D supplementation."	
Notes		
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Enrolled children were randomised by coin toss (performed by (TDT)" (p808, 'Intervention').
Allocation concealment (selection bias)	Unclear risk	Comment: method of allocation concealment not described.
Blinding of participants and personnel (performance bias) – growth pattern	Low risk	Comment: unclear whether participants and personnel were blinded, outcome measure unlikely influenced by potential lack of blinding.
Blinding of participants and personnel (performance bias) – healing of rickets	Low risk	Comment: unclear whether participants and personnel were blinded, outcome measure unlikely influenced by potential lack of blinding.
Blinding of outcome assessment (detection bias) – growth pattern	Low risk	Comment: outcome measure unlikely influenced by potential lack of blinding.
Blinding of outcome assessment (detection bias) – healing of rickets	Low risk	Quote: Radiographic assessment: "All radiographs were scored independently by 2 of the authors (TDT and PRF)" (p808, 'Statistical analysis'). Biochemical assessment: "Serum samples were stored at -20 °C until transported frozen to the Mayo Clinic for analysis" (p808, 'Intervention', 2nd paragraph). Comment: outcome measure unlikely influenced by potential lack of blinding.
Incomplete outcome data (attrition bias) – growth pattern	Unclear risk	Comment: proportion of participants lost to follow-up was higher in the calcium group (calcium + vitamin D 2.3%, calcium + placebo 10.7%), unclear whether outcome was influenced by attrition rate.

Thacher 2014 (Continued)

Incomplete outcome data (attrition bias) – healing of rickets	Unclear risk	Comment: proportion of participants lost to follow-up was higher in the calcium group (calcium + vitamin D 2.3%, calcium + placebo 10.7%), unclear whether outcome was influenced by attrition rate.
Selective reporting (reporting bias)	High risk	Comment: primary outcome was stated as 'combined attainment of a radiographic score of ≤ 1.5 and a SAP concentration of ≤ 350 U/L in the publication' but as 'XR [radiological] healing of rickets' in ClinicalTrials.gov. Comment: adverse events and growth pattern were associated with high risk of outcome reporting bias in ORBIT (Outcome Reporting Bias In Trials), see Appendix 8 .
Other bias	Low risk	Comment: no other bias detected.

SAP: serum alkaline phosphatase.

Note: where the judgement is 'Unclear' and the description is blank, the study did not report that particular outcome.

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Arya 2000	Not a randomised trial but a commentary on 1 of the included studies.
Atabek 2013	Open-label non-randomised prospective trial.
Barr 1969	Not a randomised controlled trial.
Curtis 1983	Not a randomised controlled trial.
Davis 1978	Not a randomised controlled trial.
Kutluk 2002	Quasi-randomised controlled trial.
NCT01512537	Intervention was ultraviolet radiation compared with calcium + vitamin D.
Rooze 2016	Not a randomised controlled trial; participants not children with nutritional rickets.
Zauche 2017	Case study. Not a randomised controlled trial.

DATA AND ANALYSES
Comparison 1. Vitamin D versus calcium

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Healing of rickets (normal alkaline phosphatase and bone radiograph)	2		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.1 Proportion healed at 12 weeks	1	36	Risk Ratio (M-H, Fixed, 95% CI)	0.75 [0.14, 3.94]
1.2 Proportion healed at 24 weeks	1	71	Risk Ratio (M-H, Fixed, 95% CI)	3.26 [1.59, 6.69]
2 Healing of rickets (biochemical parameters). serum alkaline phosphatase	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
2.1 Serum alkaline phosphatase at 12 weeks	2	107	Mean Difference (IV, Random, 95% CI)	-36.65 [-129.30, 56.00]
2.2 Serum alkaline phosphatase at 24 weeks	1	71	Mean Difference (IV, Random, 95% CI)	-148.0 [-241.47, -54.53]
3 Healing of rickets (biochemical parameters): serum 25-OHD	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
3.1 Serum 25-OHD at 12 weeks	2	107	Mean Difference (IV, Random, 95% CI)	-8.45 [-13.89, -3.02]
3.2 Serum 25-OHD at 24 weeks	1	71	Mean Difference (IV, Random, 95% CI)	-14.0 [-20.34, -7.66]
4 Healing of rickets (radiological)	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
4.1 Radiographic score at 12 weeks (Thacher's 10-point scale)	2	107	Mean Difference (IV, Random, 95% CI)	0.42 [-1.15, 1.99]
4.2 Radiographic score at 24 weeks (Thacher's 10-point scale)	1	71	Mean Difference (IV, Random, 95% CI)	-0.5 [-1.10, 0.10]
5 Morbidity (fractures)	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

Analysis 1.1. Comparison 1 Vitamin D versus calcium, Outcome 1 Healing of rickets (normal alkaline phosphatase and bone radiograph).

Analysis 1.2. Comparison 1 Vitamin D versus calcium, Outcome 2 Healing of rickets (biochemical parameters). serum alkaline phosphatase.

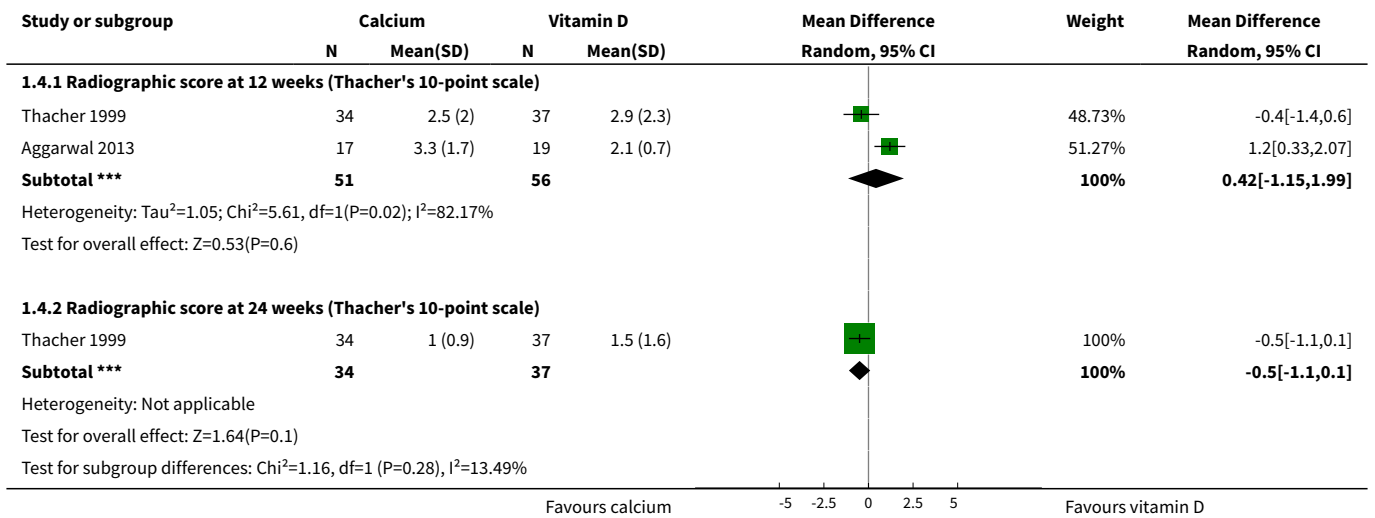

Analysis 1.3. Comparison 1 Vitamin D versus calcium, Outcome 3 Healing of rickets (biochemical parameters): serum 25-OHD.

Analysis 1.4. Comparison 1 Vitamin D versus calcium, Outcome 4 Healing of rickets (radiological).

Analysis 1.5. Comparison 1 Vitamin D versus calcium, Outcome 5 Morbidity (fractures).

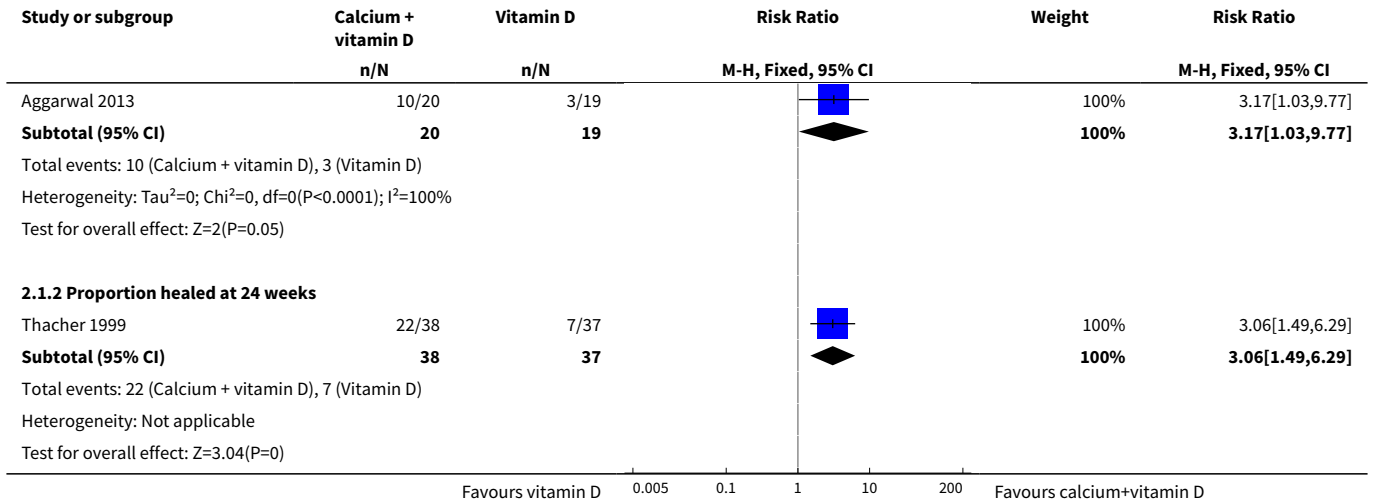

Comparison 2. Vitamin D plus calcium versus vitamin D

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Healing of rickets (normal alkaline phosphatase and bone radiograph)	2		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.1 Proportion healed at 12 weeks	1	39	Risk Ratio (M-H, Fixed, 95% CI)	3.17 [1.03, 9.77]
1.2 Proportion healed at 24 weeks	1	75	Risk Ratio (M-H, Fixed, 95% CI)	3.06 [1.49, 6.29]
2 Healing of rickets (biochemical parameters): serum alkaline phosphatase	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
2.1 Serum alkaline phosphatase at 12 weeks	2	114	Mean Difference (IV, Random, 95% CI)	-156.52 [-245.10, -67.93]
2.2 Serum alkaline phosphatase at 24 weeks	1	75	Mean Difference (IV, Random, 95% CI)	-155.0 [-242.73, -67.27]
3 Healing of rickets (biochemical parameters): serum 25-OHD	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
3.1 Serum 25-OHD at 12 weeks	2	114	Mean Difference (IV, Random, 95% CI)	7.03 [-3.00, 17.07]
3.2 Serum 25-OHD at 24 weeks	1	75	Mean Difference (IV, Random, 95% CI)	6.0 [-1.47, 13.47]
4 Healing of rickets (radiological)	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
4.1 Radiological score at 12 weeks (Thacher's 10-point scale)	2	114	Mean Difference (IV, Random, 95% CI)	-0.72 [-1.06, -0.39]
4.2 Radiological score at 24 weeks (Thacher's 10-point scale)	1	75	Mean Difference (IV, Random, 95% CI)	-1.0 [-1.56, -0.44]
5 Morbidity (fractures)	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
6 Adverse events	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

Analysis 2.1. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 1 Healing of rickets (normal alkaline phosphatase and bone radiograph).

Analysis 2.2. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 2 Healing of rickets (biochemical parameters): serum alkaline phosphatase.

Analysis 2.3. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 3 Healing of rickets (biochemical parameters): serum 25-OHD.

Analysis 2.4. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 4 Healing of rickets (radiological).

Analysis 2.5. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 5 Morbidity (fractures).

Analysis 2.6. Comparison 2 Vitamin D plus calcium versus vitamin D, Outcome 6 Adverse events.

Comparison 3. Vitamin D plus calcium versus calcium

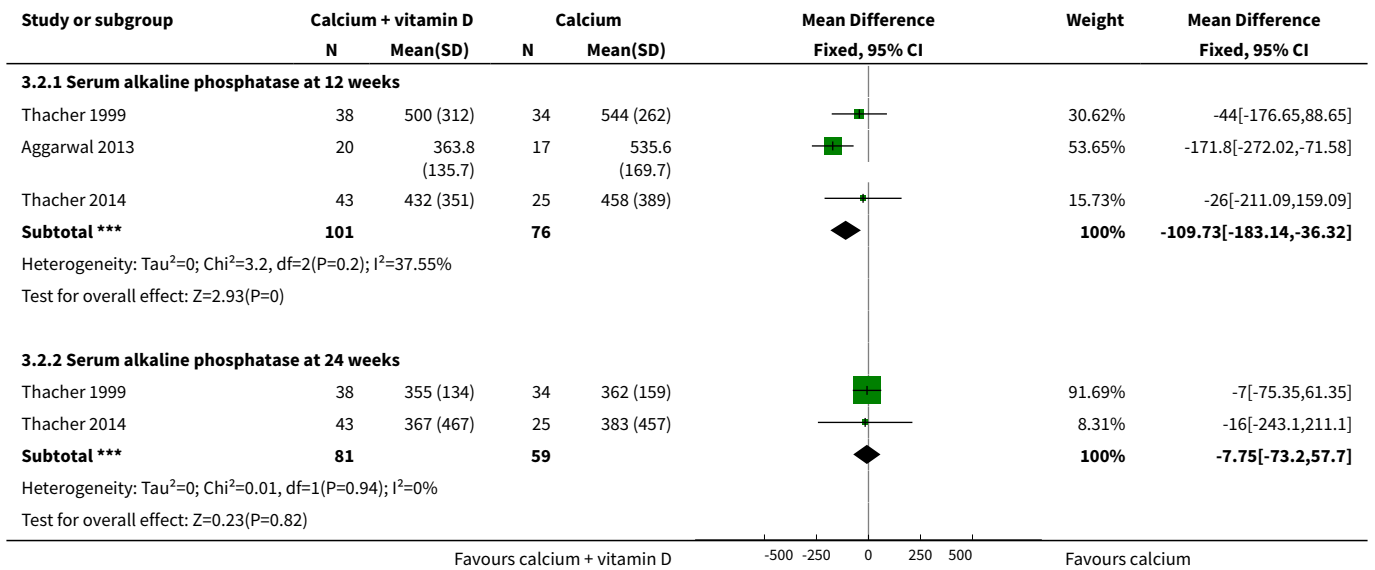

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Healing of rickets (normal alkaline phosphatase and bone radiograph)	4		Risk Ratio (M-H, Random, 95% CI)	Subtotals only
1.1 Proportion healed at 12 weeks	3	113	Risk Ratio (M-H, Random, 95% CI)	2.81 [0.25, 31.22]
1.2 Proportion healed at 24 weeks	2	140	Risk Ratio (M-H, Random, 95% CI)	1.17 [0.72, 1.90]
2 Healing of rickets (biochemical parameters): serum alkaline phosphatase	3		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
2.1 Serum alkaline phosphatase at 12 weeks	3	177	Mean Difference (IV, Fixed, 95% CI)	-109.73 [-183.14, -36.32]
2.2 Serum alkaline phosphatase at 24 weeks	2	140	Mean Difference (IV, Fixed, 95% CI)	-7.75 [-73.20, 57.70]
3 Healing of rickets (biochemical parameters): serum 25-OHD	3		Mean Difference (IV, Random, 95% CI)	Subtotals only
3.1 Serum 25-OHD at 12 weeks	3	177	Mean Difference (IV, Random, 95% CI)	10.43 [-0.81, 21.68]
3.2 Serum 25-OHD at 24 weeks	2	140	Mean Difference (IV, Random, 95% CI)	13.21 [0.48, 25.94]
4 Healing of rickets (radiological)	3		Mean Difference (IV, Random, 95% CI)	Subtotals only
4.1 Radiological score at 12 weeks (Thacher's 10-point scale)	3	177	Mean Difference (IV, Random, 95% CI)	-1.30 [-2.18, -0.42]
4.2 Radiological score at 24 weeks (Thacher's 10-point scale)	2	140	Mean Difference (IV, Random, 95% CI)	-0.56 [-0.91, -0.21]
5 Morbidity (fractures)	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
6 Adverse events	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

Analysis 3.1. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 1 Healing of rickets (normal alkaline phosphatase and bone radiograph).

Analysis 3.2. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 2 Healing of rickets (biochemical parameters): serum alkaline phosphatase.

Analysis 3.3. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 3 Healing of rickets (biochemical parameters): serum 25-OHD.

Analysis 3.4. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 4 Healing of rickets (radiological).

Analysis 3.5. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 5 Morbidity (fractures).

Analysis 3.6. Comparison 3 Vitamin D plus calcium versus calcium, Outcome 6 Adverse events.

Appendix 2. 'Risk of bias' assessment

'Risk of bias' domains

Random sequence generation (selection bias due to inadequate generation of a randomised sequence)

For each included trial, we described the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

- Low risk of bias: trial authors achieved sequence generation using computer-generated random numbers or a random numbers table. Drawing of lots, tossing a coin, shuffling cards or envelopes, and throwing dice were adequate if an independent person performed this who was not otherwise involved in the trial. We considered the use of the minimisation technique as equivalent to being random.
- Unclear risk of bias: insufficient information about the sequence generation process.
- High risk of bias: the sequence generation method was non-random or quasi-random (e.g. sequence generated by odd or even date of birth; sequence generated by some rule based on date (or day) of admission; sequence generated by some rule based on hospital or clinic record number; allocation by judgment of the clinician; allocation by preference of the participant; allocation based on the results of a laboratory test or a series of tests; or allocation by availability of the intervention).

Allocation concealment (selection bias due to inadequate concealment of allocation prior to assignment)

We described for each included trial the method used to conceal allocation to interventions prior to assignment and we assessed whether intervention allocation could have been foreseen in advance of or during recruitment or changed after assignment.

- Low risk of bias: central allocation (including telephone, interactive voice-recorder, Internet-based and pharmacy-controlled randomisation); sequentially numbered drug containers of identical appearance; sequentially numbered, opaque, sealed envelopes.
- Unclear risk of bias: insufficient information about the allocation concealment.

(Continued)

- High risk of bias: used an open random allocation schedule (e.g. a list of random numbers); assignment envelopes used without appropriate safeguards; alternation or rotation; date of birth; case record number; any other explicitly unconcealed procedure.

We also evaluated trial baseline data to incorporate assessment of baseline imbalance into the 'Risk of bias' judgement for selection bias (Corbett 2014).

Chance imbalances may also affect judgements on the risk of attrition bias. In the case of unadjusted analyses, we distinguished between trials that we rated at low risk of bias on the basis of both randomisation methods and baseline similarity, and trials that we judged at low risk of bias on the basis of baseline similarity alone (Corbett 2014). We reclassified judgements of unclear, low or high risk of selection bias as specified in Appendix 3.

Blinding of participants and study personnel (performance bias due to knowledge of the allocated interventions by participants and personnel during the trial)

We evaluated the risk of detection bias separately for each outcome (Hróbjartsson 2013). We noted whether endpoints were self-reported, investigator-assessed or adjudicated outcome measures (see below).

- Low risk of bias: blinding of participants and key study personnel was ensured, and it was unlikely that the blinding could have been broken; no blinding or incomplete blinding, but we judged that the outcome was unlikely to have been influenced by lack of blinding.
- Unclear risk of bias: insufficient information about the blinding of participants and study personnel; the trial did not address this outcome.
- High risk of bias: no blinding or incomplete blinding, and the outcome was likely to have been influenced by lack of blinding; blinding of trial participants and key personnel attempted, but likely that the blinding could have been broken, and the outcome was likely to have been influenced by lack of blinding.

Blinding of outcome assessment (detection bias due to knowledge of the allocated interventions by outcome assessment)

We evaluated the risk of detection bias separately for each outcome (Hróbjartsson 2013). We noted whether endpoints were self-reported, investigator-assessed or adjudicated outcome measures (see below).

- Low risk of bias: blinding of outcome assessment was ensured, and it was unlikely that the blinding could have been broken; no blinding of outcome assessment, but we judged that the outcome measurement was unlikely to have been influenced by lack of blinding.
- Unclear risk of bias: insufficient information about the blinding of outcome assessors; the trial did not address this outcome.
- High risk of bias: no blinding of outcome assessment, and the outcome measurement was likely to have been influenced by lack of blinding; blinding of outcome assessment, but likely that the blinding could have been broken, and the outcome measurement was likely to be influenced by lack of blinding.

Incomplete outcome data (attrition bias due to quantity, nature or handling of incomplete outcome data)

For each included trial or each outcome, or both, we described the completeness of data, including attrition and exclusions from the analyses. We stated whether the trial reported attrition and exclusions, and we reported the number of participants included in the analysis at each stage (compared with the number of randomised participants per intervention/comparator group). We also noted if the trial reported the reasons for attrition or exclusion, and whether missing data were balanced across groups or were related to outcomes. We considered the implications of missing outcome data per outcome such as high dropout rates (e.g. above 15%) or disparate attrition rates (e.g. difference of 10% or more between trial groups).

- Low risk of bias: no missing outcome data; reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to introduce bias); missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk was not enough to have had a clinically relevant impact on the intervention effect estimate; for continuous outcome data, plausible effect size (mean difference or standardised mean difference) among missing outcomes was not enough to have had a clinically relevant impact on observed effect size; appropriate methods, such as multiple imputation, were used to handle missing data.
- Unclear risk of bias: insufficient information to assess whether missing data in combination with the method used to handle missing data were likely to induce bias; the trial did not address this outcome.
- High risk of bias: reason for missing outcome data was likely to have been related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk was enough to induce clinically relevant bias in the intervention effect estimate; for continuous outcome data, plausible effect size (mean difference or standardised mean difference) among missing outcomes was enough to have induced clinically relevant bias in observed effect size; 'as-treated' or similar analysis done with substantial departure of the intervention received from that assigned at randomisation; potentially inappropriate application of simple imputation.

(Continued)

Selective reporting (reporting bias due to selective outcome reporting)

We assessed outcome reporting bias by integrating the results of [Appendix 7](#) 'Matrix of trial endpoints (publications and trial documents)' ([Boutron 2014](#); [Jones 2015](#); [Mathieu 2009](#)), with those of [Appendix 8](#) 'High risk of outcome reporting bias according to the Outcome Reporting Bias In Trials (ORBIT) classification' ([Kirkham 2010](#)). This analysis formed the basis for the judgement of selective reporting.

- Low risk of bias: the trial protocol was available and all the trial's prespecified (primary and secondary) outcomes that were of interest to this review were reported in the prespecified way; the study protocol was unavailable, but it was clear that the published reports included all expected outcomes (ORBIT classification).
- Unclear risk of bias: insufficient information about selective reporting.
- High risk of bias: not all the trial's prespecified primary outcomes were reported; one or more primary outcomes were reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not prespecified; one or more reported primary outcomes were not prespecified (unless clear justification for their reporting was provided, such as an unexpected adverse effect); one or more outcomes of interest in the Cochrane Review were reported incompletely so that we could not enter them into a meta-analysis; the trial report failed to include results for a key outcome that we would have expected to have been reported for such a trial (ORBIT classification).

Other bias

- Low risk of bias: the trial appeared free from other sources of bias.
- Unclear risk of bias: information was insufficient to assess whether an important risk of bias existed; insufficient rationale or evidence that an identified problem introduced bias.
- High risk of bias: the trial had a potential source of bias related to the specific trial design used; the trial was claimed to be fraudulent or the trial had some other serious problem.

Appendix 3. Selection bias decisions

Selection bias decisions for trials that reported unadjusted analyses: comparison of results obtained using method details alone versus results obtained using method details and trial baseline information^a

Reported randomisation and allocation concealment methods	'Risk of bias' judgement using methods reporting	Information gained from study characteristics data	'Risk of bias' using baseline information and methods reporting
Unclear methods	Unclear risk	Baseline imbalances present for important prognostic variable(s)	High risk
		Groups appear similar at baseline for all important prognostic variables	Low risk
		Limited or no baseline details	Unclear risk
Would generate a truly random sample, with robust allocation concealment	Low risk	Baseline imbalances present for important prognostic variable(s)	Unclear risk^b
		Groups appear similar at baseline for all important prognostic variables	Low risk
		Limited baseline details, showing balance in some important prognostic variables ^c	Low risk
		No baseline details	Unclear risk

(Continued)

Sequence is not truly randomised or allocation concealment is inadequate	High risk	Baseline imbalances present for important prognostic variable(s)	High risk
		Groups appear similar at baseline for all important prognostic variables	Low risk
		Limited baseline details, showing balance in some important prognostic variables ^c	Unclear risk
		No baseline details	High risk

^aTaken from [Corbett 2014](#); judgements highlighted in bold indicate situations in which the addition of baseline assessments would change the judgement about risk of selection bias compared with using methods reporting alone.

^bImbalance was identified that appears likely to be due to chance.

^cDetails for the remaining important prognostic variables are not reported.

Appendix 4. Description of interventions

Study ID	Intervention(s) (route, frequency, total dose/day)	Comparator(s) (route, frequency, total dose/day)
Thacher 2014	Oral calcium 3.5 g powdered limestone (containing approximately 938 mg of elemental calcium) twice daily + oral vitamin D2 as 50,000 IU (ergocalciferol) once every 4 weeks for 24 weeks.	Oral calcium, 3.5 g powdered limestone (containing approximately 938 mg of elemental calcium) twice daily + placebo, which was a single vitamin B complex tablet, once every 4 weeks for 24 weeks.
Aggarwal 2013	I1: vitamin D 600,000 IU single intramuscular injection and elemental calcium 75 mg/kg in 3 divided doses per day for 12 weeks. I2: elemental calcium 75 mg/kg orally in 3 divided doses per day for 12 weeks.	Vitamin D 600,000 IU single intramuscular injection.
Balasubramanian 2003	Calcium carbonate 1 g as 3 divided doses per day + vitamin D either as 6000 IU oral daily for 3 months or 600,000 IU in a single oral dose.	Calcium carbonate 1 g orally as in 3 divided doses per day for 3 months.
Thacher 1999	I1: vitamin D 600,000 U intramuscular injection at enrolment and after 12 weeks) and calcium carbonate 200 mg tablets – 2 tablets in morning and 3 in evening ≥ 30 minutes before eating (total dose, 1000 mg of elemental calcium daily). I2: calcium carbonate 200 mg chewable tablets – 2 tablets in the morning and 3 in the evening ≥ 30 minutes before eating (total dose, 1000 mg of elemental calcium daily) and an injection of placebo (light mineral oil) at enrolment and after 12 weeks.	Vitamin D 600,000 U intramuscular injection at enrolment and after 12 weeks and chewable placebo tablets (candy containing no calcium but similar in appearance to calcium tablets) 2 in the morning and 3 in the evening ≥ 30 minutes before eating.
I: intervention.		

Appendix 5. Baseline characteristics (I)

Study ID	Intervention(s) and comparator(s)	Duration of intervention (duration of follow-up)	Description of participants	Study period (year to year)	Country	Setting	Ethnic groups (%)	Duration of rickets
Thacher 2014	I: oral calcium + oral vitamin D C: oral calcium + placebo	24 weeks (24 weeks)	Children with active rickets aged 15–144 months	2004–2007	Nigeria	Tertiary teaching hospital, outpatients	African	0.5–108 months
Aggarwal 2013	I1: oral calcium + single dose intramuscular vitamin D I2: oral calcium alone C: single dose intramuscular vitamin D alone	12 weeks (12 weeks)	Children aged 6 months to 5 years with nutritional rickets	2007–2009	India	Tertiary teaching hospital, outpatients	Asian	—
Balasubramanian 2003	I: oral calcium + oral vitamin D C: oral calcium alone	3 months (3 months)	Children aged 11 months to 10 years with nutritional rickets	—	India	Hospital facility, outpatients	Asian	—
Thacher 1999	I1: oral calcium + intramuscular vitamin D I2: oral calcium + placebo C: intramuscular vitamin D + placebo	24 weeks (24 weeks)	Children aged 1–14 years	1996–1997	Nigeria	Tertiary teaching hospital, outpatients	African	—

—: denotes not reported.
 C: comparator; I: intervention.

Appendix 6. Baseline characteristics (II)

Study ID	Intervention(s) and comparator(s)	Sex (girls %)	Age (months, range)	Comedications/Cointerventions (% of participants)	Comorbidities (% of participants)
Thacher 2014	I: calcium + vitamin D	57	15–144	—	—
	C: calcium + placebo	61	16–91		
Aggarwal 2013	I1: calcium + vitamin D	59	6–60	—	—
	I2: calcium alone	41	6–60		
	C: vitamin D	43	6–58		
Balasubramanian 2003	I: calcium + vitamin D	54	11–120	—	—
	C: calcium				
Thacher 1999	I1: calcium + vitamin D	Figure given for total group: 55	Figure given for total group: 12–168	—	—
	I2: calcium + placebo				
	C: vitamin D + placebo				

—: denotes not reported.

C: comparator; I: intervention.

Appendix 7. Matrix of study endpoints (publications and trial documents)

Study ID	Endpoints

Study limitations (risk of bias)^a	Was random sequence generation used (i.e. no potential for selection bias)?	Unclear	Unclear	NR	NR	NR	NR	NR
	Was allocation concealment used (i.e. no potential for selection bias)?	Yes	Yes					
	Was there blinding of participants and personnel (i.e. no potential for performance bias) or outcome not likely to be influenced by lack of blinding?	Unclear	Unclear					
	Was there blinding of outcome assessment (i.e. no potential for detection bias) or was outcome measurement not likely to be influenced by lack of blinding?	Yes	Yes					
	Was an objective outcome used?	Yes	Yes					
	Were more than 80% of participants enrolled in studies included in the analysis (i.e. no potential reporting bias)? ^b	Yes	Yes					
	Were data reported consistently for the outcome of interest (i.e. no potential selective reporting)?	Unclear	Unclear					
	No other biases reported (i.e. no potential of other bias)?	Yes	Yes					
	Did the studies end up as scheduled (i.e. not stopped early)?	Yes	Yes					

(Continued)

Inconsistency^c	Point estimates did not vary widely?	NA	NA
	To what extent did confidence intervals overlap (substantial: all confidence intervals overlap ≥ 1 of the included studies point estimate; some: confidence intervals overlap but not all overlap ≥ 1 point estimate; no: ≥ 1 outlier: where the confidence interval of some of the studies do not overlap with those of most included studies)?	NA	NA
	Was the direction of effect consistent?	NA	NA
	What was the magnitude of statistical heterogeneity (as measured by I^2 statistic) low ($I^2 < 40\%$), moderate ($I^2 40\text{--}60\%$), high ($I^2 > 60\%$)?	NA	NA
	Was the test for heterogeneity statistically significant ($P < 0.1$)?	NA	NA
Indirectness	Were the populations in included studies applicable to the decision context?	Highly applicable	Highly applicable
	Were the interventions in the included studies applicable to the decision context?	Highly applicable	Highly applicable
	Was the included outcome not a surrogate outcome?	Yes	Yes
	Was the outcome timeframe sufficient?	Sufficient	Sufficient
	Were the conclusions based on direct comparisons?	Yes	Yes
Imprecision^d	Was the confidence interval for the pooled estimate not consistent with benefit and harm?	Yes	No (\downarrow)
	What is the magnitude of the median sample size (high: 300 participants, intermediate: 100–300 participants, low: <100 participants)? ^e	Low (\downarrow)	Low (\downarrow)

(Continued)

	What was the magnitude of the number of included studies (large: >10 studies, moderate: 5–10 studies, small: < 5 studies)? ^e	Small (↓)	Small (↓)
	Was the outcome a common event (e.g. occurs more than 1/100)?	Yes	Yes
Publication bias	Was a comprehensive search conducted?	Yes	Yes
	Was grey literature searched?	Yes	Yes
	Were no restrictions applied to study selection on the basis of language?	Yes	Yes
	There was no industry influence on studies included in the review?	Yes	Yes
	There was no evidence of funnel plot asymmetry?	NA	NA
	There was no discrepancy in findings between published and unpublished studies?	Unclear	Unclear

^aQuestions on risk of bias are answered in relation to the majority of the aggregated evidence in the meta-analysis rather than to individual studies.

^bDepends on the context of the systematic review area.

^cQuestions on inconsistency are primarily based on visual assessment of forest plots and the statistical quantification of heterogeneity based on I^2 statistic.

^dWhen judging the width of the confidence interval it is recommended to use a clinical decision threshold to assess whether the imprecision is clinically meaningful.

^eQuestions address comprehensiveness of the search strategy, industry influence, funnel plot asymmetry and discrepancies between published and unpublished studies.

(↓): key item for potential downgrading the quality of the evidence (GRADE) as shown in the footnotes of the 'Summary of finding' table(s); NA: not applicable; NR: not reported.

Appendix 15. Checklist to aid consistency and reproducibility of GRADE assessments (vitamin D plus calcium versus vitamin D)

		(1) Healing of rickets (normal alkaline phosphatase and bone radiograph at 24 weeks)	(2) Morbidity (fractures at 24 weeks)	(3) Adverse events	(4) All-cause mortality	(5) Growth pattern	(6) Health-related quality of life	(7) Socio-economic effects
Study limitations (risk of bias)^a	Was random sequence generation used (i.e. no potential for selection bias)?	Unclear	Unclear	Yes	NR	NR	NR	NR
	Was allocation concealment used (i.e. no potential for selection bias)?	Yes	Yes	Yes				
	Was there blinding of participants and personnel (i.e. no potential for performance bias) or outcome not likely to be influenced by lack of blinding?	Unclear	Unclear	No (↓)				
	Was there blinding of outcome assessment (i.e. no potential for detection bias) or was outcome measurement not likely to be influenced by lack of blinding?	Yes	Yes	Yes				
	Was an objective outcome used?	Yes	Yes	Yes				
	Were more than 80% of participants enrolled in studies included in the analysis (i.e. no potential reporting bias)? ^e	Yes	Yes	No (↓)				
	Were data reported consistently for the outcome of interest (i.e. no potential selective reporting)?	Unclear	Unclear	Yes				
	No other biases reported (i.e. no potential of other bias)?	Yes	Yes	Yes				
	Did the studies end up as scheduled (i.e. not stopped early)?	Yes	Yes	Yes				

(Continued)

Inconsistency^b	Point estimates did not vary widely?	NA	NA	NA
	To what extent did confidence intervals overlap (substantial: all confidence intervals overlap ≥ 1 of the included studies point estimate; some: confidence intervals overlap but not all overlap ≥ 1 point estimate; no: ≥ 1 outlier: where the confidence interval of some of the studies do not overlap with those of most included studies)?	NA	NA	NA
	Was the direction of effect consistent?	NA	NA	NA
	What was the magnitude of statistical heterogeneity (as measured by I^2 statistic) low ($I^2 < 40\%$), moderate ($I^2 40\text{--}60\%$), high $I^2 > 60\%$)?	NA	NA	NA
	Was the test for heterogeneity statistically significant ($P < 0.1$)?	NA	NA	NA
Indirectness	Were the populations in included studies applicable to the decision context?	Highly applicable	Highly applicable	Highly applicable

CONTRIBUTIONS OF AUTHORS

All review authors contributed to, read and approved the final review draft.

Moriam T Chibuzor (MC): protocol draft, acquisition of study reports, study selection, data extraction, data analysis, data interpretation, review of drafts and review updates.

Diepiriye Graham-Kalio (DG): protocol draft, acquisition of study reports, study selection, data extraction, data analysis, data interpretation and review updates.

Joy O Osaji (JO): protocol draft, acquisition of study reports, study selection, data extraction and review updates.

Martin M Meremikwu (MM): protocol draft, data analysis, data interpretation and review updates.

DECLARATIONS OF INTEREST

MC: This review was partly funded by a grant from Department for International Development (DFID) through UKAid funding provided to the Effective Health Care Research Consortium at the Liverpool School of Tropical Medicine.

DG: none known.

JO: none known.

MM: none known.

SOURCES OF SUPPORT

Internal sources

- No sources of support supplied

External sources

Grant: HRPC09 Evidence Building and Synthesis Research

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We did not search Embase, as specified in the protocol (Chibuzor 2017), because this database is no longer available to us. Randomised controlled trials indexed in Embase are now prospectively added to CENTRAL via a highly sensitive screening process.

We did not perform subgroup or sensitivity analyses or draw funnel plots due to the limited number of studies.

NOTES

Portions of the background and methods sections, the appendices, additional tables and figures of this review are based on a standard template established by the Cochrane Metabolic and Endocrine Disorders Group.

INDEX TERMS

Medical Subject Headings (MeSH)

Calcium [*therapeutic use]; Fractures, Bone [epidemiology] [prevention & control]; Randomized Controlled Trials as Topic; Rickets [etiology] [*therapy]; Vitamin D [*therapeutic use]; Vitamin D Deficiency [complications] [therapy]; Vitamins [*therapeutic use]

MeSH check words

Adolescent; Child; Child, Preschool; Humans; Infant
