

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

## Letter to the Editor

SARS CoV-2 viral load might not be the right predictor of COVID-19 mortality<sup>☆</sup>

In their recent correspondence, Pujadas et al. have reported SARS-CoV-2 viral load at diagnosis as an independent predictor of mortality. They've reported the Mean log<sub>10</sub> viral load significantly differed between patients who were alive (n=807; mean log<sub>10</sub> viral load 5.2 copies per mL [SD 3]) versus those who had died (n=338; 6.4 copies per mL [2.7]) by the end of the study period.<sup>1</sup> The author would like to argue the clinical significance of their findings as it's apparent from the standard deviation of their reported results that some patients have survived though their initial detected viral load has been like or above the mean viral load in the deceased group and vice versa. Noteworthy, a systematic review of literature has previously demonstrated that seven studies observed increases in SARS CoV-2 viral loads prior to clinical deterioration and vice versa, yet it's also reported other seven studies that found little to no difference in viral load between pre-symptomatic, asymptomatic and symptomatic patients.<sup>2</sup> In a trial to explain the apparent contradictory results found in different studies as well as the lack of a distinct boundary between the viral loads that might be associated with a higher mortality rate or a higher recovery rate; the author would like to suggest that SARS CoV-2 viral load should be only considered as a personalized reflection of the immune response to COVID-19 as well as of the genetic polymorphisms in SARS CoV-2 receptors.<sup>3</sup> ACE2 polymorphisms might be a better field of study than SARS CoV-2 viral load wishing to develop a genetic test that might predict and exempt, if possible, from COVID-19 related duty those who are more vulnerable to complications and mortality.<sup>4</sup>

## Declaration of Competing Interest

None.

## Funding/financial disclosure

None
