Supporting Information

**ABSTRACT:** Theoretically, the two aldehydes of terephthalaldehyde (TPA) are equivalent, so the single or double Schiff base from TPA and D-glucosamine (Glc) may be formed at the same time. However, it is preferred to produce separately a single Schiff base ( $L_1$ ) or double Schiff base ( $L_2$ ) for different synthesis systems of anhydrous methanol or water–methanol. We calculated the  $\Delta_rG$  of the formation of compounds  $L_1$  and  $L_2$  by density functional theory (DFT). In an anhydrous methanol system, the  $\Delta_rG$  values of  $L_1$  and  $L_2$  are both below zero and  $L_2$  is lower, suggesting the spontaneous formation of the two Schiff bases. Though adjusting the molar ratio of Glc to TPA,  $L_1$  and  $L_2$  both were separately formed in anhydrous methanol. However, in the water–methanol system,  $L_2$  was absent, which is most likely due to higher  $\Delta_rG$  (4.95 eV) and better water solubility. The results also exhibits that the positive charge of C in  $-CHO$  for TPA is smaller in a mixed solvent than that in methanol, which confirms that the nucleophilic reaction of the Schiff base is more difficult in a mixed solvent. Therefore, we could realize to control the synthesis of a pure single or double Schiff base from Glc and TPA by adjusting the molar ratio and solvent. The as-prepared two kinds of Schiff bases have strong optical properties, high bacteriostatic activity, and can be used as fluorescent probes for tumor cell imaging.

## INTRODUCTION

Condensation of carbonyl compounds with primary amines was discovered in 1864 by Hugo Schiff.<sup>1</sup> Thus, this kind of compound is hereafter called the Schiff base. It refers to the reaction between a class of compounds containing aldehydes and the others with amino groups, which results in imine groups ( $-C=N-$ ).<sup>2–4</sup> The Schiff base is not only used as a pigment, dye, catalyst, intermediate in organic synthesis, a supercapacitor, and so on<sup>5–8</sup> but also shows a wide range of biological activities, including anti-fungal, anti-bacterial, anti-malaria, anti-proliferation, anti-inflammatory, anti-virus, etc.<sup>9–13</sup>

As a natural amino monosaccharide, D-glucosamine (Glc) exists in a variety of organisms, and it has excellent biological activity.<sup>14–19</sup> It has a good killing effect on cancer cells but has little cytotoxicity to normal human cells.<sup>20,21</sup> Currently, Glc and its derivatives have attracted more attention due to their special nature of the molecular structure, one amino group, and four hydroxyls. In addition, the various products have been applied in many fields like biology, medicine, and so on.<sup>22</sup> The amino group can condense with aldehyde compounds to prepare the Schiff base. If sugar is introduced into the structure of the Schiff base, then it is expected that the drugs with less toxicity and better anticancer activity can be obtained. In addition, Glc contains rich hydroxyl groups, which can make the synthesized Schiff base with good water solubility.

Therefore, the synthesis of the Schiff base with Glc as a lead compound has important significance in the field of biomedicine and other fields.<sup>23</sup>

At present, some scholars have reported the Schiff bases from Glc; however, few bis-Schiff bases were synthesized from Glc. In this work, we report a single Schiff base and a symmetric bis-Schiff base (marked as  $L_1$  and  $L_2$ ) both from Glc and terephthalaldehyde (TPA). According to previous works,<sup>24,25</sup> the synthesis process of the compounds is designed, as shown in Figure 1, and the two Schiff bases can be separated by adjusting the solvent and molar ratio. The two compounds are with good water solubility, optical properties, and bacteriostatic activity, which could be applied for biological imaging and anti-bacteria.

## RESULTS AND DISCUSSION

Schiff bases  $L_1$  and  $L_2$  were synthesized in different synthesis methods. In the first method ( $M_1$ ), Glc and TPA of different proportions were mixed in anhydrous methanol and reacted

for 50 min at 35 °C and then stood overnight. The difference in the second method ( $M_2$ ) was that it was a mixed solvent of water and methanol where TPA methanol solution was added into Glc aqueous solution and stirred at room temperature for 3 h. The two aldehydes of TPA are equivalent in theory, so the single or double Schiff base should be formed at the same time. However, the results show that, in the anhydrous methanol synthesis system, the product was changed from  $L_1$  to  $L_2$  when the molar ratio of Glc to TPA was from 1:1 to higher than 2:1. However, in water–methanol solution, only  $L_1$  was formed even if the molar ratio was higher than 2:1.

As seen from Figure S2,  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR spectra of compounds  $L_1$  and  $L_2$  are without impurity peak, which proves that the two Schiff bases have high purity. Using compound  $L_1$  as an example, characteristic peaks of  $-\text{HC}=\text{N}-$  appear in both  $^{13}\text{C}$  NMR spectra at 161.79 ppm and  $^1\text{H}$  NMR spectra at 8.32 ppm, indicating that the Schiff base was successfully synthesized. Furthermore, the characteristic peaks of  $-\text{CHO}$  at 193.40 ppm for  $^{13}\text{C}$  NMR and 10.07 ppm for  $^1\text{H}$  NMR also appear for  $L_1$ , which indicates that only one  $-\text{CHO}$  is replaced. For  $L_2$ , the peaks of  $-\text{CHO}$  in  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR spectra are absent.

To explore the synthesis mechanism, we calculated  $\Delta_r G$  of compounds  $L_1$  and  $L_2$  synthesized by two methods, and the values of  $\Delta_r G$  are as follows. Based on the optimized structures, the zero-point-corrected Gibbs free energies ( $G$ ) at 298.15 K were calculated at the  $\omega\text{B97XD}/6\text{-311++g(d, p)}$  level to obtain  $\Delta_r G$  of the considered reactions. As  $\Delta_r G$  shows, in an anhydrous methanol system, the  $\Delta_r G$  values of  $L_1$  and  $L_2$  are both below zero, suggesting the spontaneous formation of the two Schiff bases in which  $L_2$  is easier to generate. Nevertheless, with the water–methanol method, the value of  $\Delta_r G$  is higher than that prepared with  $M_1$ . Furthermore, the  $\Delta_r G_{2,2}$  value is up to 4.95, which indicates the difficult formation of  $L_2$ , and

this phenomenon coincides with the experimental results. The results show that the water solubility of  $L_2$  (20 mg/mL) with rich  $-\text{OH}$  is stronger than that of  $L_1$  (16 mg/mL), although it is highly symmetrical. Furthermore, the positive charge of C in  $-\text{CHO}$  for TPA is smaller in the mixed solvent than that in methanol (Figure 2). The reason for varied charge distribution is that the solvation and dipole moment reduce in water–methanol, resulting in a decrease of charge separation. Because the formation of the Schiff base is a nucleophilic reaction, the low positive charge of C means that the synthesis reaction could be difficult. In the water–methanol system, the absence of  $L_2$  is most likely due to lower positive charge of C atom in  $-\text{CHO}$ , good solubility, and higher formation energy in this system.

$$: \Delta_r G_{2,1} = 0.28$$

$$: \Delta_r G_{2,2} = 4.95$$

where the units are in kcal/mol.

The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) are critical parameters to characterize the kinetic stability of the molecule, and the energy gap between HOMO and LUMO determines the molecular chemical reactivity and stability and explains the intermolecular electrical transport.<sup>26</sup> The orbital distributions and energies of HOMO and LUMO have been performed for the two compounds in different solvents at the  $\omega\text{B97XD}/6\text{-311++g(d, p)}$  level. Orbital distributions and energies of HOMO and LUMO in different solvents are shown in Figure 3. It can be found that HOMO electrons are localized over the

Figure 3. Optimized structures, molecular orbital, and energy level in different solvents for Schiff bases L<sub>1</sub> and L<sub>2</sub>.

glucose, C=N, benzene, and aldehyde of compounds L<sub>1</sub> and L<sub>2</sub>. Meanwhile, LUMO electrons have a centralized distribution in C=N, benzene, and aldehyde of compounds L<sub>1</sub> and L<sub>2</sub>. The orbital energies of HOMO and LUMO for both L<sub>1</sub> and L<sub>2</sub> in a mixed solvent are higher than those in pure methanol or water. As seen in Figure 3, L<sub>1</sub> has a lower LUMO energy level and L<sub>2</sub> has a higher HOMO energy level. It indicates that L<sub>1</sub> is likely to behave as an electron acceptor, and L<sub>2</sub> presents as an electron donor. The energy gap between HOMO and LUMO for compound L<sub>1</sub> is the largest in the mixed solvent but that for L<sub>2</sub> is the smallest. However, the energy gaps for L<sub>1</sub> and L<sub>2</sub> in

the three kinds of solvents are all larger than 8.0 eV, which means good stability of the two compounds.

The organic functional groups of the two compounds were analyzed by Fourier transform infrared (FT-IR) spectra. Figure 4a depicts the FT-IR spectra of compounds L<sub>1</sub> and L<sub>2</sub>, and the data is shown in Table S1. The C=N stretching vibration, which is the most characteristic band of the Schiff base derivatives, occurs at 1640 cm<sup>-1</sup>. The OH stretching bands of the Glc group of compound L<sub>1</sub> are observed in 3481 cm<sup>-1</sup>, while the C-OH stretching bands are found at 1268, 1219, 1165, and 1151 cm<sup>-1</sup>. The observed bands at 603, 573, and 549 cm<sup>-1</sup> can be assigned to the pyranose skeleton, and the

**Figure 5.** (a) Anti-bacterial activity against *S. aureus*, *E. coli*, and *C. albicans*. (b) Cytotoxicity on HepG2 cells for Schiff bases L<sub>1</sub> and L<sub>2</sub>.

**Figure 6.** Inverted fluorescence imaging of HepG2 cells with 20× objectives. (a) Bright-field image of HepG2 cells, (b) HepG2 cells stained with DAPI, (c) HepG2 cells stained with the Schiff bases, and (d) the overlay image.

band at  $1087\text{ cm}^{-1}$  belongs to pyran ether. The  $\text{C}=\text{C}$  bands of the aromatic nucleus are observed at 1572, 1439, and  $1410\text{ cm}^{-1}$ . Characteristic absorption peaks of  $\text{C}=\text{N}$ , the sugar ring, and the aromatic nucleus appear in FT-IR spectra at the same time, which illustrates the formation of the Schiff base. What is more, the FT-IR spectra of compound L<sub>1</sub> show the characteristic absorption peaks of  $-\text{CHO}$  at  $1689\text{ cm}^{-1}$  while those of compound L<sub>2</sub> disappear, which proves that the two  $-\text{CHO}$  groups are all replaced and also confirms the formation of compound L<sub>2</sub>.

The UV-vis absorption spectra of the compounds (1 mg/mL) in ultrapure water were recorded within 200–800 nm at room temperature. From Figure 4b, we can see that the spectra of the two Schiff bases are similar. The strong absorption peak at 200 nm is caused by the  $\pi-\pi^*$  transition of the  $\text{C}=\text{N}$  connected with the sugar ring. The absorption peak of aromatic aldehydes is generally about 250 nm,<sup>25</sup> while the Schiff bases have a stronger absorption due to the larger conjugated carbon  $\pi$ -system. The absorption peaks of compounds L<sub>1</sub> and L<sub>2</sub> can be attributed to  $n-\pi^*$  at 266 nm.

The fluorescence excitation and emission spectra of Schiff bases (1 mg/mL) in ultrapure water were determined at room temperature (see Figure 4c). The excitation wavelength was 360 nm, and the emission wavelength was about 450 nm. Since the Schiff base molecules contain a  $\pi$ -electron conjugated system and an aromatic nucleus with a rigid plane structure,

the synthesized molecules L<sub>1</sub> and L<sub>2</sub> have good fluorescence performance. The emission QY values of L<sub>1</sub> and L<sub>2</sub> are 5.65 and 15.28%, respectively. It can be seen from Figure 3c that the different substituents attached to the aromatic nucleus caused different fluorescence wavelengths. Even so, the fluorescence spectra are very similar due to similar structures.

To research the anti-bacterial activity of compounds L<sub>1</sub> and L<sub>2</sub>, the OD<sub>600</sub> of the bacteria after being treated with the two Schiff bases (0.08 mg/mL) for 24 h were recorded, including *Staphylococcus aureus*, *Escherichia coli*, and *Candida albicans*. As shown in Figure 5a, L<sub>1</sub> and L<sub>2</sub> at the low concentration have the best bacteriostatic effect on *C. albicans* with an inhibition rate of about 70% and the second one is *S. aureus*. L<sub>2</sub> has a certain inhibitory effect on *E. coli*, whereas L<sub>1</sub> has no inhibitory effect on *E. coli* at all. Nevertheless, as shown in Figure S1a, the inhibition rates of Glc (0.08 mg/mL) against *S. aureus*, *E. coli*, and *C. albicans* are 3.26, 12.04, and 2.58%, respectively, and those for TPA are 8.00, 15.66, and 2.79%, respectively. Overall, the two Schiff bases synthesized in this study have good bacteriostatic activity, which is competitive compared with other Schiff bases derived from D-glucosamine.<sup>27</sup> It can also be found that the bacteriostatic effect of L<sub>2</sub> is better than that of L<sub>1</sub>. The previous study has established that the presence of imine or azomethine subunits in various compounds was critical to their biological activities.<sup>28</sup> Accordingly, the

bacteriostatic activity of the double Schiff base ( $L_2$ ) is better than that of the single Schiff base ( $L_1$ ).

For the study of cytotoxicity for the two Schiff bases, the MTT test was carried out. In the test, the human hepatocellular carcinoma cells (HepG2 cells)<sup>29</sup> were dyed with 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) and treated with various concentrations of the two compounds for 24 h. Then, an absorbance at 490 nm was measured to calculate the cell survival rate. The larger the absorption at 490 nm after drug treatment, the smaller the cytotoxicity. Figure 5b displays the cytotoxicity of compounds  $L_1$  and  $L_2$  to HepG2 cells. The cell survival rate is more than 70% at even a concentration of 100  $\mu\text{g}/\text{mL}$ . At the same concentration, the cell survival rate of TPA is lower than 55% (Figure S1b). This demonstrates that both  $L_1$  and  $L_2$  have low cytotoxicity and good biocompatibility, which provided potential possibilities for bioimaging. Overall, because of the  $-\text{CHO}$  of  $L_1$ , the cytotoxicity of  $L_1$  is higher than that of  $L_2$ .

The feasibility of fluorescence imaging with compounds  $L_1$  and  $L_2$  in HepG2 cells was studied (Figure 6). It exhibits that compounds  $L_1$  and  $L_2$  can be used as a fluorescent probe for tumor cell imaging. The bright-field images of HepG2 cells and HepG2 cells stained with 4',6-diamidino-2-phenylindole (DAPI) are shown in Figure 5a and Figure 5b, respectively. After being incubated with compounds  $L_1$  and  $L_2$  for 1 h, the HepG2 cells show a clear and bright green fluorescence stimulated by a blue channel, and the image background is clean. It demonstrates that compounds  $L_1$  and  $L_2$  have excellent permeability of the cell membrane, which made it easy to dye HepG2 cells (Figure 5c). In addition, the overlay image in Figure 5d displays that the staining position of compounds  $L_1$  and  $L_2$  on cells overlaps with that of DAPI nuclear dyes, and the cytoplasmic part also shows the green fluorescence, which indicates that compounds  $L_1$  and  $L_2$  can enter both the cytoplasm and nucleus.

d

## CONCLUSIONS

In this work, two new Schiff bases  $L_1$  and  $L_2$  were prepared, which have strong optical properties and high anti-bacterial activity. Therefore, the prepared Schiff bases can be used as fluorescent probes for tumor cell imaging. Comparing the two compounds, the advantages of water solubility, bacteriostatic activity, and cytotoxicity of  $L_2$  are better than those of  $L_1$ . It is worth noting that we have realized the controllable synthesis of single and double Schiff bases by adjusting the molar ratio of Glc to TPA and explained the selection of the reaction mechanism.

## EXPERIMENTAL SECTION

All chemicals were obtained from commercial suppliers and used without further purification. The  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded in  $\text{DMSO}-d_6$  on a Bruker ascend 500 m spectrometer operating at 500 and 126 MHz. Mass spectrometry was collected by a Solan 70 FT-MS high-resolution mass spectrometer in  $\text{DMSO}$  with an electrospray ionization source (ESI). IR spectra were obtained using a Nicolet ISS0 FT-IR spectrometer with KBr pellets in the range of 400–4000  $\text{cm}^{-1}$ . The data of elemental analysis were measured by an Elementar Vario EL cube organic element analyzer. UV-vis spectra were measured using a Shimadzu UV-2600 spectrophotometer. Fluorescence measurement was

performed at room temperature on a Cary Eclipse fluorescence spectrometer in a 300  $\mu\text{L}$  quartz cuvette. Cell imaging was performed on a DFC450C inverted fluorescence microscope (Leica, Germany).

**Synthesis of Schiff Base.** Glc hydrochloride (2.5 mmol), NaOH (2.5 mmol), and anhydrous methanol (5 mL) were added into a 50 mL beaker. The mixture was stirred and refluxed for 5 min, and then, NaCl was filtered out.

Terephthalaldehyde (TPA) (2.5 mmol) anhydrous methanol solution was slowly added to the filtrate and reacted for 50 min by stirring at 35  $^\circ\text{C}$ . The white precipitate was formed for one night. Finally, the solid was filtered and washed several times with cold anhydrous methanol. This is the first system to prepare the Schiff base, marking as  $M_1$ . Compound  $L_1$  was obtained by air drying (yield 70.98%). M.wt.: 295.286; MS (ESI) ( $[\text{M} + \text{Na}]^+$ ) = 318.095 (Figure S3).  $^1\text{H}$  NMR (500 MHz,  $\text{DMSO}-d_6$ ),  $\delta$  ppm, 2.91 (t, 1H,  $\text{CH}_2$ ), 3.18–3.49 (m, 4H, GlcH), 3.70–3.78 (m, 1H,  $\text{CH}_2$ ), 4.62 (t, 1H, OH), 4.78 (t, 1H, OH), 4.98 (d, 1H, CH-N), 5.04 (d, 1H, OH), 6.67 (d, 1H, OH), 7.99 (s, 4H, ArH), 8.32 (s, 1H,  $-\text{CH}=\text{N}-$ ), 10.07 (s, 1H,  $-\text{CHO}$ ) (Figure S2).  $^{13}\text{C}$  NMR (126 MHz,  $\text{DMSO}-d_6$ ),  $\delta$  ppm, 95.87–61.68 (6C, GlcC), 141.61–129.04 (4C, ArC), 161.79 (1C,  $-\text{C}=\text{N}-$ ), 193.40 (1C,  $-\text{CHO}$ ) (Figure S2).<sup>25</sup>

The synthetic method of compound  $L_2$  was similar to that of  $L_1$  where the amount of TPA was changed to 1 mmol, and the other steps were the same (yield 51.80%). M.wt.: 456.444; MS (ESI) ( $[\text{M} + \text{Na}]^+$ ) = 479.164 (Figure S3).  $^1\text{H}$  NMR (500 MHz,  $\text{DMSO}-d_6$ ),  $\delta$  ppm, 2.93–2.84 (m, 1H,  $\text{CH}_2$ ), 3.17–3.54 (m, 4H, GlcH), 3.70–3.78 (ddd, 1H,  $\text{CH}_2$ ), 4.59 (t, 1H, OH), 4.75 (t, 1H, OH), 4.92 (d, 2H, CH-N), 4.98 (d, 1H, OH), 6.62 (d, 1H, OH), 7.83 (s, 2H, ArH), 8.25 (s, 1H,  $-\text{CH}=\text{N}-$ ) (Figure S2).  $^{13}\text{C}$  NMR (126 MHz,  $\text{DMSO}-d_6$ ),  $\delta$  ppm, 95.94–61.69 (6C, GlcC), 138.31–128.68 (4C, ArC), 162.13 (1C,  $-\text{C}=\text{N}-$ ) (Figure S2).

For the second method (marked as  $M_2$ ), due to the different solubility of Glc and TPA, the water–methanol method was used to synthesize the Schiff base. Glc hydrochloride (2.5 mmol),  $\text{NaHCO}_3$  (2.5 mmol), and ultrapure water (5 mL) were added to a 50 mL beaker. After complete dissolution, 5 mL of 2.5 mmol of TPA anhydrous methanol solution was added and the mixture was stirred at room temperature for 3 h. Compound  $L_1$  was obtained overnight from the reaction solution. Surprisingly, no compound  $L_2$  was formed even if the amount of TPA was changed to 1 mmol (yield 73.95%). The elemental analysis of compounds  $L_1$  and  $L_2$  is shown in Table 1.

**Table 1. Elemental Analysis of Compounds  $L_1$  and  $L_2$**

compound	measured value	theoretical value
$L_1$	C56.40, H5.80, O33.39, N4.47	C56.95, H5.75, O32.54, N4.75
$L_2$	C49.04, H6.68, O38.67, N5.61	C52.62, H6.18, O35.05, N6.14

**Computational Procedures.** All the density functional theoretical (DFT) calculations in this work were carried out by using the  $\omega\text{B97XD}$  density functional in conjunction with the 6-311++G(d, p) split valence basis set in the GAUSSIAN 16 software package.<sup>30</sup> The analyses of vibration frequencies have been also implemented at the same theoretical level to make sure that all the optimized structures are true minima without any imaginary frequencies on their potential energy surfaces. Based on the optimized structures, the zero-point-corrected

Gibbs free energies ( $G$ ) at 298.15 K were calculated at the  $\omega$ B97XD/6-311++g(d, p) level to obtain  $\Delta_r G$  of the considered reactions. The solvation model based on density (SMD)<sup>31</sup> was used to take the effect of the solvent into account in all the calculations. Dimensional plots of molecular configurations and orbitals were generated with the GaussView program.<sup>32</sup>

**Anti-Bacterial Activity.** The anti-bacterial activity of the drugs (compounds  $L_1$  and  $L_2$ ) was studied by the 96-well plate titration method. The bacteria were plated in a Luria–Bertani (LB) medium composed of tryptone, yeast extract, and sodium chloride. The specific process was as follows: *S. aureus*, *E. coli*, and *C. albicans* were resuscitated by adding 5 mL of the LB medium to the freeze-dried bacterial powders overnight. After that, amplification was cultured by adding 5 mL of the LB medium to 1 mL of the resuscitated bacterial solutions. The experiment was carried out when the value of OD 600 nm reached 0.6 (logarithmic growth period). We prepared 0.08 mg/mL of the drugs with ultrapure water. The *S. aureus*, *E. coli*, and *C. albicans* solution were evenly planted into a 96-well plate with 100  $\mu$ L per hole, and then, the drug solutions were added into the plate with 100  $\mu$ L per hole. The value of OD 600 nm was measured after incubating at 37 °C for 24 h.

**Cytotoxicity Study.** The cytotoxicity of compounds  $L_1$  and  $L_2$  to HepG2 cells was studied following a reported MTT test. 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium bromide (MTT)<sup>33</sup> is a yellow dye, which can specifically recognize living cells. Briefly, (i) HepG2 cells in the logarithmic phase were seeded into a 96-well plate at 10,000 cells per well and grown in an incubator (37 °C, 5% CO<sub>2</sub>) for 24 h. (ii) These cells were incubated with 100  $\mu$ L of compounds  $L_1$  or  $L_2$  (0, 6.25, 12.5, 25, 50, and 100  $\mu$ g/mL) for 24 h. (iii) MTT solution (100  $\mu$ L, 1.0 mg/mL) was added into each well and then coincubated for 4 h. (iv) The supernatant was removed, and 150  $\mu$ L of DMSO was added. The absorbance at 490 nm was measured by a microplate reader after shaking for 10 min. (v) The cell survival rate was acquired by  $A/A_0 \times 100\%$  ( $A$  and  $A_0$  represent the absorbance of the  $L_1$  or  $L_2$  treat group and control group, respectively).

**In Vitro Cell Imaging.** Human cancer cells were seeded into a Petri dish at a density of  $10 \times 10^4$  cells per well and cultured in a Roswell Park Memorial Institute (RPMI) medium supplemented with 10% fetal bovine serum (FBS) and 1% PS in an incubator (37 °C, 5% CO<sub>2</sub>) for 24 h. Then, the medium was removed and the adherent cells were washed with phosphate-buffered saline (PBS) three times. Subsequently, 1 mL of the incomplete medium containing compounds  $L_1$  or  $L_2$  (39.22  $\mu$ g/mL) was added to the wells. After incubation for 1 h, the medium was cleaned with PBS three times and dyed with 4',6-diamidino-2-phenylindole (DAPI) (1  $\mu$ g/mL) PBS solution for 10 min. DAPI can emit a blue fluorescence to sign the cell nucleus.<sup>34</sup> Then, it was cleaned with PBS twice, and 1 mL of 2.5% GD was used to fixed cells for 10 min. Before imaging, the solution was removed, and then, the cells were washed with PBS three times. The bright-field and fluorescent images of cells were obtained on an inverted fluorescence microscope.
