Abstract

BACKGROUND

Since the beginning of the pandemic, coronavirus disease-2019 (COVID-19) in children has shown milder cases and a better prognosis than adults. Although the respiratory tract is the primary target for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), cardiovascular involvement is emerging as one of the most significant and life-threatening complications of SARS-CoV-2 infection in adults.

AIM

To summarize the current knowledge about the potential cardiovascular involvement in pediatric COVID-19 in order to give a perspective on how to take care of them during the current pandemic emergency.

METHODS

Multiple searches in MEDLINE, PubMed were performed using the search terms "COVID-19" or "SARS-CoV-2" were used in combination with "myocardial injury" or "arrhythmia" or "cardiovascular involvement" or "heart disease" or "congenital heart disease" or "pulmonary hypertension" or "long QT" or

"cardiomyopathies" or "channelopathies" or "Multisystem inflammatory system" or "PMIS" or "MIS-C" or "Pediatric multisystem inflammatory syndrome" or "myocarditis" or "thromboembolism to identify articles published in English language from January 1st, 2020 until July 31st, 2020. The websites of World Health Organization, Centers for Disease control and Prevention, and the Johns Hopkins Coronavirus Resource Center were reviewed to provide up to date numbers and infection control recommendations. Reference lists from the articles were reviewed to identify additional pertinent articles. Retrieved manuscripts concerning the subject were reviewed by the authors, and the data were extracted using a standardized collection tool. Data were subsequently analyzed with descriptive statistics. For Pediatric multisystemic inflammatory syndrome temporally associated with COVID-19 (PMIS), multiple meta-analyses were conducted to summarize the pooled mean proportion of different cardiovascular variables in this population in pseudo-cohorts of observed patients.

RESULTS

A total of 193 articles were included. Most publications used in this review were single case reports, small case series, and observational small-sized studies or literature reviews. The meta-analysis of 16 studies with size > 10 patients and with complete data about cardiovascular involvement in children with PMIS showed that PMIS affects mostly previously healthy school-aged children and adolescents presenting with Kawasaki disease-like features and multiple organ failure with a focus on the heart, accounting for most cases of pediatric COVID-19 mortality. They frequently presented cardiogenic shock (53%), ECG alterations (27%), myocardial dysfunction (52%), and coronary artery dilation (15%). Most cases required PICU admission (75%) and inotropic support (57%), with the rare need for extracorporeal membrane oxygenation (4%). Almost all of these children wholly recovered in a few days, although rare deaths have been reported (2%). Out of PMIS cases we identified 10 articles reporting sporadic cases of myocarditis, pulmonary hypertension and cardiac arrhythmias in previously healthy children. We also found another 10 studies reporting patients with pre-existing heart diseases. Most cases consisted in children with severe COVID-19 infection with full recovery after intensive care support, but cases of death were also identified. The management of different cardiac conditions are provided based on current guidelines and expert panel recommendations.

CONCLUSION

There is still scarce data about the role of cardiovascular involvement in COVID-19 in children. Based on our review, children (previously healthy or with pre-existing heart disease) with acute COVID-19 requiring hospital admission should undergo a cardiac workup and close cardiovascular monitoring to identify and treat timely life-threatening cardiac complications.

Key Words: COVID-19; SARS-CoV-2; Congenital heart diseases; Myocardial dysfunction; Pediatric Multisystem Inflammatory Syndrome; Cardiac Biomarkers

Core Tip: Cardiovascular involvement has emerged as a remarkable risk-factor for poor outcomes of primary respiratory diseases such as coronavirus disease-2019 (COVID-19). Nevertheless, the body of evidence of cardiac complications in pediatric COVID-19 is still scarce to extract definitive conclusions about the adequate management for these patients. This review establishes a perspective on how COVID-19 impacts on the heart of both previously healthy children and those with pre-existing heart diseases, and how to take care of them during the current pandemic emergency.

INTRODUCTION

The coronavirus disease-2019 (COVID-19) was first discovered in a cluster of patients with severe respiratory symptoms in Hubei Province, China, in December 2019^[1,2]. By early January 2020, analysis of bronchoalveolar lavage (BAL) fluid from infected patients revealed that COVID-19 is caused by the novel coronavirus strain, named the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)^[3], a single-stranded RNA virus belonging to the beta genus coronavirus in the coronaviridae family. COVID-19 rapidly swept China and spread worldwide, becoming a global pandemic causing significant mortality and morbidity^[4]. The current count of confirmed cases and deaths from COVID-19 worldwide can be found at the website of the Johns Hopkins Coronavirus Resource Center. At the time of this review (July 31, 2020), COVID-19 has caused more than 18 million cases and an estimate of more than 700000 associated deaths^[5].

Since the beginning of the pandemic, COVID-19 in children has shown milder cases and a better prognosis than adults^[6]. Children have worldwide so far accounted for approximately 2%-5% of diagnosed COVID-19 cases^[7-14]. A review of 72314 patients by the Chinese Center for Disease Control and Prevention showed that only 1% of COVID-19 cases were in children younger than 10 years old^[15]. Epidemiological studies have consistently demonstrated across the world that children are at a lower risk of developing severe symptoms or critical illness compared with adults. Dong *et al*^[16] reported, in the most extensive pediatric study in China, that only 5.2% had severe disease, while 0.6% had a critical illness, with a low case-fatality rate of less than 0.1%. In North America, data from the Centers for Disease Control and Prevention (CDC) as of March 2020 found that 2% to 3% of pediatric patients with positive SARS-CoV-2 testing required hospitalization, with hospitalization rates for children of 0.3/100000 in patients aged 0 to 4 years and 0.1/100000 in patients aged 5 to 17 years. At the time of this publication, there had been relatively few reported cases of pediatric deaths attributed to COVID-19. In the United States the CDC reported a total of 121/391814 (0.03%) deaths associated with SARS-CoV-2 infection among persons aged < 21 years from February to July 2020. This supposed 121/190000 (0.06%) of all reported death associated with COVID-19 in the same period. The median age of death in this age group was 16 years, with 30% of deaths occurring in children younger than 10 years old^[17-21]. DeBiasi *et al*^[22] reported that 9/177 (5%) cases of confirmed COVID-19 required pediatric intensive care unit (PICU) admission (no mortality) in Washington, DC Metropolitan region. Chao *et al*^[23] observed in New York City that 13/67 (28%) of pediatric COVID-19 cases required PICU admission with a mortality rate of 1.5%. Shekerdemian *et al*^[24] reported that only 48 pediatric cases required PICU admission between March 14 and April 3, 2020, in 46 North American PICUs, with a mortality rate of 4%. Götzinger *et al*^[25] in a multicenter (82 hospitals) cohort study, including 582 individuals with PCR-confirmed SARS-CoV-2 infection across 25 European countries, found that 363 (62%) individuals were admitted to hospital and 48 (8%) individuals required PICU admission. Only four children died (case-fatality rate 0.69%) suggesting that the case-fatality rate of COVID-19 in children is substantially lower than in older adult patients. The mechanism by which children seem less susceptible to severe infection caused by SARS-CoV-2 has yet to be elucidated (Table 1)^[26-31].

Clinical manifestations of COVID-19 in children overlap with many other pediatric viral infections. Most commonly, children presented with a mild flu-like state that can progress to potentially lethal acute respiratory distress syndrome, fulminant pneumonia, and multi-organ failure^[10,32-35]. Although the respiratory tract is the primary target for SARS-CoV-2, the virus may interact with the cardiovascular system producing myocardial injury through different mechanisms (Table 2)^[36-40], increasing morbidity in both, previously healthy patients and those with underlying cardiovascular conditions. Thus, cardiovascular involvement is emerging as one of the most significant and life-threatening complications of SARS-CoV-2 infection in adults^[41,42].

Given the smaller numbers of pediatric cases of COVID-19 regarding adults, there is still scarce data about the role of cardiovascular involvement in COVID-19 in children. Of note, up to 34% of children with COVID admitted to the PICU in Spain presented with signs of heart dysfunction^[43]. Besides, there is a suggestion that, as with other

Table 1 Hypothesized mechanism for the lower susceptibility of children to coronavirus disease-2019

Factor involved	Explanation
ACE2 receptor	The ACE2 receptor is necessary for the entry of the COVID-19 into the cells. It is postulated that in children the development, function, or activity of this protein could be lower. Also, ACE2 receptors are up-regulated in those with chronic obstructive pulmonary disease or hypertension, which may partially explain more serious disease in those with comorbid conditions.
Reduced exposures	Children may have fewer opportunities than adults to be exposed to the virus or to those with COVID-19. Children have fewer outdoor activities and make fewer international trips, making infection less likely. Compared to adults, children have had less lifetime exposure to toxins such as cigarette smoke and air pollution, factors which may affect the health of an individual's epithelium.
Comorbidities	Compared to adults, children have a low rate of comorbidities and most children with COVID-19 infection are young and previously healthy.
Other viruses	Children are susceptible to a wide variety of viral illnesses. The presence of other viruses may limit COVID-19 infection by competitive mechanism. In addition, cross-reactive antibodies generated by exposure to other viruses may cause a partial protective response.
Inflammatory response	Children have fewer pro-inflammatory cytokines secretion than adults. This may mean that adults experience a more pronounced inflammatory response than children with a similar exposure to SARS-CoV-2.
Immune response	Children have a more active innate immune response than adults. The innate immune system, which acts earlier than the adaptive immune response, is more active in children, and may prevent more serious illness. Natural involution of the thymus over time leads to a decline in circulating naïve T cells. Due to this normal process, immune systems in adults are less able to be adaptive than those of children.

ACE2: Angiotensin-converting enzyme 2; COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2.

Table 2 Hypothesized pathophysiological mechanisms for cardiac injury in coronavirus disease-2019

Mechanism	Explanation
COVID-19-related myocarditis	SARS-CoV-2 may directly cause myocardial damage by entering cardiomyocytes using the ACE2 receptor, a human cell receptor with a strong binding affinity to the virus spike protein of SARS-CoV-2 (highly expressed in the heart). The virus is also capable of active CD8+ T lymphocytes migrate to the cardiomyocytes and cause myocardial inflammation through cell-mediated cytotoxicity. There is evidence demonstrating that SARS-CoV-2 infects the myocardial tissue.
Deregulated immune response & cytokine storm	SARS-CoV-2 infection may lead to deregulated immune response with higher neutrophil-lymphocyte-ratio, lower levels of both T helper and T suppressor cells, and higher expression of pro-inflammatory cytokines (IFN- γ , TNF, IL-1, IL-6 and IL-18), which are released into the circulation. This cytokine storm syndrome has a role in cardiovascular system injury, causing multi-system inflammation and multi-organ failure with direct cardiotoxicity and rapid onset of severe cardiac dysfunction, hemodynamically instability and vascular leakage with peripheral and pulmonary edema.
Oxygen supply and demand imbalance	Myocardial injury may result from the imbalance between oxygen supply and demand due to a severe acute respiratory distress syndrome and systemic hypotension with myocardial hypo-perfusion in association with increased cardio metabolic demand in the myocardial tissue. This can result in myocytes hypoxia and necrosis.
Thromboembolic events	The systemic inflammation secondary to the cytokine storm also causes endothelial dysfunction and increases the procoagulant activity of the blood, which can further contribute to the formation of multi-organ micro thrombi and also occlusive thrombi over a ruptured coronary plaque.
Cardiotoxicity of drugs used against SARS-CoV-2	Off-label drugs available for COVID-19 treatment can produce myocardial dysfunction, severe systemic hypotension, QT prolongation with ventricular arrhythmia and AV block
Deleterious effects of inotropes and mechanical ventilation	Mechanical ventilation in critically ill children is another possible cause of cardiovascular adverse effects, such as a decrease in cardiac output due to decreased venous return to the right heart, right ventricular dysfunction, and impaired left ventricular elastics. Increased right ventricular after-load due to the pulmonary infection can be worsened by mechanical ventilation with high PEEP, leading to right ventricular failure and subsequent myocardial injury. Inotropes can provoke an increased cardio metabolic demand during an hypoxic condition,
Pre-existing Heart diseases	Patients with pre-existing heart diseases have increased morbidity and mortality related to viral infection It is reasonable to assume that patients with underlying heart diseases with low cardiopulmonary reserve are susceptible to cardiac injury, and once such patients are infected with COVID-19, myocardial ischemia or infarction, and left ventricular systolic dysfunction or ventricular arrhythmia are more likely to occur, ultimately leading to a sudden deterioration.

ACE2: Angiotensin-converting enzyme 2; COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2; IFN: Interferon; TNF: Tumor necrosis factor; IL: Interleukin.

viral illnesses such as respiratory syncytial virus or influenza, children with underlying cardiac conditions are also at greater risk of cardiac complications or develop a more severe SARS-CoV-2 infection^[21]. Furthermore, from April 2020, increasing cases of previously healthy children showing a hyper-inflammatory state and features similar to Kawasaki-Shock disease are being reported in Europe and

America^[44-49]. Remarkably, initial reports suggest many of these patients have myocardial dysfunction and coronary artery involvement with high requirements of PICU admission, hemodynamic, and respiratory support. All the above brings out that cardiovascular involvement could be a significant risk factor for severe COVID-19 in children. Thus, all health care providers must be aware of the potential impact of COVID-19 on children.

In this article, we aimed to summarize the current knowledge about the potential cardiovascular involvement in pediatric COVID-19 to give a perspective on how to take care of them during the current pandemic emergency.

MATERIALS AND METHODS

A literature search was conducted by all the authors using PubMed and MEDLINE. Also, the websites of the health organizations including World Health Organization and CDC and the website of the Johns Hopkins Coronavirus Resource Center were reviewed to provide up to date numbers and infection control recommendations. Multiple searches were performed during the writing of this article, as the COVID-19 pandemic is still evolving. Search terms "COVID-19" or "SARS-CoV-2" were used in combination with "myocardial injury" or "arrhythmia" or "cardiovascular involvement" or "heart disease" or "congenital heart disease" or "pulmonary hypertension" or "long QT" or "cardiomyopathies" or "channelopathies" or "Multisystem inflammatory system" or "PMIS" or "MIS-C" or "Pediatric multisystem inflammatory syndrome" or "myocarditis" or "thromboembolism" to identify publications from January 1st, 2020 until July 31st, 2020. Reference lists of the articles identified by this search strategy were reviewed to capture additional studies. No randomized trials neither interventional studies were available at the time this article was written; hence, observational studies, long-term prospective cohort studies, case-control, cross-sectional studies, case series, or case reports were also included in this review. Few additional articles before our search time period were included if they were referenced in existing articles and included pertinent essential data for this present article. Only articles published in the English language were included in this review. After the initial search, the authors separately screened all abstracts based on the eligibility criteria. Any abstracts or articles for which there was disagreement or uncertainty were reviewed again and discussed until consensus was reached. We finally included 193 articles. The included studies were categorized by whether the study involved previously healthy patients or patients with pre-existing cardiac conditions. As the vast majority of cases reported of pediatric cardiovascular involvement are patients with pediatric multisystemic inflammatory syndrome temporally (PMIS) associated with COVID-19, multiple meta-analyses were conducted to summarize the pooled mean proportion of different cardiovascular variables in this population. All the statistical analyses were performed using the STATA 14.0 (StataCorp. College Station, TX, United States).

RESULTS

Most publications used in this review were single case reports, small case series, and observational small-sized studies or literature reviews. The most relevant articles were 16 studies with size > 10 patients and with complete data about cardiovascular involvement in children with PMIS, 10 articles reporting sporadic cases of myocarditis, pulmonary hypertension and cardiac arrhythmias in previously healthy children, and another 10 studies reporting patients with pre-existing heart diseases. Most cases consisted in children with severe COVID-19 infection with full recovery after intensive care support, but cases of death were also identified. The management of the different cardiac conditions was extracted from the correspondent clinical guidelines or expert panel recommendations.

Cardiovascular involvement in children with COVID-19 but without a pre-existing heart disease

Pediatric multisystemic inflammatory syndrome temporally associated with COVID-19: The incidence of severe COVID-19 in children is lower than in adults; however, Pediatric multisystemic inflammatory syndrome temporally associated with COVID-19 (PMIS) has been recognized worldwide over the past few months, changing

the paradigm that children are not severely affected by SARS-CoV-2. Since April 2020, various alerts were issued in Italy, United Kingdom, and Spain about a local increase in the number of these cases^[44-46]. After these reports, the first cases in North America were reported in May 2020^[47,48]. Recently, cases of PMIS are currently also diagnosed in Latinamerica^[49]. In May 2020, case definitions for PMIS have been produced by the U.S. Centers for Disease Control and Prevention and the U.K.'s Royal College of Paediatrics and Child Health, as well as by the World Health Organization (Table 3)^[50-52]. Following these case definitions, 570 cases of PMIS have been notified to the CDC from March to July 2020^[53]. Taking into account that on July 29th there were 4.5 million cases of COVID-19 and that children account for 2%-5% of these cases, the estimated incidence PMIS accounts for approximately 0.2%-0.6% of pediatric SARS-CoV-2 infections. The case definition is nonspecific, and confirmatory laboratory testing does not exist. Therefore, it might be challenging to distinguish PMIS from other conditions with overlapping clinical manifestations such as severe acute COVID-19 and Kawasaki disease (KD), making challenging to know the exact incidence of the disease.

As the COVID-19 pandemic has evolved, case reports have appeared describing school-aged children and adolescents presenting with persistent high fever and systemic hyper-inflammation, reflected in a constellation of symptoms involving multiple organ systems^[54-89]. They frequently manifested abdominal pain and gastrointestinal symptoms, KD-like features, myocardial dysfunction, coronary artery dilation, and cardiogenic shock. Most cases required PICU admission and inotropic support, with the rare need for extracorporeal membrane oxygenation (ECMO). Almost all of these children wholly recovered in a few days, although rare deaths have been reported. These patients tested positive for SARS-CoV-2 infection either by nasopharyngeal reverse transcriptase-polymerase chain reaction (RT-PCR) assay or by antibody testing. Epidemiological studies have demonstrated that higher regional incidences of PMIS are associated with the larger COVID-19 outbreaks in the countries mentioned above, with most PMIS diagnoses occurring approximately four weeks after COVID-19 diagnoses peaks^[80,83]. This temporal and spatial association suggests a causal link between SARS-CoV-2 and PMIS.

If PMIS is indeed related to infection with SARS-CoV-2, the pathophysiological mechanism of disease is unclear. PMIS is presumed to reflect a post-infectious cytokine-mediated hyper-inflammatory process, triggered by COVID-19 infection^[89-95]. Of note, there are striking similarities between the overall clinical picture of children affected by PMIS and the late phase of adult COVID-19 infection, characterized by cytokine storm, hyper-inflammation, and multi-organ damage^[96-98]. Thus, they had laboratory findings associated with the cytokine storm described in adults, including high serum C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), procalcitonin, ferritin, Dimer-D, interleukin (IL)-6, Troponin and pro B-type natriuretic peptide (proBNP) levels. These findings suggest similar pathogenesis and a spectrum of illness from children to adults, leading to the hypothesis that PMIS is due to a post-infectious inflammatory state that occurs several weeks after a primary infection with SARS-CoV-2. Accordingly, most of the patients with PIMS were positive for IgG antibodies to SARS-CoV-2 (which typically appears 2-4 wk after primary infection) when the hyper-inflammatory symptoms appeared. Proposed mechanisms include direct triggering of auto-inflammatory response and deregulation of immune responses after COVID-19 infection, which could result in other environmental insults triggering a hyper-inflammatory pathology in predisposed patients^[89-98]. One hypothesis for the marked cytokine storm experienced by children with PMIS derives from the ability of coronaviruses to block type I and type III interferon responses, which can lead to an uncontrolled viral replication in those with initially high SARS-CoV-2 viral load^[99]. Myocarditis has been demonstrated by late gadolinium enhancement on cardiac magnetic resonance imaging in various children with PMIS^[77]. Recently, the presence of viral particles of SARS-CoV-2 in different cell types of cardiac tissue in the autopsy of a PMIS case has been demonstrated^[72]. This finding points out that SARS-CoV-2 could also produce a direct myocyte injury similar to other viral myocarditis as the mechanism of myocardial injury and heart failure during the PMIS course. Both the virus-induced damage and the local inflammatory response to cell injury could lead to necrosis of cardiomyocytes. The finding of viral particles in neutrophils within the myocardium supports the idea of local virus-induced inflammation. Of note, infection of endothelial cells in the endocardium could result in the hematogenous spread of SARS-CoV-2 to other organs and tissues, facilitating the typical multisystem failure.

Currently, available data so far suggests that PMIS shares a common pathophysiological pathway and overlapping symptoms with that described in

Table 3 Different case-definitions for the novel hyperinflammatory syndrome described during coronavirus disease-2019 pandemic

Royal College of Pediatrics and Child Health (United Kingdom)	World Health Organization	Centers for Disease Control and Prevention (United States)
A child presenting with persistent fever, inflammation (neutrophilia, elevated CRP, and lymphopenia) and evidence of single or multiorgan dysfunction (shock, cardiac, respiratory, kidney, gastrointestinal, or neurological disorder) with additional clinical features, including children fulfilling full or partial criteria for Kawasaki disease 2	Children and adolescents 0-19 yr of age with fever > 3 d AND 2 of the following: (1) Rash or bilateral nonpurulent conjunctivitis or mucocutaneous inflammation signs (oral, hands, or feet); (2) Hypotension or shock; (3) Features of myocardial dysfunction, pericarditis, valvulitis, or coronary abnormalities (including ECHO findings or elevated troponin/NT-proBNP); (4) Evidence of coagulopathy (by PT, APTT, elevated D-dimers); (5) Acute gastrointestinal problems (diarrhea, vomiting, or abdominal pain). ¹ Consider this syndrome in children with features of typical or atypical Kawasaki disease or toxic shock syndrome	An individual aged < 21 yr presenting with fever, laboratory evidence of inflammation, and evidence of clinically severe illness requiring hospitalization, with multisystem (> 2) organ involvement (cardiac, kidney, respiratory, hematologic, gastrointestinal, dermatologic, or neurological). ¹ Fever > 38.0 °C for ≥ 24 h or report of subjective fever lasting ≥ 24 h. ¹ Laboratory evidence including, but not limited to, ≥ 1 of the following: an elevated CRP level, ESR, fibrinogen, procalcitonin, D-dimer, ferritin, lactic acid dehydrogenase, or IL-6; elevated neutrophils; reduced lymphocytes; and low albumin
And exclusion of any other microbial cause, including bacterial sepsis, staphylococcal or streptococcal shock syndromes, infections associated with myocarditis such as enterovirus (waiting for results of these investigations should not delay seeking expert advice)	And elevated markers of inflammation such as ESR, CRP, or procalcitonin.	And no alternative plausible diagnoses
And SARS-CoV-2 PCR test results may be positive or negative	And no other obvious microbial cause of inflammation, including bacterial sepsis, staphylococcal or streptococcal shock syndromes And evidence of COVID-19 (RT-PCR, antigen test, or serology positive), or likely contact with patients with COVID-19	And positive for current or recent SARS-CoV-2 infection by RT-PCR, serology, or antigen test; or COVID-19 exposure within the 4 wk prior to the onset of symptoms Additionally, ¹ some individuals may fulfil full or partial criteria for Kawasaki disease but should be reported if they meet the case definition for MIS-C. ¹ Consider MIS-C in any pediatric death with evidence of SARS-CoV-2 infection

Reproduced from references^[50-52]. COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2; APTT: Activated partial thromboplastin time; CRP: C-reactive protein; ECHO: Echocardiography; ESR: Erythrocyte sedimentation rate; MIS-C: Multisystem inflammatory syndrome in children; NT-proBNP: N-terminal pro-B-type natriuretic peptide; PT: Prothrombin time; RT-PCR: Reverse transcriptase-polymerase chain reaction.

¹Criteria for Kawasaki disease include persistent fever and 4 of 5 principal clinical features: Erythema and cracking of lips, strawberry tongue, and/or erythema of oral and pharyngeal mucosa; bilateral bulbar conjunctival injection without exudate; rash (maculopapular, diffuse erythroderma); erythema and edema of the hands and feet and/or periungual desquamation; and cervical lymphadenopathy. Incomplete KD can be diagnosed if there are only 2 or 3 of these criteria.

KD^[100-106]. However, clinical, laboratory, and epidemiological characteristics of PMIS appear to be different from those of KD, raising the question if they are the same entities. As the outcomes are distinct and PMIS seems to be more aggressive, it is critical to make the subtle distinction between classical KD and PMIS. The absence of cases in Asia, the predisposition of Afro-Caribbean people, the older age of the patients, the presence of gastrointestinal symptoms in almost patients, the presence of lymphopenia/Leucopenia, the abnormal coagulation indexes, the higher levels of ferritin, D-dimer, inflammatory and cardiac markers, the higher rates of cardiogenic shock, myocardial dysfunction, PICU admission, intravenous immunoglobulin (IVIG) resistance, the requirement of advanced respiratory or circulatory support and mortality could be the main differences (Table 4)^[100-106].

For this review we selected only those studies that included at least 10 patients with PMIS and with complete data about cardiovascular involvement (cardiogenic shock, cardiac biomarkers, ECG, echocardiography), treatment (inotropes, mechanical ventilation, ECMO support, anti-inflammatory and immunomodulatory) and outcomes^[45-48,54,56,60-62,65,66,68,70,76,78,86]. We excluded those articles with suspected overlapping of patients due to multiple communications of the same patients in different papers. In our review, we found a total of 688 PMIS cases (56.8% male sex; mean age of 9 years) reported by 16 different authors from April to July 2020 across Europe and North America (Table 5, Figure 1). Of note, the vast majority of patients were previously healthy (74.4%), and the most common associated comorbidities observed were asthma and obesity, with a minimal prevalence of previous cardiac diseases. Since the first cases were reported, it was noticed that PMIS could be a severe acute condition,

Table 4 Differential characteristics between Kawasaki disease and the novel Pediatric Multisystem Inflammatory Syndrome in children with SARS-CoV-2 infection

Characteristic	Kawasaki disease	PMIS
Age	6 mo-5 yr (most cases under 2-yr-old)	School-aged children (mean age 9-yr-old)
Sex	Male predominance	Male = Female
Race	Asiatic	African/Caribbean
Region	Most cases at Asia	Most cases at Europe and America. No asiatic cases
Seasonality	Spring-Autum	Regional incidences associated with the larger regional COVID-19 outbreaks
Related with acute infection	Yes	2-4 wk after primary infection (can occur also during acute phase)
Incomplete KD criteria	Up to 30%	< 25%
Gastrointestinal symptoms	Uncommon	Almost 100%
KD shock syndrome	2%-7%	50%-60%
Increased inflammatory biomarkers (CRP, Procalcitonin, Ferritin)	++	++++
Lymphocyte count	Lymphopenia rare	Lymphopenia in up to 80%
Platelet count	Thrombocytosis	Thrombocytopenia
Coagulation indexes	Normal values	Increased indexes; Very increased Dimer-D levels
Increased cardiac biomarkers	Natriuretic peptides (> 50%) ++; cTn (< 20%-30%) +/-	Natriuretic peptides (87%) +++++; cTn (73%) +++++
Myocardial dysfunction	< 1%	Up to 52%
Coronary arteries anomalies	25% without adequate treatment	15%
IVIG resistance	10%-20%	50%-60%
Biologic therapy	Very rare	15 %
Long-term Cardiac sequel	< 5% with adequate treatment	5.5%
PICU admission	4%-5%	75%
Mechanical Ventilation	Very rare	22 %
ECMO support	Extremely rare	4%-5%
Exitus or Sequelae	< 1%	2%

especially focusing on the cardiovascular system. Thus, the cardiac troponin and natriuretic peptides [N-terminal (NT)-proBNP or proBNP] were increased in most cases of PMIS (73.6% and 86.8% respectively). ECG alterations were not infrequent (27.6%), overall in the form of unspecific ST segment and T wave alterations, prolonged QT interval, and very few ventricular arrhythmia or AV blocks. However, there have also been reported cases of sustained arrhythmias leading to hemodynamic collapse and the need for ECMO support. Most important, as myocardial dysfunction and heart failure have been observed in up to 52%-53% of cases, PMIS must be bear in mind as a cause of new-onset heart failure in children during the pandemic. Also, and similar to KD, PMIS can lead to the development of coronary artery alterations (15%). Although infrequent, most of the cases of PMIS require hospitalization and intense clinical management because of the severity of the disease. Two recent multicenter studies in Spain reported that up to 31/252 (12%) of hospitalized children with COVID-19 and that 27/50 (54%) of cases that required PICU admission were diagnosed as PMIS^[43,86].

In our review, we found that a PICU admission rate of 75.6%, with up to 56.4% of cases presenting with shock requiring inotropic support, and 4.3% requiring ECMO support. Conversely, only 22% of patients required mechanical ventilation, suggesting that the primary pulmonary involvement could not be a significant issue in PMIS

Table 5 Summary of the data about cardiovascular involvement reported by the case series with more than 10 children with Pediatric Multisystem Inflammatory Syndrome

cases. Despite prolonged PICU admissions (mean PICU stay 4-7 d), the reported clinical outcomes for pediatric patients with PMIS appear favorable. Almost all patients (93.7%) presented a rapid full recovery within the first week of the disease. Most patients recovered when the severe inflammatory state associated with the SARS-CoV-2 infection is resolved. For this purpose, a high proportion of patients diagnosed as PMIS have been treated initially with IVIG (77.8%) and steroids (58%) in a similar way to KD^[100-106]. However, to resolve this severe inflammatory state associated is challenging, as these patients exhibit an increased resistance rate to these anti-inflammatory therapies regarding those rates reported for KD. Hence, biologic therapy blocking IL-1 (anakinra) and IL-6 (tocilizumab) receptors have been used in up to 14.5% of PMIS cases. COVID-19 prothrombotic effects are concerning in adults^[107-110], increased use of anticoagulation (33.2%; mainly low weighted enoxaparin) and antiplatelet agents (12.5%; primarily aspirin) have been observed in these patients. Children with PMIS are at risk of thrombotic complications from multiple causes, including hypercoagulable state, possible endothelial injury, stasis from immobilization, ventricular dysfunction, and coronary artery aneurysms^[111]. Therefore, antiplatelet and anticoagulation are recommended^[112,113]. The low-rate of aspirin use could be explained by its prescription, especially in patients with KD-like clinical presentations (20%-25%), or in those with evidence of coronary involvement (15%). Cardiac sequelae in the form of mild myocardial dysfunction or coronary artery alterations were present in up to 5.5% of cases. Furthermore, although the case-fatality rate is known to be minimal in pediatric COVID-19, PMIS account for 15/121 (12%) of SARS-CoV-2 associated deaths among persons aged < 21 years in the United States from February 12th 2020 to July 31st 2020. Thus, we found a mortality rate of 1.8% in this review, which is higher than the 0.1%-0.6% mortality rate for pediatric COVID-19 reported before the emergence of PMIS.

As the prognosis is excellent after treatment, the early diagnosis of PMIS and prompt initiation of anti-inflammatory therapy is crucial for a successful, rapid, and full recovery and preventing end-organ damage and mortality. For this purpose, a high index of clinical suspicion is needed. As cardiovascular involvement is present in

Figure 1 Forest plot that summarizes the pooled mean proportion of the cardiovascular characteristics of children with pediatric multisystem inflammatory syndrome associated with coronavirus disease-2019. Multiple separate meta-analyses were conducted. Considering the high likelihood of between study variance, a random effects model was used. Continuity correction for total zero events studies was performed to include these in the meta-analysis as recommended. Pooled data were presented with 95%CI and displayed using forest plots. Heterogeneity within studies was assessed using I^2 statistics. For all the factors analyzed, the P value for heterogeneity was determined to be > 0.10 and the I^2 values were $< 50\%$ (adequate heterogeneity between studies).

any form in almost patients with PMIS, the screening of cardiac alterations through cardiac biomarkers, ECG, or echocardiography could be useful for the early identification of PMIS cases. Data from this review indicate that PMIS cases have similar manifestations and outcomes from different studies across the world. Therefore, there are arguments to consider PMIS a new syndrome with a strong link with SARS-CoV-2 infection. As fundamental aspects of PIMS remain unknown, future studies will improve prospects for the prevention and treatment of this severe pediatric condition. Until then, a close multidisciplinary collaboration among various disciplines including pediatrics, intensive care, rheumatology, cardiology, and immunology is warranted for the adequate management of these patients.

Cardiovascular involvement in previously healthy children out of PMIS: There is also evidence of cardiac manifestation in previously healthy children out of the setting of PMIS in children. Since the beginning of the pandemic, a few cases have been reported with cardiovascular involvement similar to adults, in the form of myocarditis, pericarditis, heart failure, cardiogenic shock, cardiac arrhythmia, and pulmonary hypertension (PH) (Table 6)^[114-124]. Although infrequent, these cases are usually reported as severe or critically ill patients, pointing out the relevance of the cardiac involvement also in previously healthy children with COVID-19.

Myocardial dysfunction and heart failure: Myocarditis is an inflammatory disease of the myocardium, diagnosed by established histological, immunological, and immunohistochemical criteria, caused mostly by infectious, immune-mediated or toxic agents^[125]. Remarkably, SARS-CoV-2 may represent another viral etiology of myocarditis. Acute myocardial injury by SARS-CoV-2 may be due to the coincidence

Table 6 Description of the case or case series of cardiac involvement in pediatric patients without pre-existing cardiac condition and coronavirus disease-2019

Ref.	Mechanism	Description
Dong <i>et al</i> ^[116]	Myocardial injury	Nationwide case series of 2135 pediatric patients with COVID-19 reported to the Chinese Center for Disease Control and Prevention. Cardiovascular involvement was found in 13 patients with myocardial injury or heart failure. No deaths were reported.
Cui <i>et al</i> ^[115]	Myocardial injury	Description of a 55-d-old otherwise healthy female case with COVID-19 in China. Abnormal myocardial enzyme values on admission and increased troponin I indicated myocardial injury. The patient evolved favourably.
Del Barba <i>et al</i> ^[116]	Myocardial injury	A 38-d-old male tested positive for SARS-CoV-2 and developed mild cardiovascular inflammation. An increase in troponin T was observed and a cardiac magnetic resonance was also performed which showed a minimal amount of pericardial effusion. The patient evolved favourably.
Gnecchi <i>et al</i> ^[117]	Myocardial injury	A previously healthy 16-yr-old boy presented at the emergency department with fever and chest pain. The ECG showed inferolateral ST-segment elevation and the echocardiogram showed hypokinesia of the inferior and anterolateral segments of the left ventricle, with preserved function (EF 52%). Troponin I was very increased. Cardiac MRI supported the diagnosis of myocarditis. On day 3 of illness a nasopharyngeal swab test confirmed SARS-CoV-2 infection. The patient presented a full recovery on day 12 of illness.
Craver <i>et al</i> ^[122]	Myocardial injury	The authors reported a previously healthy 17-yr-old male that presented with sudden cardiac death. The autopsy showed diffuse myocarditis with mixed inflammatory infiltrate with a predominance of eosinophil as the cause of the death.
Sun <i>et al</i> ^[123]	Myocardial injury	In a small series of 8 critically ill patients infected by SARS-CoV-2, the authors reported the case of a 13-mo-old male who developed heart failure within a multiple organ failure with full recovery after support therapy (plasmapheresis and oxygen).
Su <i>et al</i> ^[124]	Myocardial injury	Clinical data from nine previously healthy children and their 14 families were collected, including general status, clinical, laboratory test, and imaging characteristics. In this study, they found six children with high CK-MB, which means that SARS-CoV-2 could cause heart injury. All children presented a full recovery.
Kesici <i>et al</i> ^[119]	Myocardial injury	A 2-yr-old, otherwise healthy boy with a history of respiratory distress secondary to COVID-19 developed cardiogenic shock the second day of hospitalization. The patient presented elevated cardiac Troponin and severe left ventricular failure on echocardiography. The patient required ECMO support and presented cardiac arrest. The autopsy confirmed a dilated cardiomyopathy secondary to viral myocarditis with SARS-CoV-2 RT-PCR positivity in the cardiac tissue as the cause of the death.
Giacomet <i>et al</i> ^[118]	Myocardial injury	A 2-mo-old boy presented with fever, vomiting and diarrhoea within a confirmed SARS-CoV-2 infection. The cardiac work-up revealed increased Troponin I and NT-proBNP levels and mild left ventricular dysfunction on echocardiogram. IL-6 was elevated. After therapy with IVIG the patient presented a rapid full recovery. The clinical diagnosis was myocarditis.
Rodriguez-Gonzalez <i>et al</i> ^[114]	Pulmonary hypertension	A 6-mo-old male with history of small bowel disease presented with a pneumonia, cardiogenic shock and severe hypoxemia. Cardiac biomarkers and IL-6 were increased, and echocardiography showed severe pulmonary hypertension and severe right ventricular failure. Pulmonary thromboembolism was ruled-out through angio-CT scan. The patient received inotropic and respiratory support and improved rapidly with full recovery after the initiation of Tocilizumab. SARS-CoV-2 infection was confirmed by serology.
Samuel <i>et al</i> ^[120]	Arrhythmia	Thirty-six pediatric patients with active PCR positive SARS-CoV-2 infection were included in the study. No patients presented pre-existing cardiac condition. Of them 6 cases developed significant arrhythmias (non-sustained ventricular tachycardia in 5 and sustained atrial tachycardia in 1). All were self-resolving episodes, and 3 of them were started on prophylactic anti-arrhythmic therapy. Four of them presented abnormal echocardiograms with mild dilation/dysfunction of the left ventricle that recovered at discharge.
Xia <i>et al</i> ^[121]	Arrhythmia	The authors reported the clinical, laboratory, and chest CT features of 20 pediatric inpatients with COVID-19 infection confirmed by pharyngeal swab COVID-19 nucleic acid test. The authors observed self-limited ECG alterations in four of these patients during admission (Sinus tachycardia, Atrial arrhythmia, First-degree atrioventricular block, atrial and ventricular premature beats). The patients did not require any treatment and presented a full recovery.

COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2; IL: Interleukin; IVIG: Intravenous immunoglobulin; MRI: Magnetic resonance imaging; ECMO: Extracorporeal membrane oxygenation; NT-proBNP: N-terminal pro-B-type natriuretic peptide; RT-PCR: Reverse transcriptase-polymerase chain reaction.

of various mechanisms including a direct viral myocardial injury, a secondary inflammatory response in the form of cytokine storm, the severe hypoxemia due to pneumonia, and the side-effects of therapy against SARS-CoV-2 infection (Table 1 and 2)^[126-129].

To date, sporadic cases of myocarditis have been reported in pediatric COVID-19 patients as the first clinical presentation of the disease, alone or in the clinical context of pneumonia. Dong *et al*^[116] found myocardial injury and heart failure occurring in up to 0.6% (13/2135) of pediatric patients with COVID-19 reported to the Chinese Center for Control and Prevention. In the following months, more sporadic cases have been reported around the world^[115-124,130,131]. The myocardial injury affected all age ranges, from neonates to adolescents, and a not low number of these children presented in an

unexpected form of severe SARS-CoV-2 infection with increased morbidity (PICU admission, inotropic support, mechanical ventilation...) and mortality, including cases of sudden cardiac death. Of note, the presence of viral particles of SARS-CoV-2 in the myocardium of children with sudden cardiac death reinforces the direct viral damage as one of the main mechanisms of myocardial injury in healthy children^[72]. Based on the few published data, SARS-CoV-2 may represent a potential novel etiology of fulminant myocarditis, which it should be suspected in COVID-19 patients with acute-onset chest pain, ST-segment changes, cardiac arrhythmias and hemodynamic instability^[131,132]. Also, left ventricular dilatation, left ventricular hypo-contraction (on echocardiography), and a significant increase in cardiac troponin and proBNP levels could also be present. Myocarditis seems to be a rare event in pediatric COVID-19, but when occurred, appears early in patients' clinical history and could lead to sudden cardiac death. However, as few studies described myocardial injuries in these COVID-19 patients, the impact on clinical prognosis needs to be clarified in this population.

Pulmonary hypertension secondary to the primary pulmonary infection or PTE:

Right heart failure with increased pulmonary vascular resistance and PH should also be considered as a possible cardiac manifestation in previously healthy children, especially in the context of moderate-severe pneumonia with acute respiratory distress syndrome and hypoxemia^[132]. PH is a well-known complication of pulmonary viral infections leading to adverse outcomes when present, also in the COVID-19 scenario^[114,133-136]. Interestingly, nonetheless, concomitant pneumonia, PH has not been reported as one of the main characteristic of the disease in children. Thus, we only found one case of severe PH and right ventricular failure secondary to a severe pulmonary infection in our literature review^[114]. In this case, the increased levels of cardiac troponin and proBNP prompted an echocardiogram realization that diagnosed severe PH. Previous cases reported of severe pulmonary hypertension in adults were secondary to pulmonary thromboembolism (PTE), but no cases of massive PTE have been demonstrated in children^[137-139]. Therefore, it has been hypothesized that the pulmonary endothelial cell damage leading to the endothelium, the activation of coagulation pathways, and deregulated inflammatory cell infiltration with cytokine storm could be the primary pathophysiological mechanism of the severe PH observed in these patients^[88-91,140]. Small segmental pulmonary emboli (PE) have been observed in some pediatric patients affected by PMIS supporting this theory^[141-143], but the clinical significance of these findings is still unclear. Finally, pulmonary artery vasoconstriction due to severe hypoxemia and respiratory acidosis may act as a coadjuvant factor for the development of PH^[144,145].

Cardiac arrhythmia in healthy children: There are little data about the occurrence of arrhythmias in the context of pediatric COVID-19. Data from 2 small-sized studies showed that hospitalized pediatric COVID-19 cases could present a rate of cardiac arrhythmia as high as 16%-20%^[120,121]. Initial data from Chinese observations suggest that contrary to adult patients, whose myocardial involvement is sometimes correlated with the appearance of life-threatening arrhythmias, children with COVID-19 share less harmful rhythm troubles, such as supraventricular tachycardia, premature atrial and ventricular complexes, first-degree atrioventricular blocks, and incomplete right bundle branch block^[16,36,121]. Recently, Samuel *et al*^[120] observed non-sustained ventricular tachycardia in 5/6 patients that developed cardiac arrhythmia in a case series of 36 children. Although all were self-resolving episodes, up to 50% of cases required the initiation of antiarrhythmic drugs. Based on these few data, arrhythmias represent a not rare clinical presentation of COVID-19, which could complicate the clinical course of disease during hospitalization and worsen the prognosis of infected patients. For this reason, careful electrocardiographic monitoring should be performed in COVID-19 patients to early detect paroxysmal arrhythmia that does not match the disease status and might be a red flag of worsening disease.

Ventricular arrhythmias seem to be directly correlated to the COVID-19 induced myocardial injury. Accordingly, a higher incidence of ventricular arrhythmia was reported in adult patients with elevated troponin-T levels^[37-42]. Notably, 4 of 5 of the cases of ventricular arrhythmia reported by Samuel *et al*^[120], presented abnormal echocardiograms with mild dilation/dysfunction of the left ventricle. Furthermore, ventricular fibrillation has been documented in some cases of fulminant myocarditis and sudden cardiac death in children^[117-119,122]. Therefore, the direct myocardial injury seems to be a determinant factor for arrhythmia also in children. Hypoxemia and electrolyte imbalance are not rare in the acute phase of severe COVID-19 and can also trigger cardiac arrhythmias^[146]. The potential role of pharmacological treatments such as hydroxychloroquine (HCQ) and azithromycin in enhancing the susceptibility to QT-

related life-threatening ventricular arrhythmias, particularly Torsades de pointes (TdP), is increasingly recognized in adults^[147-149]. Nevertheless, pediatric observations have shown that these drugs are safe in previously healthy children^[150].

The characteristic hyper-inflammatory systemic state of COVID-19 has been proposed as a potentially crucial pro-arrhythmic factor. This fact is supported by the occurrence of arrhythmic events in PMIS cases mentioned above. Strong evidence from basic and clinical studies points to pro-inflammatory cytokines, mainly IL-6, as a novel and essential risk factor for long QT-syndrome and TdP^[151-153]. Systemic inflammation might additionally predispose to long QT-syndrome/Td as a result of indirect mechanisms, such as the induction of cardiac sympathetic system hyperactivation and the inhibition of cytochrome p450, particularly CYP3A4, leading to an increased bioavailability of several medications, including QT-prolonging drugs.

The coexistence of myocardial injury and cardiac arrhythmias with COVID-19 makes it challenging the diagnosis and management of this entity. The early recognition of cardiac symptoms and their timely treatment may be of pivotal importance to improve the prognosis of pediatric patients, overall in those with severe disease.

COVID-19 in children with pre-existing heart disease

Congenital heart diseases: Congenital heart diseases (CHD) affects approximately up to 8/1000 (0.8%) newborns and remains the leading cause of infant mortality due to congenital malformations^[154]. Currently, there are no reliable data with regards to the burden of infected children with CHD and the COVID-19 related morbidity and mortality in this setting. Few studies are focusing on children with CHD and COVID-19, mainly limited to sporadic case reports or small case series (Table 7)^[155-162]. These children seem to be a vulnerable population to a potential clinical deterioration in the presence of bilateral pneumonia or acute respiratory distress syndrome caused by SARS-CoV-2, especially those with non-corrected complex cardiac defects and decreased cardiopulmonary functional reserve. Furthermore, even patients with corrected CHD can present with relevant residual lesions such as residual valvular or shunt lesions, ventricular dysfunction, heart failure, arrhythmias, pulmonary vascular disease, or cyanosis. Apart from the hemodynamic burden, some of these children might have associated comorbidities such as lung disease, liver impairment, renal failure, neurological sequelae, and impaired immunity associated with possible concomitant syndromes (Down syndrome, DiGeorge syndrome, heterotaxy syndromes with asplenia). Due to the documented myocardial involvement of SARS-CoV-2 infection in both adults and children, and the increased mortality observed in adult patients with pre-existing cardiovascular disease and pediatric CHD with other viral infections (Influenza and respiratory syncytial virus)^[163-166], there is a possibility that SARS-CoV-2 infection may produce new-onset of cardiac complications or a worsening of the basal status in this vulnerable population. It is essential to bear in mind that, as in other viral respiratory infections, it can be challenging to differentiate pneumonia from cardiac complications in these children due to an overlapping presentation. For example, children with non-cyanotic CHD with increased pulmonary blood flow have higher than standard resting respiratory rates even in a basal state, and some signs of respiratory distress can be secondary to heart failure. Children with cyanotic CHD have low baseline saturation (< 92%) and cyanosis due to their cardiac pathology. Due to these reasons, delayed diagnosis and treatment of critical cardiac complications could also increase morbidity and mortality.

Children with underlying medical conditions represent 25% of the total pediatric COVID-19 cases and 80% of those hospitalized. Hoang *et al*^[167], in an early systematic review including 7780 pediatric COVID-19 cases from 26 different countries, found that a pre-existing cardiovascular condition was present in up to 14% of patients. In the United States the CDC established on 6 April 2020 that chronic lung disease (including asthma) is the most prevalent preexisting condition (50%), followed by cardiovascular disease (31%; including obesity) and immunosuppression (12.5%). Regarding the mortality rate associated with pre-existing conditions, the CDC reported 121 deaths among persons younger than 21 years old in the United States from February to July 2020. Of them, only 25% were previously healthy people. The most frequently reported medical underlying conditions were chronic lung disease (28% including asthma), obesity (27%), neurologic conditions (22%) and cardiovascular conditions (18%). However, these reports did not analyze the association with outcomes. To date, only one multicenter observational study that only included 2 pediatric cases has focused on the clinical characteristics and outcomes in patients with CHD infected by SARS-CoV-2. The authors found that of the 76 patients included, cardiovascular complications were mainly found in the CHD-COVID-19

Table 7 Description of the case or case series of cardiac involvement in pediatric patients with pre-existing cardiac condition and coronavirus disease-2019

Authors	Description
Grafmann <i>et al</i> ^[158]	A 16-yr-old girl with history of treated congenital mitral valve disease with pulmonary hypertension, atrial arrhythmias and mitral valve stenosis, who is admitted for signs of respiratory infection positive for SARS-CoV-2 which produced no signs of myocardial involvement with a full recovery.
Zheng <i>et al</i> ^[161]	A 8-mo and 1-yr-old boys with pre-existing congenital heart disease, presented critical COVID-19 with increased cardiac enzymes, requiring mechanical ventilation and venous-venous hemodiafiltration. These two patients presented the more aggressive SARS-CoV-2 infection among the 25 patients reported in this case series. They presented a full-recovery.
Krishnan <i>et al</i> ^[157]	A 3-yr-old boy with Down syndrome, repaired atrioventricular septal defect (AVSD), and pulmonary hypertension was presented a critical case of COVID-19 confirmed by PCR test. He received methylprednisone, azithromycin, and hydroxychloroquine, and continuous positive airway pressure. The patients presented prolongation of the QTc interval on electrocardiogram with posterior full recovery.
Salik <i>et al</i> ^[159]	A 15-d-old baby girl was diagnosed with Tetralogy of Fallot prenatally. The infant's mother was diagnosed with COVID-19 postpartum. On day 7 of life, the infant experienced desaturation to SpO ₂ 60–65%, tachypnea, worsening cyanosis. A COVID nasopharyngeal swab was positive; and the infant exhibited frequent spells requiring supplemental oxygen. Due to sustained hypoxemia with SpO ₂ 55%–65%, so it was decided that Blalock-Taussig shunt placement with good clinical evolution.
Russell <i>et al</i> ^[160]	A 3-yr-old female patient with history of heart transplant in 2017 for congenital dilated cardiomyopathy. In the first week of March she developed a mild clinical picture consisting of rhinorrhoea and a productive cough and nasal congestion that did not require hospital admission. Several weeks later, in a review by protocol, COVID 1 PCR was performed with positive results. The patient evolved favourably.
Linnane <i>et al</i> ^[156]	A 10-yr-old boy with a background of double inlet left ventricle, pulmonary atresia, atrial septal defect, and a right aortic arch. He proceeded to have a bidirectional Glenn procedure and completed a total cavopulmonary connection <i>via</i> an extra cardiac fenestrated Fontan surgery at 3 yr and 10 mo. He was admitted for signs of respiratory infection positive for SARS-CoV-2. The patient required admission to intensive care, with gradual improvement and good evolution.
Sabatino <i>et al</i> ^[176]	An Italian, observational, multi-center survey of patients with congenital heart disease affected by COVID-19 was conducted and included two pediatric-aged patients. The first patient is one year old with a history of transposition of great arteries, pulmonary atresia and ventricular septal defect. The second patient had pulmonary atresia and ventricular septal defect and the third patient had a transposition of great arteries. No increase in mortality was observed in this group, with full recovery of all patients.
Xia <i>et al</i> ^[128]	The authors reported the clinical, laboratory, and chest CT features of 20 pediatric inpatients with COVID-19 infection confirmed by pharyngeal swab COVID-19 nucleic acid test. Two patients presented a pre-existing cardiac condition and survived previous surgery for atrial septal defect. The patients did not require any intensive treatment and presented a full recovery.
Simpson <i>et al</i> ^[155]	They presented seven children with congenital heart disease and COVID-19. Three patients had atrioventricular canal defect and trisomy 21, one had double inlet left ventricle with Fontan palliation by cardiac transplant 8 years ago, one had hypertrophic cardiomyopathy, one history of anomalous left coronary artery from the pulmonary artery surgically repaired at 2-mo-of-age. Four of the seven developed cardiac arrhythmias or new electrocardiogram abnormalities. All seven developed acute decompensation, with one death in an 18-yr-old with hypertrophic cardiomyopathy.
Climent <i>et al</i> ^[162]	A 5 mo-old infant with personal history of Hurler syndrome and severe dilated cardiomyopathy with myocardial dysfunction presented a worsening of his cardiac status during SARS-CoV-2 infection, leading to cardiac arrest and death after 72 h of admission.

PCR: Polymerase chain reaction; CT: Computed tomography.

group, but they did not observe the worst outcome in this population^[167]. An early systematic review by Sanna *et al*^[166], including only the Chinese experience, concluded that the presence of CHD is a high-risk factor for severe COVID 19 in children. Götzinger *et al*^[25], in a multicenter cohort study that involved 25 European countries and included 582 children, found that 25% of pediatric COVID-19 cases presented pre-existing medical conditions, which resulted in an independent risk factor for PICU admission (OR, 5.06, 95% CI: 1.72–14.87; $P = 0.0035$) in multivariate analysis. Of note, a total of 25 (4%) children had a previously known CHD as comorbidity, and they present a higher risk for PICU admission (OR, 2.9, 95% CI: 1.0–8.4; $P = 0.029$) in the univariate analysis. DeBiasi *et al*^[22] reported a cohort of 177 children with COVID-19 in the United States. Of them, 3% presented a pre-existing cardiac condition, and these patients were more common in hospitalized as a non-hospitalized group (9% *vs* 1%; $P = 0.004$). However, when comparing the SARS-CoV-2 infected non-critically ill and critically ill hospitalized patients, there were no significant differences in the presence of underlying cardiac conditions (22% *vs* 6%; $P = 0.180$).

From these data, we can state that although plausible, there is not yet enough evidence currently to support the association of CHD and severe COVID-19 in children. It is necessary to bear in mind that these data could instead be a reflection of the overprotective management that is usually given to these patients, with preventive hospitalizations for monitoring even though they do not require treatment, nor do they have severe clinical affectations. Hence, using recommended clinical criteria for hospital admission in children with CHD might lead to many of these being hospitalized, who could otherwise have been managed at home^[12]. Remarkably, the

admission of these high-risk patients must be overweighted with the risk for SARS-CoV-2 nosocomial infection, and the presence of CHD should not be used in isolation for hospitalization. CHD constitutes a very heterogeneous group of patients and not all the CHD have the same risk for adverse outcomes during viral infections. Therefore, the identification of vulnerable CHD cases is crucial to improve the efficiency of the management of this population, avoiding unnecessary hospitalizations and also the late recognition of life-threatening complications in this population. In the absence of strong pediatric evidence, risk stratification, and further recommendations are currently performed based on the adult CHD anatomic and physiological classification (Table 8)^[168]. In summary, any child with a CHD requiring medication for heart failure or arrhythmia may experience a worsening of their clinical status because of the hemodynamic impact of the lung involvement and the myocardial injury of SARS-CoV-2 infection. On the other hand, children with complete and successful surgical correction of the CHD and without the need for cardiac medications could be managed as healthy children. This approach requires individual assessment and adjustment for consistency with current local recommendations. The specialized evaluation by the pediatric cardiology team could be essential for the adequate selection of cases that will benefit from hospitalization and more therapies than supplemental oxygen, such as heart failure drugs.

In addition to the increased risk for severe infection, CHD patients are facing the tremendous impact of the pandemic on outpatient visits and surgical programs around the world^[169-172]. To minimize SARS-CoV-2 spread, extensive preventive measures are essential for these patients. Similar to the general population, children with CHD and their caregivers must adopt physical and social distancing measures, meticulous hygiene with frequent hand washing, and use appropriately of facemasks. Nevertheless, social distancing can be particularly challenging for pediatric CHD patients, especially newborns and infants, who are a fragile population in need of immediate and continuing care. Due to the declared lockout to restrict physical contact, the many sick leaves for healthcare professionals, and the reallocation of CHD specialists to general care facilities to deal with these sick leaves, the volume of CHD outpatient visits may have to be reduced to essential visits only. Likewise, a profound reorganization with prioritization of emergent and urgent procedures, and the cessation of all-elective surgical activity has been adopted (Table 9). Therefore, there is an expanding increase of the waiting lists, leading to a delay of the diagnosis and adequate management of CHD complications and a delay of the optimal timings for corrections of some stable CHD, with a potential direct effect on morbidity and mortality. This problem is particularly significant in newborns and infants, who are a fragile population in need of close and continuing care and often require surgery during a narrow window of time to avoid death and provide for optimal outcomes. To avoid preventable complications due to canceled visits and diagnostic or therapeutic procedures, pediatric cardiology specialists should review outpatient appointments and ensure that high-risk patients are prioritized. For most patients listed on class IA, scheduled clinic visits should be converted to telehealth visits whenever possible, to maintain social distancing to avoid disease spread^[173,174]. However, pediatric cardiology teleservices could be not enough for complex chronic conditions. In these patients, the risk of SARS-CoV-2 exposure must be weighed against the needful in-person visits case-by-case. It is still unclear the real impact of this reorganization in terms of increased morbidity and mortality in this population. Of note, it would be essential to catching up with all surgical interventions and outpatient visits deferred during the pandemic at the same time that timely diagnosis and surgical corrections of all new patients are being carried out.

Genetic heart diseases: Genetic heart diseases (GHD) represent a very heterogeneous group of congenital disorders affecting the heart muscle (cardiomyopathies) or the electrical system (channelopathies). Of them, the most prevalent conditions in children are long QT syndrome (LQTS), catecholaminergic polymorphic ventricular tachycardia (CPVT), Brugada syndrome, dilated cardiomyopathy (DCM), and hypertrophic cardiomyopathy (HCM)^[175]. These rare conditions are often the underlying cause of life-threatening arrhythmias, myocardial dysfunction, heart failure, and sudden cardiac death in children and adolescents. The role of SARS-CoV-2 infection in these diseases is still not well known. The experience with COVID-19 in these patients is even scarcer than the existent of CHD patients. To date, we only have found 1 case report of a 5-mo-old infant with a personal history of DCM that presented a worsening of his cardiac status during SARS-CoV-2 infection, leading to cardiac arrest and death (Table 7)^[162]. Also, a case of Brugada syndrome uncovered by fever has been reported in the adult population^[176].

Table 8 Classification of Congenital heart diseases regarding the risk of severe coronavirus disease-2019 based on their anatomical and physiological characteristics

High risk of poor outcomes with COVID-19		Low risk ¹ of poor outcomes with COVID-19	
Physiological stage B	Physiological stage A	Physiological stage A	NYHA FC I symptoms
	Mild hemodynamic squeal		No hemodynamic or anatomic squeal
	Mild valvular disease		No arrhythmias
	Trivial or small shunt		Normal exercise capacity
	Arrhythmia not requiring treatment		Normal renal/hepatic/pulmonary function
	Abnormal objective cardiac limitation to exercise		
Physiological stage C	NYHA FC III symptoms		
	Significant valvular disease moderate or greater ventricular dysfunction		
	Moderate aortic enlargement		
	Venous or arterial stenosis.		
	Mild-moderate hypoxemia/cyanosis		
	Hemodynamically significant shunt		
	Arrhythmias controlled with treatment		
	Mild-Moderate Pulmonary hypertension		
	End-organ dysfunction that is responsive to therapy.		
Physiological stage D	NYHA FC IV symptoms		
	Severe aortic enlarge		
	Arrhythmias refractory to treatment		
	Severe hypoxemia (associated with cyanosis)		
	Severe pulmonary hypertension		
	Eisenmenger syndrome		
	Refractory end-organ dysfunction		

COVID-19: Coronavirus disease-2019.

¹Patients with congenital heart diseases and complex anatomy are always at high-risk for poor outcomes independent of the physiological stage: Double-outlet ventricle, truncus arteriosus, transposition of the great arteries, pulmonary atresia, mitral atresia, interrupted aortic arch, fontan procedure, single ventricle, other abnormalities of atrioventricular and ventriculoarterial connection (crisscross heart, isomerism...), cyanotic heart defects (excluding fully repaired defects).

As mentioned above, SARS-CoV-2 infection can produce myocardial dysfunction and ventricular arrhythmia through direct myocardial damage and hyper-inflammatory state. Also, as a viral infection, COVID-19 can provoke situations that can act as triggers for myocardial dysfunction and ventricular arrhythmias such as fever, hyper-adrenergic states, increased energetic and oxygen consumption, dehydration, ion alterations (especially potassium, calcium, and magnesium), metabolic crises with lactic acidosis... Finally, some drugs used against SARS-CoV-2 (hydroxychloroquine, Remdesivir, azithromycin, tocilizumab) could be deleterious^[177-180]. Therefore, patients with genetic heart diseases may be at an increased risk in the setting of COVID-19, necessitating additional precautions, and specialized management. As a very heterogeneous group, disease-specific recommendations and precautions should be employed. In the absence of enough evidence, recommendations for the management of these rare diseases are based on previous experience with other viral infections and following expert panel recommendations (Table 10)^[181,182]. For example, fever must be managed aggressively in Brugada syndrome; potassium levels must be higher than expected in the case of LQTS. Situations of dehydration can be dangerous in the context of hypertrophic

Table 9 Classification of surgical and catheter-based procedures based on their relevance for the prognosis of the patients with congenital heart diseases and genetic heart diseases

Emergency cases (Not delay more than 24-48 h)	Urgent cases (Not delay more than days to weeks)	Elective cases (Delay > 2 mo)
ECMO in hemodynamically unstable patient	Surgical or catheter procedures	
PDA stent in unstable patient on prostaglandin treatment	Transposition of great vessels	Valvular regurgitations managed medically
Thrombosed shunt	Norwood procedure for hypoplastic left heart syndrome	Slow progressive aortic stenosis scheduled for Ross procedure
Pericardial tamponade	Truncus arteriosus	Pre-Fontan catheterization with adequate saturations on room air (> 75%)
Rashkind procedure	Obstructive lesions stabilized with prostaglandins	
Heart transplant	Glenn procedure with decreasing saturations (< 75%)	
Obstructed total anomalous pulmonary venous return	Persistent heart failure in shunts on maximal anti congestive therapy	
ALCAPA	Endocarditis in hemodynamically stable patient	
Stenotic right ventricle-Pulmonary artery conduit with severe ventricular dysfunction		
	Electrophysiological procedures	
Emergency cases (Not delay more than 24-48 h)	Urgent cases (Not delay more than days to weeks)	Elective cases (Delay > 2 mo)
Cardiac arrest in association with pre-excited atrial fibrillation	Primary prevention defibrillator implants after life-threatening ventricular arrhythmia	Tilt-table test
Arrhythmia causing need for ECMO	Cardiac resynchronization therapy	Implantable loop recorder implants
Incessant arrhythmia with severe ventricular dysfunction	Ablation for medically refractory ventricular tachycardia	Ablation of stable arrhythmias adequate managed with drugs without cardiomyopathy
Pacemaker insertion for advanced AV-block	Ablation of SVT though to contribute to cardiomyopathy	Upgrades of devices
Defibrillator implant for secondary prevention of sudden death		Generator replacements with > 6 wk of battery remaining
Pacemaker generator replacement for pacing-dependent patients		Pacemaker implant for sinus node dysfunction, non-high-grade AV block and tachy-brady syndrome in middle symptomatic patients
Defibrillator generator replacement for patients with appropriate defibrillator therapies.		
Ablation of supra ventricular arrhythmias causing hemodynamic deterioration and WPW syndrome associated with cardiac arrest		
Transvenous lead extraction		

ECMO: Extracorporeal membrane oxygenation; ALCAPA: Anomalous left coronary artery originating from the pulmonary artery.

cardiomyopathy. In the case of DCM, there is an increased risk of metabolic decompensation or lactic acidosis with associated severe myocardial dysfunction. The increased adrenergic tone may be harmful in almost all cases, overall HCM, LQTS, and CPVT. Finally, Covid-19 infection in patients with cardiomyopathies represents a substantial risk of worsening patient clinical status, particularly in those who experienced previous heart failure, arrhythmic events, or myocardial dysfunction on echocardiography requiring medications.

Patients with GHD are suitable for multiple outpatient clinic visits, hospitalizations, and surgical or electrophysiological interventions to have the reasonable control of the disease. During the pandemic, similarly to those patients with CHD, only urgent

Table 10 Recommendations for the management of pediatric cases of genetic heart diseases during coronavirus disease-2019 pandemic

Disease	Recommendations for management during COVID-19 pandemic
General recommendations	Preventive measures to minimize SARS-CoV-2 infection: Social distancing, hand-washing, facial mask. Limit outpatient clinic visits and electrophysiological and surgical procedures to life-threatening arrhythmias requiring immediate treatment, non-deferrable treatments and urgent diagnostic devices. Rule-out the presence of ventricular arrhythmia or heart failure when common overlapping COVID-19 symptoms appear: Dyspnea, syncope, cough, fatigue. Aggressive management of fever, diarrhoea and adrenergic stress as the main triggers for cardiac complications. Balance fluid and electrolyte intake according to clinical status. Influenza, pneumococcal and respiratory syncytial virus vaccination are recommended to reduce the possibility of co-infection of COVID-19. Consider at home management as first option whenever possible. Consider initial hospitalization for closely monitoring and intensive treatment in high-risk patients for heart failure or sudden cardiac death episodes. Pediatric cardiologist evaluation is highly advised when hospitalization is required. Careful use of specific COVID-19 treatment (antivirals and immunomodulatory drugs). Not discontinue usual cardiac basal.
LQTS	Avoid hyper-adrenergic states as triggers of Ventricular Tachycardia and Torsade de Pointes. Fever is not a main issue in LQTS. Aggressive control of fever is only recommended for LQTS type-2 cases. Beta-blocker therapy must be continued. QT prolonging drugs should be avoided. Flecainide can interact with antivirals but must not be discontinued. Avoid and correct dehydration states with ion alterations, overall potassium). Check serum electrolyte levels (especially potassium) in case of vomiting and diarrhoea. Keep potassium level above 4mEq/l with potassium supplements. Consider hospitalization in high-risk patients: Previous syncope. High-risk mutation. Infants younger than 1 year-old. Whenever an in-hospital admission is needed, a careful QT monitoring and a telemetric system should be used. Specific therapies for COVID-19 that are known to prolong the QT interval, specially hydroxychloroquine, azithromycin and ritonavir, should be avoided or used with caution.
Brugada	Aggressive management of Fever is the main issue. All patients should self-treat with paracetamol immediately if they develop signs of fever and stay at home. Consider hospitalization in high-risk patients: Children without an ICD and with previous syncope, spontaneous Brugada type-1 pattern on ECG, persistent fever despite paracetamol treatment at home, presence of palpitations or syncope. Management in the hospital should include monitoring of ECG abnormalities and arrhythmia as well as efforts to reduce the body temperature. If an ECG shows the type 1 Brugada ECG pattern, then the patient will need to be observed until fever and/or the ECG pattern resolves. If all ECGs show no sign of the type 1 Brugada ECG pattern, then they can go home. Specific drugs for COVID-19 do not influence on Brugada syndrome patients.
CPVT	At present, there are no data suggesting that patients with CPVT are at increased risk of infection with COVID-19. Avoid hyper-adrenergic states as triggers of Ventricular Tachycardia. Whenever possible, avoid the use of adrenaline in situations of ventricular tachycardia/ventricular fibrillation (VT/VF). Adrenaline is contraindicated in the event of cardiac arrest. Beta-blocker therapy must be continued. QT prolonging drugs should be avoided. Flecainide can interact with antivirals but must not be discontinued. An increased heart rate alone (pacing-induced), as an important symptom of fever or stressful circumstances, does not appear to be sufficient for the induction of ventricular arrhythmias. The antiviral or immunomodulatory therapy proposed for COVID-19 is not expected to influence on CPVT patients.
Cardiomyopathies	Avoid hyper-adrenergic and dehydration states that can provoke or increase left ventricular outflow obstruction leading to syncope and sudden cardiac death in HCM. Avoid hyper-adrenergic states with increased energetic and oxygen consumption leading to a worsening the myocardial function and decompensated heart failure in DCM. Consider hospitalization in high risk patients: Basal left ventricular outflow tract obstruction, end stage cardiomyopathies, decompensated HF with no response to intensification of oral treatment at home, syncope Hospital management include balance fluid and electrolyte intake according to the clinical status. Predisposition to Pulmonary edema. Negative hydric balance in case of pulmonary edema in DCM. Positive hydric balance in case of LVOTO in HCM. ECG monitoring watching for VA. QT monitoring, especially in patients on disopyramide and COVID-19 therapies). Echocardiography is mandatory to assess LVOTO and myocardial function.

COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2; LQTS: Long QT syndrome; CPVT: Catecholaminergic polymorphic ventricular tachycardia; HCM: Hypertrophic cardiomyopathy; DCM: Dilated cardiomyopathy.

surgical procedures and electrophysiological studies are performed, delaying all elective procedures (Table 9) following expert panel recommendations^[181,182]. When possible, most patients should at first be offered telehealth consultation, outpatient clinic visits must be warranted for all the new patients with a history likely of a life-threatening condition and the follow-up of patients with known genetic heart disease when treatment cannot be optimized remotely. Patients with high-risk GHD and SARS-CoV-2 infection could benefit from hospitalization for close monitoring and management of cardiovascular complications. Again, expert evaluation of a pediatric cardiologist may be essential in determining how best to minimize the risk of cardiac events during hospitalization.

Issues with cardiac medication during SARS-CoV-2 infection: Many children with underlying heart diseases are under treatment with cardiac medications during the pandemic. Concern exists about the potential risks of deleterious effects of these drugs when they are administered during SARS-CoV-2 infection. Anti-inflammatory drugs (Aspirin, Ibuprofen, colchicine, steroids) are used in cases of pericarditis and KD^[102, 183, 184]. They have been widely used in a safe and effective way in the treatment of PMIS cases. Beta-blockers are commonly used in pediatric cardiology, mainly as a treatment for heart failure in CHD or DCM, minimizing left ventricular outflow tract obstruction in HCM patients, and preventing VT in LQTS and CPVT. Amiodarone, sotalol, and flecainide do have interactions with other QT interval-prolonging drugs such as ritonavir/Lopinavir and chloroquine but is an important enough therapy not

to discontinue in these particularly stressful circumstances where paroxysms of tachycardia could occur^[185]. Digoxin and diuretics should be used cautiously. Digoxin action depends on potassium/calcium levels and toxicity may occur in case of vomiting or diarrhea during COVID-19. Diuretics can provoke alterations on the electrolyte imbalance and dehydration with deleterious effects for some patients^[186]. As there is no evidence for the harmful effects of most of these drugs in the setting of COVID-19, the general recommendation is to continue on these medications unless contraindications or side effects appear.

Only the safety of Renin-angiotensin-aldosterone system (RAAS) inhibitors has been questioned early after the beginning of the pandemic. RAAS is widely used in children with CHD and heart failure as an agent to minimize afterload and avoid the abnormal myocardial remodeling^[185,186]. It has been argued that RAAS inhibitors and angiotensin receptor blockers may up-regulate of angiotensin-converting enzyme 2 (ACE2), hereby increasing susceptibility to the virus and hence may cause a more severe infection^[40-42,187]. Anyway, treatment with RAAS inhibitors may down-regulate the expression of ACE2, but it seems not to have a significant effect on its activity. Thus, the data is currently insufficient to provide any definitive recommendation to discontinue these medications in children taking them for indications for which the agents are known to be beneficial. Therefore, the leading international cardiovascular scientific societies recommend maintaining or initiating the ACEIs/ARB's treatment in patients with heart diseases when indicated, irrespective of SARS-CoV-2 infection.

Cardiovascular effects of drugs used for COVID-19 treatment: Once a patient with underlying cardiac disease is diagnosed with COVID-19, the management of the infection is similar to the general population, with a particular focus in the surveillance of clinical signs of heart failure and ventricular arrhythmia. Currently, the primary treatment for COVID-19 disease is supportive care, ensuring adequate oxygenation, symptomatic relief with antipyretics, and nutritional support for the patient^[12,188,189]. Most children can be managed conservatively and do not require specific treatment. In the case of cardiovascular complications, the management should be done following current guidelines and local protocols for each manifestation. In severe cases of COVID-19, specific treatment with antiviral drugs (lopinavir/ritonavir, chloroquine/hydroxychloroquine) to control viral replication at early stages or immunomodulatory drugs (steroids or tocilizumab) to control the hyper-inflammatory response at later stages of the disease may be considered^[190]. However, these drugs are not considered the standard of care at this point. They are mostly off-label and investigational drugs with only positive pre-clinical data. Of note, many specific COVID-19 therapies have potential cardiovascular side effects, which can further increase the risk of myocardial dysfunction and arrhythmias associated with SARS-CoV-2 infection (Table 11).

Early in the pandemic, concerns have appeared about the potential of pro-arrhythmic events due to the use of prolonging-qt drugs that have raised, particularly the combined use of chloroquine (CQ), HCQ and azithromycin^[147-149,191,192]. The authors of a small single-center, the retrospective study found no risk of QT prolongation or TdP in children with COVID-19 under treatment with HCQ^[150]. However, the patients included were not severely affected by the disease, and none of them required intensive care, had cardiovascular comorbidity, and were taking corrected QT-prolonging medications, nor had ionic alterations. Therefore, caution must be used when applying them to patients with pre-existing heart disease. In the absence of clear benefit and safety data, therapies associated with greater QT prolongation and arrhythmic risk should be avoided, particularly if they are administered in combination with CYP3A4-inhibiting drugs. If they are considered to be beneficial, a step-by-step approach with the specialized supervision of the pediatric cardiology team must be made to minimize the occurrence of cardiac toxicity (Table 12)^[193].

DISCUSSION

In this review, we have summarized the actual evidence about the cardiovascular involvement in children with COVID-19. Although respiratory illness is the dominant clinical manifestation of COVID-19, cardiovascular issues are emerging as one of the most significant complications of SARS-CoV-2 infection in pediatric patients. As described above, patients with pre-existing cardiovascular diseases and with PMIS accounted respectively for 18% and 12% of pediatric deaths associated with COVID-19. Remarkably, PMIS has approximately a ten-fold mortality rate regarding

Table 11 Potential cardiovascular side-effects of the different drugs used against severe acute respiratory syndrome coronavirus 2 infection

Drugs	Cardiovascular adverse effect	Cardiovascular monitoring
Hydroxychloroquine	Vomiting with low-potassium levels. QT-prolonging and TdP. Conduction abnormalities; Heart block. Myocardial injury and Cardiomyopathy.	Monitor QTc interval, specially when using in combination with other QT-prolonging drugs and CYP3A4-inhibiting drugs. Monitor myocardial function by echocardiography and pro-BNP levels.
Azithromycin	QT-prolonging and TdP. Moderate CYP3A4 inhibitor.	Monitor QTc interval, specially when using in combination with other QT-prolonging drugs and CYP3A4-inhibiting drugs.
Lopinavir/Ritonavir	Vomiting with low-potassium levels. PR-prolonging. QT-prolonging and TdP. Major CYP3A4 inhibitor.	Monitor QTc interval, specially when using in combination with other QT-prolonging drugs and CYP3A4-inhibiting drugs.
Remdesivir	Limited data. Severe Hypotension and cardiac arrest after loading dose in Ebola patients. Possible CYP3A4 inducer.	Monitor Hemodynamics with infusion. Careful with unstable patients.
Steroids	Exacerbation of Lymphopenia. Can induce hypertension.	Monitor Hemodynamics with infusion. Monitor LVOTO in HCM by echocardiography. Careful in HCM.
Tocilizumab	Hypertension. Volume retention. Hypersensitivity. Increased lipid profile.	Monitor Hemodynamics with infusion. Monitor myocardial ischemia (ECG; Troponin). Careful in patients with myocardial dysfunction, chamber dilation or pulmonary edema.

SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2; HCM: Hypertrophic cardiomyopathy.

Table 12 Summary of the recommendations that should be kept in mind when treatment with prolonging-QT interval are going to be used during coronavirus disease-2019 pandemic

Step-by-step approach to administer prolonging-etc drugs during SARS-CoV-2 infection

- 1 QTc intervals should be monitored at baseline and at 4 h after the administration of any QTc-prolonging drug.
- 2 QTc interval monitoring previously to combine any drugs prolonging the QTc interval or CYP3A4-inhibiting drugs.
- 3 QTc interval monitoring in patients with Known LQTS, acquired QT prolongation, or conditions associated with acquired QT prolongation (*e.g.*, use of other QT-prolonging drugs, underlying heart disease, bradycardia, liver and renal disease electrolyte alterations...)
- 4 Serum potassium, calcium and magnesium should be evaluated at baseline and monitored and optimized daily.
- 5 Avoiding hypokalaemia is not enough. Patients with acquired LQTS or patients using a combination of QT-prolonging drugs should have a high serum potassium level (5 mEq/L).

If QTc increases by > 60 milliseconds or absolute QTc > 500 milliseconds (or > 530-550 milliseconds if QRS > 120 milliseconds) is observed

- 1 Consultation with a pediatric cardiologist ("QT specialist") for guidance in case of important QT prolongation. A careful balance of pros and cons should guide the decision to discontinue therapy.
- 2 Intensified ECG monitoring
- 3 Raising potassium levels
- 4 Correct QT-prolonging factors (calcium, magnesium, potassium...)
- 5 Consider to increase beta-blocker dosage

COVID-19: Coronavirus disease-2019; SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2.

the rest of pediatric COVID-19 cases. These data indicate that prognosis is worse when the cardiovascular system is impaired during SARS-CoV-2 infection in children.

Those patients with underlying heart diseases seem to be a vulnerable population at high risk if they contract COVID-19. Both, the new-onset acute cardiac complications and worsening of the basal state in patients with a low basal cardiopulmonary reserve or high-risk pro-arrhythmic profile, can occur in these children. Of note, not all patients with pre-existing heart diseases have the same risk for complications, and therefore, the hospital admission and anti-COVID drugs administration must be outweighed with the risk of nosocomial infections and side effects through a case by case approach. Furthermore, the delay of timely elective procedures and the radical decrease of in-person visits for the adequate follow-up at outpatient clinics may provoke those not-expected complications before the pandemic occur. To avoid preventable complications due to canceled visits and diagnostic or therapeutic

procedures, pediatric cardiology specialists should review outpatient appointments and ensure that high-risk patients are prioritized.

Remarkably, a not negligible number of previously healthy infected children have experienced severe cardiovascular acute events in the form of the new PMIS, arrhythmia, pulmonary hypertension, heart failure, and even fulminant myocarditis. The commonest complication in this population was PMIS, which affects mostly previously healthy school-aged children and adolescents presenting with Kawasaki disease-like features and multiple organ failure with a focus on the heart. They frequently presented cardiogenic shock (53%), ECG alterations (27%), myocardial dysfunction (52%), and coronary artery dilation (15%). Most cases required PICU admission (75%) and inotropic support (57%), with the rare need for extracorporeal membrane oxygenation (4%). Almost all of these children wholly recovered in a few days, although rare deaths have been reported (2%). These observations point out that, although infrequent, no child is free of the occurrence of cardiovascular events during the SARS-CoV-2 infection.

Failure to accurately identify and timely manage cardiovascular complications could lead to increased morbidity and mortality of these patients. Therefore, we recommend that those pediatric COVID-19 cases who are ill enough to require hospitalization should undergo a workup to the screening of cardiovascular issues (Figure 2). Also, close cardiovascular monitoring during hospitalization to avoid misdiagnosing these life-threatening entities should be warranted. The pediatric cardiology team should be involved in the management of any children with a pre-existing cardiac condition and any previously healthy children with abnormalities on the screening workup. In absence of enough evidence, the management of cardiac complications once they are identified should be based on the current guidelines, local protocols and the physician's experience for each individual condition^[194].

CONCLUSION

There is still scarce data about the role of cardiovascular involvement in COVID-19 in children. Based on our review, the cardiovascular involvement seems to be a relevant factor of SARS-CoV-2 infection in children. Patients with pre-existing heart diseases constitute a high-risk population for development of a severe acute COVID-19 and for decompensation of cardiac conditions. In previously healthy children, PMIS has emerged as a novel and severe condition during the pandemic. Furthermore, COVID-19 can also produce fulminant myocarditis, ventricular arrhythmias and pulmonary hypertension in previously healthy children. Data suggest that prognosis is worse when the cardiovascular system is impaired during pediatric SARS-CoV-2 infection, and that the vast majority of cardiac complications present a full recovery with a timely support. As the early identification and treatment of this entities is crucial, the performance of a cardiac workup and close cardiovascular monitoring of children with severe SARS-CoV-2 infection is highly recommended.

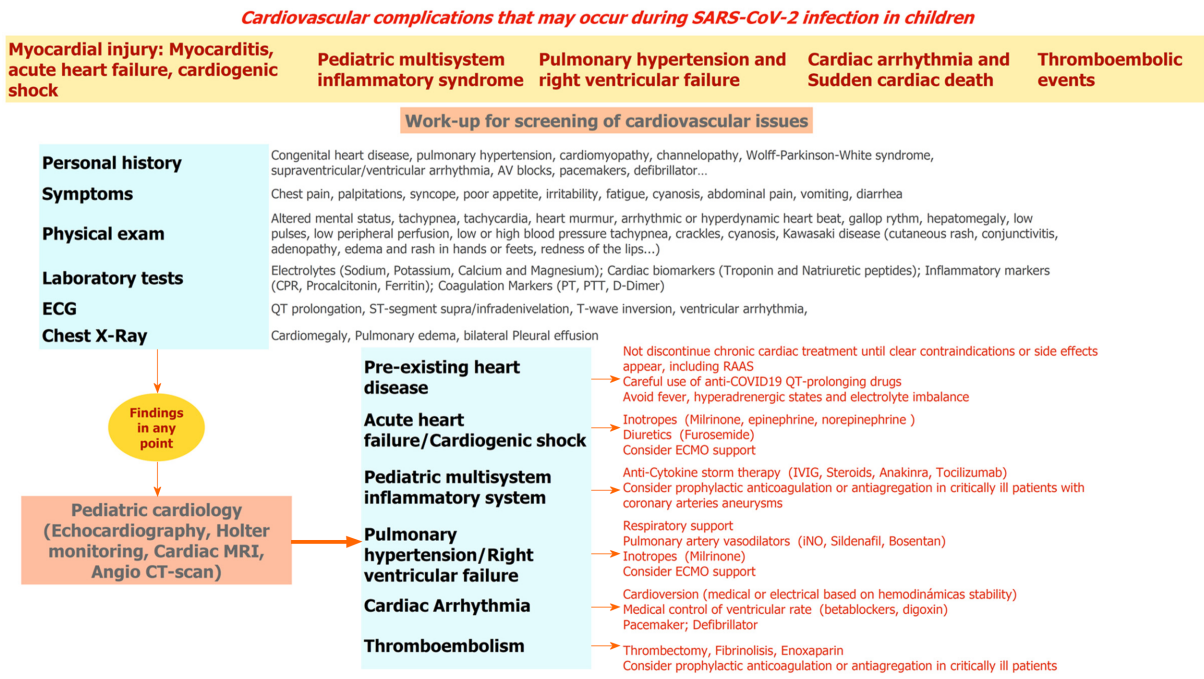

Figure 2 Summary of the potential cardiac complications and recommended cardiac work-up and management of cardiac complications for patients that require hospitalization due to severe coronavirus disease-2019 or for patients with pre-existing heart diseases.

ARTICLE HIGHLIGHTS

Research background
 Since the beginning of the pandemic, coronavirus disease-2019 (COVID-19) in children has shown milder cases and a better prognosis than adults. Cardiovascular involvement is emerging as one of the most significant and life-threatening complications of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection in adults.

Research motivation
 To investigate if cardiovascular involvement could be a significant risk factor for severe COVID-19 in children.

Research objectives
 We aimed to summarize the current knowledge about the potential cardiovascular involvement in pediatric COVID-19, in order to give a perspective on how to take care of them during the current pandemic emergency.

Research methods
 A literature search to identify publications from January 1st, 2020 until July 31st, 2020. was conducted using PubMed and MEDLINE. Also, the websites of the health organizations including World Health Organization and Centers for Disease Control and Prevention and the website of the Johns Hopkins Coronavirus Resource Center were reviewed to provide up to date numbers and infection control recommendations. The included studies were categorized by whether the study involved previously healthy patients or patients with pre-existing cardiac conditions. For pediatric multisystemic inflammatory syndrome (PMIS) temporally associated with COVID-19, multiple meta-analyses were conducted to summarize the pooled mean proportion of different cardiovascular variables in this population in pseudo-cohorts of observed patients. All the statistical analyses were performed using the STATA 14.0 (StataCorp. College Station, TX, United States).

Research results
 We included a total of 193 articles in this review. The most relevant articles were 16 studies with size > 10 patients and with complete data about cardiovascular involvement in children with PMIS, 10 articles reporting sporadic cases of myocarditis,

pulmonary hypertension and cardiac arrhythmias in previously healthy children, and another 10 studies reporting patients with pre-existing heart diseases. The meta-analysis of 16 studies with size > 10 patients and with complete data about cardiovascular involvement in children with PMIS showed that PMIS affects mostly previously healthy school-aged children and adolescents presenting with Kawasaki disease-like features and multiple organ failure with a focus on the heart, accounting for most cases of pediatric COVID-19 mortality. Out of PMIS cases we identified 10 articles reporting sporadic cases of myocarditis, pulmonary hypertension and cardiac arrhythmias in previously healthy children. We also found another 10 studies reporting patients with pre-existing heart diseases. Most cases consisted in children with severe COVID-19 infection with full recovery after intensive care support, but cases of death were also identified. There is an increasing concern about the delay of the diagnosis and adequate management of congenital heart diseases (CHD) complications and a delay of the optimal timings for corrections of some stable CHD due to the pandemic, with a potential direct effect on morbidity and mortality.

Research conclusions

There is still scarce data about the role of cardiovascular involvement in COVID-19 in children. Based on our review, all children (previously healthy or with pre-existing heart disease) with acute COVID-19 requiring hospital admission should undergo a cardiac workup and close cardiovascular monitoring to identify and treat timely life-threatening cardiac complications. The management of the different cardiac conditions should be based on the correspondent clinical guidelines, expert panel recommendations and physician's experience.

Research perspectives

Although cardiovascular involvement seems to be a crucial risk factor associated with severe pediatric SARS-CoV-2 infection, more evidence in the form of multicenter collaborative studies is necessary to elucidate this association.
