Background: Radiotherapy (RT), one of the main treatments for cervical cancer, has tremendous potential for improvement in the efficacy. Poly (ADP-ribose) polymerase (PARP) is a key enzyme in the repair of DNA strand breaks (DSB). Olaparib (Ola) is a PARP inhibitor that is involved in preventing the release of PARP from RT-induced damaged DNA to potentiate the effect of RT. Although the basic mechanism of Ola's radiosensitization is well known, the radiosensitization mechanism of its nanomedicine is still unclear. In addition, the lack of tumor tissue targeting is a major obstacle for the clinical success of Ola.

Materials and Methods: In this study, we developed folate-conjugated active targeting olaparib nanoparticles (ATO) and investigated the anti-tumor effect of ATO combined with radiotherapy (RT) in nude mice using cervical cancer xenograft models. We used folate (FA)-conjugated poly (ϵ -caprolactone)-poly (ethylene glycol)-poly (e-caprolactone) (PCEC) copolymer to prepare ATO via emulsification/solvent diffusion. Further, we evaluated ATO particle size, potential, encapsulation efficiency, and in vitro release characteristics, and evaluated the shape of ATO via transmission electron microscopy (TEM). We then performed MTT and cell uptake assays to detect cytotoxicity and targeting uptake in vitro. We investigated the anti-tumor properties of ATO in vivo by apoptosis test, 18 F-FDG PET/CT, and immunohistochemical analysis. Finally, the xenografted tumor in nude mice was subjected to RT and/or ATO treatment.

Results: The results confirmed that ATO in combination with RT significantly inhibited tumor growth and prolonged survival time of tumor-bearing mice. This may be related to the inhibition of tumor proliferation and DNA damage repair and induction of cell apoptosis in vivo.

Conclusion: The ATO developed in this study may represent a novel formulation for olaparib delivery and have promising potential for treating tumors with an over-expression of folate receptors.

Keywords: olaparib, cervical cancer, folate, anti-cancer effect, active targeting

Introduction

Cervical cancer is one of the most common cancers in women worldwide,¹ and RT is the main treatment for advanced cervical cancer. However, not so many effective methods to improve the efficacy of RT currently exist. Although cisplatin is traditionally widely used in combination with RT, it has severe side effects in patients. Therefore, exploring new approaches to improve the efficacy of RT has important clinical value. Research suggests that the mechanism of killing tumor

cells by RT involves DNA strand breaks (DSBs).² Poly (ADP-ribose) polymerase (PARP) is a key enzyme for DNA repair, and PARP inhibitors can selectively inhibit PARP activity, thereby inhibiting DNA strand repair and forming a large number of broken single-stranded DNAs, which eventually cause the double-stranded DNA to break at the replication fork and improves the efficiency of RT.^{3–5} Olaparib (Ola) is a well-known highly selective PARP inhibitor. Although current studies about the anti-tumor effects of Ola combined with RT in vitro are relatively detailed, there are few studies regarding this in vivo; thus, further research needs to be conducted.^{6–8} Nevertheless, with the lack of tumor tissue targeting, Ola use clinically leads to common adverse reactions such as anemia, nausea, and vomiting.⁹ In addition, issues such as poor water solubility, high toxicity, and poor stability have largely prevented the popularization and application of Ola in clinical use. In recent years, there are many studies about nano-delivery system for cancer therapy, which can enhance the efficacy and targeting of drugs.^{10–12} Therefore, developing a targeted nano-delivery system capable of solving the abovementioned issues is important.

Folate receptors have recently been confirmed to be over-expressed on the surfaces of some tumor cells such as those of cervical cancer, ovarian cancer, and nasopharyngeal cancer.¹³ The differential expression of folate receptors in tumor tissues and normal tissues makes them ideal targets for targeted drug delivery.¹⁴ Therefore, a new folate-conjugated nano-drug delivery system capable of targeting the folate receptor has emerged, which is considered to be a promising anti-cancer drug carrier, thus providing a feasible solution to the abovementioned problems.^{15,16} Our previous study had shown that Ola nanoparticles can enhance the radiosensitivity of lung cancer xenografts in nude mice.¹⁷ Furthermore, folate-conjugated honokiol nanoparticles show active-targeted inhibitory effect on nasopharyngeal carcinoma xenografts enriched with folate receptors on the cell surface.¹⁸ Therefore, in this study, we prepared folate-conjugated Ola nanoparticles that actively targeted folate receptors.

A large number of studies have reported anti-tumor effects of Ola combined with RT, including details on the drug and radiation doses.^{5,17} Thus, an optimal drug dose of Ola (50 mg/kg/d, 3 days) and radiation dose (10 Gy) were used for subsequent experiments. The purpose of this study was to prepare ATO and study the anti-tumor effects of ATO in combination with RT on cervical carcinoma subcutaneous xenograft model.

Materials and Methods

Materials

Ola with a purity level of 99.8% was purchased from Meilun Co., Ltd (Dalian, China). ϵ -Caprolactone (ϵ -CL), poly (ethylene glycol) (PEG, Mn=4000), and stannous octoate (Sn (Oct)₂) were purchased from Sigma-Aldrich (St. Louis, MO, USA). Dicyclohexylcarbodiimide (DCC), N-hydroxysuccinimide (NHS), N,N'-Diisopropylcarbodiimide (DIC), MTT, and fluorescein isothiocyanate (FITC) were purchased from Sigma-Aldrich. Further, dimethyl sulfoxide (DMSO), folate, petroleum ether, anhydrous ethanol, acetonitrile, and methanol (HPLC grade) were purchased from KeLong Co., Ltd (Chengdu, China). Tetrahydrofuran (THF) was purchased from Bioway (New York, NY). γ -H2AX, Ki-67, and CD-31 polyclonal antibodies were purchased from Bioworld Technology Co., Ltd (Nanjing, China).

Hela and A549 cell lines were provided by Zhongke Quality Inspection Biotechnology Co., Ltd (Beijing, China). BALB/c mice (female, nu/nu, 4–5 weeks old) were purchased from Chongqing TengXin biotechnology Co., Ltd (Chongqing, China).

Synthesis of Folate-Conjugated PCEC (FA-PCEC)

The synthesis route of FA-PCEC is shown in [Figure 1](#). First, PCEC was synthesized from polyethylene glycol and ϵ -CL via ring-opening polymerization using Sn (Oct)₂ as a catalyst, as reported previously.¹⁹ Next, the target polymer FA-PCEC was synthesized in three steps.^{20,21} Boc-L-Phe-terminated PCEC was obtained as follows: a nitrogen-purged flask containing 10 g of PCEC and 3.1 g of Boc-L-Phe, dissolved in 80 mL anhydrous dichloromethane, was cooled to -10°C . The mixture was then poured into a solution containing 0.8 g of DCC and 0.08 g of DAMP and incubated for 48 h at 0°C . Second, 6 g of Boc-L-Phe end-capped PCEC was added to 70 mL dry methylene dichloride; the mixture was then cooled to 0°C . Following this, 15 mL trifluoroacetic acid was added to the solution under nitrogen atmosphere for 2 h. Amino-terminated PCEC was obtained by vacuum drying at room temperature for 48 h. Finally, 806.4 mg of amino-terminated PCEC was dissolved in 60 mL DMSO, and mixed with 440 mg of folate. Subsequently, 253 mg of DIC and 230 mg of NHS were added to the solution as catalysts. The reaction was performed at 37°C for 24 h; the supernatant was collected, dialyzed for 72 h, and dried in

Figure 1 The synthesis route of FA-PCEC block copolymer.
Abbreviation: PEG, polyethylene glycol.

a freeze dryer to obtain FA-PCEC. A proton NMR spectrometer was used to detect the characteristic peaks of protons to verify whether folate was attached to PCEC.

Preparation of ATO

ATO was prepared by emulsification/solvent diffusion method.^{22,23} Ola (4 mg) and FA-PCEC copolymer (46 mg) were dissolved in 2 mL DMSO to induce a diffusing phase; the solution was then added to 10 mL dispersing phase (PVA 0.5% in water) that was under a magnetic stirrer (300 rpm, 10 min) using a syringe. The nanoparticles were obtained by dialyzing against water for 48 h to remove DMSO and free Ola. A sterile filter with a 220-nm pore size was used to filter the

suspension. The nanoparticles were then centrifuged at 20,000 g for 15 min, followed by several washing steps with distilled water. The orange-colored active targeting nanoparticles were then freeze-dried and stored at 4°C . Non-active targeting olaparib nanoparticles (NATO), which were not modified with folate, were prepared by a similar method, with the replacement of FA-PCEC copolymer with PCEC copolymer.

Characterization of ATO

The size distribution and Zeta potential of ATO were measured by dynamic light scattering (DLS, NanoBrook90 plus Zeta, Brookhaven, USA) at 25°C . All results were averages of three test runs. The structure of ATO was determined

using a transmission electron microscope (TEM, Tecnai G2 F20, USA).

Drug Loading (DL) and Encapsulation Efficiency (EE)

The DL and EE of ATO were determined via high-performance liquid chromatography (HPLC, Agilent, Richardson, TX), and chromatographic analysis was performed using a reversed-phase C18 column (4.6 × 150 mm, 5 μm, USA) as per a previously reported method.²⁴ The specific steps are as follows. ATO was dissolved in the mobile phase, which contained acetonitrile/water (64/36, v/v). The air from mobile phase was exhausted 30 min before use, and the mobile phase was applied with a flow rate of 1.0 mL/min through the column at 25°C. The volume of each injection was 20 μL, and the detection wavelength was set at 276 nm. DL and EE were calculated according to the following formula:

$$DL = \text{Olaparib} / \text{Olaparib} + \text{Polymer}$$

$$EE = \text{Actual DL} / \text{Theoretical DL}$$

In vitro Drug Release of Ola and ATO

The release of Ola from ATO in vitro was evaluated as follows: 1 mg Ola or ATO containing 1 mg Ola (theoretical DL, 8%) were separately dissolved in 1 mL DMSO (1 mg/mL) and 1 mL distilled water (1 mg/mL), and then separately poured into corresponding sealed dialysis bags (molecular weight cutoff, 3.5 kDa). The bags were individually incubated at 37°C in 30 mL PBS (pH = 7.4), containing Tween-80 (0.5%, w/w), with gentle stirring (100 rpm). The incubation medium was replaced with the same volume (2 mL) of freshly preheated medium (37°C) at predetermined time points. Subsequently, the collected release drug was centrifuged at 12,000 rpm for 15 min at 4°C. Following this, 1 mL of supernatant from each group was collected and stored at -20°C for further analysis. All supernatant samples were analyzed via HPLC and experiments were performed at least in triplicates.

Cytotoxicity Assay and Cellular Uptake of Nanoparticles

The cytotoxicity was evaluated via MTT assay. In brief, HeLa cells were seeded in 96-well plates at a density of 5×10^3 cells/well and incubated for 24 h at 37°C; the cells were then exposed to free Ola, NATO, and ATO at different concentrations (0 to 5 nmol/L) for 24 h. Subsequently, 10 μL of MTT solution was added to the cells, and cell viability was analyzed after incubation for 4 h by dissolving the

formazan precipitate in DMSO and recording the absorbance at 490 nm using a microplate reader (iMark, Bio-RAD, USA).

FITC-labeled PCEC nanoparticles and FA-PCEC nanoparticles were prepared as described previously.²⁵ An ethanol solution of FITC was added to 1.0 mg/mL of PCEC or FA-PCEC nanoparticle solution, and the FA-PCEC nanoparticles to FITC molar ratio was controlled at 1:4. The solution was stirred (400 rpm) for 24 h at room temperature in a dark environment. The reaction product was then dialyzed against deionized water for 24 h using a dialysis membrane (MWCO: 3.5 kDa) to remove un-reacted FITC. HeLa cells and A549 cells were then seeded at a concentration of 1×10^5 cells/well in a 6-well plate and incubated for 24 h. Following this, 50 μL of medium containing 10 μg/mL FITC-PCEC nanoparticles was added to the 6-well plate with HeLa cells and incubated for 6 h. The FITC-FA-PCEC nanoparticles were added to a separate 6-well plate with HeLa cells and A549 cells. For comparison, free FA dissolved in DMSO was added to a fresh medium containing FITC-FA-PCEC nanoparticles at a concentration of 10 μg/mL and poured into a 6-well plate with HeLa cells. After washing the cells three times with PBS (0.01 M, pH = 7.4), they were observed under a fluorescence microscope (Olympus, Tokyo, Japan).

In vivo Evaluation of Anti-Tumor Efficacy

Animal experiments were performed according to Guidelines for the Feeding, Management and Use of Laboratory Animals and were approved by the Institutional Animal Care and Treatment Committee of Southwest Medical University (Luzhou, China). In brief, the tumor xenograft model was established by subcutaneously injecting HeLa cells (1×10^6 cells in 100 μL PBS) into the right thigh of athymic BALB/c nude mice (female, 4–5 weeks old). When the average volume of the subcutaneous tumor reached 150–200 mm³ ($V = a \times b^2/2$, where a and b are the longest and shortest diameters of the tumor, respectively), the mice were randomly divided into six groups as follows (n = 12 per group): Control (0.9% normal saline [NS]); NATO; ATO; RT (a single dose of 10 Gy); NATO+RT; and ATO+RT. Subsequently, each mouse in the drug-treated group was intravenously administered 50 mg/kg of Ola standard for 3 days. RT was only conducted 30 min after the first drug administration. The long and short diameters of the tumor were measured every 2 days from the first day of drug administration using a Vernier caliper, and the tumor volume was calculated based on the tumor

volume calculation formula described before. The measurement was stopped after the tumor volume reached four times the initial tumor volume. The tumor growth delay (TGD) was calculated by $T_{i4} - T_4$, where T_{i4} is the time taken for the tumor volume to reach four times the initial tumor volume after treatment and T_4 is the time taken for the control tumor volume to reach four times the initial tumor volume. On day 10 after drug administration, mice from each group were selected and dissected to resect the heart, liver, spleen, lung, and kidney for H&E staining for evaluating drug toxicity. The remaining mice in each group were used to observe median survival.

Small animal PET/CT was performed to explore therapy response and early metabolism of tumor tissue with different treatments. The mice were randomly selected from each group for the scan and were not allowed to drink or eat for at least 8 h before the scan. The mice were then anesthetized with 1% pentobarbital (5 mg/kg) intraperitoneal injection and injected with 100–200 μCi FDG (0.1 mL) in the tail vein. PET/CT scan imaging was performed at least 30 min after the intravenous injection. The parameters were as follows: voltage, 80 kV; current, 500 μA ; section thickness, 1.5 mm, and 10 min per bed position.

Immunohistochemical Analysis

Within 48 h after the first administration, three nude mice were randomly selected from each group to obtain tumor tissues for immunohistochemical detection of $\gamma\text{-H2AX}$. Further, 10 days after drug administration, the obtained tumor tissue was used for the detection of other immunohistochemical indicators such as Ki-67. Specific steps are as follows: the tumor tissue was fixed in 10% neutral formaldehyde for at least 24 h, it was then embedded in paraffin and cut into 3–4- μm -thick sections and stained with H&E for immunohistochemical analysis. The detailed procedures for $\gamma\text{-H2AX}$ and Ki-67 expression detection were according to the manufacturer's instructions (Bioworld Technology, Nanjing, China) and pictures were taken using an optical microscope (Olympus, Tokyo, Japan). The expression levels of $\gamma\text{-H2AX}$ and Ki-67 were calculated at three randomly selected areas in each tumor sample at 200 \times magnification as the number of positive cells/total number of cells.

Apoptosis Analysis

Ten days after drug administration, the obtained tumor tissue was used for apoptosis analysis. Cellular apoptosis was analyzed by flow cytometry (BD FACSVerser, Piscataway,

NJ). The tumor tissue was shredded and added to 2 mL trypsinization buffer placed in a 37°C incubator with gentle shaking to digest. After 40 min of digestion, the serum-containing medium was added to stop the digestion. Following this, the mixture was filtered using a nylon gauze of pore size 70 μm to remove the undigested tumor tissue. The collected cell suspension was centrifuged at 1000 rpm for 2 min and washed twice with physiological saline. Subsequently, 5 μL of propidium iodide and 5 μL of fluorescein isothiocyanate were added to each test tube. Cells were incubated at room temperature in the dark for 15 min, and 400 μL of pre-cold 1 \times binding buffer was then added. After gentle mixing, the cell suspensions were analyzed via flow cytometry (BD FACSVerser, Piscataway, NJ).

Statistical Analysis

Data analysis was processed by SPSS 18.0 software using *t*-test for two-group comparisons and one-way ANOVA for comparisons of more than two groups. The value obtained is expressed as mean \pm standard deviation ($x \pm s$). $P < 0.05$ was considered statistically significant.

Results

Characterization of FA-PCEC Copolymer

In this study, we successfully synthesized FA-PCEC copolymer. The structure of the FA-PCEC copolymer was detected via nuclear magnetic resonance hydrogen spectroscopy. As shown in Figure 2, the copolymer shows characteristic PCL peaks at 1.4 ppm, 1.6 ppm, 2.3 ppm, and 4.1 ppm and a typical PEG characteristic peak at 3.5 ppm. The characteristic peaks of PCL and PEG appeared in the same position in the NMR hydrogen spectrum for both PCEC and FA-PCEC, but the typical peaks of folate were seen in FA-PCEC at 6.6 ppm, 7.6 ppm, and 8.6 ppm. Based on this analysis, it can be concluded that folate was successfully branched on PCEC and the target polymer FA-PCEC was successfully synthesized.

In vitro Characterization of ATO

The particle size and morphology of ATO were detected by DLS and TEM. The average hydrodynamic diameter of ATO was 240.62 ± 8.79 nm (Figure 3A), furthermore, the zeta potential of ATO was -10.5 ± 1.09 mV (Figure 3C). As a comparison, the average hydrodynamic diameter of ATO was 205.43 ± 3.13 nm (Figure 3B), the zeta potential of ATO was 4.67 ± 1.17 mV (Figure 3D). The obtained ATO was mono-dispersed and stabilized in an aqueous

Figure 2 H-NMR spectra of PCEC (A) and FA-PCEC (B). The gray circle represents the characteristic peak of FA.
Abbreviation: H-NMR, NMR hydrogen spectroscopy.

solution; the appearance of ATO was spherical as shown in the TEM image (Figure 3E).

As mentioned before, the theoretical DL of ATO was set at 8%. However, HPLC results showed that the actual DL and EE of ATO were $6.44\% \pm 0.05\%$ and $80.54 \pm 0.63\%$, respectively. As shown in Figure 3F, in vitro release of free Ola showed a rapid release trend and approximately 90% of Ola was released into the medium within 4 days. In contrast, ATO showed a slow and long-lasting release trend, and 80% of Ola was released from ATO within 10 days.

Cytotoxicity Assay and Cellular Uptake

To evaluate the cytotoxicity of ATO, MTT assay was performed using HeLa cells. The dose-dependent inhibitory effect of free Ola, NATO, and ATO on HeLa cells is illustrated in Figure 4A. The cytotoxicity of ATO was superior to that of free Ola basically. Moreover, compared with free Ola and NATO, ATO showed a stronger inhibitory effect when the concentration was 200 $\mu\text{g/L}$. When the concentration was 200 $\mu\text{g/L}$, the viability of cells treated with ATO was $53.2 \pm 1.5\%$, which was significantly lower than that of cells treated with NATO and treated with NATO, indicating that the therapeutic effect of Ola was enhanced when Ola was incorporated into nanoparticles to form ATO. Figure 4B illustrates the

cytotoxic effect of FA-PCEC on HeLa cells. No cytotoxicity was detected among all the tested concentrations, indicating that the anti-tumor activity of ATOs was attributed to Ola, which released from the nanoparticles. This indicated that FA-PCEC copolymer has good cytocompatibility and can be considered a safe drug delivery vehicle.

To verify the targeting ability of ATO, cell uptake experiments were conducted in HeLa cells and A549 cells. Because A549 cells do not have folate receptors, thus A549 cells were chosen as negative control group. Fluorescence images obtained after incubation with FITC-labeled NATO and ATO are shown in Figure 4C. In HeLa cells, no fluorescence spot was observed in the Control group, and fluorescence intensity of FITC-labeled ATO was more pronounced than that of FITC-labeled NATO, indicating that folate-conjugated nanoparticles show a better cell uptake efficiency than unconjugated nanoparticles. However, after adding free FA to the medium containing FITC-labeled ATO, a lower fluorescence intensity was observed, indicating that free FA prevents ATO from transporting into HeLa cells by competitive binding to folate receptors on the cell surface. In addition, A549 cells showed relatively low fluorescence uptake on addition of FITC-labeled ATO. These results indicated that FA-conjugated nanoparticles are a potential drug delivery system that targets tumor cells through folate receptor-mediated endocytosis.

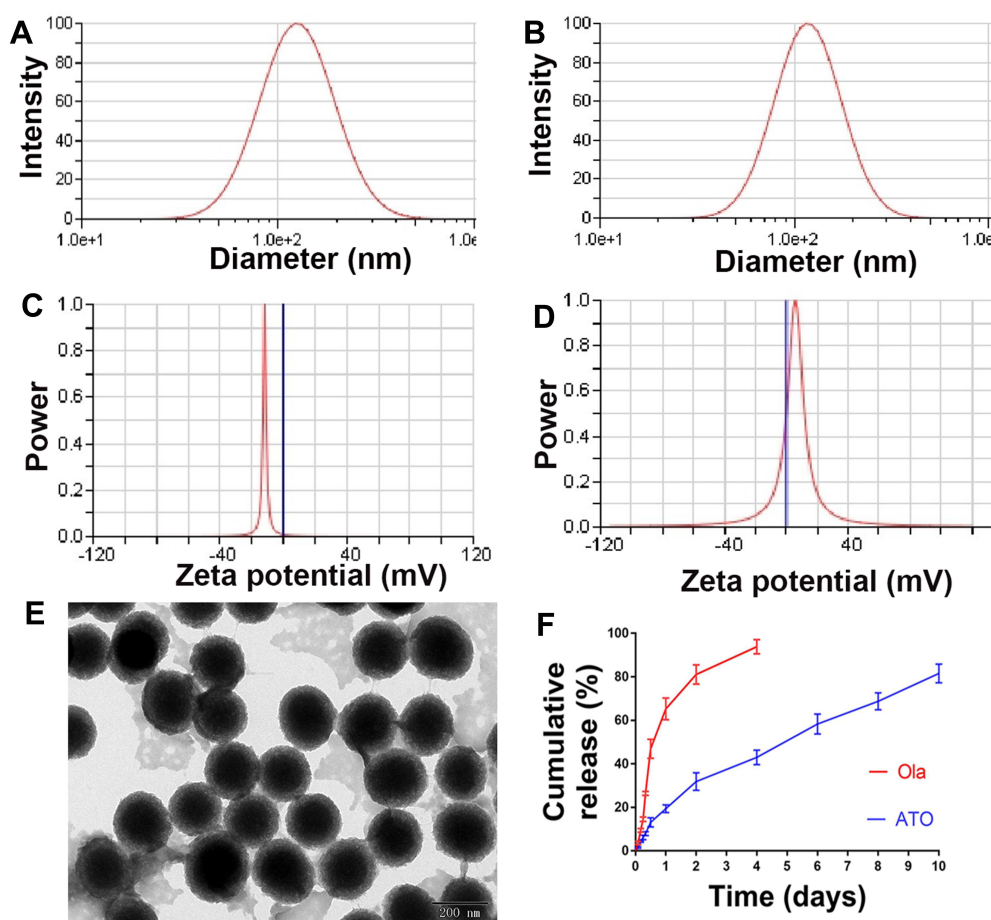

Figure 3 The characterization of ATO. (A) Particle size distribution of ATO, presented a mean size of 240.62 ± 8.79 nm. (B) Particles size distribution of NATO, presented a mean size of 205.43 ± 3.13 nm. (C) Zeta potential of ATO, showed a negative surface charge of -10.5 ± 1.09 mV. (D) Zeta potential of NATO, showed a positive surface charge of 4.67 ± 1.17 mV. (E) Transmission electron microscopy image of ATO (the scale is 50 nm). (F) Drug release study of Ola and ATO.

In vivo Anti-Tumor Efficacy of Radiotherapy Combined with ATO

The therapeutic efficacy of ATO+RT on Hela xenografted mice was assessed as shown in Figure 5. The PET/CT images and tumor appearance in mice in each group are shown in Figure 5A and B. According to the tumor appearance, the tumor volume was the largest in the mice in the Control group, whereas the tumor volume in the mice in the ATO+RT group was the smallest. Based on the results of PET/CT imaging (Figure 5C), the mean SUVmax of the tumor in each group was observed: 2.73 ± 0.25 (control), 2.26 ± 0.25 (NATO), 1.77 ± 0.15 (ATO), 1.63 ± 0.25 (RT), 1.33 ± 0.15 (NATO+RT), and 0.93 ± 0.05 (ATO+RT). The SUVmax of mice in the ATO+RT group was the lowest when compared to NATO+RT, RT and other groups, indicating that the tumor in this group has the lowest metabolism, and thereby implying a more powerful anti-tumor effect of ATO+RT. In addition, the tumor volume in mice in different groups after treatment was

measured and plotted as shown in Figure 5D. Tumor growth was delayed by 3 days in mice treated with NATO alone ($P < 0.05$), whereas the ATO group and RT group showed a delay in tumor growth by 6 and 12 days, respectively ($P < 0.05$). The NATO+RT group showed a tumor growth delay of 18 days and the ATO+RT group exhibited a tumor growth delay of 24 days, which was longer than the other five groups mentioned above. These results indicated that ATO+RT had a more effective synergistic effect in inhibiting tumor growth compared with other therapies. At the same time, a similar effect was observed for the median survival time in mice (Figure 5E). The median survival time of mice in the ATO+RT group (50 days) was significantly longer than that of mice in the NATO+RT (42 days), RT (38 days), ATO (38 days), NATO (34 days) and Control (32 days) groups ($P < 0.05$).

Immunohistochemical Analysis

The immunohistochemical analysis results are demonstrated in Figure 6A. The results showed that ATO+RT significantly

Figure 4 In vitro cell viability and fluorescent images. **(A)** Cell viability of free Ola, NATO and ATO on HeLa cell after 24 h incubation. * $P < 0.05$; ** $P < 0.01$; no statistical significance between unlabeled groups. **(B)** Cell viability of FA-PCEC. **(C)** Fluorescent images of HeLa cells treated with culture medium, FITC-labeled NATO, FITC-labeled ATO and FITC-labeled ATO+FA for 2 h and fluorescent images of A549 cells treated with FITC-labeled ATO for 2 h.

increased the expression of γ -H2AX and reduced the expression of Ki-67 in mice.

The proportion of γ -H2AX-positive cells in the ATO+RT group was $76.65\% \pm 2.88\%$, which showed an increased apoptotic rate when compared to NATO+RT ($63.8\% \pm 3.77\%$), RT ($53.86\% \pm 3.32\%$) and other treatment groups (Figure 6B) ($P < 0.05$).

Ki-67 is an immune indicator that reflects tumor cell proliferation. The percentage of Ki-67-positive cells in different groups is as follows (Figure 6C): Control group, $84.82\% \pm 2.11\%$; NATO group, $56.78\% \pm 1.41\%$; ATO group, $42.43\% \pm 3.35\%$; RT group, $41.55\% \pm 1.95\%$; and NATO+RT group, $30.4\% \pm 2.54\%$. In addition, there was an obvious decrease in the percentage of Ki-67-positive cells in ATO+RT group

($19.51\% \pm 3.04\%$) compared with that in other groups ($P < 0.01$).

Flow Cytometry

Flow cytometry was used to detect the apoptosis levels of tumor tissues in each group (Figure 7A). As shown in Figure 7B, there was no significant difference in apoptosis rate between ATO+RT group and NATO+RT group ($P > 0.05$). But the rate of apoptosis in ATO+RT and NATO+RT groups were higher than that in RT ($60.56\% \pm 4.12\%$), ATO ($52.33\% \pm 3.6\%$) and other groups. This result indicated that a combination of ATO or NATO with RT significantly increased the apoptosis rate of tumor cells.

Evaluation the Side Effects of ATO

In this experiment, the in vivo toxicity of different treatments was evaluated by observing the pathological changes in important organs of nude mice in each group. After the nude mice were sacrificed, the heart, liver, spleen, lung and kidney of the mice were prepared for H&E staining. As shown in Figure 8, no obvious pathological changes were found in each treatment group.

Discussion

Cervical cancer, as a common malignant tumor that seriously threatens women's health, has shown a high incidence in recent years.²⁶ RT is one of the most important treatment options for cervical cancer as it not only improves tumor control but also reduces complications.^{27,28} The mechanism of RT is mainly to cause DNA strand breaks in tumor cells, but the self-repair function of the tumor tissue makes the tumor tissue less sensitive to radiation. Therefore, targeted inhibition of DNA repair to improve the efficacy of RT has become one of the research hotspots in recent years.²

PARP is a well-known enzyme closely associated in DNA damage repair. PARP inhibitors can precisely inhibit the activity of PARP and the repair of single-stranded DNA breaks, causing a synthetic lethal effect that leads to the death of tumor cells and enhancing the effect of RT.⁴ Ola is a representative PARP inhibitor, which is approved for use in the treatment of advanced ovarian cancer patients with BRCA1/2 mutation.²⁹ Previous studies have confirmed that Ola can be used in combination with RT to enhance its anti-tumor effects.^{8,30,31} At the same time, our research group has previously confirmed that Ola nanoparticles combined with RT showed enhanced anti-tumor effects on lung cancer A549 xenografts in nude mice at an early stage,¹⁷ which further improves the feasibility of its clinical promotion. According to research reports, drug-loaded nanoparticles can achieve passive targeting in tumors because of enhanced permeability and retention effect (EPR).³² However, only a small fraction of nanoparticles accumulating in solid tumors through passive targeting can be absorbed.^{33,34} Thus, to improve the targeting efficiency, it is necessary to introduce targeting molecules (such as folic acid and monoclonal antibodies)

Abbreviation: ns, no statistical significance.

that can recognize and bind to specific receptors on cancer cells.^{35–37} Furthermore, a preliminary study by our research group confirmed that folate-conjugated nanoparticles have an active targeting inhibitory effect on tumors rich in folate receptors on their cell surface.¹⁸ This work reveals that it is possible to target DNA damage to tumor cells and improve the therapeutic effect of RT.

Therefore, this study aimed to prepare ATO and explore the targeted enhancement of therapeutic effect when using ATO in combination with RT. First, an emulsification/solvent diffusion method was used to successfully prepare injectable ATO. Compared with other recently reported nanoparticles, ATO showed a stable particle size and higher DL.^{38,39} In addition, the sustained slow release trend of ATO may be attributed to the

relatively stable structure of the folate polymer carrier. The cytotoxicity experiments suggested that ATO lead to decreased cell viability of tumor cells, which was associated with the lack of BRCA2 in cervical cancer cells and is consistent with previous research.^{40,41} However, FA-PCEC showed almost no cytotoxic effect. These findings indicated that the inhibitory effect of ATO was attributed to the Ola wrapped in it. In this study, the uptake of folate-conjugated nanoparticles by Hela cells was more significant. In addition, a lower fluorescence intensity was observed after adding free folate into the medium. Moreover, a lower fluorescence intensity was observed in A549 cells that are negative for folate receptor; this proves our hypothesis that the active endocytosis of ATO by Hela cells was mediated by folate receptors. Thus, these results

indicated that ATO prominently inhibited cancer cell growth by delivering more Ola into Hela cells by folate-mediated endocytosis.

We subsequently established a nude mouse xenograft model using cervical cancer Hela cells to investigate the

therapeutic effect of ATO+RT. A RT dose of 10 Gy has always been used in studies reporting combined use of olaparib and RT.^{5,42,43} In our in vivo anti-tumor study, TGD and survival duration of mice treated with ATO+RT were significantly higher than those of mice treated with other treatment

measures; this further confirmed that ATO combined with RT had a better anti-tumor effect on cervical cancer xenograft model. The abovementioned results are consistent with the results of our previous study concerning the combined use of Ola and RT.¹⁷ This is probably because of the active targeted uptake of ATO by Hela cells resulting in a high concentration of Ola in the cells, which further results in a more pronounced therapeutic effect when combined with RT.¹⁸ ¹⁸F-FDG PET/CT was used to understand the early therapeutic effects in nude mice. Previous studies have shown that ¹⁸F-FDG PET/CT can reflect the level of glucose metabolism, which is closely associated with the therapeutic effect on the tumor.³⁸ In tumor tissues, high glucose metabolism indicates a worse therapeutic effect, whereas low glucose metabolism often demonstrates a better therapeutic effect. The mice in the ATO+RT group showed the lowest glucose uptake compared with those in other groups, suggesting that ATO+RT had a better effect of inhibiting tumor growth.

In this study, immunohistochemical analysis was used to detect γ -H2AX and Ki-67 expressions in tumor tissue. The results suggested that mice in the ATO+RT group showed a higher expression level of γ -H2AX than those in other groups. Previous studies have shown that Ola combined with RT can increase DNA double-strand breaks. Therefore, the expression of γ -H2AX, a biomarker for DNA double-strand breaks, was detected to confirm the DNA damage in each group. Ki-67 is a tumor proliferation index; our results indicated that the mice in the ATO+RT group had the lowest proportion of Ki-67-positive cells among all groups. These results were similar to those reported in previous studies.^{2,44} The increased expression of γ -H2AX and the decreased expression of Ki-67 in the ATO+RT group may be because of the active targeting uptake of ATO in Hela cells to form high concentrations of Ola in Hela cells. The results of flow cytometry also showed that tumor tissues in ATO+RT group had the highest rate of apoptosis, which is similar to previously reported results.⁴⁵ The increased sensitivity of tumor cells to apoptosis may be associated with the down-regulation of the anti-apoptotic protein.^{46,47}

In summary, these results indicate that ATO in combination with RT has a synthetic lethal effect on cervical cancer xenografts. Although the results are encouraging, shortcomings and limitations of our research clearly exist. Therefore, the tissue distribution of nanoparticles in vivo needs to be evaluated further in subsequent experiments. Also, further in vivo studies with folate receptor-negative cell lines should be conducted in the future.

Conclusion

In this study, ATO was successfully prepared. Data showed that ATO had outstanding targeted effect on cervical cancer xenograft tumor. ATO+RT significantly inhibited the growth of cervical cancer cells and prolonged the median survival duration of mice. In addition, we explored the mechanism of synthetic lethal effect of ATO+RT and found that ATO+RT induces DSBs and increases the apoptosis of tumor cells. In summary, ATO has good application prospects for tumors with an over-expression of folate receptors.

Acknowledgments

This study was supported by the Major Project of the first Affiliated Hospital of Southwest Medical University, project number P2017001.

Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch[®], Current Contents[®]/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
