## Perceived Versus Demonstrated Understanding of the Complex Medications of Medically Complex Children

Allison B. Blackmer, PharmD; David Fox, MD; Dave Arendt, PhD; Kyle Phillips, BS; and James A. Feinstein, MD, MPH

**OBJECTIVES** Parents and caregivers of children with medical complexity (CMC) manage complex medication regimens (CMRs) at home. Parental understanding of CMRs is critical to safe medication administration. Regarding CMR administration, we 1) described the population of CMC receiving CMRs; 2) assessed parental perceived confidence and understanding; and 3) evaluated parental demonstrated understanding.

**METHODS** Cross-sectional clinic-based assessment of knowledge and understanding of CMC using CMRs who received primary care in a large pediatric complex care clinic. CMRs were identified by the receipt of  $\geq 1$  of the following: 1)  $\geq 10$  concurrent medications; 2)  $\geq 1$  high-risk medication; or 3)  $\geq 1$  extemporaneously compounded medication. Parents reported their perceived confidence and understanding of CMRs, and then demonstrated understanding through 3 medication-related tasks.

**RESULTS** Of 156 CMCs, most were <10 years of age (63.5%), white (75%), had neurologic impairment (76.9%), and used a median of 8 medications (IQR, 5–10). Parents were female (76.9%) with a mean age of  $38.8 \pm 11.5$  years, white (69.9%), spoke English (94.2%), and had some college education (82.1%). On 11 confidence and understanding statements, most parents reported a high perceived level of understanding and confidence, with combined agreement or strong agreement ranging between 81.2% and 98.7%. Only 73.1% correctly identified medications taken for specified conditions, 40.4% reported complete dosing parameters, and 54.8% correctly measured 2 different medication doses. Significant differences existed between parental perceived understanding versus the 3 demonstrated tasks (all p < 0.05).

**CONCLUSIONS** Substantial opportunities exist to improve medication safety and efficacy in the outpatient, in-home setting including improved medication-specific education and medication-related supports.

### Introduction

Parents and caregivers (subsequently referred to as parents) of children with medical complexity (CMC) manage complex medication regimens (CMRs). CMRs may consist of numerous, complex, and high-risk medications. Literature supports that CMC can be regularly prescribed  $\geq$ 5 scheduled medications, with parents administering up to 35 daily doses, often via alternative routes of administration requiring dosage form manipulation.<sup>1</sup> In outpatient, in-home settings, the administration and monitoring of medications are performed most frequently by parents, rather than trained health care professionals. Although some CMC have available home nursing resources, parents have the primary responsibility in the care of CMC, including accurate administration of CMRs. Correct administration and adherence require knowledge and understanding of CMRs, including indications and medication-specific information (e.g., dosage form, instructions, expected

outcomes). However, gaps in understanding of medication instructions across all literacy levels have been identified; in a study evaluating comprehension of after-visit instructions after primary care visits, parents were only able to accurately name 71% of the medications and describe administration instructions 37% of the time.<sup>2</sup>

While CMRs and polypharmacy are often medically necessary for CMC, the concomitant use of multiple medications increases the potential risk of administration errors, interactions, adverse events, adherence issues, and parental misunderstanding, which may affect patient safety.<sup>3</sup> For example, certain high-risk medications (e.g., clonidine and non-stimulant psychotropic medications) have been reported in the literature to be associated with major safety events such as inadvertent dosing errors resulting in significant toxicity.<sup>4,5</sup> Two recent systematic reviews<sup>6,7</sup> argued for expanded research in children, aimed at interventions targeted at reducing medication errors and improving adherence. Parental knowledge of and skills related to CMRs are critical to ensuring safety. Thus, the primary objectives of this study were to 1) describe the population of children with CMC receiving CMRs, including the types of medications used; 2) assess parents' perceived confidence related to CMRs; 3) assess parents' understanding of CMRs; and 4) compare differences in parental perceived confidence and understanding versus demonstrated understanding and knowledge of CMRs.

### **Materials and Methods**

**Study Design.** This was a single-center crosssectional study of CMC using CMRs who received primary care in a large pediatric complex care clinic serving >4000 patients. The study was approved by the Colorado Multiple Institutional Review Board, an administrative body that protects the rights and welfare of human research subjects participating in research activities conducted under the auspices of the University of Colorado and its affiliates.

Identification of Subjects. Subjects between the ages of 0 and 21 years with CMC and CMRs who could speak and understand English were consecutively enrolled between November 1, 2015, and May 31, 2016. Children with medical complexity were identified by using the Pediatric Medical Complexity Algorithm and further categorized by neurological impairment status and AHRQ's (Agency for Healthcare Research and Quality's) chronic condition indicator.8-10 CMRs were identified by meeting  $\geq 1$  of the following criteria: 1)  $\geq 10$ concurrent scheduled medications (polypharmacy); 2) receipt of  $\geq$ 1 high-risk medication; and/or 3) receipt of  $\geq 1$  extemporaneously compounded medication. For this study, high-risk medications were defined as scheduled, long-term opioids; anticoagulants; antiepileptic agents; stimulant medications; psychotropic medications; agents to treat tone/spasticity; or sleep aids.<sup>11,12</sup> These medications were chosen owing to their association with adverse drug reactions and owing to CMC use patterns. Parents were approached for study participation during routine, in-person clinic visits.

**Consent, Enrollment, and Survey Administration.** After consent and enrollment, demographic, diagnoses, and medication regimen–specific data were manually extracted from the electronic health record. Parents then completed an in-person survey adapted from similar previously published surveys and accounting for key pharmacotherapy aspects required for complete understanding, adherence, and outcomes (for full survey, see Supplemental Table 1).<sup>13–16</sup> The survey included demographic questions as well as 5-point Likert scale questions about perceived understanding/knowledge and confidence pertaining to CMRs. Study data were managed with REDCap electronic data capture tools.<sup>17</sup>

**Parental Understanding.** Parents demonstrated knowledge of CMRs through assessment of 3 tasks.

First, a live, in-clinic and observed assessment of the parent's ability to accurately draw up 2 doses of liquid medication, using oral syringes. Accuracy was defined strictly as no errors in measurement, including no air bubbles, in order to account for all medication types. Because parent medication measurement accuracy may have different implications based on a specific medication's therapeutic window, we defined accuracy by using the strictest definition. To isolate measuring technique irrespective of specific medications, parents performed this assessment using water.

The second assessment of parental understanding was correct identification of medications prescribed for 2 patient-specific complex conditions identified by the principal investigator. Selected conditions were those of highest clinical relevance. Owing to the medical complexity of the patient population, the correct recall and identification of medications associated with 2 patient-specific complex conditions served as a proxy measure to represent knowledge of all patient-specific conditions and associated medications.

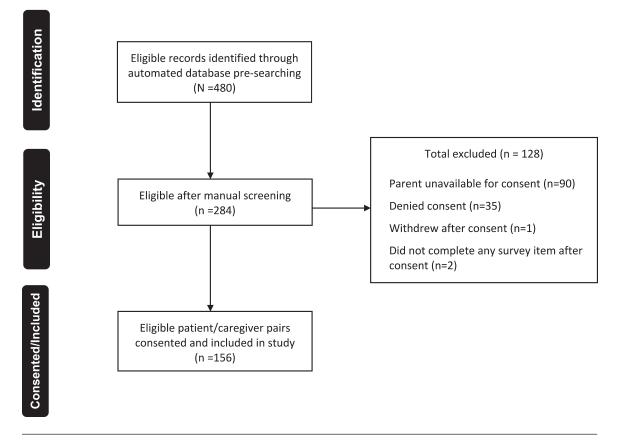

The third and final assessment of demonstrated parental understanding was parents' recall and description of complete medication instructions for 1 patientspecific complex medication identified by the principal investigator, including indication, formulation (e.g., tablet/capsule versus liquid, and milligram strength or concentration), dose, frequency, and route of administration.<sup>13,15</sup> The selected medication was chosen on the basis of clinical relevance. Complete accuracy required correct identification of all parameters. For both the patient-specific indications and the complex medication regimen, parents were asked to recall this information without any written information in front of them.

Statistical Analysis. Descriptive statistics were calculated for patient demographics and for survey responses. Five-point Likert survey responses were collapsed into binary responses, with Strongly Agree or Agree indicating a positive response. The McNemar test for paired proportions was used to compare parental perceived versus demonstrated understanding. Confounding variables (e.g., socioeconomic status, highest level of education, presence of home nursing) were accounted for in a multivariable logistic regression in order to describe the relationship between parental characteristics and demonstrated understanding, adjusting for the type of CMR. Only survey items with <5% missing data, unless noted otherwise, were analyzed. Owing to extremely low usage of intravenous and intramuscular medications in our subjects, only data pertaining to enteral or inhaled medications were analyzed. A significance level of 0.05 was used. Data were analyzed by using Stata 16.0 (Stata Corp, College Station, TX).

### Results

Of 480 eligible CMCs identified during the study pe-

riod, 32.5% (n = 156) were consented for study participation and completed all study procedures (Figure 1). The in-clinic demonstration of measurement of medications was completed by 86.5% of parents.

**Demographics and Clinical Characteristics of** Study Population. Most patients were <10 years of age (63.5%), white (75%), had neurological impairment (76.9%), and used a median of 8 medications (IQR, 5–10) (Table 1). Of these children, 23.1% met the polypharmacy enrollment criteria, 95.5% met the high-risk medication criteria, and 35.9% met the compounded medication criteria; 41.7% of children met 2 enrollment criteria and 6.4% of children met all 3 criteria. The most common primary diagnoses included cerebral palsy, unspecified (11.5%); extreme prematurity (i.e., gestational age 24 weeks) (7.6%); and chromosomal abnormality, unspecified (6.4%) (Supplemental Table 2). Many of the study subjects had medical comorbidities; among all recorded diagnoses, comorbidities occurring with >5% frequency were disorders of psychological development (11.1%), generalized epilepsy (10.1%), and sleep disorders (5.1%) (Supplemental Table 3).

Most parents were female (76.9%) with a mean age of  $38.8 \pm 11.5$  years, white (69.9%), had a biological relationship to the child (82.1%), spoke English (94.2%), and

had at least some college education (82.1%) (Table 2).

Most Frequent Medications Used. A total of 1175 medications were prescribed. The most frequent medications included vitamins (14.5%), antiepileptic drugs (13.6%), and psycholeptic (e.g., antipsychotics, anxiolytics, hypnotics, and sedatives) drugs (8.9%) (Table 3). A full list of medications used by CMC, including non-prescription medications, is described in Supplemental Table 4. The most frequently prescribed medications differed by the type of enrollment criteria (e.g., polypharmacy, high-risk medications, or compounded medications); however, vitamins and antiepileptic drugs were commonly used amongst all 3 groups. Of the 97 unique high-risk prescription medications used, the top 3 were levetiracetam (10.3%), baclofen (6.7%), and clonidine (5.2%). Of the 27 unique compounded medications used, the top 3 were lansoprazole (17.1%), baclofen (11.8%), and zinc (7.9%). A list of all compounded medications used by CMC is described in Supplemental Table 5.

**Perceived Parental Confidence and Understanding.** On 11 confidence and understanding statements, parents reported a high perceived level of understanding and confidence, with combined agreement or strong agreement ranging between 81.2% and 98.7% (Table

4). Parents perceived a high level of understanding of handling of missed doses (90.1%) and when to call the physician (95.4%) but were less clear about potential side effects (81.2%) or how to handle adverse effects (83.2%). Parents reported confidence in their abilities to administer enteral medications (>90% for each statement).

Demonstrated Parental Understanding. Despite a high perceived understanding and confidence related to CMRs, when asked to identify the medications taken for the specified complex problem, 78.1% and 85.4% of parents correctly reported for condition 1 and condition 2, respectively. Only 73.1% were able to correctly report for both conditions. Regarding dosing parameters for high-risk medications, most parents accurately identified from memory the indication for 1 high-risk medication (94.9%), but many fewer correctly identified the route (84.5%), frequency (80%), dose (69.2%), and formulation (45.9%). Only 40.4% were able to report complete dosing parameters. For the demonstrated measurement of a liquid medication dose, 66.4% were able to accurately measure a 4-mL dose, and 63.9% measured a dose of 0.35 mL accurately. Only 54.8% were able to correctly measure both doses. Regression analyses revealed no significant relationships between parental characteristics and the ability to successfully complete any demonstrated understanding task.

Parental Perceived Versus Demonstrated Understanding. For each of the 3 measured domains of demonstrated understanding, significant differences existed between parental perceived versus demonstrated understanding (McNemar test, all p < 0.05) (Figure 2). For example, although 97.4% of parents reported confidence in accurately measuring liquid medications, 54.8% correctly measured 2 different doses of medications (p < 0.05).

### Discussion

In this study of parental understanding of CMRs used by CMC, most parents reported high confidence in understanding of CMRs, but substantially fewer parents demonstrated actual understanding of CMRs. The study population was composed of younger CMC, many of whom had polypharmacy and exposure to high-risk and compounded medications. Most of their medications many of which included CNS-active medications—were administered at home by parents. Parents tended to be in their late 30s and with some college education. Parents had some difficulty correctly identifying which medications were indicated for certain conditions. Parents struggled with identification of dosing parameters for high-risk medications and were particularly challenged by accurate measurement of medications.

While this study represents the first published report comparing parental perceived versus demonstrated confidence and knowledge pertaining to CMRs for CMC, our findings are consistent with existing litera-

ture examining the broader population. Parent liquid dosing errors have been consistently reported across all health literacy and language groups.<sup>18–21</sup> Our study similarly found substantial parent errors with liquid measurements when using oral dosing syringes even without having to first interpret a medication label, identify the current oral dosing syringe size, and then draw up doses. Unlike previously published studies, we also evaluated parents' ability to correctly identify medications for a given complex condition, as well as identify dosing parameters associated with a high-risk medication. Our study identified gaps in parental understanding of CMRs for CMC, which highlight the critical need for improved medication education and support available to parents. Such efforts represent an important target for mitigating potential medication-related errors in the population of CMC. In light of this, 3 aspects of our study findings deserve further discussion.

First, in order to intervene, we need to be able to identify CMC at the highest risk of experiencing medication-related issues. Although we used an automated medication screening process in the electronic health record, approximately 40% of potential subjects did not have a CMR upon manual review. An accurate, robust, validated tool focused on medication regimen complexity (e.g., number and type of medications, number of distinct daily doses), degree of required dosage form manipulation, health literacy, and spoken language is urgently needed to improve medication use and safety in CMC. Our data indicate that CMC with CMRs take a variety of prescription and over-the-counter medications, but also a wide range of vitamins and minerals; efficient identification of at-risk patients may need to focus on specific medications rather than polypharmacy counts. Future work focused on the identification of the most impactful medications on patient safety will be important to help with patient risk stratification. Scoring systems for the stratification of children by medical complexity and identification of resources needed (e.g., care coordination) have been reported.<sup>8,22-24</sup> The development of a clinical pharmacy priority score has been described in a family medicine setting.<sup>25</sup> However, to our knowledge, a validated, robust medication regimen acuity scoring tool for the identification of at-risk patients and their families for adverse drug events, including parental understanding, has not yet been developed. The tool should also account for transitions of care across various health care settings as well as between pediatric and adult care, where medicationrelated problems or points of confusion may be more likely to occur.26-29

The substantial gaps we observed between parental confidence and understanding reinforces the need for improved medication-related education. Standardized education tools to support correct at-home medication administration are needed. A recent article written by a

\* Significant differences were noted between each of the paired proportions using the McNemar test. and 95% Cls represent the proportion of parents reporting confidence for a specific medication-related task. and 95% Cls represent the proportion of parents who were observed in-clinic and demonstrated understanding for a specific medication-related task.

group of experienced parents of CMC notes the benefit of in-person, teach-back sessions as well as visual and written instructions to improve understanding.<sup>30</sup> Such standardized tools should be used universally to ensure understanding in the pediatric population. For particularly high-risk patients, a specialized pediatric clinical pharmacist, incorporated into the multidisciplinary care team, may be well positioned to provide one-on-one counseling, particularly as it relates to CMRs. The success of the pharmacists' roles on improving medication understanding, beliefs, and adherence has been previously reported in the adult population and in a variety of specialty care settings.<sup>31–33</sup> These models should be considered and trialed in the pediatric population, especially in the complex care setting. Specialized pediatric pharmacists, incorporated into clinic visits, can provide an initial evaluation of parental understanding, provide baseline education and ongoing assessments and educational updates at subsequent clinic visits and/ or through telehealth visits. This type of recurring assessment and education is particularly important when new high-risk medications are started or when dosing changes occur. Changes in understanding should be systematically tracked through integration of a universal and standardized approach to medication education in this vulnerable population. Additionally, assessments and educational interventions need to be developed and validated in multiple languages and cultural contexts in order to have the broadest impact.

Finally, we measured 3 discrete tasks in clinic, but it may additionally be important to understand what happens in vivo in the home setting, especially since our findings indicate most medications are administered by parents without home nursing supervision. We measured 3 aspects of importance for medication safety, but there are almost certainly additional factors related to safe medication administration. Neither this study nor previous reports account for administration errors after measurement. For example, if the concentration of an extemporaneously compounded medication changes and the family measures the previous volume rather than following new instructions on the bottle, significant dosing errors can occur. While national efforts to standardize medication concentrations are underway, a high level of variability of compounded concentrations and pediatric-specific dosage forms currently exists, which may increase the chance for errors.34-36 A lack of precision, especially for narrow therapeutic index medications, could result in significant adverse drug events. Furthermore, medications are commonly administered via alternative routes, such as through enteral feeding tubes. Finally, even if medications are perfectly administered in the in-home environment, the monitoring of medication efficacy and safety relies heavily on parental knowledge and attention. Parents must be well informed about what desired effects and

side effects should be expected with CMRs to appropriately monitor medication response.

Our findings must be interpreted in the context of several limitations. First, this study was conducted at a single center and the findings may not be generalizable to all CMCs who use CMRs. The study site, however, is one of the largest outpatient complex care programs in the country and a member of the Children and Youth with Special Healthcare Needs National Research Network (www.cyshcnet.org). Secondly, inclusion was limited to those who could understand and speak English, and most parents were white with a higher level of education. Similar assessments in non-English speakers, and a lower income, lower education, minority, underserved population may broaden applicability. Third, we provided conservative estimates of accuracy (i.e., no errors in measurement) to account for high-risk medications with narrow therapeutic windows by using a strict definition of accuracy. For medications with a wide therapeutic window, our definition of accuracy may overestimate the impact of parent measurement on clinical outcomes. Caregivers were also not allowed to use notes during the observation. If notes had been allowed, it remains possible that our results would be altered. The strict definition of accuracy and the inability to use notes was used to account for the worst-case scenario. Next, the in-clinic demonstrated measurement of medications was completed by only 86.5% of parents. It remains possible that our results may have been altered with a more complete response rate. Next, although we measured demonstrated parental understanding, using standardized tasks, the study design did not assess parental interpretation and understanding of medication labels or successful at-home administration of medications. In their specific home environment, parents might have been able to correctly demonstrate understanding of their child's specific CMR, as opposed to the in-clinic study tasks. Furthermore, this study evaluated parental understanding but did not evaluate other members of the child's care-team (e.g., home nursing), whose presence could have reduced the potential risk of medicationrelated errors. To reduce the in-clinic study burden, we selected certain complex indications and medications as a proxy of understanding of the entire regimen. This may not be representative of the parent's understanding as a whole.

These limitations notwithstanding, substantial opportunities exist to improve medication safety and efficacy in the outpatient, in-home setting including a systematic approach to identification of patients most at risk, improved education, and assessment of in-home medication use. Care in this population will remain difficult to optimize without a systemwide focus on addressing these critical gaps. With a unique focus on and understanding of medication complexity and nuance in this population, pediatric clinical pharmacists may be well positioned to participate in the development and implementation of interventions.<sup>37,38</sup> For example, clinical pharmacy telemedicine interventions in the ambulatory setting have been shown to positively impact outcomes.<sup>39–41</sup> Moving forward, pediatric clinical pharmacists may be able to engage in telehealth initiatives to better evaluate, understand, and intervene on ambulatory and in-home medication-related issues. Another potential approach is the implementation of required clinical pharmacist-led educational program in-clinic at the point of prescribing with a teach-back "check off" prior to the parent picking up the medication at the pharmacy.

### Conclusions

A substantial gap exists between parent-reported perceived knowledge and actual demonstrated understanding of CMRs, which could impact patient safety. The development, implementation, and evaluation of educational supports and assessment of parental understanding both within clinic visits as well as in the home setting are needed and may directly benefit parents of CMC who must administer CMRs at home. Ultimately, enabling parents to continue to provide safe and effective medication administration at home may improve the ability for CMC to continue to thrive in the outpatient environment.
