Wiem](https://pubs.acs.org/action/doSearch?field1=Contrib&text1="Nicholas+A.+Lentini"&field2=AllField&text2=&publication=&accessType=allContent&Earliest=&ref=pdf)[e](#page-4-0)r[\\*](https://pubs.acs.org/action/doSearch?field1=Contrib&text1="Chloe+M.+Schroeder"&field2=AllField&text2=&publication=&accessType=allContent&Earliest=&ref=pdf)

function, we prepared prodrug derivatives of the HMBPP analog C-HMBP that lack the  $(E)$ -allylic alcohol or have modified it to an aldehyde or aldoxime and evaluated their biological activity. Removal of the alcohol

multiple products (observed  $EC_{50}$  ~30 nM for expansion of Vy9V82 T cells)

completely abrogates phosphoantigenicity in these compounds while the aldoxime modifi[cation decreases potency relative to the](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=tgr1&ref=pdf) (E)-allylic alcohol form. However, homoprenyl derivatives oxidized to an aldehyde stimulate Vγ9Vδ2 T cells at nanomolar concentrations. Selection of phosphonate protecting groups (i.e., prodrug forms) impacts the potency of phosphoantigen aldehydes, with mixed aryl acyloxyalkyl forms exhibiting superior activity relative to aryl amidate forms. The activity correlates with the cellular reduction of the aldehyde to the alcohol form. Thus, the functionality on this ligand framework can be altered concurrently with phosphonate protection to promote cellular transformation to highly potent phosphoantigens.

KEYWORDS: Butyrophilin, BTN3A1, ligand, phosphoantigen, prodrugs

The V $\gamma$ 9V $\delta$ 2 T cells are a subset of human T cells that contribute to immunity against infectious diseases and cancer.<sup>1</sup> Unlike most T cells, the V $\gamma$ 9V $\delta$ 2 T cells are activated by small phosphorus-containing molecules known as "phosphoan[tig](#page-5-0)ens" rather than peptide antigens.<sup>2</sup> Isopentenyl diphosphate (IPP, 1a, Figure 1) was the first identified natural phosphoantigen for human Vγ9Vδ2 T cells.<sup>3-5</sup> Isomerization of IPP by isopentenyl diphosphate iso[me](#page-5-0)rase affords dimethylallyl diphosphate (DMAPP, 2a), [whi](#page-5-0)ch itself may function as a phosphoantigen. $6,7$  These diphosphates are more active relative to the corresponding monophosphates IP (1b, 233-fold) and DMAP (2b, [3-](#page-5-0)fold), suggesting that the  $\beta$ phosphate increases specific recognition of the phosphoantigens.8 Additional studies demonstrated that these T cells selectively recognize the methylerythritol 4-phosphate (MEP) path[w](#page-5-0)ay intermediate (E)-4-hydroxy-3-methyl-but-2-enyl diphosphate (HMBPP, 3), an immediate precursor to IPP biosynthesis. HMBPP is the most potent natural phosphoantigen, with activity at concentrations 4−6 log units lower than  $IPP.^{9-11}$  Thus, both the  $(E)$ -allylic alcohol of HMBPP and the diphosphate group are important determinants of phosphoantige[nicity](#page-5-0).

Because diphosphates of potential clinical importance have low stability, Boëdec and colleagues designed analogs and stereoisomers of the highly potent HMBPP. As a class, the isosteric analogs of HMBPP containing phosphonates, C-HMBP (4a) and C-HMBPP (4b), were more stable than

 $X = CH<sub>3</sub>$ , CHO, CHNOH

5 (bromohydrin diphosphate) 6 (3-formyl-1-butyl diphosphate)

Figure 1. [Relevant phosphoantigens. Endogenous phosphoan](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=fig1&ref=pdf)tigens (1a and 2a) and their monophosphate analogs (1b and 2b). The most potent natural ligand for BTN3A1, HMBPP (3). Phosphonate analogs C-HMBP (4a) and C-HMBPP (4b). Bromohydrin diphosphate (5) and 3-formyl-1-butyl diphosphate (6).

HMBPP, with longer duration of activity.<sup>12</sup> The E-olefins were significantly more potent relative to corresponding Z-olefin compounds, with a difference in  $EC_{50}$  [valu](#page-5-0)es of greater than 500-fold, revealing a strong preference to E-geometry for optimal Vγ9Vδ2 T cell stimulation.<sup>13</sup>

Phosphoantigens are now known to bind to a shallow, basic binding pocket in the intrace[llu](#page-5-0)lar B30.2 domain of BTN3A1.<sup>14-20</sup> BTN3A1 is a single pass transmembrane protein, which associates with other butyrophilins including BTN2A1, [BTN](#page-5-0)3A2, and BTN3A3. Phosphoantigen binding in the intracellular domain causes conformational changes to the extracellular domain which, during interactions between Vγ9Vδ2 T cells and phosphoantigen containing cells, enables the BTN3A1 complex to bind the Vγ9Vδ2 T cell receptor  $(TCR).^{21-24}$  During HMBPP binding to BTN3A1, the  $\beta$ phosphate interacts directly with arginine residues (R442, 448, and 4[99\) a](#page-5-0)nd the  $\alpha$ -phosphate interacts indirectly with tryptophan (W421) and methionine (M424) residues. Importantly, the E-allylic alcohol of HMBPP forms a hydrogen bond with the histidine (H381) side chain, an interaction that triggers a conformational transition in H381 and the movement of nearby tryptophan residues that include W421.<sup>16</sup> While not fully understood, this key interaction with H381 in the intracellular domain leads to extracellular chang[es](#page-5-0) that allow the Vγ9Vδ2 TCR to detect HMBPP-bound BTN3A1 with greater sensitivity than detection of IPP and DMAPP.<sup>16,19,25</sup>

While IPP and DMAPP lack the  $(E)$ -allylic alcohol, these endogen[ous dip](#page-5-0)hosphates do weakly stimulate Vγ9Vδ2 T cells.<sup>8</sup> It is not clear if DMAPP itself functions as a phosphoantigen, or if its activity is due to its cellular conv[er](#page-5-0)sion to IPP.<sup>26</sup> Nevertheless, some studies have focused on increasing intracellular concentrations of these phosphoan-tigens to provoke [T](#page-5-0)CR-BTN3A1 interactions.<sup>27</sup> Because C-HMBP phosphonamidates are more active than  $\text{HMBPP}^{28-30}$ we chose to evaluate whether DMAPP functi[on](#page-5-0)s as a direct phosphoantigen through preparation of a parallel pr[od](#page-5-0)r[ug](#page-6-0) analog of C-DMAP. We hypothesized that a C-DMAP phosphonamidate would require lower effective concentrations to stimulate a T cell response comparable to DMAPP. Furthermore, given that the diphosphate 5 is a known phosphoantigen $31$  and the aldehyde 6 was once proposed to be a natural phosphoantigen, $32$  the requirement for an allylic alcohol in activ[e c](#page-6-0)ompounds may be more apparent than real.

To evaluate the impact o[f r](#page-6-0)emoval of the C-HMBP  $(E)$ allylic alcohol, synthesis of C-DMAP (8) began with the previously reported phosphonate 7 (Scheme 1).<sup>19</sup> Treatment of phosphonate 7 with bromotrimethylsilane and collidine followed by sodium hydroxide afforded the sodi[um](#page-5-0) salt 8. To access the C-DMAP 1-naphthyl phosphonamidate, treatment of phosphonate 7 with oxalyl chloride and a catalytic amount of dimethylformamide followed by addition of 1-naphthol and triethylamine provided the mixed phosphonate ester 9.<sup>33</sup> The remaining methyl ester in phosphonate 9 then was cleaved selectively by reaction with sodium iodide in acetoni[tri](#page-6-0)le at reflux, and the resulting salt then was coupled to glycine ethyl ester hydrochloride in the presence of triphenylphosphine and 2,2′-dithiodipyridine to afford phosphonamidate 10. Compound 10 represents a monophosphonate analog of DMAPP protected as the phosphonamidate.

Early efforts to determine the organic framework of the more active exogenous phosphoantigen, now thought to be HMBPP, initially assigned the compound as the aldehyde 3-

# [Scheme 1. Synthesis of](pubs.acs.org/acsmedchemlett?ref=pdf) C-DMAP and Its Phosphonamidate Derivative

for[myl-1-butyl-diphosphate](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch1&ref=pdf)  $(6).^{34}$  $(6).^{34}$  Our preparation of C-HMBP phosphonamidates concludes with a selenium dioxide-mediated oxidation, whi[ch](#page-6-0) provides the required Eallylic alcohol as a single olefin isomer. $35,36$  However, this reaction step can favor an aldehyde product either by increasing reaction temperature or ti[me. I](#page-6-0)n some cases, chromatography of the crude oxidation mixture provided a percentage of recovered starting material in addition to some aldehyde product. In theory, isolation of a mixture of aldehyde and alcohol after minimal purification from the selenium dioxide step would provide material suitable for treatment with manganese dioxide to drive the mixture forward to exclusively aldehyde product. Though aldehydes are generally avoided in drug development due to chemical reactivity, we were interested in evaluation of aldehyde-containing phosphoantigens because that same reactivity can lead to useful biological probes<sup>37</sup> as well as occasionally better drug molecules.<sup>38</sup>

While the identity of the mycobacterial phosphoantigen descri[bed](#page-6-0) by Belmant and colleagues remains uncl[ear](#page-6-0), the prenyl phosphate stimulated Vγ9Vδ2 T cell proliferation at nanomolar concentrations.<sup>32</sup> Furthermore, their results provided evidence of a terminal aldehyde (C4 in the phosphate which would correspond [t](#page-6-0)o  $C_5$  in the phosphonate).<sup>34</sup> Bromohydrin diphosphate (BrHPP, 5), a modified prenyl derivative, also triggered responses of human V $\gamma$ 9V $\delta$ 2 T cells [at](#page-6-0) nanomolar concentrations. $^{31}$  Thus, to investigate the impact of other modifications of a known BTN ligand relative to their potential to stimulate an [im](#page-6-0)mune response, some C-HMBP aldehyde analogs were prepared for biological evaluation. Considering that recent literature provides strong evidence for the necessity of a ligand to interact with H381 of BTN3A1, we also prepared a phosphonate aldoxime which places a potential hydrogen bond donor off of the C5 position.<sup>16,39,40</sup>

Synthesis of the aldehyde phosphonamidates began with phenyl phosphonamidates 11-13 (Scheme 2[\).](#page-5-0)<sup>33</sup> [Tre](#page-6-0)atment of each of the phosphonamidates 11, 12, and 13 with a catalytic amount of selenium dioxide afford[ed C-HMB](#page-2-0)[P p](#page-6-0)hosphonamidates 14, 15, and 16, in addition to aldehydes 17, 18, and 19, respectively.

The C-HMBP phosphonamidates containing ethyl esters of glycine provide greater potency, on average, relative to methyl and isopropyl compounds.<sup>28</sup> Therefore, the ethyl ester compound 18 was taken to the target aldoxime (20).

<span id="page-2-0"></span>Scheme 2. Synthesis of C-HMBP C5 Aldehydes of Phosphonamidates and Their Previously Reported Alcohols<sup>28</sup>

Treat[ment of the alcohol/aldehyde mixture \(](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch2&ref=pdf)15/18) with manganese dioxide in dichloromethane provided additional aldehyde for the next synthetic step (Scheme 3). Subsequent reaction with hydroxylamine in water allowed for rapid conversion to a quantitative amount of aldoxime 20.

After [establishing reaction conditions that modify](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch3&ref=pdf) the (E) allylic alcohol of C-HMBP to an aldehyde, the bispivaloyloxymethyl (POM) derivative 22 and some mixed aryl acyloxyalkyl compounds were prepared to allow for comparison of their activities against other known prodrug forms of C-HMBP. Synthesis of compound 22 began with  $POM<sub>2</sub>-C$ -HMBP  $(21).^{19}$  Treatment of POM<sub>2</sub>-C-HMBP with Dess-Martin periodinane (DMP) afforded the target bis- (acyloxyalkyl[\) e](#page-5-0)ster 22, in sufficient quantity to allow for bioassay of this aldehyde (Scheme 4).

Mixed aryl acyloxyalkyl forms of C-HMBP have been found to increase activity relative to C-HMBP.33,41 To compare the new aldehydes across prodrug classes, we began our synthesis of the C5 aldehyde 26 with the 2-nap[hthyl](#page-6-0) phosphonate 23 (Scheme 5). $41$  The coumaryl phosphonate 24 was prepared by a parallel sequence to that of compound 23 except 2-naphthol was replace[d](#page-6-0) with 7-hydroxycoumarin. Finally, treatment of Scheme 4. Synthesis of POM<sub>2</sub>-C-HMBP Aldehyde by [Oxidation](pubs.acs.org/acsmedchemlett?ref=pdf) [with](pubs.acs.org/acsmedchemlett?ref=pdf) [the](pubs.acs.org/acsmedchemlett?ref=pdf) [Dess](pubs.acs.org/acsmedchemlett?ref=pdf)−Martin Periodinane

Sche[me 5. Synthesis of C-HMBP Aldehydes of Mixed](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch4&ref=pdf) Aryl Acyloxyalkyl Phosphonate Esters

each mix[ed phosphonate ester, either](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch5&ref=pdf) 23 or 24, with selenium dioxide resulted in oxidation to afford aldehydes 26 and 28, respectively. Chromatography of the oxidation mixture also provided the corresponding alcohol counterpart (compounds  $25^{33}$  and  $27$ ) to each of the target aldehydes. Isolation of the aldehydes proceeded in sufficient quantities to allow bioassay wi[tho](#page-6-0)ut the need for an additional manganese dioxide or DMP oxidation step.

Finally, the last target of interest in this series was the aldehyde salt 30 (Scheme 6), whose activity could be

com[pared to salts studied previously. Unfortunately,](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=sch6&ref=pdf) this compound proved to be elusive. The dimethyl ester 7 was chosen as the starting phosphonate because methyl esters should be easiest to cleave.<sup>42</sup> Oxidation of this phosphonate to the corresponding aldehyde 29 could be accomplished in good yield when the  $SeO<sub>2</sub>$  oxid[atio](#page-6-0)n was allowed to proceed for an extended time. However, all attempts to hydrolyze the ester 29 to the corresponding salt 30 under standard conditions went unrewarded. Because this might be due to the instability of the aldehyde itself, $38$  further efforts were postponed pending the results of the biological studies on the available compounds.

All of the [ava](#page-6-0)ilable compounds were tested for cellular toxicity to K562 cells using a cell viability assay (Figure S1). Only compounds 17, 22, and 26 showed cell toxicity, which was weak and only visible at a dose of 100  $\mu$ M. T[his indicate](http://pubs.acs.org/doi/suppl/10.1021/acsmedchemlett.0c00586/suppl_file/ml0c00586_si_001.pdf)s that the presence of the aldehyde in these molecules is not inherently toxic to the cells. The newly synthesized compounds

were next evaluated for their ability to stimulate proliferation of human Vγ9Vδ2 T cells from peripheral blood using a flow cytometry method to quantify the number of cells positive for the Vγ9Vδ2 TCR after stimulation and growth periods. The C-DMAP sodium salt 8 was completely inactive up to 100  $\mu$ M. Additionally, C-DMAP phosphonamidate 10 was also completely inactive up to 100  $\mu$ M (Table 1). This is in contrast to its corresponding C-HMBP 1-naphthyl/GlyOEt phosphonamidate which displayed an  $EC_{50}$  of 0.36 nM, a greater than  $270,000$ -fold difference.<sup>19,28</sup> These findings support a model in which it is unlikely that DMAPP functions as a direct phosphoantigen but rather [acts](#page-5-0) through cellular conversion to IPP or another endogenous phosphoantigen, though we cannot exclude an unrecognized defect in conversion of the C-DMAP prodrug to the active form.

Because the allylic alcohol of HMBPP plays an important role in the immune response of  $V\gamma9V\delta2$  T cells, we became interested in evaluation of a modified C-HMBP analog with a different hydrogen bond donor at this position. Despite the presence of a hydrogen bond donor at the C5 position, the aldoxime 20 was about 40-fold less potent relative to the corresponding aldehyde 18, with an  $EC_{50}$  of 790 nM vs 20 nM, respectively. It is possible that differences in molecular geometry including bond length and position contribute to the observed difference in potency.

Evaluation of the new aldehydes revealed strong stimulants of Vγ9Vδ2 T cell proliferation at nanomolar concentrations. In this assay, the most potent of the aldehyde phosphonamidate set proved to be phenyl phosphonamidate 18 bearing an ethyl ester of glycine, with an  $EC_{50}$  of 20 nM. However, as a class, the aldehyde phosphonamidates (17−19) required an average of 44-fold higher concentrations to stimulate Vγ9Vδ2 T cells proliferation relative to their corresponding C-HMBP phenyl phosphonamidates. Nevertheless, the aldehydes required comparable concentrations to those reported for 3-formyl-1 butyl-diphosphate by Belmant and colleagues.<sup>34</sup> It is possible that the activity reported then was due to HMBPP itself, rather than an aldehyde. However, our findings clea[rly](#page-6-0) indicate that the presence of an aldehyde at a comparable position within the butyrophilin ligand affords potent derivatives of the analog of HMBPP (i.e., C-HMBP) which require nanomolar concentrations to elicit an immune response. Furthermore, these bioactivity results bolster our earlier SAR finding with C-HMBP phosphonamidates of glycine, showing increased potency for ethyl ester compounds relative to methyl and isopropyl esters.

The bis(acyloxyalkyl) ester 22 stimulated proliferation of Vγ9Vδ2 T cells at comparable effective concentrations to phosphonamidates 17 and 19, with  $EC_{50}$  values of 47 nM and 49 nM, respectively. However, the activity of compound 22 was more similar to that of  $POM<sub>2</sub>-C-HMBP$  (21), with the aldehyde only 9-fold less potent than its corresponding alcohol.

Aldehydes 26 and 28 of the mixed acyloxy aryloxy class<sup>41</sup> stimulate proliferation of Vγ9Vδ2 T cells at low nanomolar levels, with  $EC_{50}$  values of 4.6 nM and 12 nM, respective[ly.](#page-6-0) These two mixed aryl acyloxyalkyl esters with an aldehyde stimulated T cell proliferation at concentrations comparable to their corresponding alcohol, only requiring 2-fold higher concentrations, which was not statistically significant by 2 way ANOVA. A similar though less pronounced pattern of activity was observed in ELISA assays for detection of interferon  $\gamma$  (Table S2) produced by V $\gamma$ 9V $\delta$ 2 T cells after exposure to phosphoantigen loaded K562 cells. Therefore, the

Table 1. Activity of C5 Modified C-HMBP Compounds for [Expansion](pubs.acs.org/acsmedchemlett?ref=pdf) [of](pubs.acs.org/acsmedchemlett?ref=pdf) [V](pubs.acs.org/acsmedchemlett?ref=pdf)γ9Vδ2 T Cells from Peripheral Blood Mononuclear Cells<sup>d</sup>

<sup>a</sup>CI = confidence interval. <sup>b</sup>[NA = not applicable \(](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=tbl1&ref=pdf)*n* = 3). <sup>c</sup>7HC = 7hydroxycoumaryl.  ${}^{d}$ Fold difference is relative to 4a (for compound 8) or its equivalent prodrug form (for other compounds) as previously determined.<sup>19,28,4</sup>

allylic functionality on this prenyl phosphate framework can be altered concurrently with phosphonate protection to retain high potency.

<span id="page-4-0"></span>Because the aldehydes may be reduced in the cytosol to the corresponding C-HMBP or form glutathione conjugates, we investigated the cellular metabolism of selected compounds. We used basic extraction conditions<sup>43</sup> and ion pairing LCMS<sup>44</sup> to quantify the phosphonate metabolites formed following treatment with selected prodrugs (S[up](#page-6-0)porting Information). [As](#page-6-0) expected, treatment of K562 cells for 1 h with the control prodrug 21 produced the free ph[osphonic acid payload i](http://pubs.acs.org/doi/suppl/10.1021/acsmedchemlett.0c00586/suppl_file/ml0c00586_si_001.pdf)n its allylic alcohol form, as well as the monoacid intermediate (Figure 2). Compound 21 was not converted to aldehyde

Figure 2. Conversion of selected aldehyde (or aldoxime) prodrugs to [their free acid alcohol forms in K562 cells. Treatment for 1 h with the](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?fig=fig2&ref=pdf) indicated compound results in a two-step biological release of the phosphoantigen payload from the prodrug groups to generate the phosphono monoacid and free-acid forms. Simultaneously, the allylic aldehyde is reduced to the alcohol form  $(n = 2)$ .

forms. All of the compounds examined in this study (18, 20, 22, and 26) were at least partially converted to the monoacid in its aldehyde (or aldoxime) form. Compounds 22 and 26 additionally drove formation of the free phosphonic acid aldehyde. Interestingly, both compounds also formed the free acid alcohol. Measurable reduction of the aldehydes to their alcohol forms was observed in the intact prodrugs, the monoacids, and the free acids. Masses consistent with compound 22 metabolites in [M+307−H]<sup>−</sup> form were also found, indicative of glutathione conjugation. Dehydration to the DMAP monoacid was also observed. Taken together, these aldehydes are reduced to the alcohol forms in cells at significant levels, and the amount of alcohol form generated correlates with the potency of the prodrug forms in cellular assays.

In conclusion, these studies report novel modifications to the allylic framework of C-HMBP and their impact on human Vγ9Vδ2 T cell proliferation. Removal of the  $(E)$ -allylic alcohol completely abrogates activity, while replacement with an aldoxime (i.e., 20) reduces but does not eliminate activity. In contrast, aldehyde replacements are well tolerated. Six examples including phosphonamidate, bis-acyloxy ester, and mixed acyloxy aryloxy ester forms of C-HMBP are provided, all modified to include an aldehyde and all function as stimulants of Vγ9Vδ2 T cell proliferation at nanomolar concentrations, with two aldehydes (26 and 28) having similar activity to alcohol 21. The latter two compounds were metabolized in cells to produce the corresponding alcohol form. We suspect that the combination of the aldehyde with a rapidly metabolized prodrug form<sup>45</sup> enables cell entry and conversion to the alcohol form, whereas the slower uptake of phosphonamidate forms [ma](#page-6-0)y allow for extracellular aldehyde metabolism that slows cell entry. In theory, this aldehyde modification could serve as a synthetic handle for further derivation of C-HMBP analogs. One example of such a

modification, the quantitative conversion of an aldehyde (18) [to](pubs.acs.org/acsmedchemlett?ref=pdf) [its](pubs.acs.org/acsmedchemlett?ref=pdf) [corresponding](pubs.acs.org/acsmedchemlett?ref=pdf) [C5](pubs.acs.org/acsmedchemlett?ref=pdf) aldoxime (20) is reported here.

<sup>V</sup>[N.A.L.](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [and](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [C.M.S.](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [contributed](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [equally](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [to](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [this](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf) [manu](https://pubs.acs.org/doi/10.1021/acsmedchemlett.0c00586?ref=pdf)script. The manuscript was written through contributions of all authors, and all authors have given approval to the final version of the manuscript.

# **Notes**

The authors declare the following competing financial interest(s): A.J.W. and D.F.W. own shares in Terpenoid Therapeutics, Inc. The current work did not involve the

<span id="page-5-0"></span>company. The other authors have no financial conflicts of interest.

# ■ ACKNOWLEDGMENTS

We thank the UI Graduate College for Ballard-Seashore Fellowships (to N.A.L. and B.J.F.), the GAANN Program at the University of Iowa (P200A150065) for a fellowship (to N.M.H.), and the American Cancer Society − Kirby Foundation for a Postdoctoral Fellowship (PF-18-119-01-LIB to M.M.P.). Financial support from the NIH (CA186935 and AI150869 to A.J.W.), the Herman Frasch Foundation for Chemical Research, Bank of America, N.A., Trustee (HF17 to A.J.W.), and the Roy J. Carver Charitable Trust through its Research Program of Excellence (01-224 to D.F.W.) is gratefully acknowledged.
