

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Review Article

Opportunities to improve COVID-19 provider communication resources: A systematic review

Health care providers

ABSTRACT

Objective: Communication related to COVID-19 between provider and the patient/family is impacted by isolation requirements, time limitations, and lack of family/partner access. Our goal was to determine the content of provider communication resources and peer-reviewed articles on COVID-19 communication in order to identify opportunities for developing future COVID-19 communication curricula and support tools.

Methods: A systematic review was conducted using the UpToDate clinical decision support resource database, CINAHL, PubMed, PsycInfo, and Web of Science. The grey literature review was conducted in September 2020 and articles published between January–September 2020 written in English were included.

Results: A total of 89 sources were included in the review, (n = 36 provider communication resources, n = 53 peer-reviewed articles). Resources were available for all providers, mainly physicians, and consisted of general approaches to COVID-19 communication with care planning as the most common topic. Only four resources met best practices for patient-centered communication. All but three articles described physician communication where a general emphasis on patient communication was the most prevalent topic. Reduced communication channels, absence of family, time, burnout, telemedicine, and reduced patient-centered care were identified as communication barriers. Communication facilitators were team communication, time, patient-centered and family communication, and available training resources.

Conclusions: Overall, resources lack content that address non-physician providers, communication with family, and strategies for telehealth communication to promote family engagement. The gaps identified in this review reveal a need to develop more materials on the following topics: provider moral distress, prevention communication, empathy and compassion, and grief and bereavement. An evidence-base and theoretical grounding in communication theory is also needed.

Practice implications: Future development of COVID-19 communication resources for providers should address members of the interdisciplinary team, communication with family, engagement strategies for culturally-sensitive telehealth interactions, and support for provider moral distress.

1. Introduction

The Coronavirus Disease 2019 (COVID-19) pandemic has created a rapid and changing health care landscape that has impacted communication between providers, patients, and families. New challenges created by the pandemic include communicating with patients while utilizing personal protective equipment and establishing new ways for patient and family to connect in the physical absence of families at the bedside [1,2]. While the pandemic has been a catalyst for widespread telehealth use to facilitate communication, technology itself can be a barrier in establishing human connection between providers, patients, and family members especially when discussing sensitive topics such as COVID-19 diagnosis, treatment options, limitations to healthcare resources, and decision-making about end-of-life care [3,4]. Patient- and family-centered communication become essential as virtual care systems rely predominantly on the quality of communication in COVID-19 interactions.

Developing ways to establish ongoing, meaningful communication with patients and family caregivers is one of the biggest challenges emerging from the COVID-19 pandemic [5]. Recommendations for providing patient and family-centered communication include routine assessment of advance care planning, optimal communication with patient and family while wearing personal protective equipment, training in online provider-family communication taking place over phone or video, and supporting family members of COVID-19 patients who are near death [2]. Health systems must adapt new communication tools to maintain family and patient-centered care yet acknowledge clinicians' limited time and attention to learn new skills [6]. Palliative care has an essential role in the COVID-19 response and is the recognized leader in developing responsive communication tools and initiatives within healthcare systems [7]. An essential role of palliative care teams is to prepare front-line healthcare providers for discussions about SARS-CoV-2, the virus that causes COVID-19, its diagnosis, treatment decisions, patient and family preferences, and end-of-life care in an empathetic manner that includes less medical jargon and more attention to emotional needs [8]. These discussions also include assessing what patients and families already know and sharing information about COVID-19 using plain language recommendations [5].

To support COVID-19 patients and families, healthcare providers need communication resources that promote ways to engage in compassionate communication with patients and families [3]. The majority of physicians currently in practice learned communication skills while in training, without a curriculum or evidence-based learning techniques, and

communication competency for interactions with patients and family members varies [9]. Research in nursing also reveals a need for communication support as nurses find it difficult to preserve family trust and fear they may upset the patient or family [10,11]. As families must remain isolated from COVID-19 patients, communication between providers, patients, and families are reduced and require communication techniques that match new and changing contexts.

It is important that effective, evidence-based provider communication resources are supplied in the context of COVID-19. Treatment guidelines for COVID-19 issued by the National Institutes of Health include advance care planning and goals of care discussions for patients and family members [12], however little is known about the scope of provider communication tools and topics for COVID-19 communication. In order to develop and implement communication strategies to facilitate communication about COVID-19 and care, initial resources provided during the first months of the pandemic require examination. These guidelines were written with limited understanding of how COVID-19 influenced patient, family, and provider experiences during an unprecedented time when physical distancing was suddenly required. Understanding provider, patient, and family experiences in the context of COVID-19 care settings is vital to the development of responsive communication strategies [2]. COVID-19 service experiences, both from the viewpoint of provider, patient, and family, are shaped by health service availability, accessibility, and quality as well as people's initial expectations and relationship [13].

1.1. Aim

Our goal was to determine the content of provider communication resources and peer-reviewed articles on COVID-19 and communication in order to identify opportunities for developing future COVID-19 communication curricula and support tools. We conducted a systematic review of both grey literature on provider COVID-19 communication resources and peer-reviewed literature of COVID-19 communication.

2. Methods

2.1. Search process

Two methods were used to locate information for this review. First, we searched grey literature by using the UpToDate clinical decision support resource database to search for society guideline links for coronavirus and guidelines for specialty care. Under

Palliative Care we chose only US organizations, which included *American Academy of Hospice and Palliative Medicine*, *Center to Advance Palliative Care*, *National Coalition for Hospice and Palliative Care*, and *National Hospice and Palliative Care Organization*. Each link was to the organization's COVID-19 resource page which was reviewed including any links provided by the organization as a COVID-19 resource. Secondly, we systematically searched four databases for peer-reviewed literature: CINAHL, PubMed, PsycInfo, and Web of Science. Working with specialist librarians, we used standardized search strings that combined MeSH terms, free text terms, and broad-based terms for the keywords: 'Coronavirus' AND 'Patient' OR 'Family' OR 'Provider' AND 'Communication'.

2.2. Selection criteria

2.2.1. Grey literature of provider communication resources

Communication resources were included if they were published specifically as a COVID-19 resource, included communication with patient/family, and available as print material. Video and webinar links, connection/picture aids, decision-making tools, public message campaigns, letter to patients/residents, hospital communication checklists, phone scripts for assessing symptoms, and patient education materials were excluded from the review. Resources were entered and organized into Excel and were listed by title, the developing organization, communication topic or goal, and specific focus of the resource.

2.2.2. Inclusion and exclusion criteria of peer-reviewed articles

This review also aimed to explore peer-reviewed articles on COVID-19 communication. To capture this breadth of material the authors decided to include all primary research of any design (qualitative or quantitative or mixed methods), reviews and case studies, editorials, commentaries, and opinion pieces. Inclusion criteria included original articles in journals with a peer-reviewed process, published between January 1, 2020 – September 1, 2020 that specifically discussed COVID-19 communication including: Provider, Patient, and Family needs and issues for COVID-19 care and Provider, Patient, and Family views or experiences during COVID-19 care. The search was restricted to English language, studies involving adult patients and family members aged 18 and over and did not include studies from developing countries where care settings differ significantly from the US.

2.3. Selection procedure

Two authors (EW and JVG) performed the grey literature search over a two-day period. These same researchers also conducted a screening of peer-reviewed articles by reviewing title and abstracts independently. Through open discussion, coders reviewed differences in coding to reach consensus. All disagreements were resolved with 100% agreement by both coders. Reasons for exclusion or ineligibility were recorded.

2.4. Data extraction and synthesis

First, data from each provider communication resource were extracted into an Excel database. Items for each extraction included reference details (URL, name of organization creating resource), communication context (face-to-face, telehealth), resource type (conversation guide or summary document), communication approach (general or proactive planning before COVID-19 diagnosis), provider audience (physician, nurse, all healthcare providers), intended recipient (to improve communication with patient, family, or both), and whether or not the resource included example clinician statements and questions (yes or no), example questions asked by patient and family, and example responses to

patient/family questions. Provider communication resources were assessed for quality using the six domains of best practices for patient-centered communication that identifies role and skills within each domain [14]. Total patient-centered communication scores were calculated based on whether or not best practices were present for role and skill. Two researchers (EW and JVG) independently assessed patient-centered communication domains and resolved differences through iterative discussions.

Second, data from peer-reviewed articles were extracted by one researcher (EW) and checked for accuracy and completeness by the second (JVG). The following information was extracted for each paper: author, journal, article type (summary, research study, or personal narrative), authors' primary clinical expertise (physician, nurse, social worker, other), whose experience was represented (patient, family, or healthcare provider). Quality was assessed by determining whether or not resources were provided (yes or no), recommendations were evidence-based, and whether or not a theoretical framework was referenced to support article content.

Using a three-stage thematic synthesis [15], authors (EW, JVG) engaged a transparent summary of existing research. In this approach, we first implemented a line-by-line text coding per article, then developed descriptive themes, and ultimately generated analytical themes. The first stage included reading and re-reading the sample (EW, JVG) until article fluency was achieved. A line-by-line coding of the results sections completed the first stage. Moving into the second stage, we sought similarities and differences across line-by-line codes to group ideas and build descriptive themes. In the final stage of thematic synthesis, these descriptive themes were incorporated into synthesized findings that ultimately produced analytical themes. Analytical themes were determined based on the frequency and relevance of codes. Consensus on these generated themes was achieved via iterative discussions between authors.

3. Results

Fig. 1 shows the PRISMA diagram of the search process for grey and peer-reviewed literature. A total of 89 sources were included in the review (36 provider communication resources and 53 peer-reviewed articles).

3.1. Characteristics of provider communication resources

Thirty-six COVID-19 provider communication resources were located through the systematic search of grey literature. Documents originated from 22 organizations. Table 1 summarizes provider communication resources included in this review. The sample represented both conversation guides [16–18,20,21,23–26,28,30–36,39,42,43] (n = 20) and summary documents [19,22,27,29,37,38,40,41,44–51] (n = 16) and primarily provided information on face-to-face communication [16,17,19–22,24,24,25,26,28–30,33,35,40,45,49,50] (n = 18) or communication in either telehealth and face-to-face encounters [23,32,34,36,41,44,47,48] (n = 8). Communication specific to telehealth encounters were also identified [18,27,31,38,51] (n = 5). The majority of resources targeted healthcare providers generally (n = 19), with nine resources specifically targeting physicians [16–18,20,22,24,26,31,33] and two resources specific to nurses [45,48]. Among all resources the most common goal was to improve communication with patients [16–19,22,23,25,27–34,43] (n = 17), followed by communication with both patient and family [20,21,24,35,31–36,38–42,44–46,48,50,45–51] (n = 16). Four resources [26,37,47,49] were available for communication with families specifically.

Twenty-one resources provided a general approach to COVID-19 communication [18,22,25,27,29,30,33,35,37–42,44,45,47–51]

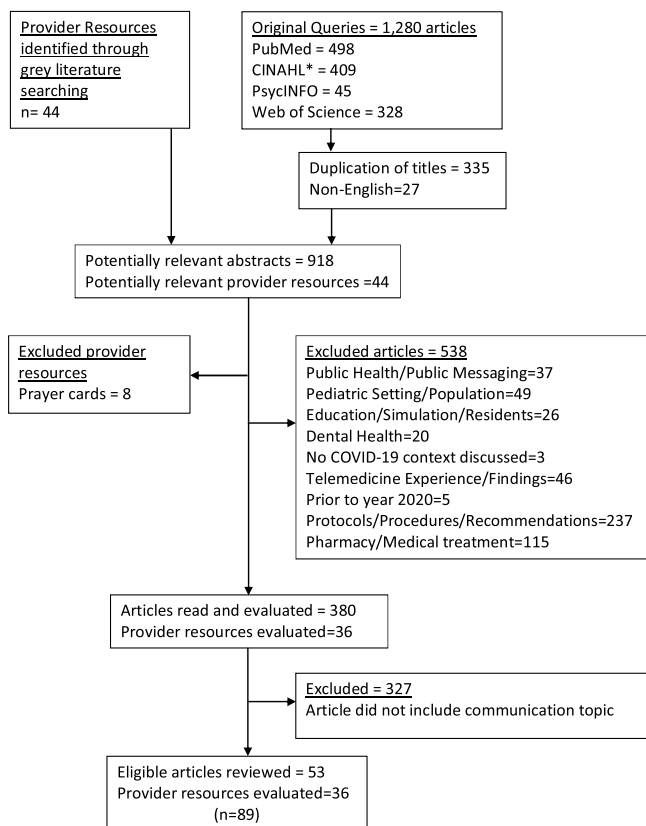

Fig. 1. Selection Process of Provider Resources and Peer-Reviewed Articles.

and fifteen resources provided a proactive approach aimed at addressing decision-making prior to a COVID-19 diagnosis [16,17,19–21,23,24,26,28,31,32,34,36,43,46]. Thirty resources included examples for clinicians and were most likely to provide example clinician statements [16,20,21,23–28,30–36,38–46,50,48–51]. Three resources [37,47,49] did not provide example statements or questions and only two resources provided example questions asked by patients or family [44,46].

Sixteen resources focused communication on care planning. These resources included ways to elicit patient preferences [16,17,21,32] and conversations to select treatment options [28,29]. One resource addressed selecting options and patient well-being [19]. General goals of care discussions were addressed in three resources [26,34,36]; two resources centered on choosing a proxy [39,41], advance care planning [23,43], and prognosis discussions in the intensive care unit [24]. One resource addressed discussing limited resources and treatment options with family [20].

Seven resources included content that addressed working with families [44,47], including family assessment [48], family meetings [45], learning about family concerns [37], and communicating policy changes and updates [22,49]. Virtual communication in telehealth platforms was the primary emphasis in six resources which highlighted how to open and close telehealth visits [18,51], topics to discuss [27,31], and telehealth guide for tele-chaplaincy services [38]. Four resources emphasized general provider communication best practices [42], including plain language materials [46], addressing racism [25] and cultural sensitivity [30]. Communicating about dying was present in four resources which focused on removing the ventilator [35] and what to say to a family when a patient is near death [33,50]. One resource was a general COVID-19 communication summary document for chaplains [40].

3.1.1. Assessment of patient-centered communication practices

Content of each resource was compared against the six domains of patient-centered communication practices defined in terms of role and skill (Supplemental Table 1). Within the best practice definitions, only four resources scored 75% or higher [19,31,36,42], followed by 18 resources scored between 50–74%, and 12 resources scored 25% or less. The average score was 38%.

3.2. Characteristics of peer-reviewed articles

Fifty-three articles focusing on COVID communication were identified (Table 2). The most common publication type was an article summary where communication was emphasized, defined, or discussed as a key element of the COVID-19 context. Five personal narratives were also included: one article summarized a doctor's experience as a COVID-19 patient [88] and four articles discussed the ways that physician communication with patients and families has changed pre-COVID to now [71,76,81,96]. Finally, the sample included three research studies: an editorial included findings of a survey of 376 healthcare providers empathic attitudes and psychosomatic symptoms that concluded that clinician's higher empathy exposed them to more psychological suffering [56]; qualitative interviews with 9 families about challenges in palliative care interventions [62]; email or telephone interview with 8 physicians and 48 cancer patients that summarized 8 oncology-specific COVID-19 scenarios which patients responded to with anger, fear, and anxiety [68].

The articles were published in the United States (n = 41), United Kingdom (n = 5), India (n = 2), Canada (n = 2), Singapore (n = 1), Australia (n = 1), and Israel (n = 1). The majority of authors were physicians (64%), followed by nurses (13%), research groups or multidisciplinary research teams (10%), social workers (5%), and other healthcare providers (8%). All but three articles described the communication experiences of physicians (94%). Communication resources or references to resources were provided in 58% of articles, with less than 13% providing an evidence-base or theoretical framework for recommended communication strategies.

A variety of communication topics were covered in the articles, with the most prevalent topic a general emphasis on patient communication (25%) where lessons learned were highlighted [59,64,71,75,80,92], barriers [96] and resources [58] shared culture humility [61] and equitable care [63] addressed, and communication in palliative care settings emphasized [62,65,101]. Goals of care discussions and telehealth were the next most common communication topics (13%, respectively). Recommendations for goals of care discussions were highlighted [52,97,77] and included end-of-life context [78], dialysis decision-making [79], family-centered care [70], and diabetes [73]. Published articles about telehealth focused on use in the intensive care unit [83], surgery [84], cancer care [74,76,104], and palliative care [77] and centered on social connectedness [57].

Empathy and compassion were the next most common communication topic (11%) with an emphasis on staying connected to patients [81,94,102] by treating mind, body, and spirit [89] in response to the lack of nonverbal communication [93]. This challenge was underscored by one physician's personal experience [88]. Grief and bereavement were also a central communication topic in 10% of the sample, with articles addressing communication with family [72,82], bereavement risk factors [95], types of grief [103], and ways to mitigate fear and suffering [54].

There were four articles each in the area of prevention, prognosis/end-of-life care, and moral distress. The clinician's communication role was described as part of prevention efforts to help the public manage the overflow of education [66,99], with a specific focus on the pharmacist's role ([60] and cardiac care [98].

F2F = Face-to-face communication; T = Telemedicine; P = Patient; F = Family.

Barriers to end-of-life care [68,58] were described, with one article addressing cancer care settings [99] and another offering a prognostic communication for clinicians [69]. Leadership [86], ethics [53], and interprofessional communication [91] were central to discussions about communication and ethics and how they influence symptoms of moral distress [56]. Finally, the sample included two articles on advance care planning [55,67].

3.3. Communication barriers in COVID-19 care

Six analytical themes with corresponding subthemes identifying communication barriers were established: reduced communication channels, family/partner cannot be present, time, burnout for providers, telemedicine, and reduced patient-centered care. Subtheme frequencies were highest within themes of family/partner cannot be present (23 articles), reduced patient-centered care (18 articles), and reduced communication channels (17 articles). Increased anxiety and fear for family made worse by isolation (7 articles) was the most frequent subtheme under the theme heading of *family/partner cannot be present*. Complementing that finding, isolation increasing fear and anxiety for patients (6 articles) was the most common subtheme under the *reduced patient-centered care* theme heading. Personal protective equipment interrupting verbal messages and nonverbal communication was the most frequent subtheme (10 articles) under the theme of *reduced communication channels*.

Table 3 summarizes the six communication barriers. The most common communication barrier during COVID-19 pandemic is that patients and family members could not recognize the face and voice

of their healthcare providers due to masking and the use of personal protective equipment (PPE) [59,71,75,76,80,81,84,93,96,100,101]. Frontline health workers in Italian emergency units in March 2020 experienced reduced communication channels resulting from masks, goggles, and face shields and struggled to recognize faces and voices [59]. Physicians in Switzerland interacted with elderly patients with hearing aids who had difficulty understanding masked voices [93]. A second communication barrier during the COVID-19 pandemic is that patients are anxious and fearful because they are left alone to face illness and their family cannot be physically present [52,53,58,64,73,77,79,82,83,85,88,89]. For example, COVID-19 patients with a diagnosis of end stage renal failure were challenged to make dialysis decisions without their family members present to help comprehend language and provide emotional support [79].

Running out of time was the third most common communication barrier during the pandemic [55,59,69,70,95,97]. Even for providers who have a deep understanding and experience of communication with the patient/family, they are overworked and lack the time to talk to the patient/family in new situations presented by the pandemic [55,59]. During the pandemic, less completion of advance care planning (ACP) prior to hospital admission was identified and resulted in prolonged grief because families were not allowed to see their loved ones in the midst of active dying or upon post-mortem [95]. The fourth communication barrier is an intense emotional impact on patient/family and providers [56,80,86,87,91,99,100,103]. Witnessing high numbers of suffering/deaths in a short period of time brought complicated grief for providers during COVID-19 pandemic [103]. Prestia (2020) suggests truthful, mindful and relevant communication for nurses

Table 2
 Characteristics of included peer-reviewed articles (n = 53).

when they talk with COVID-19 patients and their families to minimize the negative impact of moral distress [86].

Telehealth offers a pathway to connect COVID-19 patients and their family members, especially when social distancing and isolation are barriers to care delivery. However, telehealth itself can become a communication barrier [57,70,74,82,100,104], and providers should not solely rely on telehealth when communicating to patient/family. For example, for patients and their family members who live in rural areas without reliable internet access, providers should prioritize patient/family's needs and enhance engagement during communication in each encounter [70]. Telehealth created an extra layer of barriers when communicating with family members regarding medical interventions, the consequences of those decisions, and subsequent transition to end-of-life care because families needed constant and continual real-time discussions in order to comprehend unfolding medical information [82].

The last communication barrier was decreased patient-centered care [62–66,78,79,81,85,89,94,98,100]. Due to resource strain and the need to protect society from the impact of COVID-19, providers may not be able to provide patient-centered care [65]. For example, in addition to information of COVID-19 treatment, providers should provide COVID-19 patients and their families with clear and culturally sensitive information about how to take care of themselves to quarantine or self-isolate [63].

3.4. Communication facilitators in COVID-19 care

Five analytical themes with corresponding subthemes identifying communication facilitators were established: strategize team

communication, time and communication, patient-centered communication, family-centered communication, and communication training/resources. Subtheme frequencies were highest within themes of communication training/resources (23 articles), patient-centered communication (22 articles), followed by family-centered communication (14 articles). Subthemes were highly diversified across themes, with the highest frequency subthemes established under patient-centered communication; subthemes of invest in relationship with patient (6 articles) and empathize/acknowledge emotion (5 articles) were most dominant. Table 4 summarizes communication facilitators.

4. Discussion and conclusion

4.1. Discussion

In this review, peer-reviewed articles and provider resources were limited to information about face-to-face interactions and focused primarily on physician-patient communication. Articles predominantly highlighted the connection between physician and patient and resources were primarily for physician audiences. However, patient communication is often compromised or not at all possible due to advanced COVID-19 disease processes and findings from this study demonstrate that COVID-19 communication barriers pertain more to communication with family. Few provider resources reviewed in this study focused on communication with families, with even less content available for telehealth interactions.

Despite the missing content in provider resources to support family communication, family-centered communication was

Table 3
Barriers to COVID-19 communication identified from peer-reviewed articles.

Communication Barriers		
Main themes	Subthemes	References
Reduced communication channels	Nonverbals minimized on phone/videophone	[52,74,76,84]
	Trust inhibited for family	[52]
	Cannot visually identify providers under PPE	[59,93]
Family/Partner cannot be present	PPE (respirator and/or face shield) muffling voice and facial nonverbals	[71,75,76,80,81,84,93,96,100,101]
	Increased patient anxiety and fear made worse with isolation/uncertainty	[52,64,73,77,79,82,89]
	Loss of family voice/advocate/decision making	[53,58,82,83,85,88]
	Inability for goodbyes	[53,54]
	No access to patient/updates/information	[58,59,62,78,81,82]
Time	Unable to engage last wishes	[62]
	Family meetings less possible	[83]
	Reduction in time to provide care	[55]
	Timing, post-mortem contact	[59]
	Clinician bias over resources, treatment, consensus of patient	[69]
	Clinician out of time to learn new skills	[70]
	Lack of advanced care planning completed with dying patients	[95]
Empathy/Burnout for providers	Lack of training	[97]
	Risk factor	[56,80]
	Moral distress	[86]
	Lack of training and role clarity for end-of-life conversations	[87,100]
	Exposure without PPE	[91]
Telemedicine/Phone	Organization needs	[99,103]
	Relationship distance (nonverbals)	[57,100,104]
	Family with no availability	[70]
	Family with limited tech literacy	[70,74]
	Patient missing glasses/hearing aids	[70,101]
	Message/understanding is too minimal	[82]
	Policy limitations	[90]
Reduced patient-centered care	Limits to other needed care (i.e. cancer)	[62,68,98]
	Unable to engage last wishes	[62]
	Tailored and understandable messages/Interpreters needed	[63,66,88]
	Shift from individual patient to societal level of care	[65]
	Privacy impossible at times	[78]
	Isolation causes increased fear and anxiety/uncertainty	[79,81,85,89,98,100]
	Rounds not possible	[81,94]
	Worry about discharge (care at home, finances)	[64]

strongly identified as a main communication facilitator in COVID-19. Absence of family or inability to secure proxy communication created gaps and providers were in positions to rely on anyone they could link as a relative to the patient. Findings here underscore the importance of early palliative care which includes family assessment. Palliative care providers are experts in supporting family members by facilitating critical conversations, discussing goals of care, and working to identify patient's desires. When surrogates are more quickly identifiable, surrogate confidence in knowing the patient's wishes can be a barrier to advance care planning discussions [105] and this should be addressed in providers communication resources for COVID-19 care. Infection-control policies for COVID-19 often present barriers to communication with surrogate decision makers, and most surrogates will not be physically present when discussing treatment options with clinicians. Many decision-making discussions will occur via telecommunication [12].

Although telemedicine was considered an effective resolution to communication restrictions, the inconsistent availability of telemedicine was a noted communication barrier identified in peer-reviewed articles. Current research indicates that understanding human factors in technology adoption, including user awareness, acceptance and readiness, and skill impact the communication that is produced [106]. It has previously been noted that a lack of consideration of an individual's characteristics and social environment is a barrier to integrating telemedicine/telehealth tools [107]. Barriers to technology adoption should be addressed in COVID-19 care and telehealth communication assessment is needed, especially in diverse patient and family populations [108].

With little known about COVID-19, healthcare providers do not know how or have no way to explain patient prognosis and in some cases do not have time to engage the patient/family about goals, shared decision-making, or transitioning to end-of-life care [62,85,86,95]. When patients near death in the hospital, families long for proactive communication, shared decision-making, and personalized end-of-life care [109]. The loss of touch as nonverbal communication in patient-provider interactions as a result of the pandemic [110] requires healthcare providers to be creative in nonverbal communication and places an even greater emphasis on creating new ways for nonverbal expression. This is especially salient in telehealth interactions as providers' culturally sensitive communication influences a family's perception of quality of care and experience of end-of-life care [111]. As communication resources are developed for providers, greater attention is needed for communication practices that acknowledge cultural diversity [112]. This is essential as medical education includes a lack of experiential exposure to different cultures resulting in communication miscues [113].

Additionally, this review also showed that healthcare providers suffer from high emotional exhaustion due to insufficient communication skills and an absence of communication efficacy during the COVID-19 pandemic. However, none of the current provider communication resources fulfill the needs of decreasing moral distress or compassion fatigue of healthcare providers, nor do they account for the range of disciplinary providers interfacing with patients and families in this public health crisis. E-mental health interventions for COVID frontline workers are currently available and consist of social media platforms, online resources, and mobile applications, however these resources have limited

Table 4
Facilitators for COVID-19 communication identified from peer-reviewed articles.

Communication Facilitators		
Main themes	Subthemes	References
Strategize team communication	Designate communication responsibility	[52]
	Team reflection time	[52,53]
	Maintain active engagement with patient situations	[92]
Time and communication	Engage palliative care service	[54]
	Integrate technology with patient as a team	[90]
	Communicate with family before intubation	[53]
	Let patient know that more communication is coming	[76]
	Prioritize communication	[92]
Patient-centered communication	Accomplish communication with technology	[92]
	Invest in relationship with patient	[57,66,68,82,94,104]
	Adapt technology to share care plan	[64,81,82]
	Empathize/acknowledge	[65,66,68,82,88]
	Share treatment options openly/honestly and clearly	[69,80,89]
	Practice cultural humility	[73]
	Align with patient values in decision making	[77,97]
Family-centered communication	See your patients	[94]
	Seek patient privacy	[104]
	Obtain information needs and preferences from family/communication plan	[53,66,72]
	Hold family meeting(s) however possible	[54]
	Include family by using technology	[64,82]
	Empathize/acknowledge	[65,66,82]
	Enable family presence in person or with technology by communicating risks and options	[70]
	Share reasons for policies about access and PPE	[72]
	Practice cultural humility	[73]
	Align with family values in decision-making	[77]
Communication training resources	Identify substitute decision-maker	[97]
	Vital Talk	[55,58]
	SPIKES	[74,104]
	Attention to eye expression/nonverbals	[59]
	Develop and share a question/prompt list to use with patients	[60]
	Use interpreters/LEP (Limited English Proficiency) materials/algorithm	[61,63]
	Bad News resource	[87]
	COVID advance care planning tool, ACP guide	[67,87]
	Ask-Tell-Ask	[68]
	Rely on words spoken, tone, and silences/ lay terms	[71,88,101]
	Strategies to communicate with compassion to team, patient, and family	[75]
	3 Stage Protocol for goals of care	[79]
	Checklist for video calls	[84]
	PPERV (Preparation, professionalism, empathy, respect, virtual physical exam)	[84]
	“Trustful, mindful, relevant, sensitive communication”	[86,95]
What to do/What to say	[91]	
ABC (Attend mindfully, Behave Calmly, Communicate Clearly)	[93]	

empirical evaluation [114]. Resources and tools are needed to address provider stress from overloaded work and exposure to COVID-19 without PPE. Research has shown that there are no major differences in the prevalence of burnout between physicians and nurses and improving communication skills is one way to reduce symptoms of burnout [115]. Findings here highlight team communication as a communication facilitator. Notably, physicians play an important role in patient care and establishing organizational culture for collaboration with other physicians and team members [116].

Finally, the amount of materials available in the grey literature demonstrates the immense need for COVID-19 resources for healthcare providers which was further evidenced by details of the communication barriers in peer-reviewed articles. However, there remains a lack of evidence-base or theoretical framework for communication resources and information summarized in peer-reviewed articles. Best practices for patient-centered communication were primarily missing in communication resource content and peer-reviewed articles rarely included a summary of evidence-based work for communication recommendations or reference a theoretical framework. As we continue to learn more about COVID-19 and adjust to communication changes in the clinical setting, future work on understanding interactions about COVID-19 should be grounded in communication theory.

4.2. Conclusion

Gaps exist within provider communication resources and peer-reviewed accounts of the COVID-19 communication context. A comparison of topics addressed in provider resources and peer-reviewed articles demonstrates a need to develop more materials on provider moral distress, prevention communication, empathy and compassion, and grief and bereavement. Of significance is the lack of content (research or resource) that addresses nurse experiences and needs, communication with family, and telehealth interactions that promote family engagement and cultural sensitivity.

4.3. Practice implications

Three important findings shape future development of communication support for frontline providers working in any health crises (e.g., COVID-19, Ebola, SARS). First, the majority of sources in this review were physician-centered. Communication strategies demonstrated a specific focus on topics typically discussed and initiated by the physician and did not always include ways to respond when topics are initiated by patient/family, which is a more common communicative role for nurses, social workers, and other healthcare team members. Second, there continues to be a

lack of evidence-base for communication support materials. Both provider communication resources and peer-reviewed articles focused the majority of content on care planning, goals of care, and general communication practices from personal and institutional experiences. More research is needed to evaluate whether these 'best practices' are also effective for patients and families; current materials reflect only the voice of the provider (namely the physician) and there is a need to learn more about what is comforting for patients and families. Finally, it is evident that telehealth interactions will continue to be more widespread. As providers utilize new technology, more work is needed to determine best ways to engage patient and family in virtual environments.
