Keywords: SITR Model COVID-19 dynamicd Epidemic model Neural networks Radial Base functions

A B S T R A C T

Background: Mathematical modeling of vector-borne diseases and forecasting of epidemics outbreak are global challenges and big point of concern worldwide. The outbreaks depend on different social and demographic factors based on human mobility structured with the help of mathematical models for vectorborne disease transmission. In Dec 2019, an infectious disease is known as "coronavirus" (officially declared as COVID-19 by WHO) emerged in Wuhan (Capital city of Hubei, China) and spread quickly to all over the china with over 50,000 cases including more than 1000 death within a short period of one month. Multimodal modeling of robust dynamics system is a complex, challenging and fast growing area of the research.

Objectives: The main objective of this proposed hybrid computing technique are as follows: The innovative design of the NAR-RBFs neural network paradigm is designed to construct the SITR epidemic differential equation (DE) model to ascertain the different features of the spread of COVID-19. The new set of transformations is introduced for nonlinear input to achieve with a higher level of accuracy, stability, and convergence analysis.

Methods: Multimodal modeling of robust dynamics system is a complex, challenging and fast growing area of the research. In this research bimodal spread of COVID-19 is investigated with hybrid model based on nonlinear autoregressive with radial base function (NAR-RBFs) neural network for SITR model. Chaotic and stochastic data of the pandemic. A new class of transformation is presented for the system of ordinary differential equation (ODE) for fast convergence and improvement of desired accuracy level. The proposed transformations convert local optimum values to global values before implementation of bimodal paradigm.

Abbreviations: NAR, Nonlinear Autoregressive; St Dev, Standard Deviation; RBFs, Radial Basic Functions; WHO, World health organization; MSE, Mean Square Error; PDEs, Partial differential equations; ARIMA, Auto-Regressive Integrated Moving; ODEs, Ordinary differential equations Average.

Results: This suggested NAR-RBFs model is investigated for the bi-module nature of SITR model with additional feature of fragility in modeling of stochastic variation ability for different cases and scenarios with constraints variation. Best agreement of the proposed bimodal paradigm with outstanding numerical solver is confirmed based on statistical results calculated from MSE, RMSE and MAPE with accuracy level based on mean square error up to 1E-25, which further validates the stability and consistence of bimodal proposed model.

Conclusions: This computational technique is shown extraordinary results in terms of accuracy and convergence. The outcomes of this study will be useful in forecasting the progression of COVID-19, the influence of several deciding parameters overspread of COVID-19 and can help for planning, monitoring as well as preventing the spread of COVID-19.

1. Introduction

Mathematical modeling of Vector-borne diseases and forecasting of epidemics outbreak are global challenges and big point of concern worldwide. The outbreaks depend on different social and demographic factors based on human mobility which paradigm with mathematical models for vector-borne disease transmission. In Dec 2019, an infectious disease is known as "coronavirus" (officially declared as COVID-19 by WHO) emerged in Wuhan (Capital city of Hubei, China) and spread quickly to all over the china with over 50,000 cases including more than 1000 death within a short period of just one month [\[1\]](#page-16-0) after the outbreak of the pandemic. To overcome the outbreak massive type of restriction on public gathering, traveling and self-safety like wearing masks with social distancing were implemented. On initial stages, the key symptoms for this disease are fever, flu, and dry cough which might lead to difficulty in breathing, headache, and loss of taste/ smell for its critical cases. Generally, the recovery rate from the pandemic is around 80 \sim 85 % without any special treatment [\[2,3\]](#page-16-0). The COVID-19 badly affects older people (almost age of 60 or more), and those who are facing serious medical diseases like cardiovascular disease, diabetes, chronic respiratory and cancer. Those who have a fever, breathing difficulty, and dry cough should pursue medical care. As of 20th December, 2020 more than 76.11 million people have been infected and more than 1.6 million people have died with this virus but 53.83 million persons got recovered from this virus all over the world. Data of the top 10 countries mostly got infected by COVID-19 (WHO sources [\[4\]\)](#page-16-0) has been presented in Table 1, whereas the graphical trend of the spread of virus has been shown in [Fig.](#page-3-0) 1.

Some researchers studied the basic reproduction number (R_0) of COVID-19 and found that it lies in the range of 1.4 - 6.6 which is very high than influenza, Ebola, and SARS epidemics [\[5\].](#page-16-0) This disease has a very fast speed of transfer from one person to others through small droplets of coughing or sneezing. The numbers of

Table 1 Country-wise data Infected, Recovered and Died persons for COVID-19 [\[4\]](#page-16-0) (As on 20 December 2020).

S No	Country	Total infected	Total Recovered	Total Deaths
1	USA	17.888.353	10.394.286	320.845
2	India	10.005.850	9,550,712	145,178
3	Brazil	7.163.912	6.198.185	185.687
4	Russia	2.819.429	2,254,742	50.347
5	France	2.442.990	182,656	60.229
6	Turkey	1.982.090	1,753,552	17,610
7	UK	1.977.167	1.244.367	66.541

10	Argentina	1,531,374	1,356,755	41,672

infected person are hence increasing day by day at a very high rate. At present, there is no vaccine or proper treatment is available for the patients of this disease and in the opinion of medical experts, the only way to reduce its rising trend is to keep the people away from infected persons and try to keep all infected persons in isolation or quarantined to avoid their social contact with healthy persons in the society. The global economy has been badly affected by control measures taken to prevent the spread of COVID-19, however, it is still uncertain whether this type of strategy has which type of effect on the spread of COVID-19. Therefore, it is necessary to measure the influence of all these parameters over epidemic development.

Analysis of data shows that the number of deaths does not only depend on the infected persons, besides this many other factors like weather / environmental conditions, average ages of person, and natural immunity of persons against viral diseases also matters. The rising trend of COVID-19 in different countries are presented in [Fig.](#page-3-0) 2.

The average incubation period for this virus is 7 - 14 days and the time required from infection to recovery or death is about 10 days based on several factors $[6,7]$. Roosa et al. $[8]$ offered three different mathematical models to present the short term estimation of the collective number of cases for COVID-19. Kucharski et al. [\[9\]](#page-16-0) suggested an SEIR model with some necessary modifications to study the rate of spreading of COVID-19. Yang et al. [\[10\]](#page-16-0) proposed various SEIR models with employing artificial intelligence schemes to predict the rising trend, epidemic peaks, and sizes of COVID-19 in china. Ivorra et al. [\[11\]](#page-16-0) developed an innovative θ -SEIHRD model while considering various special characteristics of the disease to estimate the spread of disease with an approximate magnitude of peaks. Later on, the results proposed by this model matches the actual data of COVID-19. All through this battle against an epidemic situation, theoretical research based on the epidemiological model has the same worth and importance as biological and medical studies have. These mathematical models are very helpful in understanding, comparing, and estimating the effect of various parameters (control measure and natural phenomenon) on the spreading and decaying of an epidemic outbreak. These mathematical models have advantages over other stochastic approaches such as less computational complications and involvement of ordinary differential equations provides better analysis for understanding the model. Bonyah et al. [\[12\]](#page-16-0) numerically investigated the SEIR based epidemic model of Zika virus with constant and dependent control to measure the effect of different pa-rameters on disease spread. Yavuz et al. [\[13\]](#page-16-0) numerically investigated the schistomosiasis fractional dynamic model by utilizing the Mittag-Leffler and exponential kernals. Furthermore, authors in [\[14\]](#page-16-0) observed that in cases where determining distribution probability is very difficult, it is better to prefer mathematical modeling over the stochastic approaches. Several studies have been done to describe the epidemic dynamics of COVID-19 in China and else-

Fig. 1. Total number of infected and died persons with COVID-19 all over the world [\[4\].](#page-16-0)

Fig. 2. Trend of COVID-19 in Different Countries [\[4\].](#page-16-0)

where with the help of several conventional mathematical models [\[15-18\].](#page-16-0) Over time, development in medical treatment, as well as more exact [approaches](#page-16-0) of stochastic and statistical reasoning [19- 24] to study the epidemic behavior have stepped up.

Settati et al. [\[25\]](#page-16-0) provided computer simulations to explain various theoretical results based on SIRI epidemic model with nonlinear variation. Karimi et al. [\[26\]](#page-16-0) proposed a hybrid model based on genetic algorithm (GA) and back propagation network (BPN) for the proper assessment of nanofluid density with improved accuracy. Ramírez et al. [\[27\]](#page-16-0) presented a hybrid model by joining the neural network with fuzzy logic by means of 2-lead for irregular cardiac heartbeat. Wang et al. [\[28\]](#page-16-0) offered a hybrid model by combining the correction and heuristic intelligent optimization algorithm with outliner detection to predict the air pollution in environment. Gao et al. [\[29\]](#page-16-0) used a hybrid predictive model built on artificial neural network (ANN) and imperialist competition algorithm (ICA) to analyze the slope stability behavior of unified soils. Cheema et al. [\[30\]](#page-17-0) presented an intelligent computing solution based on artificial neural networks for the mathematical model of novel COVID-19 by dividing the population into various classes. Wieczorek et al. [\[31\]](#page-17-0) used neural networks by exploiting the NAdam training model to predict the spread of COVID-19 based on the real value data. Marques et al. [\[32\]](#page-17-0) proposed an automated medical diagnostic system by utilizing convolutional neural network with using Efficient Net architecture. Khan et al. [\[33\]](#page-17-0) applied an Auto-Regressive Integrated Moving Average (ARIMA) model on the realistic collected data to predict and forecast the affected cases of COVID-19 in future. Authors then compared the accuracy of results with a NAR based solution and found a high level of accuracy in their results.

Umar et al. [\[34\]](#page-17-0) presented a SITR model representing the dynamics of COVID-19 and then used the modern stochastic intelligent computational methodology based on feed forward artificial neural networks to solve that model to study the variation of various classes on different involved parameters. Jung et al. [\[35\]](#page-17-0) proposed a SIR model based on different classes to present the dynamics of COVID-19 in South Korea and then used neural network with deep learning to solve the model. Naik et al. [\[36\]](#page-17-0) numerically investigated a COVID-19 model based on Caputo operator and presented graphical results to envision the effectiveness of introduced arbitrary order derivative. Wang et al. [\[37\]](#page-17-0) used the latest alpha-Sutte indicator to forecast the rising trend of COVID-19. Authors compare their result with the results of ARIMA method and found alpha-Sutte indicator more efficient and reliable as compared to ARIMA on the basis of root mean square error and absolute percentage error.

Contrary to these statistical techniques [\[38,39\]](#page-17-0) mathematical modeling based on various differential equations [\[40-42\]](#page-17-0) got very less consideration, although these mathematical models can deliver more detailed information for the epidemic dynamics. Conventional SIR model (susceptible-infectious-recovered) is being broadly used for describing epidemic of COVID-19 in all over the world. In this work, spread dynamics of COVID-19 is evaluated by designing innovative SITR epidemic model with the division of susceptible class (S) into two portions and by introducing a new class of treatment (T) to observe the epidemic situation which makes the model of COVID-19 to work with the consideration of continuous treatment of affected persons. Influence of various key parameters over the spreading of COVID-19 has been investigated.

Fig. 3. Epidemic model (SITR) for COVID-19 dynamics including $\varphi(t)$ in all four classes.

Innovative contribution of the design deep learning neural network based on different capabilities are presented in the following salient features: -

- *•* Computational strength of deep learning neural network based on nonlinear autoregressive (NAR) with radial base functions (RBFs) networks enhance the computing power and level of accuracy of the solver technique.
- *•* The hybrid model can pinpoint and capture the global as well as local aspects in the modeling of nonlinear differential equations representing the SITR epidemic model.
- *•* The innovative design of the NAR-RBFs neural network paradigm is designed to model the SITR epidemic differential equation (DE) model with additional term of stochastic variation to ascertain the different features of the spread of COVID-19.
- *•* The new set of transformations are introduced for nonlinear input to achieve with a higher level of accuracy, stability, and convergence analysis.

Rest of the paper is organized as follows: -

Detailed mathematical modeling of the SITR model has been presented in Section 2. Solution methodology of the suggested model has been briefly described in section 3. Statistical analysis of the all involved variables of SITR model is investigated in section 4. In Section 5 explanation of NAR-RBFs network structure is presented. Detailed numerical and graphical result with discussion are presented in section 6. A comparative study for alternate SIR model has been presented in Section 7 and at last section 8 consist of conclusion of the research.

2. Mathematical formulation of the model

In this section, a general SITR model along with description of basic characteristics of the model is presented. A detailed structure of the SITR model with the contribution of several parameters is shown in Fig. 3. These type of mathematical models based on various types of differential equations often gives detailed necessary information regarding the dynamics of an epidemic situation.

Basic Characteristics of the Model:-

- (1) **Susceptible class S₁ (t):-** This class includes those persons who are not yet infected with the virus.
- (2) **Susceptible class** S_2 **(t):-** This class also represents that persons which are not yet been infected with the virus, but persons in

Table 2

Description and values for various involved parameters in SITR model.

Symbol	Parameter Description	Assigned Value
	Contact rate	0.3
В	Natural birth rate	0.3
δ	Reduce infection from the treatment	0.3
σ	Fever, tiredness and dry cough rate	0.005
μ	Recovery rate	0.1
α	Death rate	0.25
ρ	Rate of infection from the treatment	0.3
	Healthy food rate	0.2
ε	Sleep rate	0.1

this class have some types of sickness/illness or they are of an older age which creates greater chances for these persons to get infected by virus then class S_1 .

- (3) **Infectious class I (t):-** This class includes those persons who are infected by Covid-19 and they can further transmit the virus to other healthy persons.
- (4) **Treatment Class T (t):-** Persons in this class or either under the hospital treatment or in the state of quarantined. These persons can either move to recovered class by recovery or can die from the virus.
- (5) **Recovered class R (t):-** This class includes those persons who were previously got infected from the virus and either survived or got recovered with treatment.

Mathematical Model:-

Under those assumptions, the proposed SITR model [\[43\]](#page-17-0) can be described in term of following ordinary differential equations:-

$$
S'_{1}(t) = B - \beta I(t)S_{1}(t) - \delta \beta T(t) - \alpha S_{1}(t) + \varphi(t),
$$
\n(1)

$$
S_2'(t) = B - \beta I(t)S_2(t) - \delta \beta T(t) - \alpha S_2(t) + \varphi(t),
$$
 (2)

$$
I'(t) = -\mu I(t) + \beta I(t)[S_1(t) + S_2(t)] - \alpha I(t) + \beta \delta T(t)
$$

+ $\sigma I(t) + \varphi(t)$, (3)

$$
T'(t) = \mu I(t) - \rho T(t) - \alpha T(t) + \psi T(t) + \varepsilon T(t) + \varphi(t), \tag{4}
$$

$$
R'(t) = -\alpha R(t) + \rho T(t) + \varphi(t). \tag{5}
$$

With initial boundary conditions

$$
S_1(0) = 0.65
$$
, $S_2(0) = 0.15$, $I(0) = 0.1$, $T(0) = 0.2$, $R(0) = 0.1$ (6)

Assigned values for various parameters involved in equations (1~5) has been mentioned in Table 2. Whereas, $\phi(t)$ in the equations $(1 \sim 5)$ represents the abrupt change due to different factors including social gathering, huge travelling and public interaction at different level, that can produce any sudden rise in the number of susceptible/infectious persons. It is pertinent to highlight that recovery rate μ and death rate α can also be treated as time-dependent parameters since the recovery rate increase certainly decreases the death rate over time with proper medical treatments, an invention of vaccine or drugs and isolation of infected persons from the society. In the mathematical model, the effectiveness of increasing recovery rate and decreasing death rate over the number of susceptible, infectious, and recovered persons is studied. The behavior of other important parameters with their variation and its impact on recovery rate is calculated and modeled. Different studied are presented to study the relationships between environmental conditions (temperature, humidity, etc.) and the spread of COVID-19. Luo et al. [\[44\]](#page-17-0) observed that the spreading behavior of COVID-19 is not following the hypothesis that higher values of humidity bound the transmission and existence

Fig. 4. Non-Linear Autoregressive Neural Network (NAR).

of viruses. Whereas, Wang et al. $[45]$ find that the increase in temperature corresponds to less transmission rate and shorter survival period of the virus outside the host. Therefore, without any scientific proof regarding the influence of temperature and humidity on the spreading of COVID-19, these factors are not considered in proposed model.

3. Solution methodology

NAR network based on sigmoid function performs globally [\[46\]](#page-17-0) whereas the radial based network function deals to treat the local behavior of inputs. With the variation of input based on time interval from the center towards radii, radial displacement governed by neurons reduces which transform most of the RBF function to their zero states, however with the increase in input data sigmoid function stay close to 1. These specific characteristics enable the combination of RBF with Sigmoid function to deal simultaneously with local as well as global features of modeling.

4. Non-linear autoregressive neural network (NAR)

A maximum number of time series models are based on temporary periods and high variations, which makes them difficult to model through linear modeling therefore a non-linear attitude is proposed. Fig. 4 shows a nonlinear auto aggressive neural network (NAR) [\[47\]](#page-17-0) is a discrete model containing three different layers (input, hidden and output) with two delay steps (input and output) is being used for the prediction of non-linear time series, which can be expressed as [\[48\]:](#page-17-0)-

$$
y(t) = h(y(t-1), y(t-2), y(t-3), \ldots, y(t-p)) + \mathcal{E}(t)
$$

Through the above mathematical relation, it is easy to judge that how by using the previous *p* values of the series, NAR neural network is utilized to forecast the values any output $y(t)$ at any point *t*. The unknown function *h*(∗) is being approximated with the training of neural networks through optimizing the neural weight and number of neurons. The term at the end $\mathcal{E}(t)$ is an approximate error of the complete series*y*(*t*).

The number of neurons and hidden layers are adjustable and can be optimized through hit and trial basis depending upon the accuracy and performance of the system. It should be kept in mind that a higher number of neurons will result in better accuracy of the computation but it also makes the system more complicated to solve, whereas the lower number of neurons may limit the computing capabilities of the network. The most widely and commonly used rule for NAR neural network is the Levenberg-Marquardt technique [\[49,50\]](#page-17-0).

NAR neural network uses the mean square error (MSE) error sum of squares (SSE) to show the accuracy and reliability of the computations. Whereas, v_i are the values of *ith* data set, $\overline{v_i}$ is the value of similar data set obtained through network operation and *k* is the number of data set provided to the neural network for its operation.

$$
SSE = \sum_{i=1}^{k} (\overline{y_i} - y_i)^2
$$

 $MSE = {SSE}_{/k}$

5. Radial base function (RBF)

Most basic Radial basis function (RBF) operates on followings three layers with each layer having its task that is completely different from the other two:-

- *•* **Input layer: -** This first layer is constructed by source nodes that join the network with its environment.
- *•* **Hidden layer: -** This second layer has the role of application of nonlinear transformation from the input layer to the hidden layer.
- *•* **Output layer: -** This third layer is linear and an arrangement of hidden functions. It has the role to supply the reaction of a network to the stimulation array given to input layer.

Structure of RBFs network has been shown in Fig. 5. The basic linear model for function $f(x)$ can be written as

$$
f(x) = \sum_{j=1}^{n} w_j h_j(x)
$$

Condition for Normality of Data

If.

 p -value \geq 0.05 (Data is Normal)

If p-value 0.05 (Data is Non-normal)

Fig. 6. Probability Plots of data sets of all outputs.

Table 3 Descriptive Statistics of all classes.

Variable	Mean	St. Dev.	Variance	Min	Median	Max	Range	Skewness	Kurtosis
S1	0.78815	0.04481	0.00201	0.65000	0.80203	0.83219	0.18219	-1.24	0.85
S ₂	0.72021	0.24955	0.06227	0.15000	0.74967	1.17284	1.02284	-0.35	-0.61
	0.35246	0.16313	0.02661	0.15000	0.31232	0.71501	0.56501	0.59	-0.86
	0.16826	0.07864	0.00618	0.02632	0.15830	0.35000	0.32368	0.38	-0.58
R	0.32684	0.18550	0.03441	0.10000	0.24670	0.87314	0.77314	1.27	0.66

The f (.) can be expressed as a linear combination of 'm' basis functions, whereas, $h(x)$ normally represents the Gaussian function.

$$
h(x)=exp\left(\frac{-(x-c)^2}{2\sigma^2}\right), \ \sigma>0; \ x,c \in R
$$

Whereas, c is the center and r is the radius.

6. Statistical analysis of data

In problems governed by the system of differential equations, linear input between a fixed domain is used very often in many types of machine learning techniques by neglecting the non-linear behavior of outputs. In Fig. 6, the probability distribution curves of the outputs (S_1, S_2, I, T, R) shows their strong non-linear behavior. Here the p-value for all outputs is less than 0.005 which is ten times shorter than the minimum range for normal data. So our each of the outputs is strictly non-normal. So the use of linear input in this type of computational process not only makes the process more complicated but also decreases the accuracy of the stochastic process.

Various types of statistical data in respect of each output in place in Table 3, which also shows the non-linear distribution of the output data sets. Values of mean with maximum and minimum values tell the distribution of data. The values of Skewness also explain the placement of data from its mean position either in the left or right direction. Additionally, the values of kurtosis give the tail distribution of data from the mean position.

6.1. Introduction of non-linear transformation

[Fig.](#page-7-0) 7(a \sim d) shows the multiple nature of outputs with various type of statistical data placed against each plot. Here instead of using simple linear input against each output with different characteristics and behavior, a special transformation for input as per corresponding output is introduced. This type of transformation helps the computational process to ensure the conversion of linear input into bi-module input or as per output requirements. Therefore, in the suggested approach, a set of transformations are presented to reduce the local optimum to global optimum. In the first step, this transformation converts the linear input into the desired bimodule greater input with ensuring its convergence before being used in the machine learning process. [Table](#page-7-0) 4 shows the set of transformations to achieve the desired nature of transmuted inputs.

7. Hybrid NAR-RBF methodology

Our proposed NAR-RBF model can be expressed as

$$
x_i + \varphi(t) = L_i(x) + N_i(x)
$$

Here, $N_i(x)$ represents the non-linear neural networks working under the methodology of NAR which used Gaussian transfer function and model the global features whereas, $L_i(x)$ shows the data modeling with radial basis function (RBF) which deals very well with the local trend of the model. Structure of proposed NAR-RBFs neural network has been shown in [Fig.](#page-7-0) 8. Therefore, by using NAR and RBF, this hybrid model simultaneously entertains the global and local features of the non-linear database outputs.

8. Results of NAR and NAR-RBFs networks

The system of differential equations (1~5) representing the SITR model with initial boundary conditions in (6) for each case of all scenarios are solved separately with the help of NDSolve in Mathe-

Complete numerical analysis of NAR network for SITR model.

dation and testing each. The number of neurons is also adjusted in the range of 80 to 100 according to the desired accuracy of the computational results. The basic structure of the neural network for five outputs against one input is being shown in [Fig.](#page-9-0) 10.

Data set containing 1001 points for each output is solved with a supervised neural network as per four cases of three different scenarios as per [Table](#page-7-0) 5. Performance and accuracy analysis of the method is being given graphically in [Figs.](#page-11-0) 12, [14](#page-12-0) and [16.](#page-13-0) Comparison of all computational and statistical data containing the values of performance, gradient, Mu, epochs, number of hidden neurons, and MSE for Training, Testing & Validation for all cases of each scenario are displayed in Table 6.

[Fig.](#page-10-0) 11(a) shows that as the rate of contact increases the number of susceptible persons initially rises but after some time it shows a decline. This is because with the higher contact rate more and more persons get infected and moves to infected class therefore the number of people in susceptible class decreases. From [Fig.](#page-10-0) 11(b) increase in the rate of infected persons can be seen with the increase in contact rate. It can be seen that less contact rate results in a mild rise in infected persons while an increase in contact rate will sharply raise the infected persons, which is due to the fact that corona virus has a very fast rate of transfer from one person to others through social gathering with small droplets of coughing or sneezing. [Fig.](#page-12-0) 13(a) exhibits the rising behavior of suscep-tible persons with higher values of recovery rate. [Fig.](#page-12-0) $13(b)$ shows that as the recovery rate rises the persons in the infectious class rise slowly. It is understood that when the recovery rate is low then fewer persons will recover from the virus, indeed many of the infected persons will die from the virus. [Fig.](#page-13-0) 15(a) displays the changing behavior of infected persons with various death rates. It is obvious that increasing the death rate will result in reduction of infected persons as more and more persons from infected class moves to death class. [Fig.](#page-13-0) 15(b) shows the variation of recovered persons with different values of the death rate. It can be seen in the plots that with high death rate the number of recovered persons very sharply. This is because when the death rate is high then a large number of persons from infected and recovered class dies which results in the reduction of persons in all of these classes. As the death rate becomes very high the infectious and recovered persons approximately vanish.

Subfigures (12a, 14a, and 16a) exhibits the fitness plots showing the error i.e. the difference between target and output for training, testing, and validation at each point of the input for scenarios 1, 2 and 3 respectively. Similarly, subfigures (12b, 14b, and 16b) shows the distribution of error from the zero error line with the help of error histogram place aside the fitness plots. Accuracy and validity of the process can be judged through the number of values lies close to zero lines. Subfigures (12c, 14c, and 16c) depicts the performance analysis of the computations in term of mean square error (MSE) for Scenario 1, 2, and 3 respectively. The smaller value of MSE indicates the better accuracy and performance of solution methodology. It is being noted that Scenario 3 has a better performance among all others because mean square error (MSE) is minimum (i.e. 5.7184e -11 at 313 epochs) as compared to all other scenarios. Subfigures (12d, 14d, and 16d) shows the plots for gradient, Mu, and validation checks for scenario 1, 2, and 3 respectively. The Gradient is finding another vector during training at each epoch while Mu is the step size of the applied algorithm and validation checks show the generalization measure of the system. It can be seen that smaller the value of Mu leads to better convergence of results.

Comparison results of three different samples of infected I (t) output by the variance of analysis and Tukey simulation test have been carried out, and results are shown in [Tables](#page-10-0) 7[-9\)](#page-10-0). Achieved results of $F=0 < \alpha$ with a P-value of 1 with an accuracy of 99.99. As it can be seen through results that each set of output have equal mean which indicates the stability of result and convergence of computational model.

Method

Null Hypothesis: All means are equal Alternate Hypothesis: All means are not equal Level of Significance: $\alpha = 0.01$

Table 8

Table 7

Means and Grouping Information (Tukey Method and 95% Confidence).

Table 9

Tukey simultaneous tests for differences of means.

Difference of Levels	Difference of Means	SE of Difference	95% CI	T-Value	Adjusted P-Value
Infected (2) - Infected (1)	-0.0000	0.0114	$(-0.0267, 0.0267)$	-0.00	1.000
Infected (3) - Infected (1)	0.0000	0.0114	$(-0.0267, 0.0267)$	0.00	1.000
Infected (3) - Infected (2)	0.0000	0.0114	$(-0.0267, 0.0267)$	0.00	1.000

Comparison for accuracy of proposed model with NAR and RBFs model in term of mean square error (MSE) for each output variable during "Case2 of Scenario 1" are being presented in Appendix Section [Table](#page-15-0) A1 and [Table](#page-15-0) A2. Same values through NAR-RBFs network along with the values of MSE at different points of the domain for "Case 1 of Scenario 3" is presented in Appendix Section [Table](#page-16-0) A3. It can be seen that by applying the radial base network on the residual result of NAR the accuracy in terms of MSE up to 2.77E-24 has been achieved.

9. Comparative study for NAR methodology

Consider a stochastic Susceptible-Infected-Removed (SIR) model. $S(t)$, $I(t)$ and R (t) denotes the number of susceptible, infected but not lab-confirmed cases (including those in incubation period) and removed population (including recoveries, fatalities and confirmed cases) at time t respectively, and note that $N(t)=$ S (t)+ I (t)+R (t) is a constant. Reproduction number $R = \beta E(t) = \frac{\beta}{\gamma}$ where γ and β are the removing rate and transmission rate. So the stochastic model can be represented in the form of following ODEs [\[51,52\]](#page-17-0):-

$$
S'(t) = -\beta I(t)S(t)/N(i)
$$

\n
$$
I'(t) = \beta I(t)S_1(t) - \gamma I(t)(ii)
$$

\n
$$
R'(t) = \gamma I(t)(iii)
$$

After solution of above equations by utilizing the computational strength of Neural Network and graphical outcomes can be seen in [Fig.](#page-14-0) 17.

10. Conclusion

In this research, NAR-RBFs based hybrid neural network is presented to model the set of differential equations representing the SITR model. The error term based on stochastic variation is included to model the COVID-19 abrupt spread. This computational technique based on deep learning has shown extraordinary performance in terms of accuracy and convergence. The outcomes of this study will be useful in forecasting the progression of COVID-19 for different countries. The influence of several key parameters in overspread of COVID-19 pandemic are ideally modeled which can help for planning, monitoring as well as preventing measure the spread of COVID-19 pandemic.

In future one may utilize the computational strength of NAR-RBFs hybrid model for the solution of problems [\[53-57\].](#page-17-0)
