ABSTRACT

Aim: We aimed to address the potential impact of COVID-19 on glycemic patterns in a small pilot study.**Method:** 13 patients with mild COVID-19 who were confirmed without diabetes and another group of 18 healthy individuals with available CGM data were well matched and enrolled into the final analysis.**Results:** We noticed significantly higher TARs of >140 mg/dL (median 13.9% vs. 2.3%, $P = 0.006$), >160 mg/dL (median 4.7% vs. 0.0%, $P = 0.011$) and >180 mg/dL (median 1.9% vs. 0.0%, $P = 0.007$) among non-diabetic patients with COVID-19 than those among healthy individuals. There was no significant difference in TBR of <70 mg/dL or <54 mg/dL (all $P > 0.1$). Consequently, the TIR of 70 mg/dL to 140 mg/dL was significantly lower in non-diabetic patients with COVID-19 than that in healthy individuals (median 80.1% vs. 93.1%, $P = 0.001$). Significant postprandial glycemic fluctuations were observed among patients with COVID-19. There was a remarkable difference in CV in non-diabetic patients with COVID-19 compared to healthy individuals (median 25.6% vs. 15.7%, $P < 0.001$).**Conclusion:** Significant higher glycemic fluctuation and exposure to hyperglycemia was associated with COVID-19 among previously normoglycemic individuals, characterized with potentially impaired glucose tolerance.

More and more evidences support an active interaction between coronavirus disease 2019 (COVID-19) and diabetes (Shrestha et al., 2020). Recent researchers revealed that pancreatic β cells are highly permissive to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection with receptor angiotensin-converting enzyme 2 (ACE2) as its entry (Yang et al., 2020; Al-Benna, 2020). Therefore, hyperglycemia and glycemic fluctuations may be caused by the inflammatory cascade of the attack of SARS-CoV-2 to pancreas and the potentially impaired β -cell function (Hoffmann et al., 2020). In accord, an international group of leading diabetes researchers have recently raised their concerns on a new-onset of diabetes potentially precipitated by COVID-19⁵.

In order to address the potential impact of COVID-19 on glycemic patterns, we did a small observational pilot study. 13 patients with mild COVID-19 who were confirmed without diabetes and were admitted to Leishenshan Hospital in Wuhan city, China were invited to receive continuous glucose monitoring (CGM) for a median period of 6 days. Meanwhile, another group of 18 healthy individuals with available CGM

data for a median period of 3 days from volunteers recruited in Shanghai Sixth People's Hospital were well matched and balanced by age, sex, body mass index, fasting glucose and HbA_{1c} levels (Zhou et al., 2009), resulting in a total of 31 individuals enrolled into the final analysis. All these participants received a standardized meal regimen. All patients in this study were confirmed without use of glucocorticoids. All patients with COVID-19 received arbidol hydrochloride capsules plus traditional Chinese herbs during hospitalization. These participants also took 1-h mild to moderate physical exercises daily as instructed at bedside. Percentage times of sensor glucose levels above (TAR), below (TBR) and in certain ranges (TIR) were calculated. Glycemic fluctuation was assessed by calculation of the coefficient of variation (CV) of the sensor glucose levels. All participants were confirmed non-diabetic by fasting plasma glucose levels <100 mg/dL and HbA_{1c} levels <6.5% (48 mmol/mol). These glycemic metrics were further compared between non-diabetic patients with COVID-19 and healthy individuals using Kruskal-Wallis test. The study protocol was approved by Institutional Review Boards of both Shanghai Jiaotong University Affiliated Sixth People's Hospital

Table 1

Summary of glyceic metrics by continuous glucose monitoring in normoglycemic patients with COVID-19 and healthy individuals.

Percentage of sensor glucose levels, %	Healthy individuals N = 18	Normoglycemic patients with COVID-19 N = 13
TAR		
>10.0 mmol/L	0.0 (0.0–0.0)	1.9 (0.0–8.3) ^b
>8.9 mmol/L	0.0 (0.0–2.4)	4.7 (0.7–17.8) ^a
>7.8 mmol/L	2.3 (0.0–9.8)	13.9 (4.8–30.9) ^b
TBR		
<3.9 mmol/L	0.0 (0.0–0.0)	0.5 (0.0–11.9)
<3.0 mmol/L	0.0 (0.0–0.0)	0.0 (0.0–0.0)
TIR		
3.9–7.8 mmol/L	93.1 (86.8–99.5)	80.1 (68.9–88.2) ^b
3.9–10.0 mmol/L	100 (94.5–100)	92.1 (82.5–97.5)

Data were presented with median (interquartile range).

^b $P < 0.01$.

and Zhongnan Hospital of Wuhan University, which was subsequently registered in Chinese Clinical Trial Registry (ChiCTR2000030436). We had obtained informed consent from all patients involved in this study.

For all glyceic metrics listed in Table 1, we noticed significantly higher TARs of >140 mg/dL (median 13.9% vs. 2.3%, $P = 0.006$), >160 mg/dL (median 4.7% vs. 0.0%, $P = 0.011$) and >180 mg/dL (median 1.9% vs. 0.0%, $P = 0.007$) among non-diabetic patients with COVID-19 than those among healthy individuals. There was no significant difference in TBR of <70 mg/dL or <54 mg/dL (all $P > 0.1$). Consequently, the TIR of 70 mg/dL to 140 mg/dL was significantly lower in non-diabetic patients with COVID-19 than that in healthy individuals (median 80.1% vs. 93.1%, $P = 0.001$). Significant postprandial glyceic fluctuations were observed among patients with COVID-19 (Fig. 1). There was a remarkable difference in CV in non-diabetic patients with COVID-19 compared to healthy individuals (median 25.6% vs. 15.7%, $P < 0.001$).

In this case series study using CGM, we demonstrated a significantly greater degree of glyceic fluctuation especially postprandial excursions in non-diabetic patients with COVID-19 when compared to healthy individuals. Since normal glyceic profiles suggest very tight physiological control, with only brief postprandial excursions above 140 mg/dl (Zhou et al., 2009; Shah et al., 2019), our findings indicate that the glyceic profiles of the previously normoglycemic individuals (e.g., TAR of >140 mg/dL: 13.9%) could no longer be regarded as “normal”

after COVID-19 infection, especially at the postprandial state. Accordingly, the measurement of postprandial glucose is warranted to better address the burden of hyperglycemia in these patients. Regarding the mechanism underlying this observation, a recent study reported that human pancreatic beta cells could be infected by SARS-CoV-2², suggesting that impaired glucose tolerance may at least partially account for the glucose dysregulation, although the impact of COVID-19 on insulin resistance could not be ruled out. Based on these preliminary results, we suggest further studies and focus on the interplay between COVID-19 and diabetes. Studies on the exposure to COVID-19 and the subsequent metabolic outcomes with enough sample size will help elucidate the detrimental effect of COVID-19 on diabetes and other metabolic disorders.

Several limitations should be addressed. Although all patients have undergone a standardized diet and physical activity regimen, the quantitative metrics of lifestyle variables were not calculated. In addition, three days of CGM data may be a little bit short to assess TIR. Finally, we failed to compare the CGM data before and after infection with SARS-CoV-2 of the same patients for the accurate evaluation of the influence of COVID-19 on blood glucose levels.

In summary, in this observational pilot study, significant higher glyceic fluctuation and exposure to hyperglycemia was associated with COVID-19 among previously normoglycemic individuals, characterized with potentially impaired glucose tolerance. We recommended regular glucose monitoring on these patients on both fasting and postprandial glucose levels. These findings also underscore the concerns of new-onset diabetes in COVID-19.

Ethics approval and consent to participate

The study and the analysis plan were approved by the Institutional Review Boards (Research Ethics Committees) of Shanghai Sixth People's Hospital. We have obtained informed consent from all participants.

Consent for publication

All authors have read and approved submission of abstract and the abstract has not been published and is not being considered for publication elsewhere in whole or part in any language.

Availability of data and materials

The datasets generated and/or analyzed in the current study are not

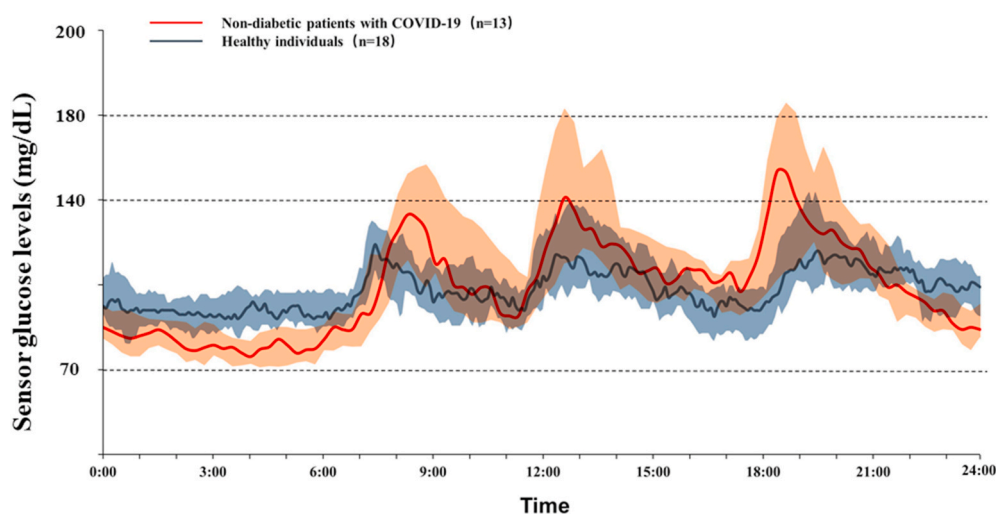

Fig. 1. Median sensor glucose levels with their 25th and 75th percentiles during a period of 24 h of non-diabetic patients with COVID-19 and healthy individuals.
