

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

COVID-19 Vaccination in Patients with Reported Allergic Reactions: Updated Evidence and Suggested Approach

Robinson, MD, MPH^{a,b}, Elizabeth Phillips, MD^d, and Kimberly G. Blumenthal, MD, MSc^{a,b,e} *Boston, Mass; and Nashville, Tenn*

BACKGROUND

As of March 25, 2021, more than 124 million people globally have been diagnosed with a coronavirus disease 2019 (COVID-19) infection and almost 2.7 million have died from COVID-19.¹ This international pandemic was met with the rapid development and Food and Drug Administration approval under Emergency Use Authorization (EUA) of 2 effective COVID-19 mRNA vaccines (Pfizer-BioNTech and Moderna) in December 2020. Unfortunately, within days, severe allergic reactions to the COVID-19 mRNA vaccines occurred, creating a potential barrier to large-scale vaccination efforts. To address this unmet need amidst great uncertainty, in December 2020, we published initial algorithms to help the allergist guide safe vaccination in individuals with allergy histories.²

Since then, more than 46 million individuals have been fully vaccinated and more than 2 million additional Americans receive their vaccinations daily.³ The Centers for Disease Control and Prevention (CDC), using Vaccine Adverse Event Reporting System and V-safe voluntary reporting data, described the rate of anaphylaxis after receipt of the mRNA COVID-19 vaccines as 4.5 cases per million doses administered, with 89% occurring within the 15- to 30-minute observation period.⁴⁻⁶ This is comparable to anaphylaxis rates with other vaccines including the inactivated influenza vaccine (1.4 per million), pneumococcal polysaccharide vaccine (2.5 per million), and the live attenuated herpes zoster vaccine (9.6 per million).⁴ However, prospective cohort data from more than 60,000 Mass General Brigham

(MGB) employees found a higher incidence rate of anaphylaxis to the mRNA COVID-19 vaccines at 2.47 per 10,000 vaccinations.⁷ The marked difference in observed incidence rates likely relates to incomplete CDC capture of cases, although the MGB cohort may have a higher rate than some US populations because of demographic or geographic effects.

JANSSEN COVID-19 VACCINE

On February 27, 2021, the Food and Drug Administration issued EUA approval for a third COVID-19 vaccine from Janssen (Johnson and Johnson) in individuals 18 years or older. This is an adenovirus type 26 vectored vaccine encoding a stabilized variant of the severe acute respiratory syndrome coronavirus 2 spike protein, showing high efficacy with 100% protection from death or hospitalization (similar to the mRNA COVID-19 vaccines available under EUA in the United States) following the currently recommended single dose. The pivotal phase III trial data reported urticaria in 5 vaccinated individuals and 1 individual who received placebo in the 7 days following vaccination. One hypersensitivity reaction deemed likely related to vaccine, not classified as anaphylaxis, was reported in 1 vaccinated individual, with urticaria beginning 2 days following vaccination and angioedema of the lips without respiratory distress beginning 4 days following vaccination.⁸ In addition, 1 case of anaphylaxis among 110,000 in an ongoing open-label study in South Africa has been reported following the Janssen COVID-19 vaccine administered in clinical studies.⁹

UPDATED CDC VACCINATION GUIDANCE

Despite increasing knowledge, the mechanism of allergic reactions to any of the COVID-19 vaccines remains unclear but the excipients within these vaccines remain a possibility. Polyethylene glycol (PEG) is the common excipient in both mRNA COVID-19 vaccines, whereas polysorbate 80 is the excipient in the Janssen COVID-19 vaccine. PEG and polysorbate are structurally related, and skin testing has shown cross-reactive hypersensitivity in rare cases when evaluation to both excipients has been pursued. Polysorbate 80 as an excipient cause of anaphylaxis is extremely rare, with just 1 case report of vaccine anaphylaxis thought to be related to polysorbate 80 in the literature.¹⁰

At the time of publication, updated CDC guidance¹¹ states (1) if you are allergic to PEG, you should not receive an mRNA COVID-19 vaccine and instead speak to your physician about receiving the Janssen COVID-19 vaccine; (2) if you are allergic to polysorbate 80, you should not receive the Janssen COVID-

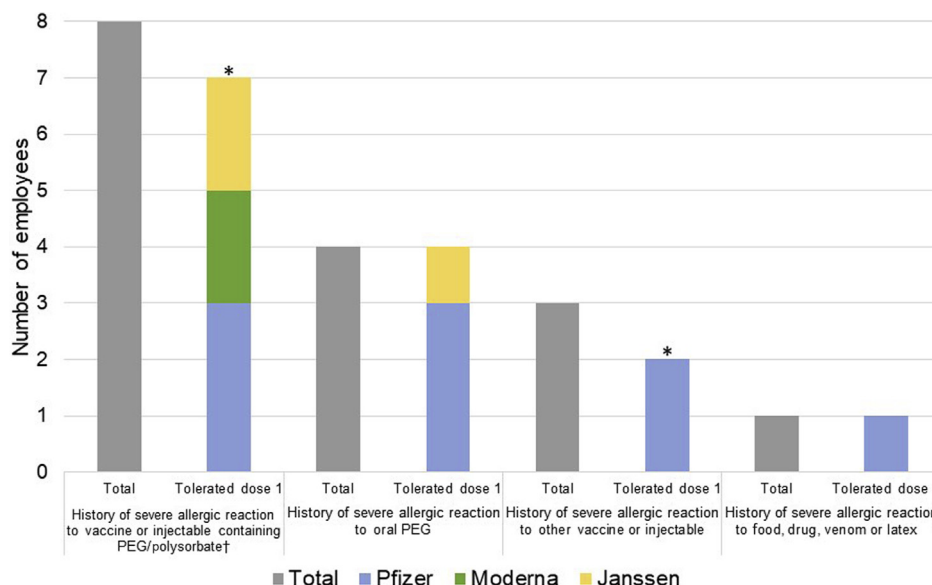

FIGURE 1. Prevaccine high risk patients and dose 1 vaccination outcome (n = 16). Among the 16 individuals skin tested after risk stratification, only 1 individual was skin test positive (oral PEG severe allergic reaction, tolerated Janssen vaccine). Thirteen of the 15 skin test negative individuals tolerated the initial dose of COVID-19 vaccine. *Two skin test negative individuals are awaiting dose 1 of the COVID-19 vaccine: 1 employee with a history of severe allergic reaction to vaccine or injectable containing PEG/polysorbate and 1 employee with a history of severe allergic reaction to vaccine or injectable. †One employee experienced pruritus on lower back immediately after Pfizer dose 1 was given 10 mg cetirizine with complete resolution of symptoms in 30 minutes. Tolerated Pfizer dose 2 without any allergic symptoms.

19 vaccine and instead speak to your physician about receiving the mRNA COVID-19 vaccines; (3) a history of polysorbate allergy is a precaution rather than a contraindication to mRNA vaccination¹²; and (4) vaccination of these individuals (ie, those with PEG or polysorbate allergy histories) should be undertaken only under the supervision of a health care provider experienced in the management of severe allergic reactions.¹² Therefore, the CDC suggests that individuals with a contraindication to the mRNA COVID-19 vaccines (due to a history of possible PEG allergy) may be considered for the Janssen COVID-19 vaccine and similarly, individuals with a contraindication to the Janssen COVID-19 vaccine (due to a history of possible polysorbate allergy) may be considered for the mRNA COVID-19 vaccines. The CDC also provides guidance around use of Janssen COVID-19 vaccine if the recipient develops a severe allergic reaction to dose 1 of an mRNA COVID vaccine, allowing for Janssen vaccination provided a delay between mRNA and Janssen vaccination of at least 28 days.¹¹ There are currently no efficacy data on this “mix and match” approach, and we do not know the long-term durability of protection from any of the current COVID-19 vaccines. Additionally, on April 13, 2021, the CDC placed the Janssen vaccine on “pause” while investigating adverse events of thrombocytopenia and central venous thrombosis.

PREVACCINE RISK STRATIFICATION: OUTCOMES

Since vaccination efforts were initiated at MGB, 472 employees with high risk allergy histories had allergist guidance prior to vaccination and we recommended 15 minute (n = 209, 44%) and 30 minute (n = 241, 51%) observations after mRNA

vaccination. Of 22 (5%) referred for pre-mRNA vaccination excipient skin testing, 16 completed skin testing to date (Figure 1). Our previous protocols were used.² Referral reasons included a history of a severe allergic reaction to a vaccine or injectable with PEG/polysorbate (n = 8), oral PEG (n = 4), other vaccine or injectable (n = 3), and food, drug, venom, or latex (n = 1). Only 1 employee, with a history of oral PEG allergy, was skin test positive to methylprednisolone acetate (4 mg/mL intradermal, 10 × 30 mm), which contains PEG as an excipient. This employee subsequently tolerated the Janssen COVID-19 vaccine. Among the skin test negative individuals (n = 15) who received the first dose (n = 13), no allergic reactions were observed (9 Pfizer-BioNTech, 2 Moderna, 2 Janssen). At the time of publication, 2 employees with negative skin testing await COVID-19 vaccination.

PREVACCINE RISK STRATIFICATION: ALGORITHM

With additional clinical data and approval of the third COVID-19 vaccine in the United States, we propose a modified approach to the evaluation of patients with reported allergy histories that remain consistent with CDC guidance (Figure 2). Although this algorithm provides guidance, until COVID-19 vaccine supply increases, the primary role of the allergist is to enable patients to safely receive the first vaccine available to them. This may require allergist evaluation for PEG and/or polysorbate allergy depending on vaccine availability.

Similar to our initial algorithm,² individuals with any history of anaphylaxis should continue to be monitored for 30 minutes after receiving an mRNA COVID-19 vaccine. Following current CDC guidance,^{11,12} individuals who self-report a PEG-allergy

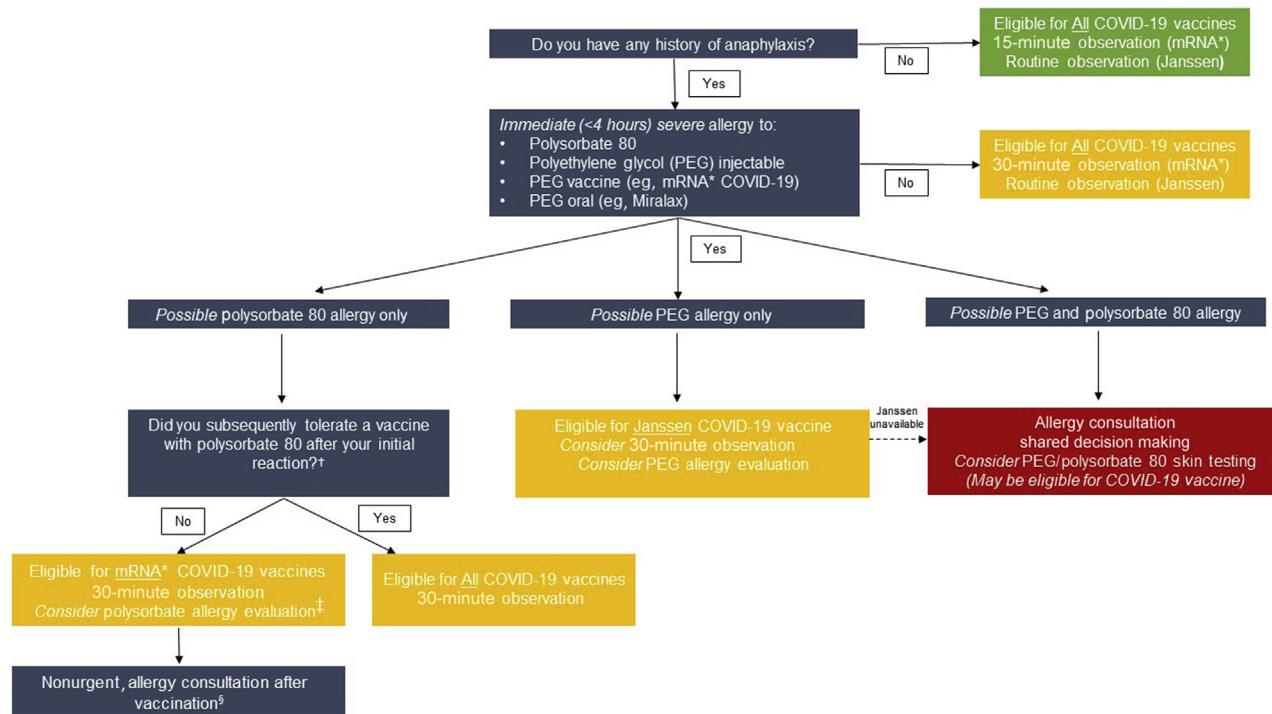

FIGURE 2. Risk stratification pathways for COVID-19 vaccination in patients with possible PEG or polysorbate allergy. The primary role of the allergist is to enable patients to safely receive the first vaccine available to them. This may require allergist evaluation for PEG and/or polysorbate allergy depending on vaccine availability. Individuals with any history of anaphylaxis, per CDC guidance, would be monitored for 30 minutes after mRNA COVID-19 vaccination. Individuals without a PEG or polysorbate allergy are eligible to receive all COVID-19 vaccines and observation time would depend on which vaccine was being given and whether there was a previous history of anaphylaxis. Individuals with a polysorbate 80 only allergy would be further assessed by asking “Did you tolerate a polysorbate 80 vaccine after your initial reaction” to a polysorbate 80 injectable or vaccine. Individuals with PEG-only allergy are eligible to receive Janssen COVID-19 vaccine without allergy evaluation. *mRNA COVID-19 vaccines from Pfizer-BioNTech and Moderna. †See Table I. ‡Consider allergy evaluation of polysorbate allergy history if patient preference is for the Janssen vaccine and it is available. §Polysorbate allergy evaluation may be useful in guiding the future use of injectables and vaccines with polysorbate.

only can be considered for Janssen COVID-19 vaccine if available, whereas individuals who self-report a polysorbate-only allergy can be considered for mRNA COVID-19 vaccines after shared decision making with their physician. For COVID-19 vaccine-naïve individuals, clarification of polysorbate allergy can be easily assessed by asking about tolerance of other common vaccines with polysorbate 80 (Table I). In patients with a history of PEG anaphylaxis, cross-reactivity to polysorbate 80 and other PEG derivatives may be a significant problem¹³ and more data are needed to assess whether these individuals will tolerate the low concentrations of polysorbate 80 present in the Janssen vaccine (and other severe acute respiratory syndrome coronavirus 2 vaccines in development). Pending the CDC’s ongoing evaluation of the Janssen vaccine, our algorithms may require additional modifications.

CONCLUSIONS

Severe allergic reactions to COVID-19 vaccines remain exceedingly rare, and the mechanism of these reactions requires further investigations. All vaccine sites should continue to observe higher risk individuals following CDC guidelines and have staff trained in recognizing and managing anaphylaxis. The

vast majority of individuals with high risk allergy histories will not need excipient skin testing prior to vaccination. As our experience and knowledge with COVID-19 variants vaccines increases, we must continue to remain flexible with our approach. Our updated prevaccine risk stratification algorithm can be used in conjunction with the previously published skin testing guidance.² In the meantime, the potential life-saving benefit of vaccination makes it essential that allergists continue to carefully evaluate and advise all patients with allergy histories and prevent denying access to the vaccine unnecessarily.

Acknowledgments

We thank many colleagues in the Mass General Brigham health system for the design and implementation of the COVID-19 vaccination program, including Paul D. Biddinger, MD, Upeka Samarakoon, MS, PhD, MPH, Rajesh Patel, MD, MPH, Caroline L. Sokol, MD, PhD, Michelle E. Conroy, MD, Leeann Ouimet, MBA, Allen Judd, BA, Lily Li, MD, Tanya M.
